AutoCAD Civil 2010

# User's Guide

Autodesk

April 2009

# Contents

# Getting Started

# New Features

**1**

AutoCAD Civil 2010 contains many new features and enhancements.

For more information about the new features included in AutoCAD Civil 2010, see the *New Features Workshop*.

## New User Interface Features

**New User Interface Features**

| Feature | Description | Location |
|---------|-------------|----------|
| Ribbon | The ribbon provides a new access method for AutoCAD Civil commands. Displayed at the top of the drawing window, the ribbon provides one location for commands, in an organization that provides the most-frequently used commands in the most accessible places.<br>Object-specific ribbon tabs are displayed when you select objects in the drawing, or they can be opened independently of object selection.<br>For more information, see AutoCAD Civil Ribbon Overview (page 71). | RIBBON command |
| Application Menu | Provides drawing-related commands, such as New, Open, Save, and Export To AutoCAD.<br>The Application Menu is accessible from the button at the upper-left corner of the application window.<br>For more information, see Menus (page 75). | |
| Proximity and rollover tooltips | Provides proximity and roll-over tooltips in an easy-to-read format. For more information, see Object Tooltips (page 106). | Move your cursor over or near objects in the drawing |
| Toolspace tooltips | Provides information about items and collections on the Toolspace tabs. | Move your cursor over objects or collections in the Toolspace |
| Ribbon tooltips | Provides tooltips for ribbon controls, with links to Help for more information. | Move your cursor over ribbon controls. Press F1 to link to a Help topic. |

| Feature | Description | Location |
| --- | --- | --- |
| Object properties exposed in Properties palette | Exposes civil-specific properties in the AutoCAD Properties palette for most civil objects, using a standard format.<br>For more information, see Object Properties (page 57). | Ribbon: View tab ➤ Palettes panel ➤ Properties  |
| Quick Properties | Provides the Quick Properties palette for civil objects.<br>For more information, see Object Properties (page 57). | QPMODE variable |
| Match Properties | Provides support for the Match Properties command for civil objects.<br>For more information, see Object Properties (page 57). | Ribbon: Home tab ➤ Modify panel ➤ Match Properties  |
| Object selection from Prospector | Provides new commands for selecting objects in the drawing from the Toolspace Prospector tab. | Toolspace Prospector tab ➤ right-click object ➤ Select |
| Data Shortcuts folder in Prospector | The Data Shortcuts folder is now available in the Active Drawing View. For more information, see Using Data Shortcuts (page 127). | Toolspace Prospector tab ➤ select Active Drawing View from the drop-down list |

# New Alignments Features

**New Alignments Features**

| Feature | Description | Location |
| --- | --- | --- |
| Create from objects | The Create Alignment From Polyline command has been renamed to Create Alignment From Objects. The command now provides the ability to select multiple lines, arcs, and polylines to use as the alignment geometry. For more information, see Creating an Alignment from Graphic Entities (page 891). | Ribbon: Home tab ➤ Create Design panel ➤ Alignments ➤ Create Alignment From Objects  |
| New Type property for alignments | Provides a Type property for alignments. Types include centerline, offset, miscellaneous, and curb return.<br>Alignment creation dialog boxes provide a control for specifying alignment type. All existing alignments from previous version drawings are assigned the centerline type.<br>In the Toolspace Prospector tree, alignments are organized according to their type.<br>For more information, see Alignment Types (page 855). | Alignment creation dialog boxes<br>Alignment Properties dialog box |
| New Alignment Properties | Provides a new tab for masking in the Alignment Properties dialog box.<br>The masking feature enables you to define ranges on an alignment where the geometry and labels are not drawn (but still exist). For more information, see To mask an alignment (page 865). | Alignment Properties dialog box ➤ Masking tab |
| Create offset alignments | Creates offset alignments that are dynamic to the parent alignment. For more information, see Creating Offset Alignments (page 895). | Ribbon: Home tab ➤ Create Design panel ➤ Alignment ➤ Create Offset Alignment |

| Feature | Description | Location |
|---------|-------------|----------|
| | |  |
| Create widening | Creates rule-based non-parallel offsets (such as bus bays and turn lanes with widening and transitions) at specified stations or geometry locations. For more information, see Creating Widening (page 896). | Ribbon: Home tab ➤ Create Design panel ➤ Alignment ➤ Create Widening  |
| Make dynamic offsets or curb returns static | Offset alignments are dependent on a parent alignment and curb returns are dependent on two parent alignments. These alignments react dynamically to their parent alignments. However, they can be changed to a static state for manual editing. For more information, see Offset Parameters Tab (Alignment Properties Dialog Box) (page 1757). | Alignment Properties dialog box, Offset Parameters /Curb Returns Parameters tab, Update Mode setting |

# New API Features

**New API Features**

| Feature | Description |
|---------|-------------|
| .NET API for selected civil objects | Provides a .NET API for Alignments, Styles, Settings, Profiles, and Pipe Networks. For more information, see .NET API. |

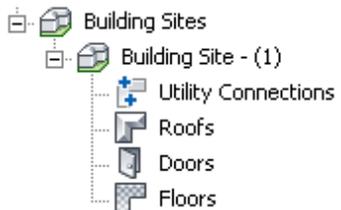
# New Corridors Features

**New Corridors Features**

| Feature | Description | Location |
|---------|-------------|----------|
| Section Editor | Provides the Corridor Section Editor commands on a ribbon tab. For more information, see Viewing and Editing Corridor Sections (page 1361). | Ribbon: Corridor context tab ➤ Modify panel ➤ Corridor Section Editor  |
| Clearing geometric overrides from corridor sections | Provides a streamlined method of clearing overrides that have been applied to cross sections. A check box has been added to the Assembly level collection in the Parameter Editor of the View/Edit Corridor Section tools. This check box is selected if overrides have been applied at a lower level. You can clear this check box to clear all the overrides that are applied at the lower level. For more information, see To override subassembly parameters by editing their values (page 1365). | Section Editor tab ➤ Corridor Edit Tools panel ➤ Parameter Editor. Override check box available at the Assembly collection level |
| Select region button | Provides a button on the Parameters tab of the Corridor Properties dialog box to select a region to make it current in the drawing. For more information, see Parameters Tab (Corridor Properties Dialog Box) (page 1815). | Corridor Properties dialog box, Parameters tab, Select Region From Drawing button |
| Naming template for baselines and regions | Provides a naming template for new corridor baselines and new/inserted corridor regions. | Corridor Properties dialog box, Parameters tab. |

| Feature | Description | Location |
|---|---|---|
| | | When you insert a new baseline or region, you can access the Name Template dialog box. |
| Edit Region | Provides an Edit Region command, which opens the Corridor Properties dialog box and makes the selected region current in the dialog box. For more information, see Adding and Editing Corridor Regions (page 1337). | Ribbon: Corridor context tab ➤ Modify panel ➤ Edit Region |
| Isolate/Show Region | Provides an Isolate Region command that turns off all other regions in the corridor, so that only the desired region is visible on the screen. Provides a Show All Regions command to turn on the visibility of any regions that are currently turned off. For more information, see Adding and Editing Corridor Regions (page 1337). | Ribbon: Corridor context tab ➤ Modify panel ➤ Isolate Region Ribbon: Corridor context tab ➤ Modify panel ➤ Show All Regions |
| Persistent targets | Provides persistent targets when changing assemblies on the Corridor Properties dialog box Parameters tab (for common target types). For more information, see To edit a corridor region (page 1337). | Corridor Properties dialog box, Parameters tab |
| Highlighting | Provides new Region Highlight Settings to control the highlighting of regions and baselines in the corridor when editing the corridor parameters in the Corridor Properties dialog box. For more information, see To change corridor creation settings (page 1334). | Toolspace Settings tab ➤ right-click Corridor collection ➤ Edit Feature Settings |
| Zoom to and Pan to region | Provides new commands to zoom and pan to corridor regions from the Corridor Properties dialog box. For more information, see Parameters Tab (Corridor Properties Dialog Box) (page 1815). | Corridor Properties dialog box, Parameters tab |
| Automatic boundary creation for corridors with multiple baselines | Provides a new automated method of creating boundaries for corridors with multiple baselines, creating a shrink wrap boundary around the entire corridor. This aids in surface creation for the corridor, as well as representing excavation limits. For more information, see To automatically create outer boundaries (page 1356). | Corridor Properties dialog box, Boundaries tab. In the dialog box, right-click corridor name ➤ Corridor Extents As Outer Boundary. NOTE This command is shown in the menu only if the corridor has multiple baselines. |
| Create a 2D polygon from corridor boundary | Provides a new command for creating a closed polygon around the extents of corridor. This aids in surface creation for the corridor, as well as representing excavation limits. For more information, see To create a polyline boundary from a corridor (page 1357). | Ribbon: Home tab ➤ Create Design panel ▾ Create Boundary From Corridor |

# New Interoperability Features

| Feature | Description | Location |
|---|---|---|
| Revit building model import | Provides the ability to import an Autodesk Revit building shell and position it in the civil engineering site model using the specified units and coordinate zone. For more information, see Importing Architectural Data (page 1685). | Ribbon: Insert tab ➤ Import panel ▼ Import Building Site |
| Autodesk Revit building model display in Prospector | Displays the properties of a building site object in the Prospector tree in a Building Sites collection. The Building Site item expands to display its collections of Doors, Floors, Roofs, and Utilities. The component collections display an item list view (which contains a property column for each item in the list). <br><br> Building Sites <br> Building Site - (1) <br> Utility Connections <br> Roofs <br> Doors <br> Floors | Toolspace Prospector tab |
| Autodesk Revit building model Properties palette support | Provides access to the building object Name, Description, Style, Insertion Point X,Y,Z, and Rotation Angle properties in the AutoCAD Properties palette. | Ribbon: View tab ➤ Palettes panel ➤ Properties |
| Autodesk Revit building model grip point support | Provides grip points for the building model base point and utility connection points. | |


# New Intersection Features

| Feature | Description | Location |
|---|---|---|
| Create Intersection wizard | The new Create Intersection wizard automates roadway intersection design, including curb returns and widening, from specified main and side road alignments. For more information, see Creating Intersections (page 1428). | Ribbon: Home tab ➤ Create Design panel ➤ Intersection . When prompted to select an intersection, use an Osnap to select the intersection of two crossing alignments in the drawing. |

| Feature | Description | Location |
|---|---|---|
| Intersection object | A new object type, the intersection object, is created by using the wizard. It dynamically updates if its constituent parts are updated. For more information, see The Intersection Object (page 1424). | Ribbon: Home tab ➤ Create Design panel ➤ Intersection |
| Intersection grading | Provides support for the following two types of intersection grading:<br>■ Maintain the crown of the highest priority road and warp the side road cross section.<br>■ Maintain both centerlines and warp all pavements around the intersection area.<br><br>For more information, see Intersection Corridor Type (page 1434). | Ribbon: Home tab ➤ Create Design panel ➤ Intersection |
| Intersection corridors | Provides the ability to create automated intersection corridors (with all targets) and intersection-based corridor regions, using a specified assembly set.<br>Provides dynamic update of corridor regions after the intersection is created. For more information, see Creating Corridors in the Intersection Area (page 1435). | Ribbon: Home tab ➤ Create Design panel ➤ Intersection |
| Intersection profile locking | Provides the ability to lock the elevation of a lower-priority (side road) design profile to the elevation of the high priority road (main road) at the intersection location. For more information, see Changing Road Priority (page 1433). | Ribbon: Home tab ➤ Create Design panel ➤ Intersection |

# New Labels Features

**New Labels Features**

| Feature | Description | Location |
|---|---|---|
| Contour labeling masking | Provides an option in the Properties palette to mask a contour line which can improve the visibility of a contour label. For more information, see Background Mask (page 1496). | Right-click contour label ➤ Properties. In the Properties palette, on the Design tab, under Labels select Masking ➤ Contour Line Only |
| Profile and Section Label Enhancements | Provides options for staggering profile and section labels to avoid collisions in densely populated graph views. For more information, see Staggering Profile and Section Labels (page 1527). | Ribbon: Annotate tab ➤ Labels & Tables Panel ➤ Add Labels ➤ Profile View ➤ Add Profile View Labels |

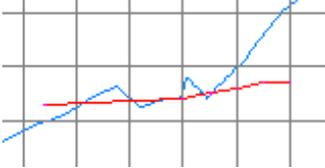
| Feature | Description | Location |
|---|---|---|
| |  | |
| | Profile labels that can be staggered include Grade Break, Major/Minor Station, and Horizontal Geometry Point.<br>Section labels that can be staggered include Major/Minor Offsets and Grade Break. | |
| Band label enhancements | Provides profile and section band labels as label objects. Band labels can now be selected, dragged, and grip edited like other label objects. Band labels can also now be staggered to avoid label collisions. For more information, see Staggering Data Band Labels (page 1528). | Profile View Properties ➤ Bands tab |
| Label leader enhancements | Provides enhancements to label leaders including the ability to add and move leader vertices, to hide leader tails, and to reset the leader grip. For more information, see Managing Leader Vertices (page 1520). | Available through label leader grips |
| Major and minor increments | Provides major and minor increment options for profile and section band sets and for profile and section views.<br>This feature provides an option to match major/minor increments to vertical grid intervals. For more information, see Bands Tab (Profile View Properties Dialog Box) (page 2181). | Profile View Properties ➤ Bands tab |

# New LandXML Features

**New LandXML Features**

| Feature | Description | Location |
|---|---|---|
| LandXML version support | Provides the ability to specify which version of LandXML (1.0, 1.1, or 1.2) is used when exporting LandXML data. For more information, see Export To LandXML Dialog Box (page 1983). | Export To LandXML dialog box |
| Pipe network import settings | Provides settings to support the import of pipe network data from the Storm Sewers application. For more information, see Import Tab (LandXML Settings Dialog Box) (page 1978). | LandXML Settings dialog box, Import tab |

# New Object Projection Features

| Feature | Description | Location |
|---|---|---|
| Draw projected objects in profile and section views | Provides the ability to project an object that is visible in plan view into a profile or a section view to show the object location.<br><br><br><br>Each projected object retains a dynamic link to the source object and reflects any edits to the source. For more information, see Working with Projected Objects (page 1118). | Ribbon: Home tab ➤ Profile & Section Views panel ➤ Profile View ➤ Project Object To Profile View<br><br><br>Ribbon: Home tab ➤ Profiles & Section View panel ➤ Section View ➤ Project Object To Section View<br> |
| Grip edit projected objects | Provides the ability to grip edit projected objects in profile and section views. | |
| Label projected objects | Provides the ability to label projected objects in profile and section views. Projection label styles are managed in the Profile View and Section View label style collections. For more information, see To add a projection label (page 1038). | Ribbon: Annotate tab ➤ Add Labels ➤ Add Projected Object Label |
| Object properties exposed in Properties palette | Provides properties for projected objects in the AutoCAD Properties palette. | Ribbon: View tab ➤ Palettes panel ➤ Properties<br> |


# New Parcels Features

| Feature | Description | Location |
|---|---|---|
| Parcel Slide Line and Swing Line layout and editing commands | Provides the ability to control parcel layout by specifying a minimum frontage as an offset, and/or by a minimum width and depth.<br>Certain parameters (such as area and frontage) are now required during the parcel sizing commands, so the Parcel Layout Tools dialog box expands when these commands are selected.<br>Provides graphics in the layout dialog box to illustrate the setting options. For more information, see Parcel Layout Tools (page 2009).<br><br> | Ribbon: Home tab ➤ Create Design panel ➤ Parcel ➤ Create Parcel By Layout<br> |

| Feature | Description | Location |
|---|---|---|
| Preview graphics in the drawing | Provides temporary preview graphics in the drawing to show the impact of the options and values you specify when doing parcel layout. For more information, see Creating Parcels by Subdividing (page 816). | Toolspace Settings tab ➤ Parcel ➤ Commands ➤ CreateParcelByLayout |

| Feature | Description | Location |
|---|---|---|
| Slide Angle & Direction command consolidation | Consolidates the Slide Angle and Slide Direction creation commands into a single Slide Line - Create command. For more information, see To create parcels by subdividing with the Slide Line - Create command (page 817).<br>Consolidates the Slide Angle and Slide Direction editing commands into a single Slide Line - Edit command. To edit parcels by subdividing with Slide Line - Edit command (page 821). | Ribbon: Home tab ➤ Create Design panel ➤ Parcel ➤ Create Parcel By Layout |

# New Pipe Network Features

**New Pipe Network Features**

| Feature | Description | Location |
|---|---|---|
| Multiple pipe network support | Provides the ability to import multiple networks from Storm Sewers. For more information, see Importing Pipe Network Data from an .stm File (page 1278). | Ribbon: Insert tab ➤ Import panel ➤ Storm Sewers |
| Part matching logic on import | Provides new part matching logic when importing Storm Sewers data into AutoCAD Civil. During import, the part names are used as the unique identifier for pipe networks.<br>If a line or inlet/junction does not have a name during import, it is named based on the naming template within the pipe network feature settings.<br>During import, if there is a part size that does not exactly match the AutoCAD Civil parts list, the closest matching larger size is used. For more information, see Preparing for Migrating Storm Sewers Data (page 1275). | Toolspace Settings tab ➤ Pipe Network ➤ Commands ➤ ImportStormSewerData, Storm Sewers Migration Defaults settings |
| Export pipe networks to Storm Sewers | Provides the ability to export Pipe Networks to Storm Sewers so pipe networks can be analyzed. For more information, see Exporting Pipe Network Data to an .stm File (page 1279). | Ribbon: Output tab ➤ Export panel ➤ Export To Storm Sewers |

| Feature | Description | Location |
|---------|-------------|----------|
| Parts list with all catalog parts | Provides a command to create a parts list that contains all the parts that exist in AutoCAD Civil.<br>This new command can be useful if you are migrating pipe network data between AutoCAD Civil and the Storm Sewers application, for example. For more information, see Creating a Full Parts List (page 1239). | Ribbon: Home tab ➤ Create Design panel ➤ Create Full Parts List |
| LandXML Import settings | Provides Pipe Network Import Settings in the existing LandXML Settings dialog box. This option is to support the import of pipe network data from the Storm Sewers application. For more information, see Import Tab (LandXML Settings Dialog Box) (page 1978). | Toolspace Settings tab ➤ right-click drawing collection item ➤ Edit LandXML Settings |
| Hydraulic Grade Lines and Energy Grade Lines | Provides the ability to display and label hydraulic grade lines (HGL) and energy grade lines (EGL) for pipes and structures in profile views.<br>The Pipe Properties dialog box and the Structure Properties dialog box now have items for HGL and EGL on the Part Properties tabs. For more information, see Adding Hydraulic Property Data to AutoCAD Civil Pipe Networks (page 1280). | Pipe Properties dialog box ➤ Part Properties tab, Geometry values<br>Structure Properties dialog box ➤ Part Properties tab, Geometry values |
| Display of HGL/EGL components in profile view | Provides display options for HGL and EGL components in the pipe and structure style dialog boxes. To represent the hydraulic grade line and energy grade line in a profile view, you must enable their display in the pipe and structure styles.<br>The visibility for these components is off by default. For more information, see Viewing Hydraulic Data in Profile Views (page 1282). | Pipe Style dialog box ➤ Display tab ➤ Profile View Direction, Hydraulic Grade Line and Energy Grade Line components<br>Structure Style dialog box ➤ Display tab ➤ Profile View Direction, Hydraulic Grade Line and Energy Grade Line components |
| HGL/EGL Labels | Provides the ability to label hydraulic grade lines and energy grade lines for pipes and structures in profile view. For more information, see Labeling Hydraulic Properties in Pipe Networks (page 1270).<br>The following new label properties are available for pipes:<br>■ Hydraulic Grade Line Up<br>■ Hydraulic Grade Line Down<br>■ Energy Grade Line Up<br>■ Energy Grade Line Down<br><br>The following new label properties are available for structures:<br>■ Hydraulic Grade Line<br>■ Energy Grade Line | Pipe and Structure label styles |

| Feature | Description | Location |
|---|---|---|
| New Pipe Network Parts Catalog Content | Enhancements have been added to the pipe network parts catalog. For example, the following new part types are now available: | Toolspace Settings tab ➤ Pipe Network ➤ Parts List ➤ Add Part Family |

**Circular pipes**

- Corrugated Metal Pipe
- HDPE Pipe
- Corrugated HDPE Pipe

**Elliptical pipes**

- Concrete Horizontal Elliptical Arch Pipe

**Structures (Inlet\Outlet)**

- Concrete Flared End Section
- Concrete Rectangular Winged Headwall
- CMP Rectangular End Section

In addition to these new part types, various new sizes have been added to existing part families.

# New Profile Features

**New Profile Features**

| Feature | Description | Location |
|---|---|---|
| Profile hatching | Provides the ability to add hatch patterns to a profile view that contains multiple profiles. The hatch patterns can be used to show cut, fill, multiple boundaries, and quantity takeoff in the profile.<br>You can specify a Shape Style for each hatch area, which defines which hatch pattern is used. For more information, see Adding Hatch Areas to a Profile View (page 1116). | Create Profile View wizard, Profile View Properties dialog box |

# New Surfaces Features

**New Surfaces Features**

| Feature | Description | Location |
|---|---|---|
| Clip boundaries | Enables data clip boundaries to be applied to imported surfaces including TIN, LandXML, grid, or corridor surfaces. For more information, see Applying a Data Clip Boundary to Imported Surfaces (page 614). | Ribbon: Surface context tab ➤ Modify panel ➤ Add Data ➤ Boundaries |
| AutoCAD polylines from contour data | Provides a command to insert contours that are used in a surface into a drawing as polylines.<br>If a polyline has been added as contour data, you can run the Insert To Drawing command and one or more AutoCAD polylines are added to the drawing. In addition, the record of the | ■ On the Toolspace Prospector tab, select the Contour collection in a surface definition to display the list view at |

| Feature | Description | Location |
|---|---|---|
| | contours (in the surface operations list) is converted from a list of coordinates to a reference to the new polylines.<br>For more information, see Inserting Contour Data Into a Drawing (page 634). | the bottom of Prospector.<br>■ Right-click a contour in the list and click Insert To Drawing. |
| New command and feature settings | ■ SurfaceExportToDEM command setting: Null-elevation and grid spacing.<br>■ AddSurfaceBreaklines/AddSurfaceContours command settings: Weeding and supplementing factors and mid-ordinate distance.<br>■ Rebuild Surface feature setting: Value in Surface Defaults collection for automatic rebuild of a surface.<br><br>For more information, see Edit Feature Settings - Surface Dialog Box (page 2329). | Toolspace Settings tab ➤ Surface collection ➤ Commands collection ➤ right-click command name ➤ Edit Command Settings |

# New Survey Features

**New Survey Features**

| Feature | Description | Location |
|---|---|---|
| Import survey data wizard | Provides a wizard to streamline the import of a field book file, LandXML file, point file, or points from the drawing, into the survey database. For more information, see Import Survey Data Wizard (page 239). | Ribbon: Home tab ➤ Create Ground Data panel ➤ Import Survey Data |
| Linework code sets | Provides the ability to define a linework code set that can be used for importing a field book file, LandXML file, point file, or points from the drawing.<br>You can create a named field coding convention, where <begin>, <continue>, <end>, <line/curve commands>, and so on, are defined. You can define one-to-many conventions, where a specific convention can be specified at import time.<br>Linework code sets are grouped in a Linework Code Sets collection on the Toolspace Survey tab.<br>For more information, see Linework Code Sets (page 230). | Toolspace Survey tab ➤ right-click Linework Code Sets ➤ New |
| Import Field Book file | Provides the ability to import a field book and specify which named import convention and feature code table to use.<br>The survey points and line features are added to the drawing and to the survey database. For more information, see Importing a Field Book File (page 241). | Toolspace Survey tab ➤ Survey Databases ➤ <named database> ➤ Networks ➤ right-click <named network> ➤ Import ➤ Import Field Book |
| Import ASCII point file | Provides the ability to import an ASCII point file containing a Point ID, X-coordinate, Y-coordinate, Z-coordinate, and Description.<br>To import an ASCII point file, you specify the point file format, the import convention, and the feature code table. The survey points and line features are added to the drawing and to the | Ribbon: Home tab ➤ Create Ground Data panel ➤ Import Survey Data |

| Feature | Description | Location |
|---|---|---|
| | survey database. For more information, see To import a point file (page 248). | |
| Import points from drawing | Provides the ability to import points from the current drawing into the survey database and network as either control points or non-control points, and provides an option to perform line-work processing. For more information, see Importing Points From a Drawing (page 249). | Toolspace Survey tab ➤ Survey Databases ➤ <named database> ➤ Networks ➤ right-click <named network> ➤ Import ➤ Import Points From Drawing |
| Import LandXML | Provides the ability to import a LandXML file using a named import convention. For more information, see Importing Survey LandXML Data (page 244). | Toolspace Survey tab ➤ Survey Databases ➤ <named database> ➤ Networks ➤ right-click <named network> ➤ Import ➤ Import Field Book |
| Import Events item in database collection | Provides the ability to update data after importing from a field book or ASCII File. Upon completion of the import process, you can edit the appropriate point descriptions and reprocess the data using the current import convention and feature code table, replacing erroneous line features with the corrected line features. You can perform these steps iteratively until satisfied that field coding errors have been minimized. For more information, see Import Events (page 249). | Toolspace Survey tab ➤ Survey Databases ➤ <named database> ➤ Import Events |

# Changes to Drawing Templates

**Included Templates**

| Feature | Description |
|---|---|
| Templates included in the product | The "Extended" templates included in previous releases are now named as follows:<br>■ _AutoCAD Civil 3D (Imperial) NCS<br>■ _AutoCAD Civil 3D (Metric) NCS<br><br>Some styles in the "LDT" template that was included in previous releases have been moved into these templates. The "Base" and "LDT" templates are no longer included in the product. |

**Drawing Settings**

| Feature | Description |
|---|---|
| Drawing Settings ➤ Object Layers tab | **New layer settings**<br>■ Building Site<br>■ Intersection<br>■ Intersection-Labeling<br>■ Grading-Labeling<br>■ Parcel-Labeling |

| Feature | Description |
|---|---|
| | ■ Parcel Segment-Labeling |
| | **Changed layer settings** |

| Section View feature settings and command settings for ProjectObjectsToSect | ■ Projection Style<br>■ Section Projection Label Style<br>■ Default Projection Label Placement |

**Parcel Settings**

| Feature | Description |
| --- | --- |
| CreateParcelByLayout command settings | **Parcel Sizing Properties**<br>■ Parcel Selection Method<br>■ Minimum Area<br>■ Use Minimum Frontage At Offset<br>■ Frontage Offset<br>■ Minimum Width<br>■ Minimum Depth<br>■ Use Maximum Depth<br>■ Maximum Depth<br>■ Multiple Solution Preference |
| CreateParcelByLayout command settings | ■ Preview Graphics |

**Grading Settings**

| Feature | Description |
| --- | --- |
| CreateFeatureLineFromAlign command settings | Spiral Tessellation Factor |

**Alignment Settings**

| Feature | Description |
| --- | --- |
| Alignment feature settings | ■ Default Name Format ➤ Offset Alignment Name Format<br>■ Dynamic Alignment Highlight Options |
| CreateAlignmentEntities command settings | Alignment Type Option ➤ Alignment Type |
| AddWidening command settings | Widening Options |
| CreateOffsetAlignment command settings | Dynamic Offset Alignment Options |
| Alignment styles | ■ Intersection Basic style<br>■ Offsets style |

**Profile and Profile View Settings**

| Feature | Description |
| --- | --- |
| Station and grade break labels | Staggering options |

| Feature | Description |
|---|---|
| Profile View feature settings ➤ Default Styles | ■ Cut Area Shape Style<br>■ Fill Area Shape Style<br>■ Multiple Boundary Area Shape Style |
| Profile View feature settings ➤ Default Name Format | ■ Cut Area Name Template<br>■ Fill Area Name Template<br>■ Multiple Boundary Area Name Template |
| Profile View styles ➤ Display tab | Profile Hatch setting |
| Band Set styles | ■ Major Interval<br>■ Minor Interval<br>■ Stagger Labels<br>■ Stagger Line Height<br>■ Check box for match major/minor increments to vertical grid intervals |
| Band label styles | Addition of Dragged State and General tabs for all label styles in all bands |

**Section View Settings**

| Feature | Description |
|---|---|
| Band Set styles | ■ Major Interval<br>■ Minor Interval<br>■ Stagger Labels<br>■ Stagger Line Height<br>■ Check box for match major/minor increments to vertical grid intervals |
| Band label styles | Addition of Dragged State and General tabs for all label styles in all bands |

**Pipe Network Settings**

| Feature | Description |
|---|---|
| Feature settings | Default Styles ➤ Structure Default Style (now Storm Sewer Manhole; was Sanitary Sewer Manhole) |
| Feature settings and the following command settings:<br>■ EditInStormSewers<br>■ CreateNetworkPartsListFull<br>■ ExportStormSewerData<br>■ ImportStormSewerData | Storm Sewers Migration Defaults |

| Feature | Description |
| --- | --- |
| Command settings for the following commands<br>■ EditInStormSewers<br>■ ImportStormSewersData<br>■ ExportStormSewerData | ■ Storm Sewers migration default settings |
| Partial Catalog Parts List | Contains a revised version of the Storm Sewers parts list |
| Pipe style ➤ Display tab (for Double Line (Sanitary) and Double Line (Storm) styles) | ■ Hydraulic Grade Line<br>■ Energy Grade Line |

### Corridor Settings

| Feature | Description |
| --- | --- |
| Feature settings | Region Highlight Graphics category |

### Intersection Settings

| Feature | Description |
| --- | --- |
| Feature settings | All new |
| Command settings | All new |
| Intersection style | Intersection Marker Style |
| Label style | Intersection Label |

### Building Site Settings

| Feature | Description |
| --- | --- |
| Building Site style | All new |
| Command settings | All new |

### Plan Production Template Settings

| Feature | Description |
| --- | --- |
| Plan Production templates | No changes |

# Feature Overview

<div style="text-align: right; font-size: 3em; font-weight: bold;">2</div>

This section explains and illustrates the concepts underlying AutoCAD Civil features.

Each feature section has one or more corresponding illustrations to reinforce the concepts introduced in that section.

## Points

Points are the basic building blocks used to identify entities in land development plans such as ground locations and design elements. Each point is uniquely identified and has properties that include information such as northing, easting, elevation, and description.

You can insert or import points from different sources and in different formats. For example, you can define sets of description keys to help organize the insertion of points. Description keys use the raw description of incoming points to control the creation of each drawing point, including the following actions:

■ Assigning the point to a specific layer

■ Assigning a point style

■ Assigning a point label style

■ Translating the raw description into a full description

■ Rotating or scaling the point symbol

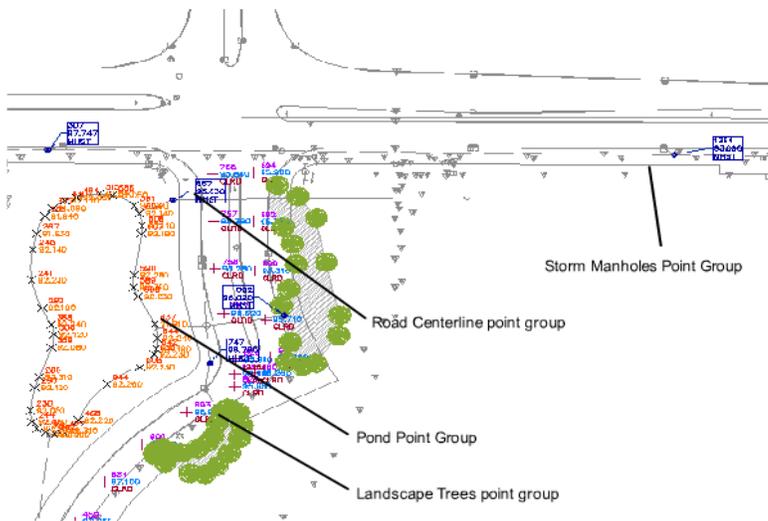
Points can also be created directly in the drawing, using a variety of methods.

You can use point groups to organize points and to control their appearance in a drawing. Point groups reference the point data directly and are responsible for drawing the points. Point groups have an override that forces all points in the group to use both that group's preferred point style and point-label style, rather than the styles assigned to the individual points.

Storm Manholes Point Group

Road Centerline point group

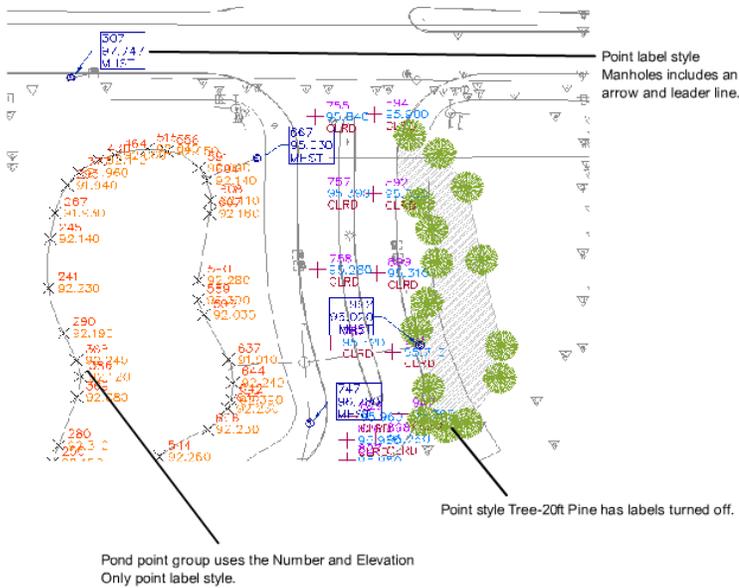
Pond Point Group

Landscape Trees point group


**Point groups showing different uses of point styles**

Point label style
Manholes includes an
arrow and leader line.

Point style Tree-20ft Pine has labels turned off.

Pond point group uses the Number and Elevation
Only point label style.


**Examples of point label styles**

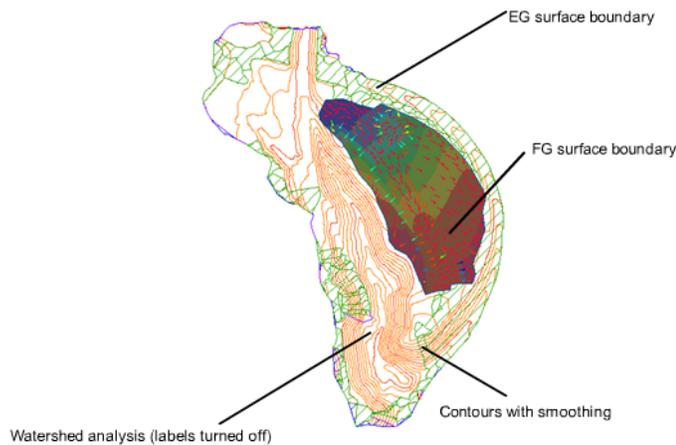
| Workflow | Points Workflow |
| Tutorials | Points Tutorials |

# Surfaces

You can work with two types of surfaces: TIN (triangulated irregular network) and grid. For each of these types, you can create volume surfaces, which are differential surfaces created from two existing surfaces. Surface styles define the appearance of any surface. They can also be used to control the visibility of any analysis that has been performed on that surface. Watersheds can be drawn on the surface, with information about the type of drainage area and where each area drains to.

Boundaries define the visible area of a surface. Only the area within the boundary is included in calculations, such as for total area and volume. You can also define masks to hide or show parts of a surface for editing or presentation purposes, while still including that area in calculations.



**Surfaces displaying boundaries, contours, and elevation analysis**

Breaklines are used on TIN surfaces to define linear features that triangles cannot cross, such as retaining walls or streams. Breaklines affect triangulation of the surface.

You can define different sets of contours, for example, for different intervals. Smoothing is provided for the surface object as a whole, which gives better results than simply smoothing the contours. In AutoCAD Civil, the build process for surfaces is incremental. Whenever data is added or corrected, the surface is updated. Each surface has a definition list. This list contains all the operations performed on the surface. By turning the operations on and off, you can return a surface to a previous state or modify it to support different types of analysis.

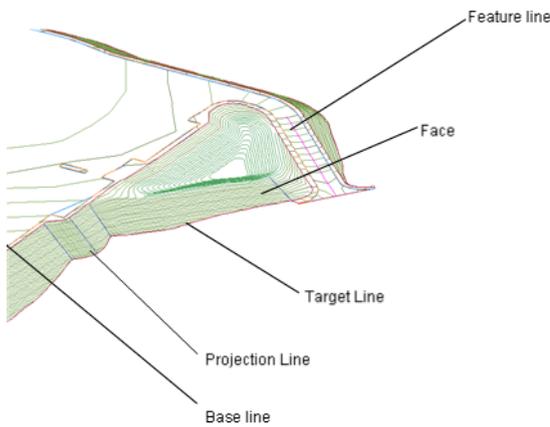
| Tutorials |  Surfaces Tutorials |
| Best Practices |  Surface Data |

# Grading

You can use the grading tools to design finished graded surfaces. Gradings are objects that have their own properties and behavior like other AutoCAD Civil objects. You create a grading by selecting a base line in the drawing, and then specifying a projection method and target, for example, grade at 3:1 to meet an existing surface. Save time and effort by predefining such values and saving them as grading criteria. Subsequent gradings you create will use the current criteria. You can also create named grading styles that combine specific display properties, such as colors. In addition to using the current criteria, any grading you create uses the current style.

A grading normally consists of a face bounded by a base line, a target line, and several projection lines. The base line can be any open or closed figure from which you want to project the grading. It can be a feature line or a lot line. A feature line is any linear feature in the drawing, such as a ridge line, building footprint, or the bottom of a swale. The target for the grading can be a surface, a distance, or an elevation (absolute or relative).

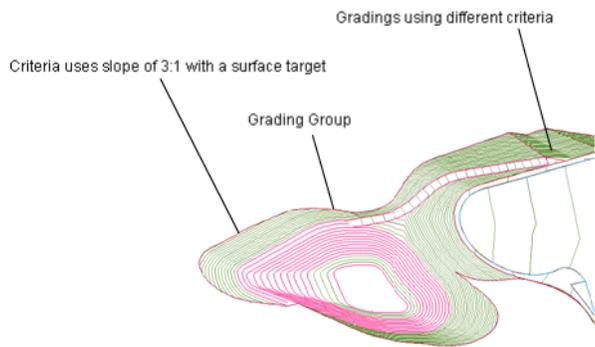


**Line components of a grading object**

Each site can include grading groups, which bundle individual gradings into named sets. Before creating a grading, you must create a new grading group, or select one that already exists. A surface can be created from a grading group, and a grading group can be pasted into a surface. The surface will then be updated if you change the grading.

After you create a grading group, volume tools within AutoCAD Civil show you the amount of cut and fill required for the grading design. You can raise or lower the grading group incrementally to adjust volume requirements. You can also change the elevation of points along a grading base line, change the grade of a base line, or modify the grading criteria.

Gradings using different criteria

Criteria uses slope of 3:1 with a surface target


Grading Group

**Grading criteria specifies the grading method**

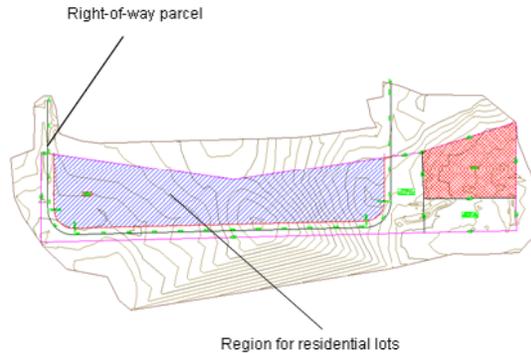
# Parcels

AutoCAD Civil provides a site topology that includes intelligent parcel objects. Each parcel is an independent object that usually represents real estate parcels or lots. You can also import parcels as simple polylines and then convert them to parcel objects. Parcels consist of a series of segments that can be edited individually. Editing parcel segments dynamically updates the parcel properties. Deleting a segment can result in one parcel merging with another.



**Parcel region before subdivision into individual lots**

Each site contains one collection of parcels. The hierarchy of parent site and child parcels is managed on the Prospector tab in Toolspace. The parent site represents the original area to be subdivided. By creating a number of separate sites, you can manage large projects with many lots grouped in separate blocks.

You can create parcels one at a time or as a group, with settings for the minimum area and minimum frontage as well as the minimum/maximum width and depth of each parcel. Parcel layout tools give you precise control over parcel area and the angle of each lot line.

Parcel styles determine the appearance of the parcel, including fill patterns for the area and linetypes for the segments. There are separate label styles for parcel areas and parcel segments.

Parcel style uses area fill

# Alignments

Horizontal alignments are used to represent roads and other linear objects. Alignments can include lines, curves, and spirals, which can be joined by constraints. When you edit an alignment, for example, by dragging a grip, the components of the alignment can maintain tangency to one another. You can create alignments from existing polylines, or by using AutoCAD Civil alignment layout tools. You can edit an alignment either by grip editing or by using the edit commands. Some of the creation and editing options are as follows:

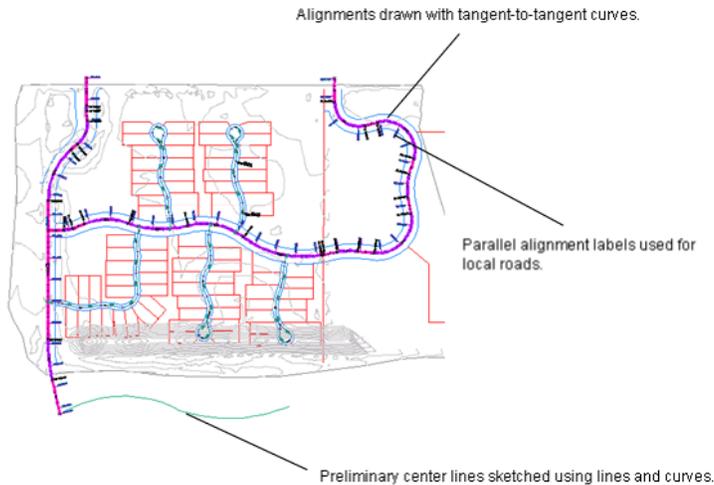
- Draw a series of tangents, then add curves or spiral-curve or spiral-line groups at the PIs (Points of Intersection).

- Draw single lines, curves, and spirals.

- View and edit the dimensions of alignment components.

- Apply superelevation to the curves along an alignment.

Use station equations to change station-distance references at any point without physically changing the geometry of the alignment.



**Alignment lines, curves, and labels**

Station reference point at start of alignment.

Major road uses different line and label styles from local roads.

| Workflow | Alignments Workflow |
| Tutorials | Alignments Tutorials |
| Best Practices | Alignments |

# Profiles

Profiles (also known as vertical alignments), are derived from horizontal alignments in the drawing. There are two types of profiles. Surface profiles, often called existing ground (EG) profiles, are extracted from a surface. Layout profiles, often called finished grade (FG) profiles, represent a designed surface such as a road. A profile can be dynamic, in which case it is linked to a surface to reflect updates to the surface or the horizontal alignment. It can also be static, to preserve a record of a surface at a particular time.You create static profiles in various ways, such as importing a text file, importing an XML file, or by using the Profile Layout Tools dialog box.

Edit a profile by grip editing or by using the edit commands in the Profile Layout Tools dialog box.

Profiles are displayed in graphs called profile views. Profile views are separate objects that have their own sets of styles. You can add data bands to annotate the profile view with stations and elevations, horizontal geometry points, or other useful data. You can save several data bands in a set that can be easily applied to other profile views.

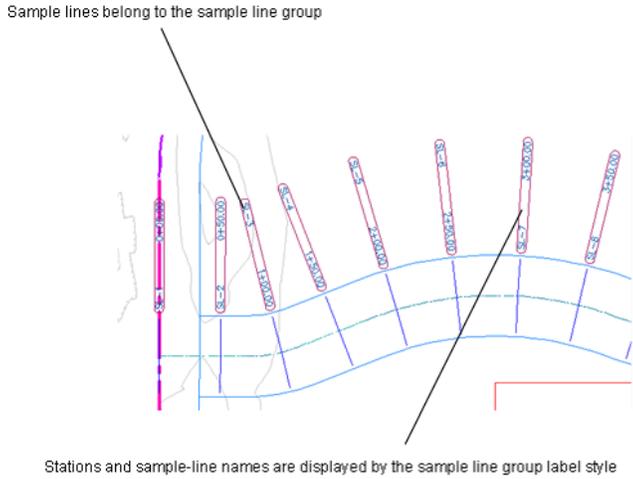
| Workflow |  Profiles Workflow |
| Tutorials |  Profiles Tutorials |
| Best Practices |  Simplify Profile and Section View Styles |

# Sections

Sections, or cross sections, are cut across a linear feature to a specified distance on the left and right of a center line. Sections are typically sampled at given stations along a horizontal road alignment. Edits to an alignment update the sections as well.

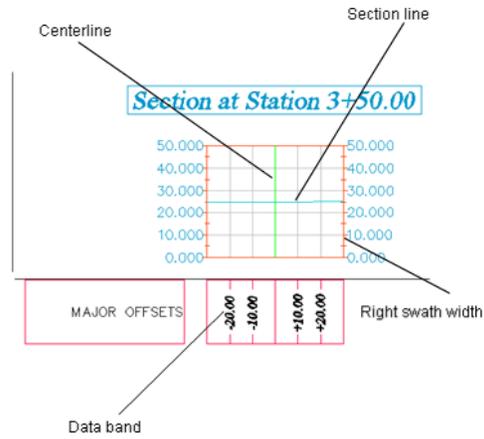
Sections are located on sample lines that cut across the alignment. Sample lines have their own styles and can be labeled. A set of sample lines makes up a named collection called a sample line group.

Sample lines belong to the sample line group

Stations and sample-line names are displayed by the sample line group label style


**A group of sample lines**

Sections are displayed in a graph called a section view. A section view is very similar to a profile view. It consists of a grid or graph with attributes that are controlled by section view styles. You can also display data bands above or below the section view. You can plot individual sections for a specific sample line, or all the sections for a group of sample lines. To plot multiple sections, use a paperspace viewport to set up the sheet.

Sections, like alignments and profiles, support label sets. Label sets enable you to save and apply an unlimited number of different types of labels.


**Section view of a sample line**

| Best Practices | Simplify Profile and Section View Styles |

# Pipe Networks

You can use the pipe networks feature to design and model networks that represent the flow and function of a utility system, such as a storm or sanitary sewer.

You build a model of a pipe network using individual parts, much like a real-world pipe network, connecting pipes in your network either with or without using structures, such as manholes or catch basins, and adding inlet or outlet structures, such as headwalls, to mark the terminating end of a pipe run. After you have created your initial network design, you can view and edit network parts in virtually unlimited ways within plan view or in a profile view. You can also view the pipe network parts in a section.

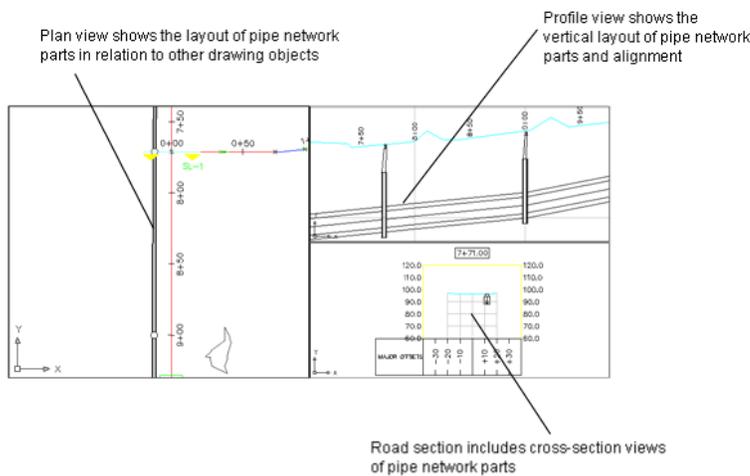
Preset design rules control the slope of pipes, their depth relative to a surface, and the sizing of the structures that connect the pipes. This is useful when you are designing a gravity system, such as a storm or sanitary sewer.

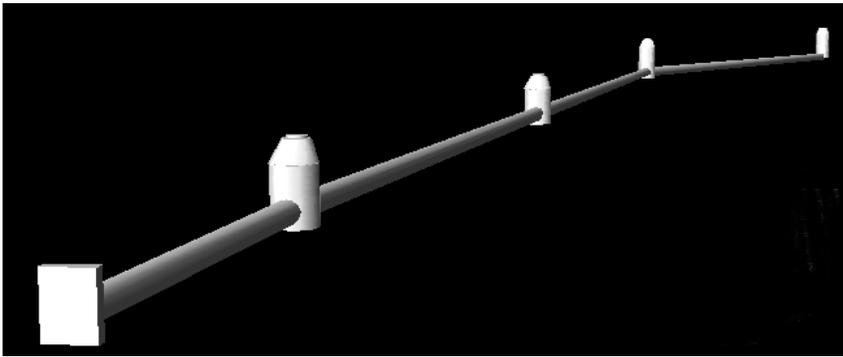
### Pipe Network Viewports

This illustration displays three viewports: the pipe network in plan view, the profile view of some of the network pipes and structures, and the same parts in a section view.

The left pane shows a pipe network segment made up of two manhole structures connected by pipes. The network parts have been placed at a specified offset from an alignment, and are drawn in a profile view created using the same alignment (upper-right pane). A sample line placed at station 7+71 was used to create a section view (lower-right pane) that shows a cross-section view of the pipe network parts located at the station.

You can edit the positions of the pipe network parts manually by using editing grips in either plan, profile, or section view, or by directly editing their properties.



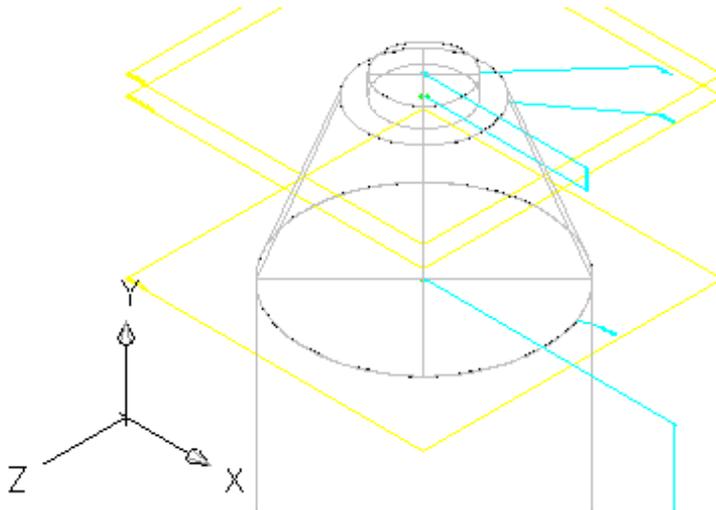
**Layout, profile, and section views of a pipe network segment**


**3D view of pipe network segment**

**Pipe Parts**

A pipe network is constructed from various pipes and structures that appear in a parts list. You can see the available lists on the Toolspace Settings tab by expanding the Pipe Network ➤ Parts Lists collection.

AutoCAD Civil includes a utility called Part Builder, which you can use to edit the dimensions of parts and create new ones. You can create a new part by saving an existing one with a new name, and then modifying its dimensions in various tables.



**Detail from a Part Builder edit window for a concentric cylindrical structure.**

# Corridors

Corridors are used for roads and similar structures that follow a designed route across the terrain.

A corridor is a detailed three-dimensional design that combines data from a horizontal alignment, a profile view, and an assembly. The corridor can automatically reflect changes to any of the parent data.

Subassembly objects such as road lanes, curbs, and shoulders form the building blocks for an assembly. When you apply the assembly to an alignment and a profile, a corridor is generated in three dimensions. At each point along its linear path, the corridor adapts to conditions, such as superelevation and cut or fill requirements.

### Intersections

You can use intersection design features to automatically create flexible 3D models of corridor intersections. Intersection objects are created from various object data, including alignments, profiles, corridors, assemblies, subassemblies, and surfaces.

### Corridor Viewports

This illustration displays three viewports. The viewports help you see the object relationships.

- In the left pane, the horizontal alignment starts at the top of the corridor and runs to the bottom.

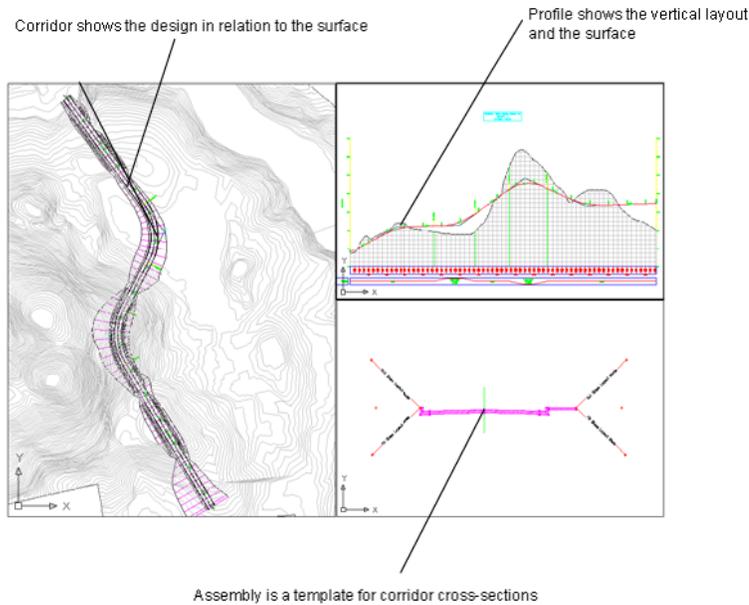
- In the profile view, station 0 is on the left side, and green vertical lines across the grid show the start and end points of the horizontal curves.

- In the assembly view, the corridor assembly includes two road lanes, a curb on the left, a sidewalk on the right, and side slopes on each side. The side slope subassembly (BasicSideSlopeCutDitch) is designed to create a ditch only on cut slopes, and the ditches are visible along the corridor.

You can use the Object Viewer to see the corridor in a three-dimensional view that shows the cut and fill regions. Click the corridor, then right-click and click Object Viewer. Click near the bottom of the Object Viewer window, then click and move the cursor up to tilt the corridor. If you want to pan or zoom the display, right-click inside the Object Viewer window.

Corridor shows the design in relation to the surface

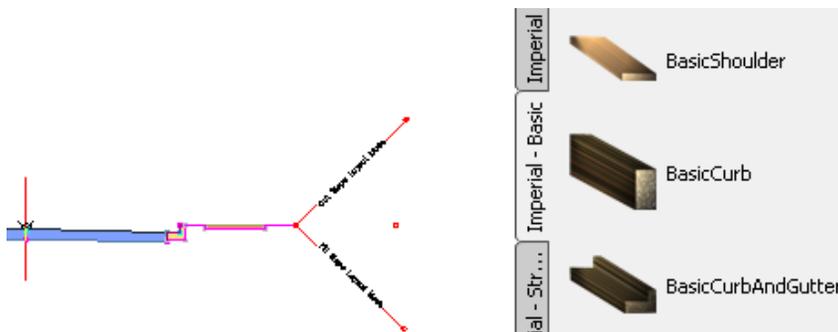
Profile shows the vertical layout and the surface

Assembly is a template for corridor cross-sections


**Elements of a corridor design**

## Assemblies and Subassemblies

A corridor is created from one or more assemblies, which are standard roadway cross-sections. You design an assembly from subassemblies, such as lanes, curbs, shoulders, and ditches. The subassemblies are provided in a set of catalogs.



**Roadway assembly (left), with subassemblies shown in a tool palette (right)**

Each subassembly has a defined cross-section, and some subassemblies automatically adapt to their location. For example, the slope of a road lane changes as superelevation is applied, and a side slope automatically creates either a cut or fill slope, depending on the relative elevation of the existing surface.

The dimensions of a subassembly, such as the width of a lane or the height of a curb are stored as properties.

You can also create custom subassemblies from AutoCAD polylines. In this case, you must also specify the subassembly behavior within an assembly and in the process of corridor creation. You can define custom subassemblies and their behavior using .NET scripts, then use the AutoCAD Civil COM application programming interface (API) to link these to the main application.

A subassembly definition references point, link, and shape codes. Points are the vertices of the subassembly, and they can be attachment points for adjacent assemblies. Links are the line segments or curves between the points. Shapes are two-dimensional polygons that represent the cross-sectional shape of the subassembly. The following figure shows a coding diagram for a Basic Curb and Gutter subassembly:

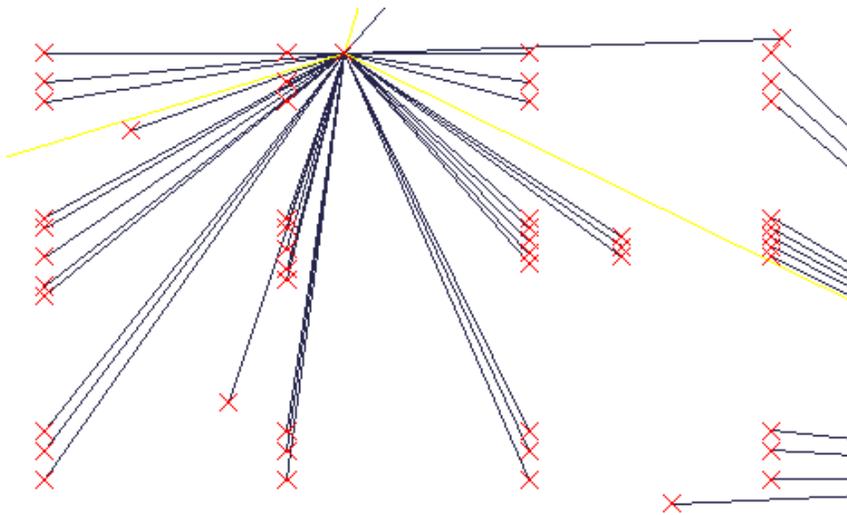
# Survey

You can use the AutoCAD Civil survey tools to import, analyze, adjust, and convert survey data. The Survey tools can also automate symbol placement and linework creation to facilitate the conversion of survey data into AutoCAD Civil objects.

Survey data is organized into databases, whose data is visible in Toolspace, on the Survey tab. The survey databases can either be integrated with your Autodesk Vault project management database, or stored locally.

During the field survey data collection process, you can use a coding convention established in AutoCAD Civil to automate the conversion of field survey data, collected with data collection equipment, into AutoCAD Civil linework.



**Survey data imported from a field book**

# Object and Label Styles

The object styles in AutoCAD Civil have general attributes, such as object color, visibility of components, linetypes, and fill patterns.

Similarly, label styles work with text format, data content, location, and graphic elements, such as leader lines and bounding boxes.

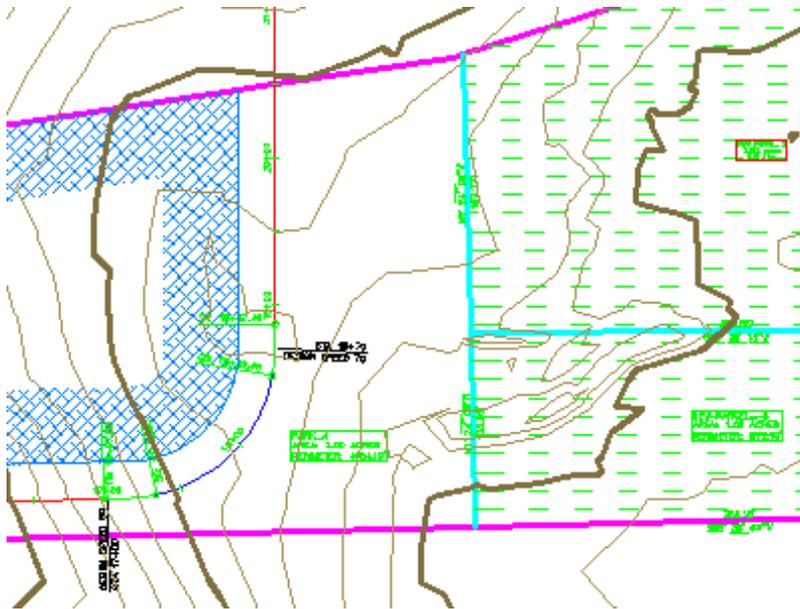
Within your design process, object and label styles should be created with specific purposes in mind, such as representing objects at different approval stages, or displaying the right information for different types of users. Before you create object styles, experiment with editing styles for different objects to learn the available controls.

Style components vary according to object type, but most object and label styles are accessible in the same two ways:

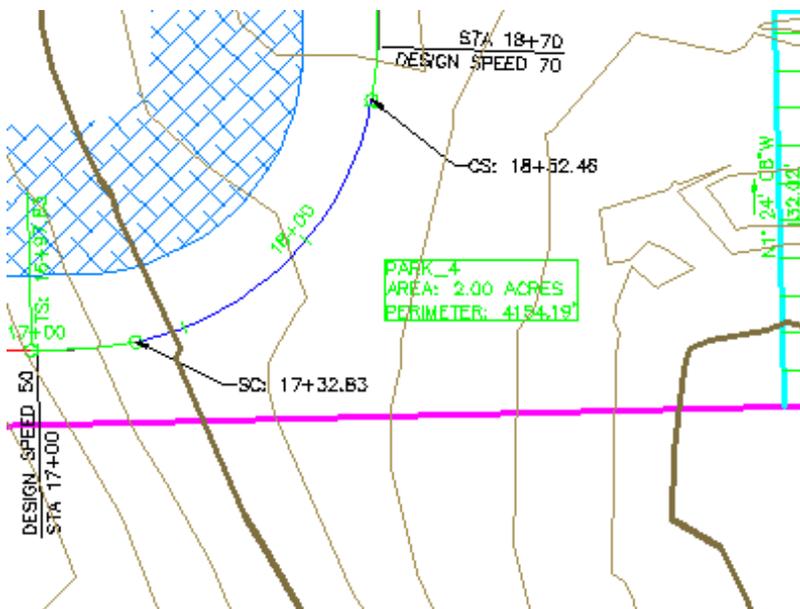
■ In Toolspace, on the Prospector tab, right-click an object and click Properties to see the object style. Some objects also show the label style here. Click the list button next to the style name and select Edit Current Selection to review or edit the style components.

■ In Toolspace, on the Settings tab, expand the object collection to see all the styles for that object, organized by types. Right-click any style name and click Edit to review or edit the style components.

For objects, you can add labels by using the Annotate tab to access the Add Labels dialog box or feature-specific label menus.

You can create sets of label styles for alignments, profiles, and sections in order to manage multiple labels easily. After the set is defined, it can be applied to or removed from an object in a single operation.


**Object styles for a surface, parcels, and an alignment, showing stylization**

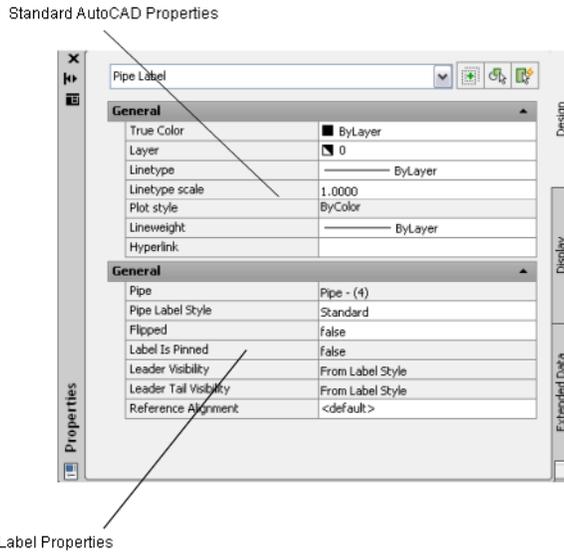


**Label styles, including two alignment labels in a dragged state**

| For information about…. | See... |
| --- | --- |
| Working with Styles | Understanding Objects and Styles (page 51) |
| Tutorials | Tutorial: Working with Label Styles |
| Best Practices | Using Styles |

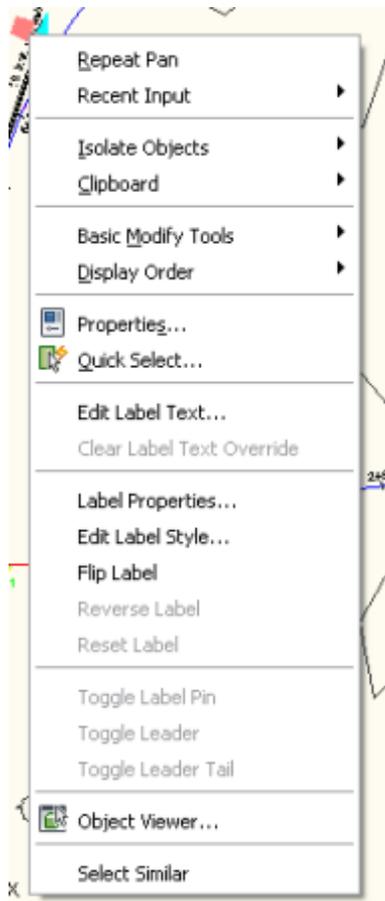
# Label Objects

You manage label objects in AutoCAD Civil with standard AutoCAD commands as well as AutoCAD Civil commands. You can use the AutoCAD Properties palette to edit multiple labels in a single operation. For example, you can use the Properties palette to access the Text Component Editor in order to simultaneously edit text content for a group of any number of labels.



**Label Properties controlled with AutoCAD Properties palette**

If you are editing a drawing that includes dozens of pipe network parts with corresponding labels, you can edit the text, change the appearance, or reset the location of all of the labels at the same time by using multiple selection. It is important to remember that you can also select subentities of group type labels with the Ctrl-click selection method in order to edit individual labels one at a time.

As independent objects, label objects are not "subentities" of a parent object. They reside on their own layer, the default of which is controlled using drawing settings. You can edit labels using object label contextual menus. Right-click a label to display the context menu which displays options for editing properties or label behavior.


**Label object context menu**

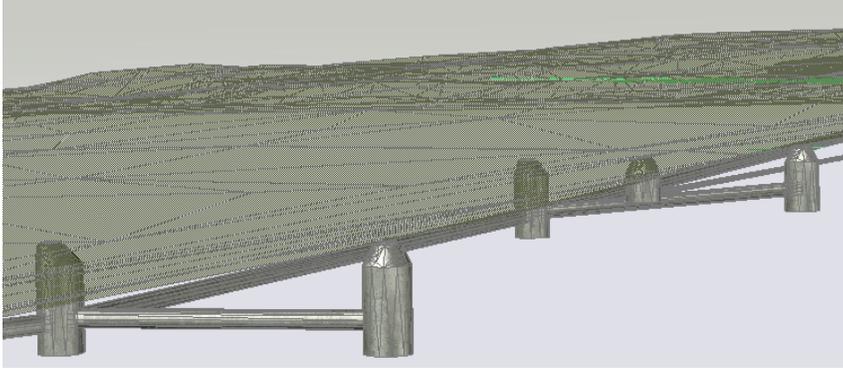
| Working with Label Objects | Understanding Labels (page 1466) and Label Objects (page 1463) |
| Workflow | Labels and Tables Workflow |
| Tutorials | Labels and Tables Tutorials |
| Best Practices | Label Styles and Labeling External References |

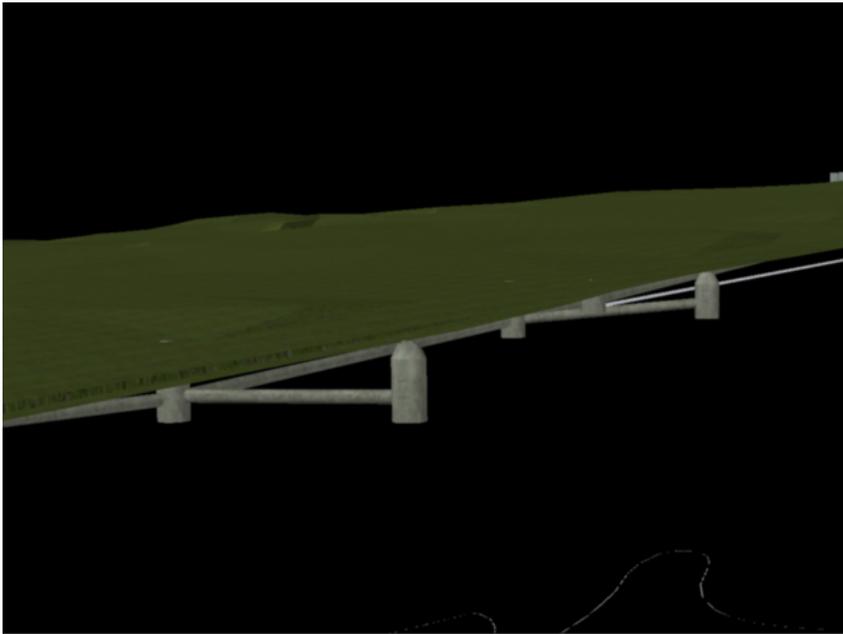
# Visualization

You can use the visualization tools in AutoCAD Civil to create enhanced design drawings using model rendering materials that correspond to specific real world materials in a design. AutoCAD render materials simulate the characteristics of materials such as asphalt, concrete, and gravel.

To visualize a material with a render material, the material must be included in the current drawing. You can easily add materials to a drawing from the tool palette or by dragging materials used in one drawing into another drawing. You can also create a new render material, and save it to use as part of a drawing template or copy it into other drawings.

In AutoCAD Civil, you can apply render materials to features, such as surfaces and surface masks, corridor surfaces and corridor surface boundaries, and pipes and structures.


**View using styles such as 2D wireframe and 3D realistic**



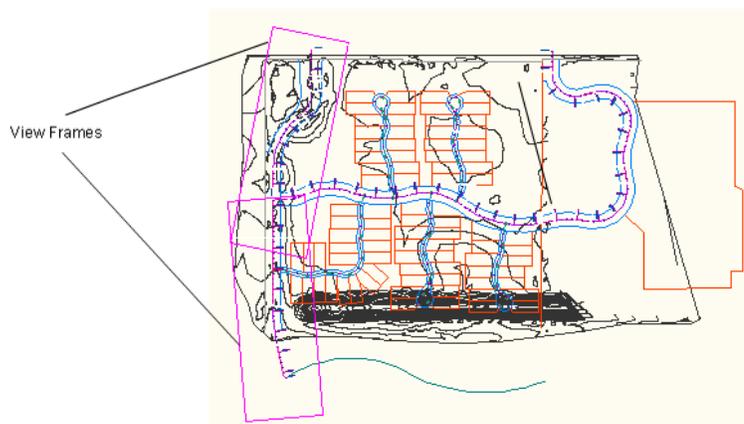
**Rendered image of a surface object simulated with grass and the underlying concrete drainage pipes and catch basins**

| For information about…. | See… |
|---|---|
| Working with Visualization | Object Rendering (page 1577) |

# Plan Production Tools

Use the Create View Frames and Create Sheets wizards to create sheets that automatically display segments of alignments and profiles in your plans. You can create view frame groups that automatically capture predefined areas along an alignment.

Instead of needing to manually create many viewports on layouts to show segments of alignments, you can create view frames that automatically capture predefined areas along an alignment. View frames are rectangular areas along an alignment that represent what is displayed in the associated viewports on the layouts (sheets) to be created. This automation saves you from making many manual changes when your design data changes.



**View frames represent the alignment data that will be displayed in layout sheets**

The plan production tools simplify the process of preparing sheets from your design drawings. After you select an alignment in your drawing, in just a few seconds you can create sheets that automatically display the desired data.

| For information about…. | See… |

# Understanding Objects and Styles

# 3

In AutoCAD Civil, objects are the basic building blocks that enable you to create design drawings.

The underlying program code for AutoCAD Civil uses an object-oriented architecture. As a result, design entities in the drawing, such as points and surfaces, are intelligent objects that maintain relationships with other objects. For example, if a horizontal alignment is modified, any profiles and sections based on that alignment are automatically changed.

The primary AutoCAD Civil object types that enable you to create civil engineering design components, and the icons that represent them, are as follows:

| | | | |
|---|---|---|---|
|  | Point |  | Point Group |
|  | Surface |  | Parcel |
|  | Grading |  | Alignment |
|  | Profile |  | Profile View |
|  | Sample Line |  | Feature Line |
|  | Section |  | Section View |
|  | Mass Haul Line |  | Mass Haul View |
|  | Pipe Network |  | Pipe |
|  | Structure |  | Pipe Interference Check |
|  | Corridor |  | Assembly |
|  | Intersection |  | Subassembly |
|  | Site |  | Building Site |

| | | | |
|---|---|---|---|
| Survey Network | | Survey Figure | |
| Match Line | | View Frame | |

These types of objects are sometimes referred to as graphical objects or drawing objects because when you use them, a graphical object or shape, for example, a pipe network, surface, or corridor, is inserted into the drawing.

Use the Prospector and Settings tabs in Toolspace to access detailed object properties and settings. For more information, see The Toolspace Window (page 80).

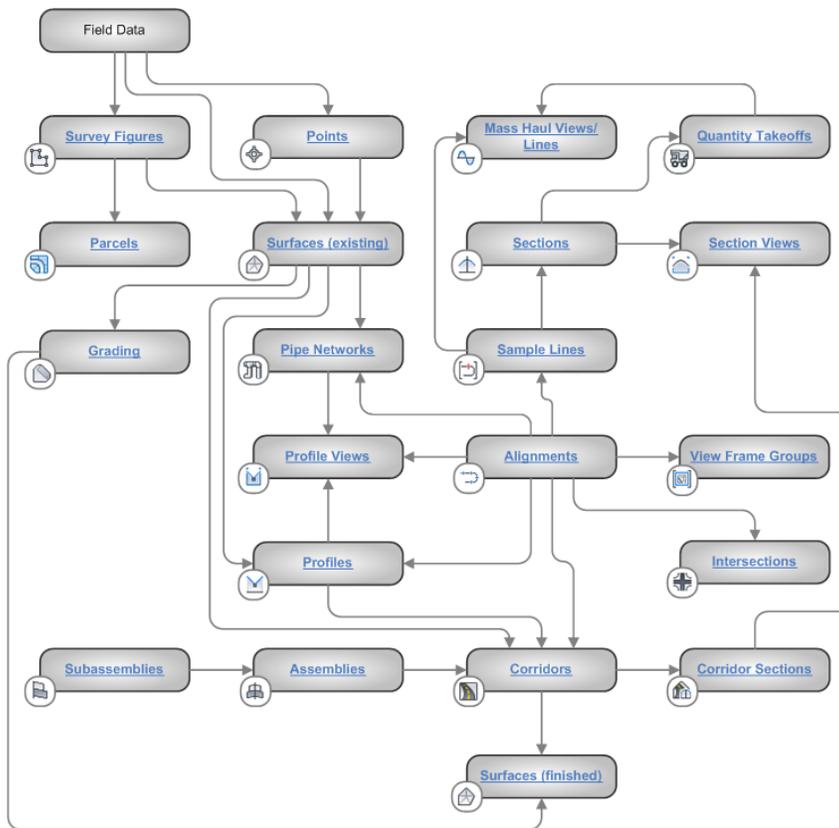
For information on basic object behavior, see the AutoCAD Help.

# Object Relationships

AutoCAD Civil objects automate the design process by interacting with other AutoCAD Civil objects.

A design team typically spends many hours ensuring that revisions are transferred correctly between surfaces, alignments, profiles, sections, and other design data. Redrafting, relabeling, and checking the work can be time-consuming tasks. AutoCAD Civil eliminates the need for most of these tasks by introducing dynamic links between design objects. This system of links and dependencies derives from the object model within the application design.

The following diagram illustrates how AutoCAD Civil data objects are related to each other.



Field data creates a set of points that are used to generate an existing ground surface. This surface is referenced by other objects as indicated by the arrows.

Parcels, existing ground surfaces, pipe networks, and gradings can be created independently, or from data sources not shown in the illustration. Such objects are usually linked to other objects during the design process, if not at the beginning.

The object type with the most complex set of relationships is the corridor, as it requires data from a surface, alignment, profile, and assembly (and typically multiple subassemblies).

Changes to any object flow downward along the arrows to dependent objects, with predictable results. For example, if you correct the elevations of an existing ground surface, updates flow to any related grading objects, pipe networks, corridors, and profiles. As a result, all values represented in labels and tables are also updated.

In the design process, after you create an alignment you can create many profiles and sections. But the display of these in profile views and section views is optional and apart from the flow of data required to create the final surface. Similarly, the data from objects such as parcels and alignments can be output to a table or report if desired.

In the object model, changes in one object can be passed on automatically to associated objects where desired. For example, if you redesign an alignment curve, any grading using that alignment as a baseline can be modified accordingly. In addition, all related stationing, labels, and other alignment-specific data is updated.

The following table shows which objects can be updated when you edit each type of object:

| When you edit this object type... | These objects may be updated... |
| --- | --- |
| Points | Surfaces |
| Surfaces | Grading, Profiles, Pipe Networks, Corridors |
| Parcels | Grading, Corridors |
| Alignments | Grading, Parcels, Corridors, Profiles, Sections, Pipe Networks, Intersections |
| Profiles | Intersections |
| Grading | Surfaces, Corridors |
| Subassemblies | Assemblies, Corridors |
| Assemblies | Corridors |
| Pipe Networks | Surfaces, Alignments |
| Feature Lines | Grading |
| Sample Lines | Sections, Mass Haul diagrams |

**Objects, Styles, and Labels**

A relationship exists between drawing objects, the styles that control their display, and the labels that control their annotation. These styles and labels are also managed as objects within AutoCAD Civil.

# Object Styles

Styles control the display and design characteristics of drawing objects.

You can use styles to efficiently manage object appearance. When you create a new object, you can apply a predefined style for its display. Later, you can apply a different style. Also, you can create new styles to suit the needs of different users and different project stages. If you change a style definition, the changes are applied automatically to all objects using that style.

Styles for each object type are managed on the Toolspace Settings tab. The General collection contains styles that can be used by more than one object type (called Multipurpose styles) as well as shared label styles. All AutoCAD Civil objects have a Basic style that can be used as is, or as the basis for building new styles. If you want to customize some attributes of a style, you can create a new style, or make changes to an existing style and save it with a new name. Groups of styles can be collected and saved as a drawing template (*.dwt*) file. All drawings created from a specific *.dwt* will share the same styles. The controls for creating styles are standardized as much as possible across all features to make the process easier.

Styles Best Practices

## Working with Styles

Use the shortcut menus to make changes in object styles or object style collections.

Right-click an object style collection in the Toolspace Settings tab to create a new style.

When you right-click an existing style, you can edit, copy or delete the style. You cannot delete a style that is referenced in the drawing.

For information on creating, editing, copying, and deleting styles for a specific feature, see the styles topics for that object type:

| Object Type | See ... |
| --- | --- |
| Points | Point Styles (page 419) |
| Surfaces | Surface Styles and Visualization (page 692) |
| Parcels | Parcel Styles (page 828) |
| Profiles/Profile Views | Styles and Display of Profiles and Profile Views (page 1027) |
| Alignments | Alignment Styles (page 885) |
| Corridors | Corridor Styles and Display (page 1329) |
| Grading | Using Grading Styles (page 737) |
| Subassemblies | Subassembly Styles (page 1395) |
| Pipe Networks | Pipe Network Styles and Display (page 1187) |
| Sample Lines/Sections/Section Views | Sample Line, Section, and Section View Styles and Display (page 1130) |
| Survey | Survey Styles and Display (page 195) |
| View Frames | View Frame Styles and Display (page 1695) |
| Match Lines | Match Lines Styles and Display (page 1697) |

## Multipurpose Styles

Use the Multipurpose Styles collection to create specific styles that can be used by more than one object type.

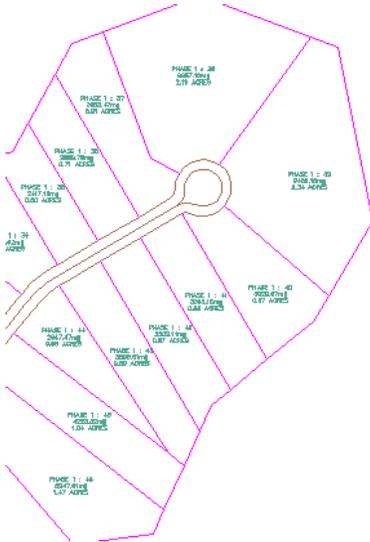
For example, Slope Pattern style can be shared by gradings and corridors and Marker Styles can be shared by points and survey components.

For more information, see General Collection (Settings Tree) (page 94).

## Label Styles

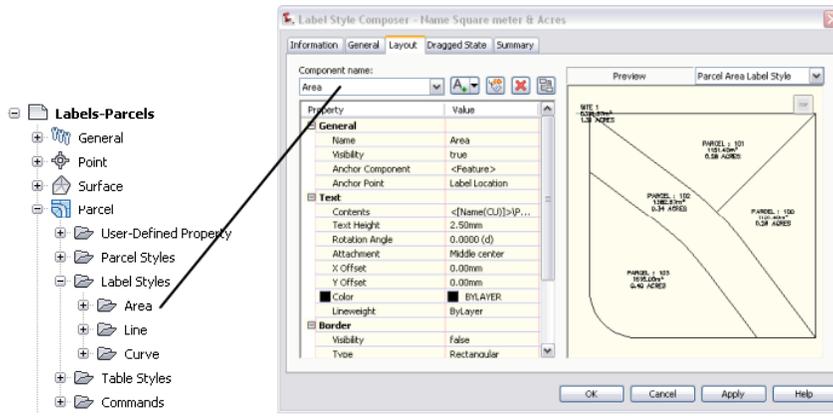
Label Styles are used to control and manage the display of labels and expressions for a class of objects.

Labels are associated with many objects, and their content is updated whenever the object itself is changed. Labels are also controlled by styles. You can modify the label styles in the same way that you modify the object styles: right-click a style name on the Toolspace Settings tab, and then click Edit.



**Parcel area labels appear in the drawing as they appear in the preview of the Label Style Composer**

You can create and save label sets for alignments, profiles, and sections, which allows you to apply multiple label types in one operation. For example, an alignment label set could include labels for major stations, minor stations, and geometry points.

Labels can include text, blocks, lines, ticks, and leaders. You can create labels and preview their appearance in the Label Style Composer dialog box, as shown in the following illustration:


**Previewing customized label style for parcel area**

For more information about the Label Styles collections, see The Label Styles Collections (Settings Tree) (page 95).

The General Label Styles are used by lines, curves, feature lines, and corridors. This collection also contains Note label styles, which are not specific to an object.

For general information about labels, see Label Objects (page 1463).

For information about managing label styles, see Creating and Editing Label Styles (page 1477).

## Table Styles

Table Styles are used to control and manage the display for the tables associated with a class of objects.

AutoCAD Civil provides automated data tables for points, surfaces, parcels, alignments, and quantity takeoff. As shown in the following illustration, these tables provide a concise display of object data as an alternative to using object labels. The table styles control the data properties and the displayed components of the table.

**Example data table for parcels**

Data properties include the data format, order of columns, text style, and whether the table title and column headers are repeated if the table is split. Display components include the borders, separators, fill, and text. You can control the visibility, color, linetype, and scale of each component.

For information on the Table Styles collections, see The Table Styles Collections (Settings Tree) (page 96).

For general information about tables, see Tables (page 1555).

## Changing Common Settings in Styles

The Styles dialog boxes for all object types include the Information (page 1801), Display (page 1801), and Summary (page 1803) tabs. Other tabs are provided to record additional data specific to the object type.

**To change Style settings**

1 On the Settings tab in Toolspace, right-click an existing object style and click Edit.

2 Review and edit settings on the various tabs of the Style dialog box.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click object style ➤ Edit

Dialog Box

Styles (page 1801)

# Object Properties

AutoCAD Civil object properties can be modified using the civil object properties dialog boxes, the Properties palette, and the Quick Properties palette.

### Civil Object Properties

Each AutoCAD Civil object has its own dialog box which contains most properties relevant to that object.

Use these dialog boxes as the primary interface for adjusting AutoCAD Civil object properties.

For example, use the Alignment Properties dialog box to adjust properties for a selected alignment object in a drawing.

### Properties Palette

The Properties palette can be used as an alternate method of editing AutoCAD Civil object properties.

In AutoCAD Civil 2010, more civil object properties are exposed in the Properties palette than in previous releases. Properties are now organized into four categories: Information, General, Data, and Geometry.

By exposing these properties in the Properties palette, they are now also available to be used with the QSELECT command.

For more information, see *Control the Properties of Objects* in the AutoCAD Help.

### Quick Properties Palette

For each civil object, the name, description, style, and layer are available for editing in the Quick Properties palette. For more information, see *Display and Change the Properties of Objects* in the AutoCAD Help.

Also, you can easily customize the quick properties for any object in the Customize User Interface (CUI) editor. For more information, see *Quick Properties* in the AutoCAD *Customization Guide*.

### Matching Object Properties

The Match Properties command can be used with AutoCAD Civil objects. When you use the Match Properties command between civil objects, the style and object display properties of the selected source object are applied to the selected destination objects. For more information, see *Copy Properties Between Objects* in the AutoCAD Help.

**To access comprehensive AutoCAD Civil object properties**

■ Select a AutoCAD Civil object and click <Object Name> Properties on the Modify panel of the contextual ribbon tab.

OR

■ Right-click an AutoCAD Civil object and click <Object Name> Properties in the shortcut menu.

**To access AutoCAD Civil object properties in the Properties Palette**

■ Select an AutoCAD Civil object and click Properties on the General Tools panel of the contextual ribbon tab.
OR

■ Right-click an AutoCAD Civil object and click Properties in the shortcut menu.

**To access AutoCAD Civil object properties in the Quick Properties Palette**

1 Enable the Quick Properties mode by entering QPMODE at the command line and entering 1. Or click the Quick Properties button on the Drawing Status Bar.

2 Select an AutoCAD Civil object in the drawing.

3 In the Quick Properties Palette, edit the desired properties.

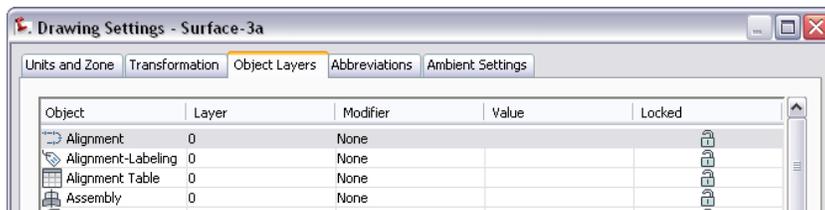
# Layers

Each object in AutoCAD Civil has a *base layer* on which the object physically resides, and *component layers* that control the display of object components, such as surface triangles or contours.

The base layer is defined in the Drawing Settings or at creation time. The component layers are defined in the object styles.

**Object Base Layer**

You specify the default base layers for objects on the Object Layers tab of the Drawing Settings dialog box.



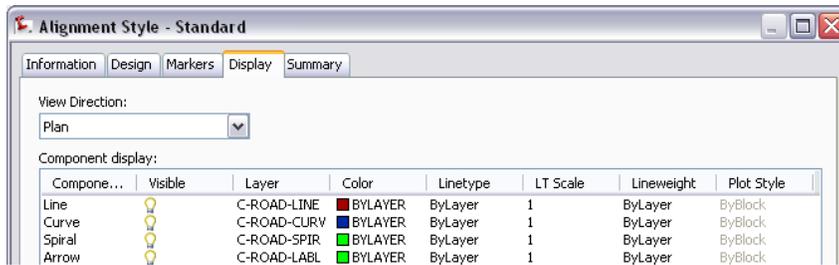
When you create an object, you can accept the default or specify a new layer. The base layers are used only for the main object types, such as surfaces and alignments.

Because the object physically resides on the base layer, you can control object visibility by changing the layer state. For example, if you turn off the base layer for surfaces, all surfaces are turned off in the drawing.

**TIP** To append an object name to the layer name for that object, add an asterisk (*) as a prefix or suffix to the base layer name.

For more information, see Object Layers Tab (Drawing Settings Dialog Box) (page 1854).

**Object Component Layers**

You specify component layers on the Display tab of the <object> Style dialog box. The following example shows layers used for alignment components:


The component layers, such as C-ROAD-LINE, allow you to work with objects as if parts of them are located on different layers. For example, to turn off only the alignment lines, you can turn off the C-ROAD-LINE layer in the drawing.

Objects are physically created on the base layer, but the display of components is governed by the associated component layers. Each object component uses the visibility settings for the component layer (such as on/off), as well as the color, linetype, lineweight, and plot style for the layer if the various Component Display settings are set to ByLayer.

**NOTE** Layer 0 has a special meaning in the Component Display settings. When the layer is set to 0, the object base layer is used for that component. For example, if the alignment base layer is C-ROAD, and the layer for the Line component is set to 0, then the alignment lines behave as if they are located on layer C-ROAD (not layer 0).

For more information, see Display Tab (Style Dialog Box) (page 1801).

**Setting Up Styles Using the ByLayer Setting or Specific Settings**

If you are accustomed to controlling objects by manipulating layers, you may want to set the various object style Component Display settings to ByLayer. Then you can simply change the layer settings using the AutoCAD Layer command rather than editing separate styles to change the color, linetype, lineweight, or plot style of an object component.

**TIP** Using the ByLayer settings provides more control over object display to people viewing AutoCAD Civil drawings in object-enabled AutoCAD.

However, if you want the object to always have the same settings regardless of component layer settings, you can set specific Component Display settings.

For more information, see Using ByLayer and ByBlock to Assign Display Values (page 1803).

# Naming Constraints for Objects and Styles

Object and style names restrict the use of certain characters.

When naming an object or style, do not use the following characters:

- < (less than)
- > (greater than)
- / (forward slash)
- \ (backward slash)
- + (plus sign)
- " (double quotes)
- : (colon)
- ; (semi colon)

- ■ = (equals)
- ■ | (vertical line)
- ■ , (comma)
- ■ * (asterisk)
- ■ ? (question mark)
- ■ ' (single quote)

# Understanding Settings

# 4

AutoCAD Civil has drawing, object, and command settings. All three levels of settings in AutoCAD Civil are saved with the drawing, and they can be saved to a drawing template.

Settings in AutoCAD Civil provide many preset values, ranging from values, such as drawing units, scale, and coordinate system, to optional defaults, such as the layers that the different objects are created on, and the use of tooltips.You can access the setting dialog box by right-clicking the appropriate collection on the Toolspace Settings tab, and then clicking Edit Feature Settings.

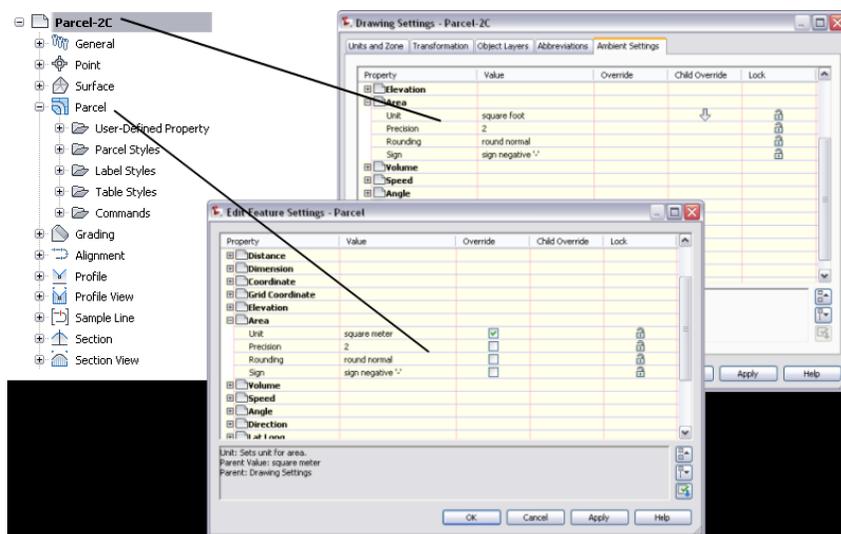
**You can work with three levels of settings:**

■ Drawing settings establish values for the whole drawing. If you are creating a drawing template, ensure that these are set correctly.

■ Feature settings control behavior for a particular feature, such as Parcels or Grading.

■ Command settings apply to individual commands within a feature, such as the CreateParcelByLayout command within the Parcels feature.

Each lower level object in the settings hierarchy can either inherit or override settings in the level above it. The following illustration shows an override set for area units at the Parcels feature level.



**Feature settings can override drawing settings**

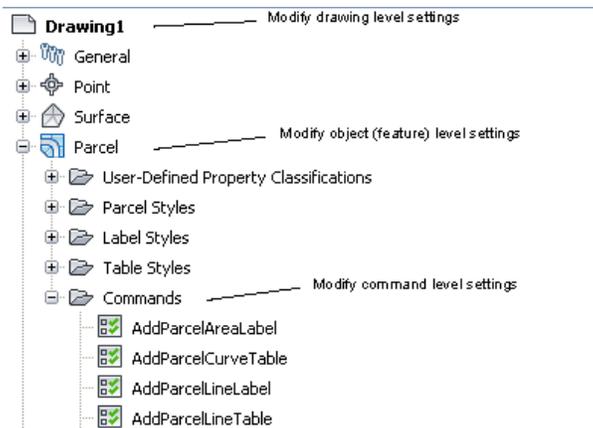
The arrow in the Child Override column of the Drawing Settings dialog box (upper drawing) indicates that an override has been set at a lower level. The check mark in the Override column in the Parcel Settings dialog box (lower drawing) indicates that the value set in this dialog box overrides the setting at a higher level.

At the drawing level you can cancel an override by clicking it. You can prevent overrides by locking a setting.

# Working with the Standard Settings Dialog Box Controls

Use a standard dialog box, accessed at three different levels, to edit settings.

You modify each level of settings at a different location in the Settings tree, as shown in the following illustration:



**Drawing-Level Settings**

There are two types of drawing-level settings:

■ Drawing-wide settings, which include units and zone, transformation settings, abbreviations, and object layers.

■ Ambient settings, which affect a variety of AutoCAD Civil behaviors. You can change ambient settings at the drawing level, and you can also override ambient setting values at either the object level or the command level.

You access drawing-level settings by right-clicking the drawing name in the Settings tree and clicking Edit Drawing Settings.

At the drawing level, the Edit Settings dialog box contains only the ambient settings for the drawing:

**Object(Feature)-Level Settings**

Use the object collection level in the Settings tree to control all settings that pertain to the object type. Change the object settings at this level in the tree, and specify overrides for the drawing ambient settings.

Access the object- or feature-level settings by right-clicking the object collection in the Settings tree and clicking Edit Feature Settings.

At the object level, this dialog box also contains object-specific settings, such as default styles, which are listed below the General settings:

| Property | Value | Override | Child Override | Lock |
|---|---|---|---|---|
| ⊞ 🗋 General | | | | |
| ⊞ 🗋 Labeling | | | | |
| ⊞ 🖫 Default Styles | | | | |
| ⊞ 🗋 Unitless | | | | |
| ⊞ 🗋 Distance | | | | |

**Command-Level Settings**

Use the Commands collection level in the Settings tree to override both the object-level settings and drawing ambient settings on a command-by-command basis. You can also specify command-specific settings.

Access the command-level settings by expanding the Commands collection for an object type in the Settings tree, right-clicking the command, and clicking Edit Command Settings.

At the command level, this dialog box also contains command-specific settings, such as the Parcels and Alignments settings that are used by the CreateSite command.

| Property | Value | Override | Chi |
|---|---|---|---|
| ⊞ 🗋 General | | | |
| ⊞ 🗋 Labeling | | | |
| ⊞ 🖫 Default Styles | | | |
| ⊞ 🗹 Parcels | | | |
| ⊞ 🗹 Alignment | | | |
| ⊞ 🗹 FeatureLine | | | |
| ⊞ 🗋 Unitless | | | |

The following summarizes the controls in the Edit Settings dialog box:

■ Use the + or – boxes to display or hide the settings in the category.

■ Use the Value column to specify a value for a setting.

■ The Override column indicates that the default value has been changed for the setting.

■ The Child Override column indicates whether the setting has been overridden at a lower level in the Settings tree.

■ Use the Lock column to control whether a setting can be changed at a lower level in the Settings tree.

For more information, see .

# Specifying Drawing Settings

Drawing Settings are the most generic settings. All commands use the drawing settings unless there is a specific override at the feature or command level.

# Specifying Units and Zone Settings

Using the Units and Zone tab of the Drawing Settings dialog box, you can select linear and angular units, a coordinate system, and scale for the drawing.

**Coordinate Systems**

Coordinates in AutoCAD Civil are expressed using northings and eastings.

The AutoCAD Civil coordinate system is always relative to the AutoCAD World Coordinate System (WCS). Northing is equivalent to AutoCAD *Y* and Easting is equivalent to AutoCAD *X*.

AutoCAD Civil object data is always presented in AutoCAD World Coordinate System coordinates. For example, the alignment data in the Alignment Entities vista in the Panorama window is listed in world coordinates. In addition, the AutoCAD Civil transparent commands are based on the AutoCAD World Coordinate System. However, when you create an object and have an AutoCAD User Coordinate System (UCS) defined, the UCS is honored when you specify locations, which means that an insertion point or a coordinate is interpreted relative to the UCS.

AutoCAD Civil objects are not aligned with the UCS. For example, labels can be oriented relative either to the current view, the World Coordinate System, or the labeled object, depending on the Orientation Reference setting, but they cannot be oriented to the UCS.

Similarly, objects, such as profiles, sections, and tables, cannot be oriented to the current UCS.

For more information about AutoCAD World Coordinate Systems and AutoCAD User Coordinate Systems, see the AutoCAD Help.

**To specify Units and Zone settings**

1 In Toolspace, on the Settings tab, right-click the drawing name at the top of the collection, and click Edit Drawing Settings.

2 In the Drawing Settings dialog box, click the Units and Zone tab (page 1851).

3 Under Drawing Units, select either Feet or Meters.

4 Under Angular Units, select an angle format.

5 Specify one of the following for the Imperial to Metric Conversion.
   ■ International Foot (1 foot = 0.3048 Meters)
   ■ US Survey Foot (39.37 Inches per Meter)

6 Select the Scale Objects Inserted From Other Drawings check box to scale objects inserted from another drawing to match drawing units in the current drawing.

7 Select the Set AutoCAD Variables To Match check box to synchronize AutoCAD settings with AutoCAD Civil settings. If there are no equivalent AutoCAD settings, a message is displayed asking if you want to match as closely as possible. The AutoCAD settings that are synchronized to theAutoCAD Civil settings include the AUNITS, DIMAUNIT, INSUNITS, and MEASUREMENT AutoCAD system variables (sysvars).

8 Under Scale, select the intended plot scale in imperial or metric units.

9 Under Custom Scale select the plotted size of various annotation-related components, such as label text, ticks, and band heights. If you change the scale, all annotation objects adjust accordingly.

10 Under Zone, select a category from the Categories list.

   Categories include Lat/Longs, US states, and so on. When you select a category, the Available Coordinate Systems list displays all the defined zones in that category.

   **TIP** If you know the coordinate system (CS) code for a zone, you can enter it in the CS Code text box and click OK to select the zone.

11 Click OK.

**Quick Reference**

Dialog Box

Drawing Settings (page 1851)

# Specifying Transformation Settings

Using the Transformation tab of the Drawing Settings dialog box, you can relate the local northing and local easting coordinates of your drawing to the grid northing and grid easting coordinates for the current zone.

The zone transformation settings do the following:

■ Relate local coordinates to grid coordinates by transforming distances measured on the Earth (or geoid) to distances on an ellipsoid.

■ Relate distances on the ellipsoid to the flat plane (projection) of the current zone's grid coordinate system.

These transformations are accomplished through the use of scaling factors. First, a sea level scale factor is applied to the local values measured on the geoid, and then a grid scale factor is applied, which relates the ellipsoid values to the grid projection. The scaling factors can be defined in two ways:

■ The sea level scale factor relates the distances on the geoid to the distances on the ellipsoid.

■ The grid scale factor relates the distances on the ellipsoid to the distances on the grid projection.

You must also specify reference points in establishing transformation settings.

These reference points are the two points that tie the local and grid coordinates together. The reference points can be defined in two ways:

■ By the grid and local coordinates of two known reference points in your drawing.

■ By the grid and local coordinates of one known point and a known rotation to grid north.

**To specify transformation settings for a drawing**

1   In Toolspace, on the Settings tab, right-click the drawing name  at the top of the collection, and click Edit Drawing Settings.

2   In the Drawing Settings dialog box, click the Transformation tab (page 1852).

   **IMPORTANT** You must specify the coordinate system on the Units and Zone tab (page 63) before you can specify settings on the Transformation tab.

3   Select the Apply Transform Settings check box to activate all the controls in the dialog box. Enter values as specified in steps 4-10. If you clear this check box, then controls in the dialog box are disabled and the AutoCAD X and Y coordinates match the coordinates in the specified zone.

4   Select Apply Sea Level Scale Factor.

> **TIP** If you know the combined scale factor, then you can clear the Apply Sea Level Scale Factor check box, select User Defined as the Grid Scale Factor, and enter a combined scale factor in the Grid Scale Factor box. The combined scale factor is the combination of the scale factor for converting local to sea level and the scale factor for converting sea level to grid.

**5** Enter a default Elevation, such as the average elevation of your project site from sea level.

**6** Optionally, change the Spheroid Radius, which is the radius of a mathematical figure close to the shape of the Earth at sea level, approximately 6,370 km. The value shown in this box is initially derived from the current zone's ellipsoid and can be changed if local observations differ. In most cases, the default value shown is the accepted value.

**7** For the Grid Scale Factor, select a method for Computation. For more information, see Transformation tab (page 1852).

**8** Specify the Reference Point values. The reference point could be a benchmark that was used in a survey. It can be any point for which you know both the local coordinates and the grid coordinates. To specify the Reference Point values, do one of the following:

- Click the Select Point button and then select a point in the drawing, or use Transparent commands.

- Enter a point number.

- Enter the point's Grid Northing and Grid Easting values.

**9** To define the rotation angle for the transformation, do one of the following:
- Click the Select Point button and then select a point in the drawing.

- Enter a point number.

- Enter the point's Grid Northing and Grid Easting values.

**10** Specify the grid rotation angle.

**11** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click the drawing name  ➤ Edit Drawing Settings

Dialog Box

Drawing Settings (page 1851)

## Specifying Object Layer Settings

Use the Object Layers tab of the Drawing Settings dialog box to preset default object layers.

For more information about object layers, see Layers (page 58).

**To specify object layer settings for a drawing**

**1** In Toolspace, on the Settings tab, right-click the drawing name  at the top of the collection, and click Edit Drawing Settings.

**2** In the Drawing Settings dialog box, click the Object Layers tab (page 1854).

**3** For each object type, click in the Layer column to display the Select Layer dialog box.

**4** In the Select Layer (page 1986) dialog box, select the layer for that object type and click OK.

**5** To add a modifier to the layer name, select Prefix or Suffix in the Modifier column and then enter the text string for the modifier in the Value column.

> **TIP** To include the object name in the layer prefix or suffix, enter an asterisk in the Value column.

**6** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click the drawing name  ➤ Edit Drawing Settings

Dialog Box

Drawing Settings (page 1851)

## Specifying Abbreviation Settings

Use the Abbreviations tab of the Drawing Settings dialog box to change the abbreviations used for the labels.

The Abbreviations tab controls various default abbreviations used in drawing labels and reports. For example, the default abbreviation for Spiral-Tangent Intersect is TS, meaning any spiral-tangent intersections in a drawing are labeled TS. If you need spiral-tangent intersection labels to be more detailed or different, you can change the abbreviation by clicking in the value column and changing the TS value.

In the Alignment Geometry Point Entity Data section the values also contain format strings that describe entity properties that will display in the label. For more information see, Property Field Modifiers (page 1509).

**To specify abbreviation settings for a drawing**

**1** In Toolspace, on the Settings tab, right-click the drawing name  at the top of the collection, and click Edit Drawing Settings.

**2** In the Drawing Settings dialog box, click the Abbreviations tab (page 1855).

**3** Specify the abbreviations for the properties by modifying the entries in the Value column.

> **NOTE** For individual abbreviation definitions, see the Glossary (page 2467).

**4** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click the drawing name  ➤ Edit Drawing Settings

Dialog Box

Drawing Settings (page 1851)

## Specifying Ambient Settings

Using the Ambient Settings tab of the Drawing Settings dialog box, you can specify default ambient (background) settings for a variety of features, including some that affect units of measurement.

These settings control parameters such as angle, area, direction, elevation, and so on. There are also settings that affect the Event Viewer, tooltips, and how curb returns are created for intersections.

**To specify ambient settings for a drawing**

1  In Toolspace, on the Settings tab, right-click the drawing name ▭ at the top of the collection, and click Edit Drawing Settings.

2  In the Drawing Settings dialog box, click the Ambient Settings tab (page 1856).

3  In the Property column, select a parameter in one of the categories.

   As you select a parameter, the description in the lower part of the dialog box reflects the selection.

4  Change the settings in the Value column.

5  Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click the drawing name ▭ ➤ Edit Drawing Settings

Dialog Box

Drawing Settings (page 1851)

# Specifying Feature-Level Settings

Specify object-specific settings and override drawing ambient settings at the object (feature) collection level of the Settings tree.

**To specify feature-level settings**

1  In Toolspace, on the Settings tab, right-click the object collection and click Edit Feature Settings.

2  To change an object-specific setting, do the following in the Edit Settings (page 1809) dialog box:
   ■  Expand the category that contains the setting.

   ■  Click the cell in the Value column. Enter the value or select a value from the list.

3  To override a drawing ambient setting, do the following:
   ■  Expand the category that contains the setting.

   ■  Click the cell in the Value column. Enter the value or select a value from the list.

   After you change the value, the check box in the Override column is automatically selected, indicating that the drawing ambient setting is overridden.

4  Click OK.

**Quick Reference**

Toolspace Shortcut Menu

Settings tab: right-click object collection ➤ Edit Feature Settings

Dialog Box

Edit Feature Settings (page 1809)

# Specifying Command-Level Settings

Override the object-level settings or the drawing ambient settings for a specific command at the command level of the Settings tree.

**To specify command level settings**

1 In Toolspace, on the Settings tab, expand the Commands collection that contains the command whose settings you want to edit.

2 Right-click the command name and click Edit Command Settings.

3 To change a command-specific setting, do the following in the Edit Settings (page 1809) dialog box:
   ■ Expand the category that contains the setting.

   ■ Click the cell in the Value column. Enter the value or select a value from the list.

4 To override object-specific settings, including drawing ambient settings, do the following:
   ■ Expand the category that contains the setting.

   ■ Click the cell in the Value column. Enter the value or select a value from the list.
   After you change the value, the check box in the Override column is automatically selected, indicating that an object-level setting is overridden.

5 Click OK.

**Quick Reference**

# The User Interface

# 5

The AutoCAD Civil user interface enhances the standard AutoCAD environment with additional tools for creating and managing civil design information.

Standard AutoCAD features, such as the command line and the design space work the same way in AutoCAD Civil as they do in AutoCAD.

## Ribbon

AutoCAD Civil commands and features are available from the ribbon.

## AutoCAD Civil Ribbon Overview

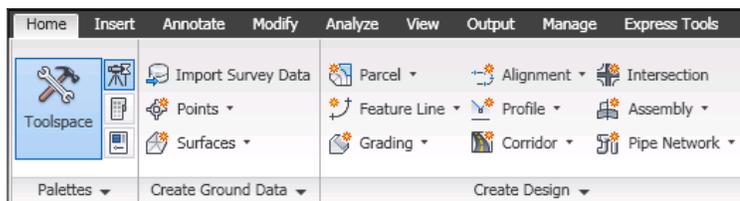
The AutoCAD Civil ribbon is the primary user interface for accessing commands and features.

Commands available from the ribbon are organized into tabs. Each tab is organized into a series of panels, which are labeled by task.

The ribbon is typically turned on (displayed) by default, and can be displayed or removed using the Ribbon and RibbonClose commands.

There are two basic types of ribbon tabs: static and contextual.

### Static Ribbon Tabs

The AutoCAD Civil static ribbon tabs include the Home, Insert, Annotate, Modify, Analyze, View, Output, and Manage tabs. Static ribbon tabs are always displayed when the ribbon is turned on, and they contain most of the functionality located on the menu bar drop-down menus and toolbars. Static ribbon tabs have a gray background color.


**Contextual Ribbon Tabs**

Contextual ribbon tabs are displayed automatically when you select an object or invoke an object-specific command. For example, when you select a pipe network object, the Pipe Network contextual tab is displayed.

Contextual tabs contain commands that are related to the currently selected object. Most contextual tabs can be closed simply be deselecting the object.

AutoCAD Civil contains the following contextual tabs:

- Alignment
- Assembly
- Cogo Point
- Corridor
- Feature Line
- Grading
- Intersection
- Label
- Mass Haul Line
- Mass Haul View
- Profile
- Profile View
- Parcel
- Plan Production
- Pipe Network
- Projected Object
- Sample Line
- Section
- Section Sheet
- Section View
- Subassembly
- Surface
- Survey
- Table

**Multiple Object Select Ribbon Tabs**

When multiple types of objects are selected simultaneously, the Multiple contextual tab is displayed in the ribbon. For example, if you select both a pipe network object and an alignment object, the Multiple contextual tab is displayed.

**Section Editor Ribbon Tab**

The Section Editor tab includes some ribbon behavior that is slightly different than the other types of contextual ribbon tabs just described. The Section Editor tab lets you perform a variety of corridor section view editing functions. You can display the Section Editor tab by clicking Corridor Section Editor on the Modify panel of the Corridor contextual tab, or by selecting View/Edit Corridor Section from the corridor object shortcut menu. This tab remains active until you click the Close button to remove it.

**NOTE** To learn more about basic ribbon functionality, see *The Ribbon* in the AutoCAD User's Guide Help.

# Contextual Tab Colors

The background color of a contextual tab depends on the type of task being performed.

### Object Select Contextual Tabs (Green)

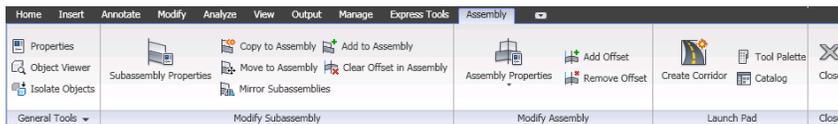
Contextual tabs that are displayed when you select an object have a green background color. For example, if you select an assembly object, the Assembly contextual tab is displayed. That tab is displayed with a green background color.

The following illustration shows the assembly object select contextual tab.

### Non-object Select Contextual Tabs (Purple)

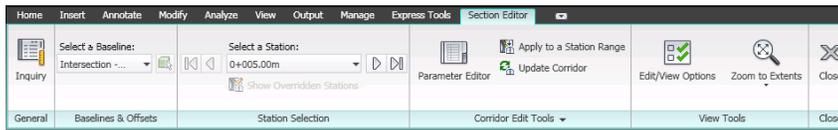
Contextual tabs that are displayed when no objects are selected have a purple background color. For example, if you click the Assembly button  on the Modify tab, the Assembly non-object select contextual tab displays, and that tab has a purple background color. This provides access to all commands related to assemblies without having to select an assembly in the drawing.

The following illustration shows an example of a contextual tab that is displayed when no objects are selected.



Non-object selection contextual tabs have a Close button at the end to dismiss them. If you select an object while this tab is displayed, the non-object selection tab is automatically closed and replaced with the object select contextual tab.

### Section Editor Tab (Blue)

Because its ribbon behavior is slightly different than the previous two types just described, the Section Editor tab has its own unique background color — light blue (teal).


## Launch Pad Panel

AutoCAD Civil contextual ribbons include a Launch Pad panel that provides access to commands that you might use next in your workflow.

For example, when you select an alignment object, the Alignment contextual tab is displayed. The Launch Pad panel on the Alignment contextual tab provides a variety of commands that you may want to do next. For example, you may want to create a corridor, intersection or data shortcut from the alignment.

Similarly, the Launch Pad on the Corridors contextual tab provides access to the variety of commands that you may want to select while you have a corridor object selected. For example, you can access the Create Sample Line command and the Create Feature Lines From Corridors command, among others, from this Launch Pad.

## Using the Where is My Command? Tool

Use the Where is My Command? tool to quickly locate AutoCAD Civil 2009 menu commands on the AutoCAD Civil 2010 ribbon.

This tool lets you look up familiar AutoCAD Civil 2009 menu commands and quickly determine where these commands now exist on the AutoCAD Civil 2010 ribbon. Access this tool from the Help drop-down menu , or click *here*.

The Where is My Command tool? contains only AutoCAD Civil 2009 menu commands. It does not identify ribbon locations for new AutoCAD Civil 2010 commands and features that did not exist in AutoCAD Civil 2009.

### Printing

It can be useful to print out some or all pages of the Where is My Command Tool? to quickly and easily reference this information any time.

To print out all of the Where is My Command? Help topics, right-click the AutoCAD Civil 2009 Menus in the left pan Contents tab, and select Print. On the Print Topics dialog box, select Print the selected heading and all subtopics.

To print out a single topic, right-click an item in the left pan, and select Print. On the Print Topics dialog box, select Print the selected topic, or place your cursor in the right pane, and select Print from the right-click shortcut menu.

### To use the Where is My Command? tool

1   In the InfoCenter toolbar located at the top right side of the application window, click the drop-down arrow next to the Help icon  .

2   Click Where is My Command?

3   In the left pane, on the Contents tab, expand AutoCAD Civil 2009 Menus.

4   In the left pane, click a menu item. For example, click Pipes to display the choices that exist on the AutoCAD Civil 2009 Pipes menu.

**5** In the right pane, look up a menu command in the Menu column, and then use the Ribbon Location column to find out where this command now exists on the ribbon.

Some AutoCAD Civil 2009 menu commands do not exist on the ribbon, but instead are available from the command line or other access method. For those commands, the Ribbon Location column lists the appropriate access method.

## Learning to Use the Ribbon

AutoCAD Civil includes several resources for learning how to use the ribbon.

Refer to the following table for links to Help topics describing ribbon functionality.

| For information about ... | See.... |
| --- | --- |
| basic ribbon functionality | *The Ribbon* in the AutoCAD User's Guide Help (User's Guide ➤ The User Interface ➤ Tools in the Application WIndow ➤ The Ribbon) |
| customizing the ribbon | *Customize The Ribbon* in the AutoCAD User's Guide Help (User's Guide ➤ The User Interface ➤ Tools in the Application WIndow ➤ The Ribbon ➤ Customize The Ribbon) |
| learning how to use the ribbon | ■ *User Interface Overview* in the AutoCAD Civil User's Guide Help (Getting Started ➤ The User Interface ➤ User Interface Overview)<br><br>■ Tutorial: Understanding the AutoCAD Civil User Interface in AutoCAD Civil Tutorials (Getting Started Tutorials ➤ Tools in the Application WIndow ➤ Understanding the AutoCAD Civil User Interface) |
| finding command locations on the ribbon | Using the Where is My Command? Tool (page 74) (User's Guide Help ➤ Getting Started ➤ The User Interface ➤ Ribbon ➤ Using the Where Is My Command? Tool) |

## Quick Access Toolbar

The Quick Access toolbar displays frequently used tools.

You can add ribbon buttons to the Quick Access toolbar, by right-clicking the button on the ribbon and then clicking Add to Quick Access toolbar. Buttons are added to the right of the default commands on the Quick Access toolbar.

For more information on the Quick Access toolbar, see *Quick Access Toolbar* in the AutoCAD User's Guide Help.

## Menus

While the ribbon is the primary access point for AutoCAD Civil commands, many commands are also available from the application menu and from shortcut menus that are displayed when you right-click an object in Toolspace or in the drawing window.

### Application Menu

The application menu provides access to file-related commands. For example, it provides commands that let you create, open, print, export, and publish a file.

Access the application menu by clicking the application menu icon at the top left of the application window  .

The application menu also provides a search tool which you can use to search for commands. Only those commands that are available in the current workspace are shown and searched. For more information, see *The Application Menu* in the AutoCAD User's Guide Help.

### Shortcut Menus

Shortcut menus are available throughout AutoCAD Civil. To display a shortcut menu, right-click your pointing device on items in the Toolspace, Panorama, or other window, or on objects in the drawing area.

### Legacy Menu Bar

The menu bar is no longer displayed across the top of the AutoCAD Civil 2010 program window by default. You can display the menu bar by clicking the drop-down arrow on the Quick Access toolbar and selecting Show Menu Bar, or by entering **menubar** at the command line. The Quick Access toolbar is located at the top-left side of the application window by default.

---

**NOTE** The legacy menu bar contains only AutoCAD Civil 2009 commands and has not been updated with new AutoCAD Civil 2010 commands and features. Therefore, if you display the menu bar, it is important to understand that it does not provide access to all AutoCAD Civil 2010 features.

---

# Workspaces

AutoCAD Civil 2010 comes with a default workspace for working with AutoCAD Civil commands. You can use this workspace as-is or modify it according to your requirements.

Workspaces are sets of user interface components, such as ribbon tabs and panels, toolbars, palettes, and menu bars, that are grouped and organized so that you can work in a custom, task-oriented drawing environment. When you select a workspace, only the user interface components specified in that workspace are displayed. You can still access other commands by entering their command names at the command line.

You can switch to another workspace by using the Workspace Switching button  , which is located in the application status bar.

Workspaces in AutoCAD Civil 2010 include:

- **Civil**: This workspace displays user interface components related to civil engineering design and survey features available in AutoCAD Civil.

- **2D Drafting & Annotation**: This workspace displays user interface components related to AutoCAD 2D drafting and annotation features available in AutoCAD Civil.

- **3D Modeling**: This workspace displays user interface components related to AutoCAD 3D modeling features available in AutoCAD Civil.

For more information about using and customizing workspaces, see the *AutoCAD User's Guide* and the *AutoCAD Customization Guide* in the AutoCAD Help.

**To set the workspace to the AutoCAD Civil default**

1 At the command line, enter **Workspace**.

**2** At the Workspace Option prompt, enter **C**.

**3** When prompted to enter the name of the workspace, enter:
**Civil**.

**To save the current menu and toolbar configuration to a new workspace**

**1** Configure your workspace. For example, you can close the Tool Palette if you do not want it to come up every time you start AutoCAD Civil.

> **NOTE** You can also use the CUI command to edit the Workspace using a dialog box interface. For more information, see *Customer User Interface Dialog Box* in the AutoCAD Command Reference.

**2** Click General menu ➤ Workspaces ➤ Save Current As.

**3** In the Save Workspace dialog box, enter a name for the new workspace. You can also select the name of an existing workspace to overwrite it with your modified configuration.

**4** Click Save.

## Quick Reference

Command Line

Workspace

# Accessing AutoCAD Civil Toolbars

AutoCAD Civil provides toolbars you can use to quickly access the transparent commands.

The two transparent command toolbars are turned on (displayed) by default when using the **Civil** workspace.

Other toolbars that were in previous versions of AutoCAD Civil are no longer available. The commands on those toolbars are now available from the ribbon.

**See also:**

- Transparent Commands (page 1581)

- *Quick Access Toolbar* in the AutoCAD User's Guide Help

**To display the AutoCAD Civil transparent command toolbars**

**1** Enter **-toolbar** at the command line.

**2** Enter **"transparent_commands"** or **"transparent_command_filters"** and then press Enter.

**3** Enter **Show**.

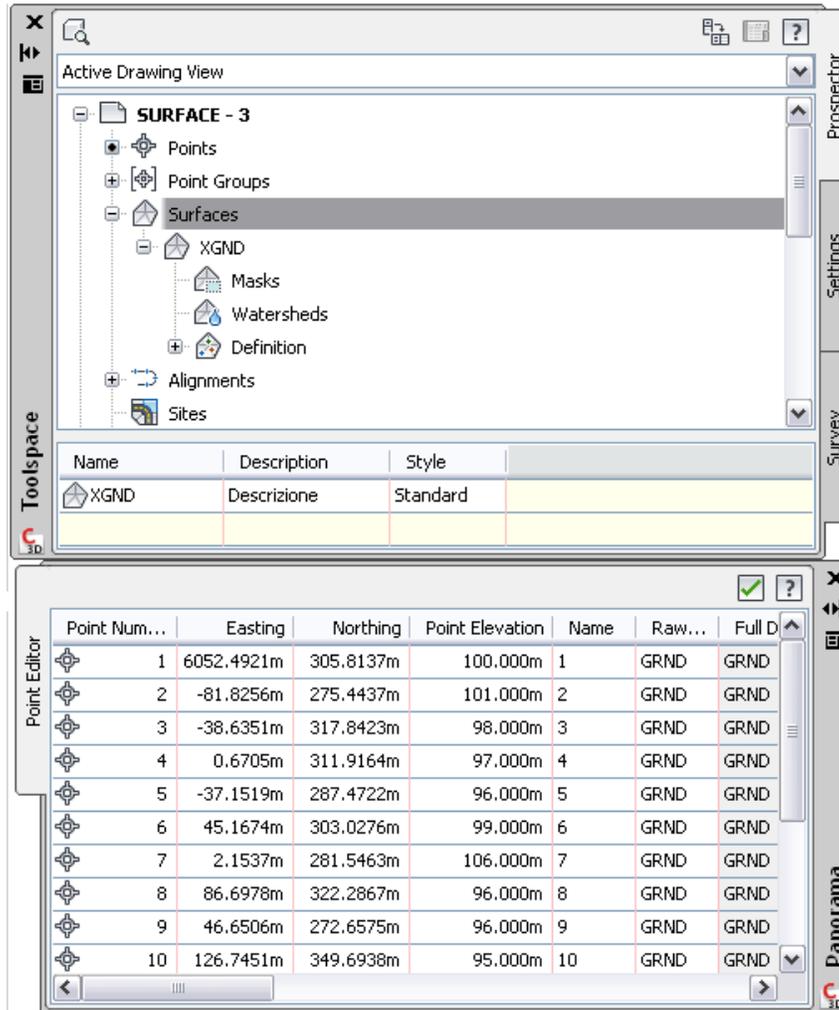
Command Line

-toolbar

# Working with AutoCAD Civil Windows

The Toolspace and the Panorama windows—the two main floating windows in AutoCAD Civil — share several features.



### Tabs

The Toolspace window always displays at least two tabs, Prospector and Settings. The Panorama window displays named tabs if you have more than one tool (vista) active in the window.

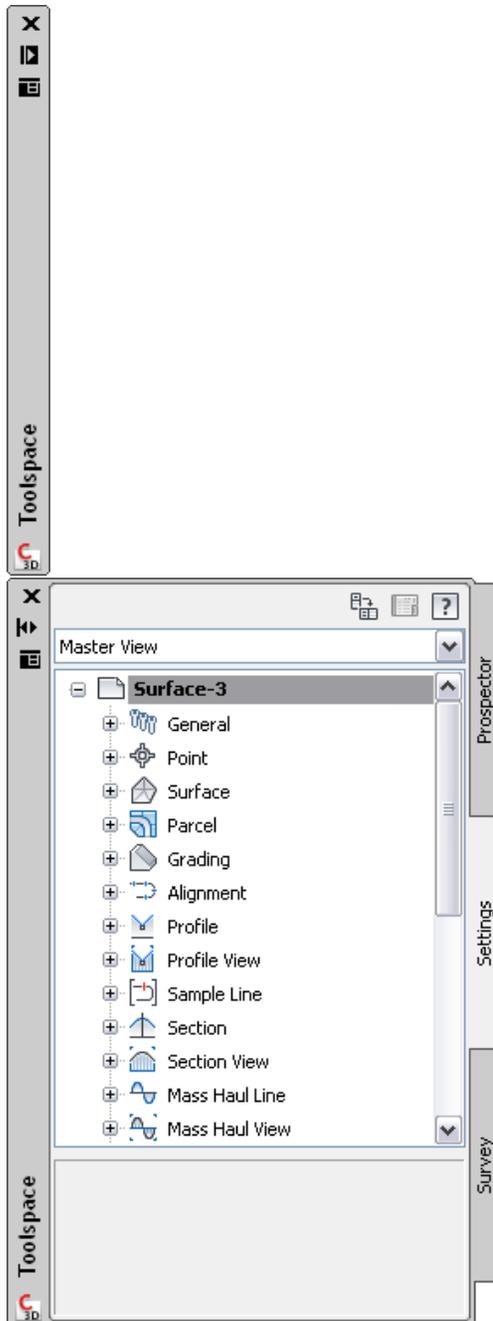
### Shortcut Menus

Right-click in the Toolspace or the Panorama window to display a shortcut menu of available commands. Right-click a single item, or select one or more items and right-click, to display a menu containing commands related to the item(s). If you right-click an area that contains no items or data, the menu contains commands related to the window.

### Auto-hide

This AutoCAD palette feature keeps the window active while maximizing the amount of available screen space. If Auto-hide is active for a window, the body of the window disappears when you move the cursor out of the window, leaving only the title bar visible. Move the cursor over the title bar to display the entire window again.

The following illustration shows the Toolspace window both closed and open, with Auto-hide active:



To activate Auto-hide for the Toolspace or the Panorama window, click  on the title bar. To deactivate Auto-hide, click  on the title bar. You can also right-click the title bar and use the shortcut menu to control Auto-hide. For more information about Auto-hide, see the AutoCAD Help.

**NOTE** Auto-hide is not available when a window is docked.

**Moving and Docking**

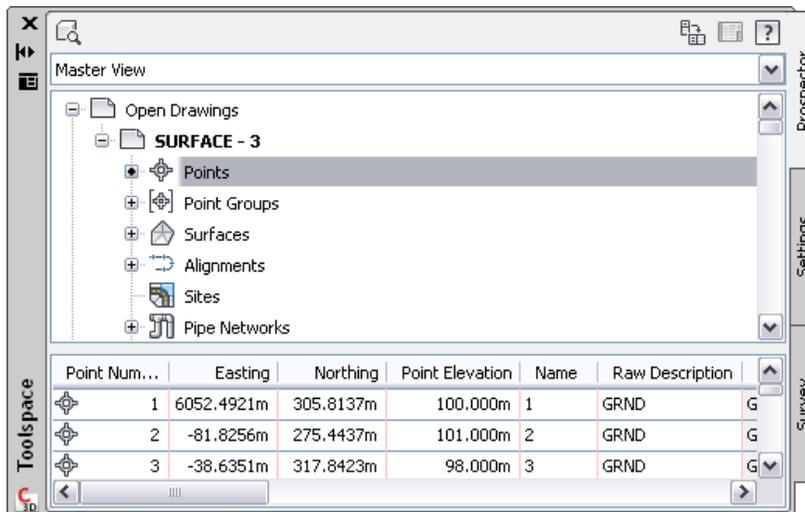
The Toolspace and the Panorama windows, like all AutoCAD palettes, can be moved and resized, and either floated in the window or docked. A docked window shares one or more edges with adjacent windows and toolbars. If a shared edge is moved, the windows change shape to compensate. To undock and relocate a window, click and drag the control bars at the top or side of the window. To prevent a window from docking while you drag it, hold down Ctrl.

**TIP** You can quickly undock a window by double-clicking the window's control bars.

For more information about working with docked and floating windows, see the AutoCAD Help.

# The Toolspace Window

The Toolspace window is an integral component in the user interface for accessing commands, styles, and data. Use it to access the Prospector, Settings, Survey, and Toolbox tabs. Right click each collection or item on these tabs to access commands.



Use the Prospector tab to manage design objects. For more information, see The Toolspace Prospector Tab (page 87).

Use the Settings tab to manage object settings, styles, and other drawing items, such as point file formats, description key sets, and grading criteria sets. For more information, see The Toolspace Settings Tab (page 90).

Use the Survey tab to manage survey projects, data, and settings. For more information, see The Toolspace Survey Tab (page 97).

Use the Toolbox tab to access reports and subscription extensions, and to add custom tools. For more information, see The Toolspace Toolbox Tab (page 100).

# Displaying the Toolspace Window

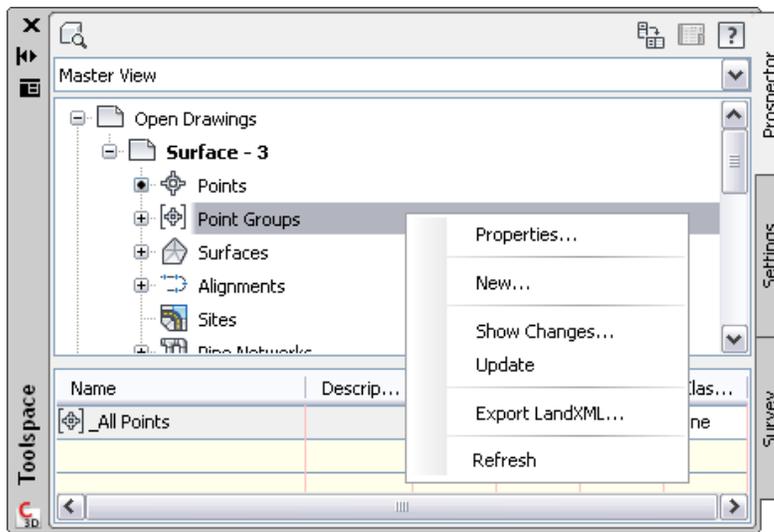
You can control whether or not the Toolspace window is visible in the AutoCAD Civil session.

| If... | Then do this... |
|-------|-----------------|
| You cannot see the Toolspace window. | Click Home tab ➤ Palettes panel ➤ Toolspace.. |

| If... | Then do this... |
|---|---|
| Only the Toolspace title bar is displayed. | Move the cursor over the title bar to display the full Toolspace window. To disable Auto-hide, right-click the Toolspace title bar and click Auto-hide to remove the check mark next to it. |
| The contents of a tab are out of date. | Right-click in the window and click Refresh. |
| You want to close the Toolspace window. | Click ✕ . |

# Functions Shared by the Prospector, Settings, and Survey Tabs

The Prospector tab, Settings tab, and Survey tab have several controls in common, including a tree structure, shortcut menus, and object icons.



**Tree Structure**

The Toolspace trees display items in a hierarchical structure. Any item that can contain other items below it in the tree is a *collection*. For example, in the illustration, Open Drawings, Points-2, and Sites are all collections. The symbol displayed at the tree *node*, to the far left of each collection name gives you information about the display of the items in the collection:

| Symbol | Meaning and Possible Action |
|---|---|
| ⊞ | The collection contains items that are not displayed. Click ⊞ to expand the tree and display the items. |
| ⊟ | The items contained in the collection are displayed. Click ⊟ to collapse the tree and hide the items. |
| ◉ | The collection contains items that cannot be displayed in the tree. Click the collection name to list the items in a Toolspace item view. For more information, see The Toolspace Item View (page 82). |

| Symbol | Meaning and Possible Action |
|---|---|
| ⧄ | The collection's data needs to be refreshed. Right-click the collection and click Refresh. |
| ↗ | The item is a reference to an item located elsewhere in the tree. Double-click the reference to navigate to the actual item. For example, this icon appears next to a drawing in the Projects node when that project drawing is open. You can then double-click the icon to move to that drawing in the Open Drawings node in the Prospector tree. |
| ⋮ | The collection contains no items. |

**Shortcut Menus**

Display a shortcut menu for any collection or item in the tree by right-clicking the item. The menu contains commands that apply to the item you selected in the tree.

**Icons**

A row of icons appears at the top of each Toolspace tab. For more information about these, see The Prospector Tab Icons (page 87), The Settings Tab Icons (page 91) and the The Survey Tab Icons (page 99).

**Tree View**

Use the drop-down list above the tree to control which items are displayed in the tree. For more information, see Controlling the Items Displayed in the Settings Tree (page 91) and Controlling the Items Displayed in the Prospector Tree (page 88).

**Item Views**

When you select items in the tree, additional information may be displayed in an item view, which is shown in a pane next to or beneath the main tree. You can adjust the size of the item view by moving the bar that separates the item view from the tree.

An item view is one of the following, depending on the item selected:

- **List view.** Displays information in a list or table. In some cases, this information can be edited.

- **Graphical view.** Displays an image of the item.

For more information, see The Toolspace Item View (page 82).

**Copying Items in the Toolspace Trees**

You can copy some items in the Toolspace trees by dragging them to another drawing or collection. For information about using this feature in the Settings tree, see Dragging Items within the Settings Tree (page 97). You can use the Prospector tree drag-and-drop feature to add drawing points to drawing point groups. For more information, see Changing Point Group Properties by Dragging Points into the Point Group (page 536).

# The Toolspace Item View

Use the Toolspace item view to display information about an item or the contents of a collection.

The item view is a secondary pane displayed beside or below the tree. To display the item view, click the item name.

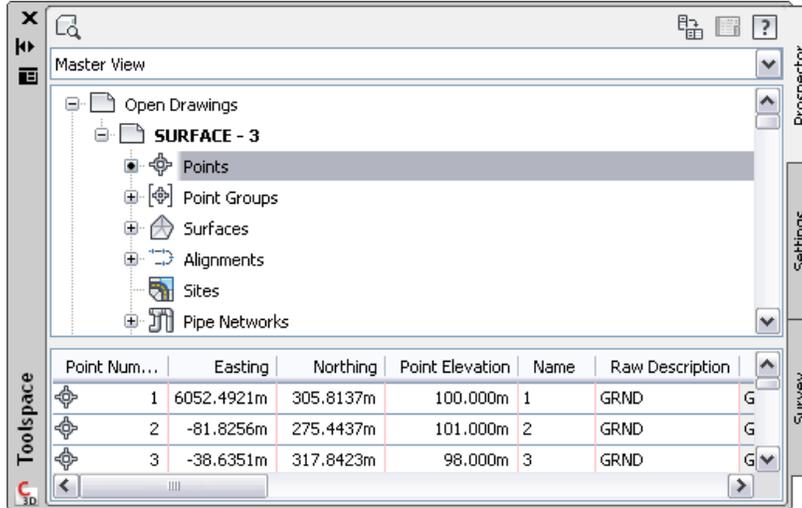
When the Toolspace window is floating, you can change the orientation of the item view by clicking the
🗗 button at the top of the Toolspace.

**NOTE** To see the item view, you may need to increase the size of the Toolspace window or move the bar that separates the item view from the Prospector, Settings, or Survey tree. To move the bar that separates the item view from the Prospector, Settings, or Survey tree, you must first select a collection that displays an item view.

An item view takes one of the following forms, depending on the selected item:

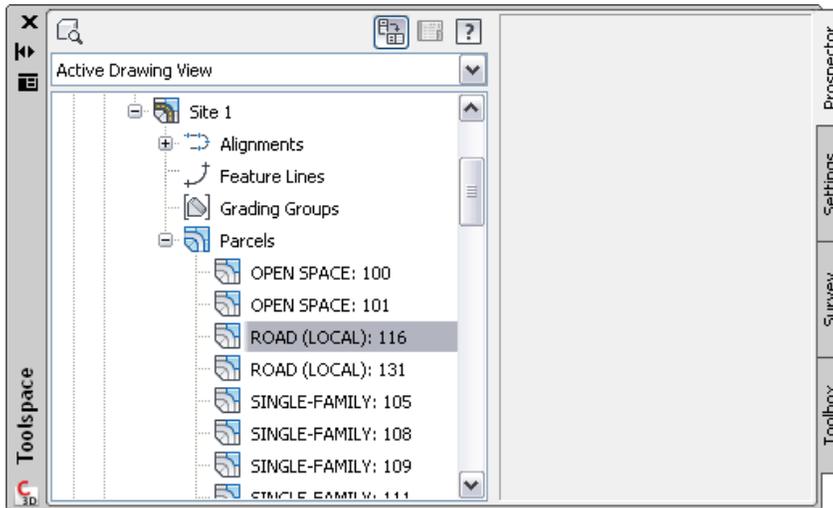
**List View**

A list view is a table displayed by the Toolspace trees for some items. In some cases, this information can be edited. The following illustration shows a Prospector list view of points:



When the Toolspace is docked, the list view is displayed below the data tree. When the Toolspace is undocked, you can display the item view either below the data tree or to one side of the data tree by clicking the item view orientation button 🗗 .

**Graphical View**

A graphical view displays an image of the selected item. The following illustration shows a Prospector graphical view of a parcel.


Right-click in the graphical preview to display a shortcut menu that allows you to manipulate the image using commands such as Pan and Zoom.

Not all items on the Prospector and Settings, or Survey trees have item views associated with them.

## Selecting Items in a List View

You can select one or more items in a Toolspace list view.

To work with an item in the list view, you must first select it in the list view by clicking the icon at the far left of the row. If you click within the row, you might select one cell but not the entire item.

**NOTE** You can quickly scroll to the top of the list view by selecting an item, holding down Ctrl and pressing Home. Scroll to the bottom of the list view by holding down Ctrl and pressing End.

**To select items in a list view**

1   In Toolspace, on the Prospector, Settings, or Survey tab, click an item that displays a list view.

    **NOTE** Some items do not have list views associated with them.

2   In the list view, click the icon at the left of the row that contains the first item you want to select.

3   Do one of the following:

    ■ To select additional contiguous items, hold down Shift and click the row containing the last item you want to select.

    ■ To select additional non-contiguous items, hold down Ctrl and click the items you want to select.

    ■ To select every item from the current item to the beginning of the list, hold down Shift and press Home.

    ■ To select every item from the current item to the end of the list, hold down Shift and press End.

## Customizing a List View

You can change the appearance of a list view by hiding columns, changing column positions, and changing column widths.

Right-click any column heading in the list view to display a shortcut menu that shows all the available columns. Checkmarks indicate which columns are currently displayed in the list view.

The value in a shaded column cannot be edited. If a displayed column is not in use, it contains a hatch pattern instead of data.

**To customize a list view**

**1**  In Toolspace, on the Prospector, Settings, or Survey tab, click an item that displays a list view.

> **NOTE** Some items do not have list views associated with them.

**2**  To show the names of all the columns that can be included in the list view, right-click any column heading.
Check marks indicate which columns are currently displayed in the list view.

**3**  To show all the columns in the list view, click Show All Columns.

**4**  To hide a column, do one of the following:
   ■  Right-click the column heading of the column you wish to hide and click Hide Column.

   ■  Right-click any column heading to display the column heading shortcut menu, and clear the check mark from the column you want to hide.

   The list view is displayed without the column.

**5**  To show a hidden column, right-click over any column heading to display the column heading shortcut menu, and select the column you want to show.

**6**  To change the position of a column in the list view, drag the column heading right or left.

**7**  To adjust the width of a column, move the cursor to the margin of the column heading until it changes to ✛ . Drag the column margin right or left.

## Changing the Contents of a Column in a List View

Use the column heading menu to change all the cells in a list view column to the same value.

For example, you can assign the same elevation to all the points in a list view.

**To change the contents of a column in a list view**

**1**  In Toolspace, on the Prospector, Settings, or Survey tab, click an item to display its list view.

> **NOTE** Some items do not have list views associated with them.

**2**  If any items in the list view are selected, press Esc to clear the selection.

**3**  Right-click the column heading of the column you want to change and click Edit.

**4**  In the edit box that is activated, enter the new value and press Enter.

## The List View Shortcut Menu

Right-click in a list view to display a shortcut menu.

Some commands apply only to items that you must select in the list view before right-clicking to display the menu. For more information, see Selecting Items in a List View (page 84).

The list view menu contains commands that apply to the selected items, plus the following standard commands if they are applicable:

| Select this menu item... | If you want to do this.... |
| --- | --- |
| Zoom To | (Drawing items only) Zoom the drawing to the selected item or items in the list view. |
| Pan To | (Drawing items only) Pan the drawing to the selected item or items in the list view. |
| Line Shading | Display the list view with a shading guide every three rows. |
| Copy To Clipboard | Copy a tab-delimited copy of the selected information to the clipboard so that you can paste it into a document for printing or editing. For more information, see Copying Items from a List View (page 86). |
| Copy Value To Clip-board | Copy the contents of the specific value in the cell. This command copies the contents of a selected cell as a raw text (floating point) value. For example, if you use this command to copy station data displayed as 2+00.00 in the list view, the value is copied to the clipboard as 200.00. |

## Copying Items from a List View

Use the Copy To Clipboard or Copy Value To Clipboard commands on the list view shortcut menu to copy the contents of an item view or single cell value to a file for editing or printing.

The Copy To Clipboard command copies a tab-delimited list of all the selected items in the list view, including the column headers, to the Windows clipboard. You can then paste the information into an Excel spreadsheet or a text file.

The Copy To Clipboard command copies all displayed columns, including columns without values. It does not copy hidden columns.

The Copy Value To Clipboard command copies the contents of the cell that your mouse is currently hovering over as a raw text (floating point) value.

For example, if you use this command to copy station data displayed as 2+00.00 in the list view, the value is copied to the clipboard as 200.00.

Each value is copied with the same precision used to display the value in the list view. You can change the precision of some values using the drawing and feature level settings. For more information, see Understanding Settings (page 61).

**To copy items from a list view**

1 Select the items you want to copy. For more information, see Selecting Items in a List View (page 84).

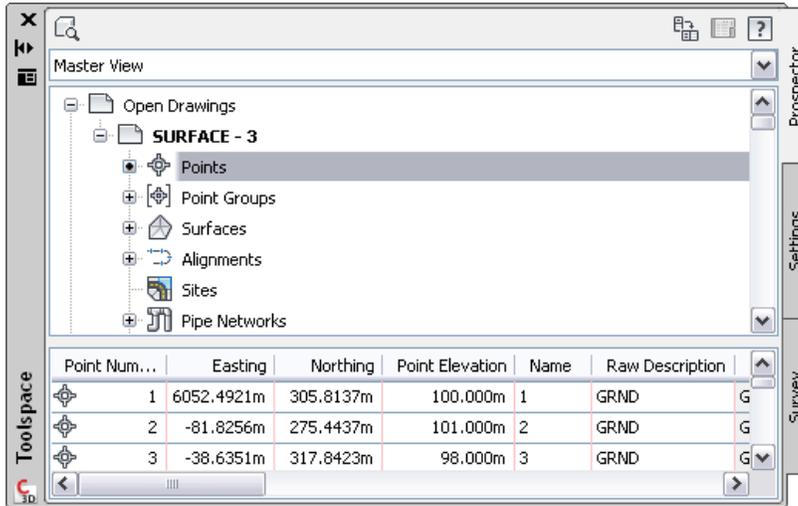
2 Right-click to display the list view shortcut menu for the selected items.

3 Click Copy To Clipboard.

4 Open a prepared Excel spreadsheet or a text file and paste the clipboard contents into the file.

# The Toolspace Prospector Tab

You can use the Prospector tab to manage project and drawing objects.



The Prospector tab is a default tab in the Toolspace window and is available if the Toolspace is displayed (page 80).

On this tab, all of the objects in a drawing or project are arranged in a hierarchy that you navigate in standard, Windows Explorer–like fashion.

**To access the Prospector tab**

■ Click Home tab ➤ Palettes panel ➤ Toolspace ⚒ .

The Prospector tab and the Settings tab share some basic functions. For more information, see Functions Shared by the Prospector, Settings, and Survey Tabs (page 81).

The Prospector tree contains the following top-level collections, which can be viewed using the Master View:

■ **Open Drawings.** For more information about this collection, see The Prospector Tree (page 88).

■ **Projects.** For more information about this collection, see Project Management (page 125).

> **NOTE** Projects lists projects available after you have logged into an Autodesk Vault server and Vault database.

■ **Drawing Templates.** For more information about this collection, see Drawing Templates (page 109).

## The Prospector Tab Icons

Use the icons at the top of the Prospector tab to control the display of icons within the Prospector tree, to display the Panorama window, and to access Help.

| Icon | Purpose |
| --- | --- |
| ⌕ | Toggles the Toolspace item preview display. Click to enable previews. When item previews are disabled, the Show Preview menu item in an item's shortcut menu is disabled. |
| ⬚ | Switches the orientation of the item and list views. Available only when the Toolspace is undocked. |

| Icon | Purpose |
|---|---|
|  | Switches the display of the Panorama window. If the Panorama window doesn't contain any active vistas, this button is not available. For more information, see The Panorama Window (page 102). |
|  | Displays Help. |

## Controlling the Items Displayed in the Prospector Tree

Use the drop-down list at the top of the Prospector tab to control which items are displayed in the Prospector tree.

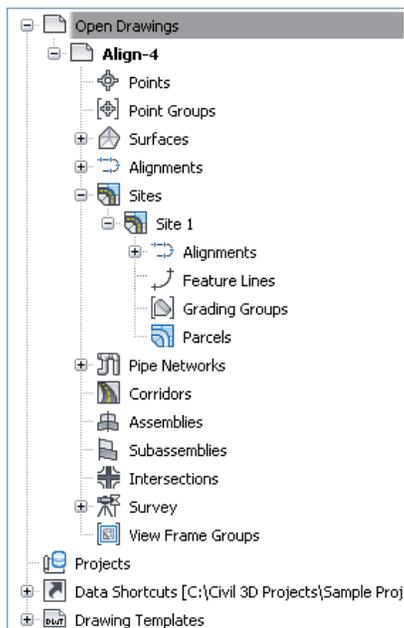
- **Master View.** Displays all project and drawing items, including drawing templates. The name of the active drawing is highlighted.

- **Active Drawing View.** Displays only items in the active drawing. If you switch to another drawing, the tree is updated to reflect the new drawing.

## The Prospector Tree

Use the Prospector tree to manage and access drawing and project objects.

The Prospector tree and the Settings tree share some basic functions. For more information about basic Toolspace tree operations, see Functions Shared by the Prospector, Settings, and Survey Tabs (page 81).

The following illustration shows an expanded Prospector tree for a drawing:


Refer to the following table for information about the drawing collections in the Prospector tree:

| For information about this item in the tree... | See.... |
| --- | --- |
| Points | Points Collection (Prospector Tab) (page 409) |
| Points Groups | Point Groups Collection (Prospector Tab) (page 522) |
| Surfaces | Surfaces Collection (Prospector Tab) (page 600) |
| Alignments | Alignment Collection (Prospector Tab) (page 856) |
| Sites | Sites Collection (page 720) |
| Pipe Networks | Pipe Networks Collection (Prospector Tab) (page 1188) |
| Corridors | Corridors Collection (Prospector Tab) (page 1330) |
| Assemblies | Assemblies Collection (Prospector Tab) (page 1379) |
| Subassemblies | Subassemblies Collection (Prospector Tab) (page 1395) |
| Intersections | Intersection Collection (Prospector Tab) (page 1426) |
| Survey | Survey Collection (Prospector Tab) (page 193) |
| View Frame Groups | View Frame Groups Collection (Prospector Tab) (page 1694) |
| Feature Lines | Feature Lines Collection (Prospector Tab) (page 733) |
| Parcels | Assemblies Collection (Prospector Tab) (page 1379) |
| Profiles | Profiles Collection (Prospector Tab) (page 1022) |
| Profile Views | Profile Views Collection (Prospector Tab) (page 1022) |
| Sample Lines | Sample Line Groups Collection (Prospector Tab) (page 1125) |
| Sections | Sections Collection (Prospector Tab) (page 1126) |
| Section Views | Section View Groups Collection (Prospector Tab) (page 1126) |
| Grading Groups | Grading Groups Collection (Prospector Tab) (page 734) |
| Data Shortcuts | Using Data Shortcuts (page 127) |

Standard shortcut menu commands are available for many Prospector tree items and collections. To display the shortcut menu, right-click a collection or item in the Prospector tree. The following commands are available on the Prospector shortcut menu whenever they are applicable to the selected item(s):

| Select this shortcut menu command... | If you want to do this.... |
| --- | --- |
| Properties | View or edit the properties of the selected item or items. |
| Edit | Edit the selected item or items. |

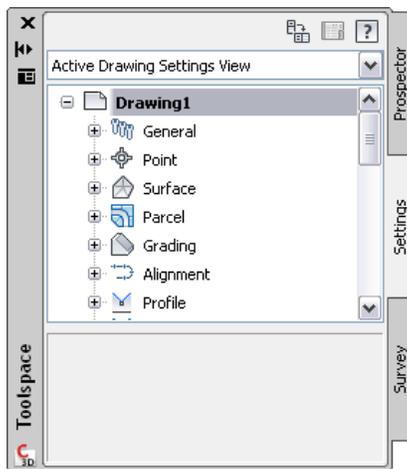
| Select this shortcut menu command... | If you want to do this.... |
|---|---|
| Delete | Delete the selected item or items. |
| Select | Selects the item or items in the drawing. |
| Zoom To | Zoom the drawing to the selected item or items contained in the collection. |
| Pan To | Pan the drawing to the selected item or items contained in the selected collection |
| Export LandXML | Export information using LandXML. |
| Refresh | Update the items displayed in the Prospector tree. |

**NOTE** Some Prospector shortcut menus do not include all the commands in the preceding table. Also, a Prospector shortcut menu can contain additional commands that are related to the selected collection or item, including project management access control commands.

The Prospector tree contains collections for projects and drawing templates. For more information, see Project and Drawing Items in the Prospector Tree (page 139).

## The Toolspace Settings Tab

You can use the Settings tab to manage styles for AutoCAD Civil objects and to control settings for drawings and commands.



The Settings tab is a default tab in the Toolspace window and is available if the Toolspace is displayed (page 80).

On this tab, styles are organized for different object types. Even in a blank drawing, most of these styles are present in a standard hierarchy. You can create and modify styles in a drawing, then save it as a template. Subsequent drawings based on the template will automatically have the same set of styles available. You can modify object, label, and table styles. You can also control settings for drawings and commands.

**To access the Settings tab**

■ Click Home tab ➤ Palettes panel ➤ Toolspace ⚒ .

The Prospector tab and the Settings tab share some basic functions. For more information about basic Toolspace tree operations, see Functions Shared by the Prospector, Settings, and Survey Tabs (page 81).

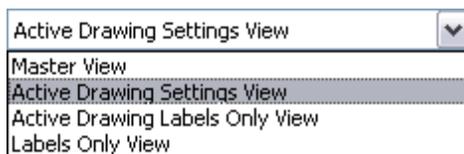
## The Settings Tab Icons

Use the icons at the top of the Settings tab to control the display of icons within the Settings tree, to display the Panorama window, and to access Help.

| Icon | Purpose |
| --- | --- |
| | Toggles the orientation of the item view when the Toolspace window is floating. For more information, see The Toolspace Item View (page 82). |
| | Switches the display of the Panorama window. If the Panorama window doesn't contain any vistas, this control is not active. For more information, see The Panorama Window (page 102). |
| | Displays Help. |

## Controlling the Items Displayed in the Settings Tree

Use the drop-down list at the top of the Settings tab to control which items are displayed in the Settings tree.

| Active Drawing Settings View |
| --- |
| Master View |
| Active Drawing Settings View |
| Active Drawing Labels Only View |
| Labels Only View |


Select one of the following tree views on the Settings tab:

■ **Master View.** Displays items for all open drawings. The name of the active drawing is shown in boldface.

■ **Active Drawing Settings View.** Displays only the items for the active drawing.

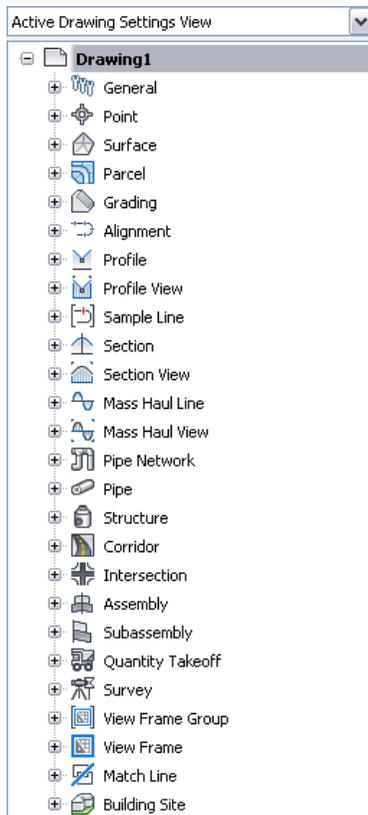
■ **Active Drawing Labels Only View.** Displays only label style collections and label styles items for the active drawing.

■ **Labels Only View.** Displays only label style collections and label style items for all drawings.

## The Settings Tree

Use the Settings tree to manage object, label, and table styles and to control settings for drawings and commands.

For more information about basic Toolspace tree operations, see Functions Shared by the Prospector, Settings, and Survey Tabs (page 81).

The following illustration shows the top-level collections in the Settings tree:


| For information about this item in the tree... | See... |
|---|---|
| General | General Collection (Settings Tree) (page 94) |
| Point | Point Collection (Settings Tab) (page 409) |
| Surface | Surface Collection (Settings Tab) (page 601) |
| Parcel | Parcel Collection (Settings Tab) (page 812) |
| Grading | Grading Collection (Settings Tab) (page 735) |
| Alignment | Alignment Collection (Settings Tab) (page 858) |
| Profile | Profile Collection (Settings Tab) (page 1022) |
| Profile View | Profile View Collection (Settings Tab) (page 1023) |
| Sample Line | Sample Line Collection (Settings Tab) (page 1127) |
| Section | Section Collection (Settings Tab) (page 1127) |
| Section View | Section View Collection (Settings Tab) (page 1128) |
| Mass Haul Line | Editing Mass Haul Line Settings (page 1178) |
| Mass Haul View | Editing Mass Haul View Settings (page 1179) |

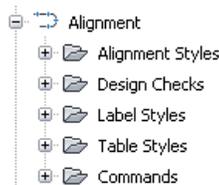
| For information about this item in the tree... | See... |
|---|---|
| Pipe Network | Pipe Network Collection (Settings Tab) (page 1188) |
| Pipe | Pipe Collection (Settings Tab) (page 1189) |
| Structure | Structure Collection (Settings Tab) (page 1189) |
| Corridor | Corridor Collection (Settings Tab) (page 1330) |
| Intersection | Intersection Collection (Settings Tab) (page 1428) |
| Assembly | Assembly Collection (Settings Tab) (page 1380) |
| Subassembly | Subassembly Collection (Settings Tab) (page 1396) |
| Quantity Takeoff | Quantity Takeoff Settings (page 1161) |
| Survey | Survey Collection (Settings Tab) (page 194) |
| View Frame Group | View Frame Group Collection (Settings Tab) (page 1694) |
| View Frame | View Frame Collection (Settings Tab) (page 1696) |
| Match Line | Match Line Collection (Settings Tab) (page 1698) |
| Building Site | Edit Feature Settings - Import Building Site (page 1793) |

Most of the object collections above conform to a standard layout and use a standard shortcut menu.

## The Object Collection (Settings Tree)

Use the object collection in the Settings tree to access object styles, settings and drawing-related information for a class of objects.

The following illustration shows an example of a Settings tree object collection:



Right-click the object collection to display a shortcut menu with the following commands:

| Select this command... | If you want to... |
|---|---|
| Edit Feature Settings | Modify the settings for all commands that pertain to the object. |
| Edit Label Style Defaults | Set default settings for all label styles belonging to the object. |
| Refresh | Update the Settings tree display. |

For detailed information about the settings, click Help in the dialog box that is displayed when you select the menu item.

## The Object Style Collection (Settings Tree)

Use an object's Styles collection in the Settings tree to manage styles for a class of objects.

The following illustration shows an example of a Settings tree object style collection:

Right-click the style collection to display a standard shortcut menu with the following commands:

| Select this command... | If you want to... |
| --- | --- |
| New | Create a new style. |
| Refresh | Update the Settings tree display. |

Right-click a style name to display a standard shortcut menu with the following commands:

| Select this command... | If you want to... |
| --- | --- |
| Edit | Change the properties of the selected style. |
| Copy | Create a new style based on an existing style. |
| Delete | Delete the selected style. This command is displayed only when the style can be deleted. |
| Refresh | Update the Settings tree display. |

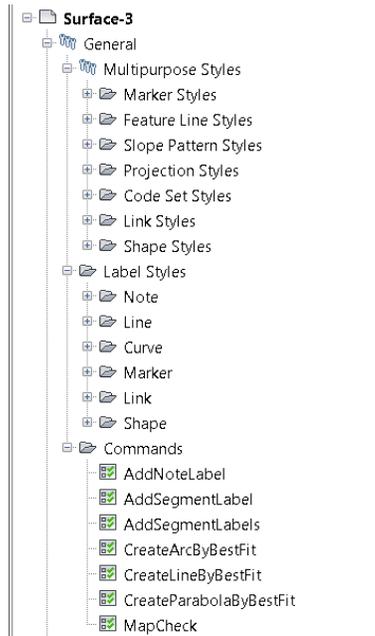
## General Collection (Settings Tree)

Use the General collection to create multipurpose and label styles that can be used by more than one object type.

Pipes and Surface objects can share the Render styles in the General Multipurpose Styles collection, while Corridors and Grading share the other styles in this folder.

The General Label Styles are used by lines, curves, feature lines, and corridors. This collection also contains Note label styles, which are not specific to an object.

The following illustration shows an illustration of the General collection:



Right-click a style name to display a shortcut menu that contains the following commands:

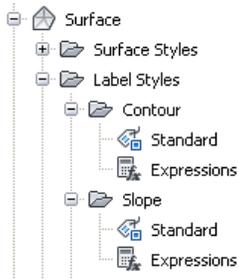
| Select this command... | If you want to... |
| --- | --- |
| Edit | Change the properties of the style. |
| Copy | Create a new style based on an existing style. |
| Delete | Delete the selected style. This command is displayed only when the style can be deleted. |
| Refresh | Update the Settings tree display. |

For detailed information about the settings, click Help in the dialog box that is displayed when you select the menu item.

## The Label Styles Collections (Settings Tree)

Use the Label Styles collections in the Settings tree to create and manage label styles and expressions for a class of objects.

Click the +/- box to expand the collection and see the label styles for the object. Some objects have multiple levels of label styles.

The following illustration shows an example of a label style collection:


Right-click a label style name to display a shortcut menu that contains the following commands:

| Select this command... | If you want to... |
| --- | --- |
| Edit | Change the properties of the label style. |
| Copy | Create a new label style based on an existing label style. |
| Delete | Delete the selected label style. This command is displayed only when the style can be deleted. |
| Refresh | Update the Settings tree display. |

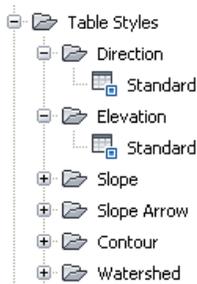
For detailed information about the settings, click Help in the dialog box that is displayed when you select the menu item.

## The Table Styles Collections (Settings Tree)

Use the Table Styles collections in the Settings tree to create and manage table styles for a class of objects.

Click the +/- box to expand the collection and see the table styles for the object. Some objects have multiple levels of table styles.

The following illustration shows an example of a Settings tree table style collection:



Right-click a table styles collection to display a shortcut menu with the following commands:

| Select this command... | If you want to... |
| --- | --- |
| New | Create a new table style. |
| Refresh | Update the Settings tree display. |

For detailed information about the settings, click Help in the dialog box that is displayed when you select the menu item.

Right-click a table style name to display a shortcut menu that contains the following commands:

| Select this command... | If you want to... |
| --- | --- |
| Edit | Change the properties of the table style. |
| New | Create a new table style. |
| Copy | Create a new table style based on an existing table style. |
| Delete | Delete the table style. This command is displayed only when the style can be deleted. |
| Refresh | Update the Settings tree display. |

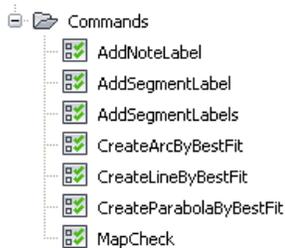
For detailed information about the settings, click Help in the dialog box that is displayed when you select the menu item.

## The Commands Collections (Settings Tree)

Use the Commands collections in the Settings tree to control the settings for a specific command at the object (feature) level.

When you change settings using the Commands collections, the changes affect a single command only. For more information, see Understanding Settings (page 61).

The following illustration shows an example of a Settings tree commands collection:



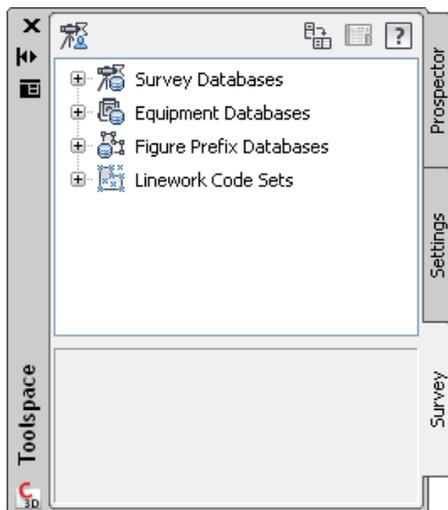
Right-click a command name and click Edit Command Settings to display the Edit Command Settings dialog box for the command. You can then change the settings.

## Dragging Items within the Settings Tree

Copy styles, description keys, and pipe rules using the Settings tree drag-and-drop capability.

For more information on dragging items within or between drawings, see Dragging Items Within or Between Drawings (page 119).

## The Toolspace Survey Tab

You can use the Survey tab to manage survey user and system settings as well as survey data.


This tab displays survey project data, organized within databases for survey projects, equipment, and figure prefixes. The project databases record the survey points, networks, and figures. The equipment databases record standard deviations and other operational parameters of individual pieces of survey equipment. The figure prefix databases record the conversion routines that are applied when creating lots, buildings, or other figures from survey points.

The contents of the Survey tab are not specific to a drawing. This tab reflects the survey data in your AutoCAD Civil Projects folder, so it facilitates access to survey data from multiple drawings.

The surveyed points and figures in a project can be converted to AutoCAD Civil points and parcels.

The Survey tab and Prospector tab share some basic functions. For more information, see Functions Shared by the Prospector, Settings, and Survey Tabs (page 81).

The Survey tab can be toggled on/off from view in the AutoCAD Civil Toolspace by clicking  Home tab ➤

Palettes panel ➤ 𝐀𝐓 Survey Toolspace.

The Survey tree provides access to survey data and settings.

## Displaying and Hiding the Survey Toolspace Tab

Use the Survey tab in the Toolspace to access and manage survey feature system settings and survey project data.

Survey data is managed on the Survey tab of Toolspace instead of on the Prospector tab like other objects.

This is a persistent setting and if you click Close, the Survey tab will not appear on the Toolspace the next time you start AutoCAD Civil.

**To display the Survey tab**

■   Click Home tab ➤ Palettes panel ➤ Survey Toolspace 𝐀𝐓

**To hide the Survey tab**

■   Click Home tab ➤ Palettes panel ➤ Survey Toolspace 𝐀𝐓

**Quick Reference**

Ribbon

Home tab ➤ Palettes panel ➤ Survey Toolspace ⛏

Command Line

OST or CST

## The Survey Tab Icons

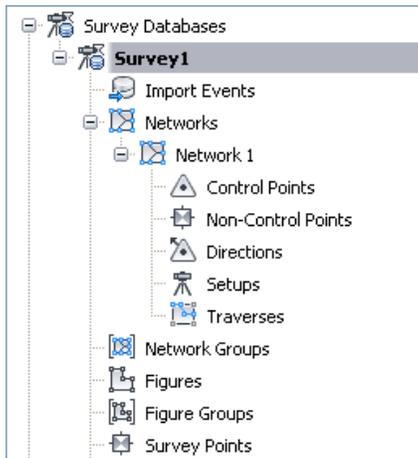
Use the icons at the top of the Survey tab to control the display of icons within the Survey tree, to display the Panorama window, and to access Help.

| Icon | Purpose |
|---|---|
| ⛏ | Displays the Survey User Settings dialog box. User settings are specific to a Windows user login account and affect the Survey feature system, not database or drawing data. |
| 🗃 | Switches the orientation of the item and list views. Available only when the Toolspace is undocked. |
| 🗐 | Switches the display of the Panorama window. If the Panorama window doesn't contain any active vistas, this control is not available. For more information, see The Panorama Window (page 102). |
| ? | Displays Help. |

## The Survey Tree

Use the Survey tree to manage and access survey settings and data.

The Survey tree and the Prospector tree share some basic functions. For more information about basic Survey tree operations, see Functions Shared by the Prospector, Settings, and Survey Tabs (page 81).

The Survey tree provides access to survey data and settings:


- **Survey Databases.** A survey database collection expands to display all the networks (page 201) (which collect the control points (page 253), non-control points (page 256), known directions (page 283), observations (page 263), setups (page 259), and traverse definitions (page 373)), figures (page 321), and survey points.

- **Equipment Databases.** Expands to display available equipment database. For more information about this collection, see Survey Equipment Database (page 199).

- **Figure Prefix Databases.** Expands to display available figure prefix databases. Figure prefix databases enable you to determine the layer that a figure is drawn on by creating a prefix for a group of figure names. For more information about this collection, see Survey Figure Prefix Database (page 200).

- **Linework Code Sets.** Expands to display available Linework Code Sets. Linework code sets are used to interpret the syntax of the field codes that are entered into the data collector by the survey field crew. For more information about this collection, see Linework Code Sets (page 230).

Standard shortcut menu commands are available for many Survey tree items and collections. To display the shortcut menu, right-click a collection or item in the Survey tree.

## The Toolspace Toolbox Tab

You can use the Toolbox tab to access the Reports Manager and subscription extensions and to add custom tools.

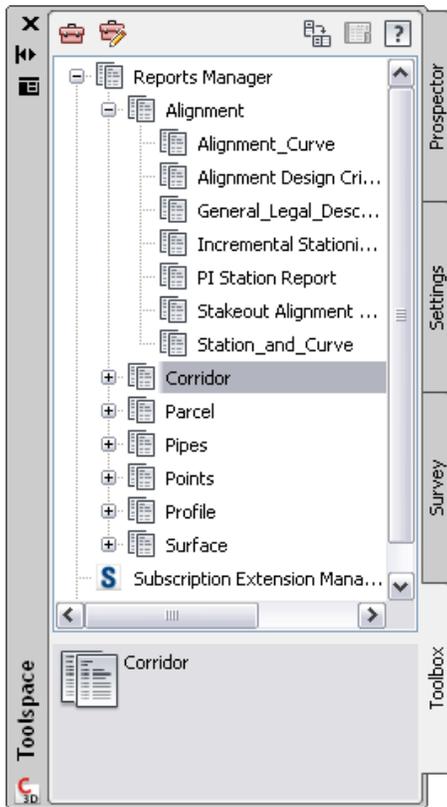
The Toolbox tab of Toolspace is the primary interface for running reports and extensions. Like the Survey tab, you can show or hide the Toolbox tab as needed.

### Reports

The Toolbox tab organizes reports for each object type. The reports provide useful engineering data from a drawing in a compact, portable format. Some are in LandXML format, with predefined or custom XSL style sheets. Other reports are .NET format, with custom dialog boxes that allow you to select the data and various options.

You can add your own reports to the Toolbox menu. These reports can be in a variety of formats, including XML, VBA, COM, or .NET.

### Subscription Extensions

When you install subscription extensions, they are added to the Subscription Extension Manager collection in the Toolbox.


**See also:**

■ Reports (page 1573)

## Displaying and Hiding the Toolbox Tab

The Toolbox can be turned on and off using the same menu command.

**To display and hide the Toolbox tab**

■ Click Home tab ➤ Palettes panel ➤ ▼ ➤ Toolbox 💼 .

## Quick Reference

Ribbon

  Home tab ➤ Palettes panel ➤ ▼ ➤ Toolbox 💼

Menu

  General menu ➤ Toolbox

Command Line

  ToolBox

## The Toolbox Tab Icons

Use the icons at the top of the Toolbox tab to edit report settings, to display the Toolbox Editor, to display the Panorama window, and to access Help.

| Icon | Purpose |
| --- | --- |
| | Opens the Edit Report Settings (page 2212) dialog box, where you can edit settings for all report types. |
| | Opens the Toolbox Editor (page 2211), where you can add custom reports. You can also add other custom tools. |
| | Switches the display of the Panorama window. If the Panorama window doesn't contain any active vistas, this control is not available. For more information, see The Panorama Window (page 102). |
| | Displays Help. |
| | Displays available report types. Expand the Reports Manager tree and double-click a report type to run it. Both LandXML and VBA reports are listed in this tree and are distinguished by their icons. |

## The Toolbox Tree

Use the Toolbox tree to access the reports available in the Reports Manager, to access Subscription Extensions, and to access other custom tools.

The following commands are available on the Toolbox shortcut menu whenever they are applicable:

| Select this shortcut menu command... | If you want to do this.... |
| --- | --- |
| Execute | Run a selected report. |
| Refresh | Update the items displayed in the Toolbox tree. |

# The Panorama Window

Use the Panorama window to display horizontally oriented data, such as point data, in a grid.

The Panorama window can display many types of data, such as the Point Editor vista and the Alignment Entities vista. To conserve screen space if more than one vista is active, the Panorama window displays a tab for each one, as shown in the following illustration.

| Point Num... | Easting | Northing | Point Elevation | Name | Raw Description | Full Description |
|---|---|---|---|---|---|---|
| 1 | 19857.2577' | 20260.4556' | 100.306' | | GRND | GRND |
| 2 | 19875.4801' | 20207.7198' | 101.093' | | GRND | GRND |
| 3 | 19887.3953' | 20692.7130' | 96.419' | | GRND | GRND |
| 4 | 19888.9069' | 21076.9713' | 95.436' | | GRND | GRND |
| 5 | 19889.7110' | 21205.2833' | 97.833' | | GRND | GRND |
| 6 | 19890.2416' | 21136.5660' | 96.612' | | GRND | GRND |
| 7 | 19891.2471' | 20986.9661' | 97.474' | | GRND | GRND |
| 8 | 19892.5010' | 20942.4705' | 97.856' | | GRND | GRND |
| 9 | 19893.3261' | 21033.2971' | 95.738' | | GRND | GRND |
| 10 | 19895.8462' | 20756.7242' | 98.217' | | GRND | GRND |

Click the tab containing a vista's name to bring it to the front of the window.

You control the display of some vistas, such as the Point Editor vista. You activate them when you want, and they remain active until you dismiss them by clicking . Other vistas, such as the Alignment Entities vista, are controlled by a specific command. This type of vista can only be activated or closed when the command is running, and its display is controlled from the command toolbar.

The active drawing controls the state of the Panorama window. When you switch between drawings, the Panorama window either becomes inactive or shows only the vistas associated with the active drawing.

You can dock the Panorama window or use Auto-hide to reduce the amount of screen space it requires. For more information, see The Toolspace Window (page 80).

## Displaying the Panorama Window

Display of the Panorama window is affected by several factors, such as the active drawing and the active vistas within that drawing.

If the Panorama window is not visible, refer to the following table for possible reasons and actions you can take to display it:

| Under these circum-stances... | Do this... |
|---|---|
| You cannot see the Panorama window or the title bar. | Click at the top of the Toolspace window. If the Panorama window contains active vistas, it is displayed. If the button is disabled, the Panorama window contains no active vistas. In some cases, you can display the Panorama window by clicking a toolbar icon. |
| The Panorama window is displayed, but the vista you want to work with is not displayed. | If the Panorama window has a tab for the vista, click the tab to display the vista. If the named tab is not visible, you must activate the vista. For instructions about activating a specific vista, refer to Help for that vista. |
| Only the Panorama title bar is displayed (Auto-hide is active). | Move the cursor over the title bar to display the full Panorama window. To disable Auto-hide, click on the Panorama title bar. |

# Layout Toolbars

Layout toolbars let you create and or edit AutoCAD Civil objects.

AutoCAD Civil has the following layout toolbars:

■ Alignment Layout Toolbar

■ Grading Creation Toolbar

■ Parcel Layout Toolbar

■ Pipe Network Layout Toolbar

■ Point Object Creation Toolbar

■ Profile Layout Toolbar

The icons or commands available on an AutoCAD Civil layout toolbar depend upon the toolbar in use.

Most AutoCAD Civil layout toolbars include the following three icons in the upper right corner:

| Icon | Purpose |
| --- | --- |
|  | Pins the toolbar, which places it in a fixed location and also shrinks the toolbar down to a small placeholder when the cursor moves outside the toolbar. To display the expanded toolbar, move the cursor over the placeholder. To unpin the toolbar, click  . |
|  | Displays Help for the layout toolbar. |
|  | Closes the layout toolbar. |

For information about the icons and commands that are available from a specific layout toolbar, refer to the following table, or click the Help button on the toolbar.

| For information on the... | see |
| --- | --- |
| Alignment Layout Toolbar | Alignment Layout Tools (page 1747) |
| Grading Object Creation Toolbar | Grading Creation Tools (page 1892) |
| Parcel Layout Toolbar | Parcel Layout Tools (page 2009) |
| Pipe Network Layout Toolbar | Network Layout Tools (page 2031) |
| Point Object Creation Toolbar | Create Points Dialog Box (page 2117) |
| Profile Layout Toolbar | Profile Layout Tools (page 2170) |

# Tool Palettes

Tool palettes provide convenient access to a variety of tools and content.

Tool palettes are a standard feature in AutoCAD. You can open tool palettes using the ToolPalettes command, or from the ribbon.

Tool palettes provide access to both AutoCAD and AutoCAD Civil tools and content. For example, the AutoCAD Civil tool palettes provide access to subassemblies and assemblies that you can use in corridor design. They also provide access to civil engineering related render materials and multi-view blocks.

The AutoCAD tool palettes provide access to items such as AutoCAD render materials, AutoCAD multi-view blocks, and AutoCAD visual styles.

You can drag and drop an item from a Tool Palette into the drawing to insert it. Any prompts that are required for inserting the item are displayed at the command line.

Tool palettes can be customized to suit your needs. For more information on working with tool palettes, see Tool Palettesin AutoCAD Help.

For information about adding render materials to a drawing from a tool palette, see Adding Materials to Drawings (page 1578).

For more information about working with the Content Browser and tool palettes, see Adding Content to a Tool Catalog in the Content Browser Help.

**To display the Tool Palettes Window and select a palette**

1   Click Home tab ➤ Palettes panel ➤ Tool Palettes Window.

2   In the Tool Palettes Window, on the title bar, click the Properties icon  .

3   From the bottom of the menu, select the tool palette to display.

**To add a subassembly or assembly to a tool palette**

1   Click Home tab ➤ Palettes panel ➤ Tool Palettes Window.

2   Switch to the tool palette you want to add the subassembly or assembly to, or create a new tool palette.

3   Click View tab ➤ Palettes panel ➤ Content Browser  .

4   In the Content Browser, locate the subassembly or assembly you want to add to a tool palette.

5   Click the i-drop icon on the subassembly or assembly.

6   Hold down your pointing device and drag the subassembly or assembly to the location in the tool palette where you want to place it.

Now you can use the procedure described in Creating a Subassembly from a Tool Palette (page 1396) to add this subassembly to a drawing. For more information about working with the Content Browser and tool palettes, see Adding Content to a Tool Catalog in the Content Browser Help.

## Quick Reference

Ribbon

Click Home tab ➤ Palettes panel ➤ Tool Palettes Window.

Menu

   Click General menu ➤ Tool Palettes Window.

Command Line

   ToolPalettes

# Content Browser

The Content Browser is a library of tool catalogs containing tools, tool palettes, and tool packages. You can publish catalogs so that multiple users have access to standard tools for projects.

Metric and imperial subassembly tool catalogs are included. You can drag and drop subassemblies from a catalog onto a tool palette for easier access.

For more information, see Understanding the Content Browser in the Content Browser Help.

**To display the Content Browser**

■   Click View tab ➤ Palettes panel ➤ Content Browser 🔳 .

### Quick Reference

Ribbon

   Click View tab ➤ Palettes panel ➤ Content Browser 🔳 .

Menu

   Click General menu ➤ Content Browser.

Command Line

   ContentBrowser

# Object Tooltips

Proximity and rollover tooltips are displayed for civil drawing objects. You can control the display of tooltips for the drawing, for an object type, or for a specific object.

■   A rollover tooltip displays information about an object when you hover the cursor directly over it. If the object highlighting setting is on, the object will be highlighted when this tooltip is displayed.

■   A proximity tooltip displays information about the current location of the cursor with respect to one or more objects in the drawing. More specifically, it displays information about the proximity of the cursor to the objects. These tooltips are displayed without having to hover the cursor over any specific entity in the drawing.

The most important object information is displayed at the beginning of the tooltip. For alignments and surfaces, the tooltip displays the station/offset information for the closest alignment to the cursor and the elevation of the topmost surface.

If you keep your cursor in the same location, additional information is displayed in an expanded tooltip that shows up to four more items. Which items are displayed depends upon the objects in the drawing and whether tooltips are enabled for that object (page 107). If there are five alignments and five surfaces in the drawing, for example, the proximity tooltip will display three alignments and three surfaces.

Alignments are shown in order of proximity to the cursor. Surfaces are shown in order from highest elevation first, to lowest elevation last.

**To control the display of tooltips for the drawing**

■ Click Application Menu ➤ Options. On the Display tab, select or clear the Show ToolTips and Show Rollover ToolTips check boxes.

> **NOTE** The Show ToolTips check box controls the display of tooltips for the ribbon and for dialog boxes, as well as proximity tooltips. The Show Rollover ToolTips check box controls the display of AutoCAD and AutoCAD Civil rollover tooltips.

**To control the display of tooltips for an object type**

1 On the Toolspace Settings tab, right-click <object> ➤ Edit Feature Settings.

2 In the Edit Feature Settings dialog box, under General, edit the Show Tooltips value.

> **NOTE** This setting can be overridden at the object level in the object properties dialog boxes.

  ■ **Yes**: Displays tooltips for all objects of the selected type by default.

  ■ **No**: Does not display tooltips for the selected object type.

3 Edit the New Entity Tooltip State.
  ■ **On**: Sets the default state of tooltips for new objects to be turned on.

  ■ **Off**: Sets the default state of tooltips for new objects to be turned off.

4 Click OK.

**To control the display of tooltips for an object**

■ In any civil object properties dialog box, on the Information tab, select or clear the Show Tooltips check box.

# User Interface Command Reference

This section provides brief descriptions of the user interface-related commands available from the command line in AutoCAD Civil.

Use the links in the following table to access more information about user interface commands available from the command line in AutoCAD Civil:

| Command | Description |
| --- | --- |
| ContentBrowser | Displays the Content Browser. |
| CST | Closes the Toolspace Survey tab (page 98). |
| DockPanorama | Docks the Panorama window (page 102). |
| DockTS | Docks the Toolspace window (page 80). |
| FloatPanorama | Changes the Panorama window from docked to floating (page 102). |

| Command | Description |
| --- | --- |
| FloatTS | Changes the Toolspace window from docked to floating (page 80). |
| HidePanorama | Hides the Panorama window (page 103). |
| HideTS | Hides the Toolspace window (page 80). |
| Menubar | Displays the legacy menu bar. (page 76) |
| OST | Opens the Toolspace Survey tab (page 98). |
| Ribbon | Displays the ribbon (page 71) |
| RibbonClose | Hides the ribbon. (page 71) |
| ShowPanorama | Displays the Panorama window (page 103). |
| ShowTS | Displays the Toolspace window (page 80). |
| ToolBox | Displays the Toolbox window (page 101). |
| ToolPalettes | Displays the Tool Palettes Window (page 104). |

# Working with Drawings

<div style="text-align: right; font-size: 3em; font-weight: bold;">6</div>

AutoCAD Civil objects are stored in drawings by default.

If you work in a multi-user environment or want to manage your drawings by having different objects in different drawings you will want to use Project Management. For more information, see Project Management (page 125).

**NOTE** AutoCAD Civil uses the standard AutoCAD drawing functionality. For more information, see the help topics.

Use the list at the top of the Prospector tab to control whether only the active drawing is listed in the prospector tree or all open drawings are listed.

## Drawing Templates

Use drawing templates to eliminate duplication of effort and to help maintain consistency across drawings.

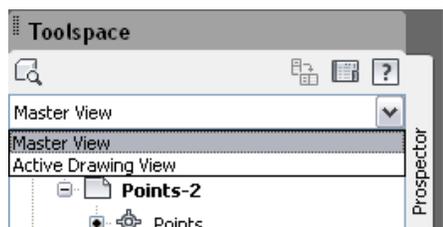
You start a new AutoCAD Civil drawing using a template file. An AutoCAD Civil drawing template can contain standard AutoCAD information, such as AutoCAD settings and layers, and AutoCAD objects, such as lines and text. In addition, it can include any AutoCAD Civil drawing information that is listed in either the Settings tree (including AutoCAD Civil settings, styles, label styles, tables, description keys, and point import/export formats) or the Prospector tree (including any AutoCAD Civil object, such as point groups).

Templates are listed under the Drawing Templates collection in the Prospector tree Master View.

The Drawing Template File Location path on the Files tab of the Options dialog box specifies where AutoCAD Civil templates are located.

**To use drawing templates**

1  In the Toolspace Prospector, click Master View from the drop-down list.



2  Expand the Drawing Templates collection and right-click a template to:
    ■  Create a new drawing based on the template.

■ Open the template.

## Out-of-the-box Templates

AutoCAD Civil drawing templates are included in the product.

The AutoCAD Civil drawing templates are based on the National CAD Standard version 3.1. The following templates are included:

■ _AutoCAD Civil 3D (Imperial) NCS

■ _AutoCAD Civil 3D (Metric) NCS

These templates contain an extended set of styles and settings.

**NOTE** These templates do not contain styles named 'Standard.' If you base a new drawing on a non-Civil 3D drawing template, such as acad.dwt, then styles named 'Standard' are created by default in the new drawing.

When you start a new drawing using the New command on the Application menu, you can choose which template you want to use.

The QNEW command, which is available on the Quick Access Toolbar, automatically uses the template specified in the AutoCAD Options dialog box. For more information, see "Select a Template When You Create a New Drawing" in AutoCAD Help.

### Drawing Template Layer Naming Conventions

The layers created in the AutoCAD Civil 2010 templates follow the National CAD Standards Rules (NCS). For more information about the National CAD Standards layering settings, see *http://www.nationalcadstandard.org*.

The layers follow the NCS standards as follows, with each element separated by a dash:

**<Discipline Designator> - <Major Group> - <Minor Group> - <Status>**

■ Discipline Designator: Required; the AutoCAD Civil templates use the C and V discipline designators, which stand for Civil and Survey/Mapping.

■ Major Group: Required; identifies elements such as roads, topographic elements, and storm sewers. To adhere to the standards, custom Major Group fields are not allowed.

■ Minor Group: Optional; identifies sub-elements such as road profiles. You can include up to two minor groups per layer name, and you can define your own custom Minor Groups. For example, the layer C-ROAD-LINE-EXTN has two Minor Groups: "Line" and "Extn".

■ Status: Optional; identifies phases of work.

For example, C-TOPO-MINR-N stands for *Civil - Topographic element - Minor Contours - New*.

### Plan Production Drawing Templates

Drawing templates for Plan Production tools are inlcuded in the Plan Prodution directory.

For information on using the Plan Production tools, see Plan Production Tools (page 1691).

## Layer Standards in Templates

Maintaining a standard for the use of layers in your drawing is easier if you have a drawing template with predefined layers, and styles that reference those layers when objects are created.

For consistency, save your template as an AutoCAD standards file (.dws format). Then, in the template, enter the STANDARDS command and in the Configure Settings dialog box, link the standards file to the template. If you want to enforce the standards, you can click the Settings button and activate notifications of standards violations, or override such violations. See AutoCAD Help for more information about the use of standards files.

For more information about layers, see Layers (page 58).

## Object and Label Styles in Templates

Consider designing styles to reflect the information requirements at different times in the project.

For example, create styles for objects in the design phase, and other styles for their final presentation. Also, you can create styles for different users of the drawings, showing object details and labels that present the data each type of user needs.

The styles for labels are another template item that should be developed with a top-down approach, similar to drawing settings and feature settings. At the drawing level, click Edit Label Style Defaults. In this context, you can set global standards such as those for text font, size, and label behavior around curves. As with the object styles, after setting label style defaults you can review the feature-level settings and apply any required overrides.

Ideally, your drawing template will have the perfect set of styles for your projects, but this usually takes some time to evolve. To assist the process, create a demonstration drawing that contains one or more surface, alignment, and other object types. Or you can explore the Sample_styles.dwg, that is supplied with AutoCAD Civil. After a default installation, you can find this file at: C:\Program Files\AutoCAD Civil 2010\Help\Civil Best Practices Guide\Sample_styles.dwg. This provides a good laboratory in which to display and develop styles. Consider designing styles to reflect the information requirements at different times in the project. For example, create styles for objects in the design phase, and other styles for their final presentation. Also, you can create styles for different users of the drawings, showing object details and labels that present the data each type of user needs.

For more information on styles, see Object Styles (page 53).

## Saving a Drawing as a Template

Create a new template from an existing drawing.

**To create a drawing template file from an existing drawing**

1   Click ![icon] ➤ Open.

2   In the Select File dialog box, select the file you want to use as a template.

3   Click OK.

4   Click ![icon] ➤ Save As.

5   In the Save Drawing As dialog box, under Files of Type, select the Drawing Template file type.

    DWT files must be saved in the current drawing file format. To create a DWT file in a previous format, save the file in the desired DWG format, and then rename the DWG file using a DWT extension.

6   In the File Name box, enter a name for the template.

7   Click Save.

**8** Enter a description of the template.

**9** Click OK.

### Quick Reference

Menu

 ➤ Save As

Command Line

SaveAs

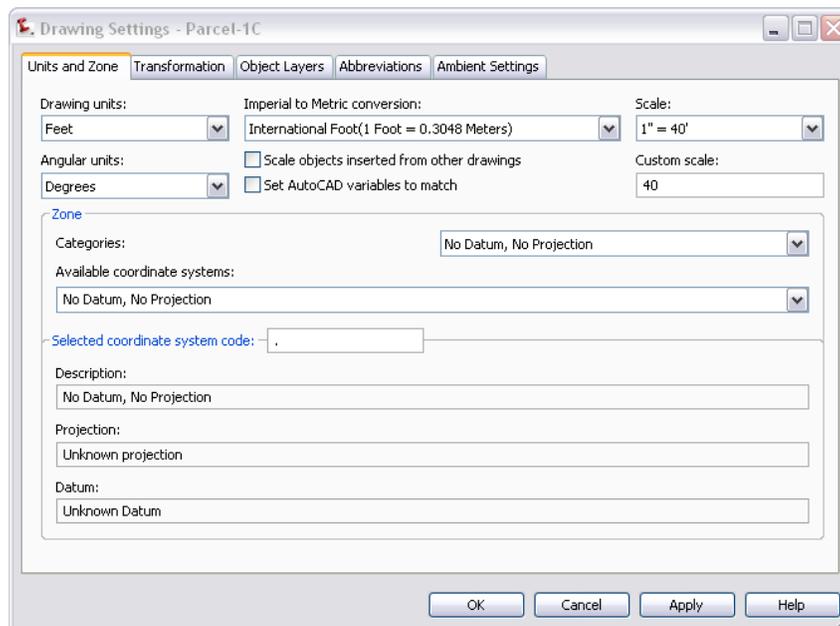
# Working with Drawing Settings

Use drawing templates to eliminate duplication of effort and to help maintain consistency across drawings.

As a basis for configuring your drawing settings, you can choose an existing template that is closest to your needs. For more information about drawing templates, see Drawing Templates (page 109).

To see the available templates, click Application Menu ➤ New. If you want some preset object styles, the templates that have names beginning with "_AutoCAD Civil 3D", are recommended.

After choosing your initial template, the next logical step is to review and edit settings. On the Toolspace Settings tab, right-click the drawing name and click Edit Drawing Settings. The Drawing Settings dialog box includes five tabs and many settings.



**Drawing Settings dialog box**

**NOTE** For detailed reference information about the Drawing Settings tabs, see

- The Units and Zones tab is used to set linear and angular units, intended plot scale, and coordinate zone for the current drawing.

- The Transformation tab provides functionality to transform the coordinate system specified on the Units And Zones tab to local specifications.

- The Object Layers tab provides a convenient table for assigning objects to layers, and creating or renaming layers. Objects on the same layer are turned on and off together if you change the layer visibility. For maximum display flexibility, spread objects and their components across several layers. The color of a layer affects all objects assigned to that layer and drawn in a style that uses the ByLayer color setting. If you set up styles this way, you can change the color of many objects by simply changing the layer color.

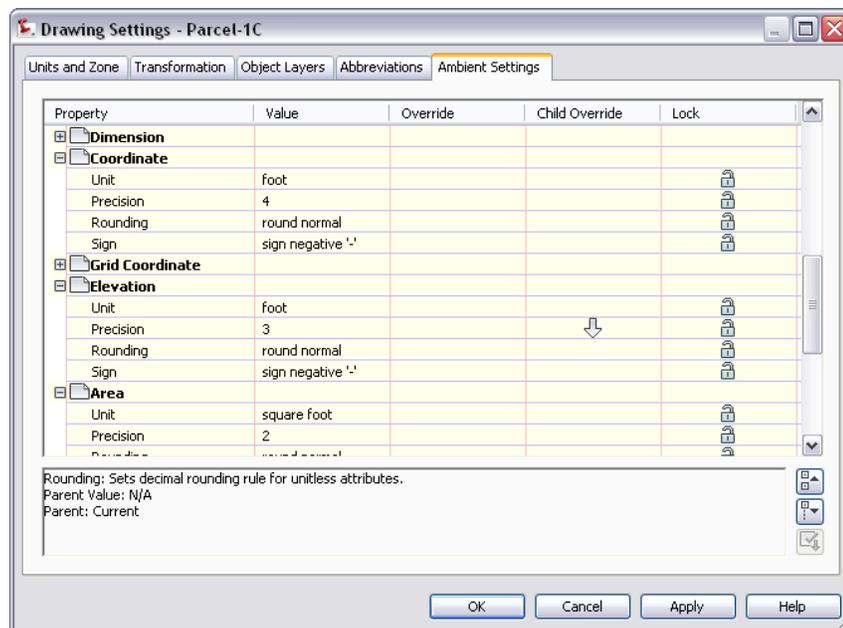
- The Abbreviations tab is a central location in which to set the abbreviations used in object labels, especially for alignment and profile geometry points.

- The Ambient Settings tab provides global default settings, such as the precision of numeric values, and the visibility of tooltips.
One setting on this tab often overlooked is the Save Command Changes To Settings under the General setting group. If you set this to Yes, then whenever you change a setting, such as the radius of an alignment curve, it is saved as the default value for next time.

  Another important setting is Independent Layer On. Set it to No if you want to be able to control object visibility by turning layers on and off.

  The ambient settings you configured at the drawing level are available at the feature level in case you want to override them.

  On the Ambient Settings tab, you see an arrow in the Child Override column next to any setting that is changed for one or more features (objects) in the drawing. You can cancel the override by clicking the arrow, and you can click the lock icon to lock any setting and prevent overrides at the feature level.



**Use Ambient Settings to cancel style overrides.**

After configuring the drawing settings, you should work down through Point, Surface, and other features in the Settings tree, right-clicking each feature and selecting Edit Feature Settings. Doing this allows you to examine the default styles for each feature and its labels, the feature name format, and other settings that you may want to modify.

For more information about AutoCAD Civil drawing settings, see Specifying Drawing Settings (page 63).

# Creating a New Drawing

Create a new drawing using standard AutoCAD commands.

**To create a new drawing**

**1** Click  ➤ New.

**2** In the Select Template dialog box, select a template on which the drawing will be based, and click Open.

## Quick Reference

Menu

 ➤ New

# Working with Drawing Data

AutoCAD Civil provides many tools and features to make it easier to work with drawing data.

For information on other AutoCAD Civil utilities, see Utilities (page 1603).

# Specifying Locations in a Drawing

When you are prompted for a location in a drawing, you can use one of several methods to specify the coordinates.

### Select an Existing Point

Use the mouse to select an AutoCAD Civil point in the active drawing.

### Specify a Location in the Drawing

Enter X, Y (and Z, if prompted) coordinates at the command line, separated by a comma. Alternatively, click a location in the drawing. You can use AutoCAD Object Snaps to select a point accurately.

### Use Civil Transparent Commands

Some of the Civil transparent commands calculate point locations from angles, distances, and drawing geometry. For more information, see Transparent Commands (page 1581).

### Use the Coordinate Tracker

You can send drawing coordinate information to the command line based on cursor location and a specified surface. For more information, see (page 1623).

# Selecting Similar Objects

Use the Select Similar command to select all objects that have the same style and that are on the same layer.

**To create a selection set of objects that have the same style and that are on the same layer**

1 Select the first object in the selection set.

2 Right-click, and click Select Similar.

### Quick Reference

　SelectSimilar

# Isolating Objects

AutoCAD Civil provides an easy-to-use feature for temporarily hiding and displaying selected objects in your drawing.

Use this operation when you want to focus on individual areas of large drawings and need to display or hide some of the objects.

Do the following:

- Create an object selection set to hide or display.

- Fine-tune the selection set by adding objects.

- Save a drawing with the visibility settings you have selected.

## Isolating Objects to Display

Isolate objects that you want to display in a drawing. This is preferable when you have a large drawing with many objects and need to display only a small number of objects.

Run the Isolate Objects command either from the shortcut menu of an object or from the AutoCAD Civil drawing window status bar.

**Isolate Objects command on the drawing window status bar**

**To isolate objects and display them in a drawing**

1　Select the objects in the drawing that you want to isolate and display.

2　Right-click, and click Isolate Objects ➤ Isolate Selected Objects.

Alternatively, you can click 💡 on the right side of the drawing window status bar, then click Isolate Objects, and select the objects you want to isolate.

When you have isolated objects in your drawing, the light bulb in the drawing window status bar turns red 💡 .

3　If you want to isolate additional objects in your selection set, select one or more isolated objects, and run the Isolate Objects command again.

Alternatively, you can click the red light bulb 💡 in the drawing window status bar and click Isolate Additional Objects.

When you end the object isolation, as described in Ending Object Isolation in a Drawing (page 118), all objects are displayed.

## Quick Reference

Ribbon

Click <object name> tab ➤ General Tools panel ➤ Isolate Objects 

Command Line

IsolateObjects

# Isolating Objects to Hide

Isolate objects that you want to hide in a drawing. This is preferable when you want to display a large number of objects and hide only a few of them.

**To isolate objects and hide them in a drawing**

1 Select the objects in the drawing that you want to hide.

2 Right-click, and click Isolate Objects ➤ Hide Selected Objects.

The objects you selected are now hidden in the drawing.

Alternatively, you can click the light bulb  in the drawing window status bar and click Hide Objects.

---

**NOTE** After isolating and hiding objects multiple times, it may be difficult to know whether any objects are hidden, or whether all objects are displayed in the drawing. When you have isolated objects in your drawing, the light bulb on the right side of the drawing window status bar is displayed in red  . When all objects are displayed and none are isolated or hidden, the light bulb is displayed in yellow  . Alternatively, to ascertain that no objects are hidden, select an object in the drawing, right-click, and click Isolate Objects. If the End Object Isolation command is unavailable, all objects are displayed. If the shortcut menu command End Object Isolation is active, there are hidden objects in the drawing. To display all objects, see Ending Object Isolation in a Drawing (page 118).

---

## Quick Reference

Ribbon

Click <object name> tab ➤ General Tools panel ➤ Hide Objects

Command Line

HideObjects

## Ending Object Isolation in a Drawing

End the object isolation in a drawing and display all hidden objects.

**To end object isolation in a drawing and display all hidden objects**

1   Select an object in the drawing.

2   Right-click and click Isolate Objects ➤ End Object Isolation.

Alternatively, click 💡 on the right side of the drawing window status bar. Click End Object Isolation.

**NOTE** If no objects have been isolated, the End Object Isolation command is unavailable and the light bulb in the drawing window status bar is displayed in yellow 💡 . In that case, no further action is necessary.

### Quick Reference

Ribbon

Click <object name> tab ➤ General Tools panel ➤ End Isolation

Command Line

UnisolateObjects

## Saving Isolated Objects

Save a drawing in which some objects are isolated for viewing while others are hidden. The next time you open the drawing, it is displayed with the isolation settings you defined.

For example, you could save a specific view setting to distribute the file to a contractor who needs to see only a specific part of the drawing. You could also save a specific view setting in a drawing that is used as an external reference within another drawing.

To save a drawing with isolated objects, create the appropriate object selection set as described in Isolating Objects to Display (page 116) and Isolating Objects to Hide (page 117). Save the drawing. The isolation settings are saved in the drawing and are displayed accordingly when you reopen the drawing.

**NOTE**  If you want to distribute a drawing with isolated objects, make sure that you and the recipient of the drawing are working with the same version of AutoCAD Civil. A recipient who is working with an earlier version of AutoCAD Civil, AutoCAD, or Object Enabler is not able to display the hidden objects. In this case, end the object isolation before saving and distributing the drawing.

## Isolating Objects in External References

When you are working with external references, you can hide and isolate objects. Consider the following points:

■   You can isolate an external reference within a host drawing as a whole by selecting it and isolating at as described in Isolating Objects to Display (page 116).

■   You can isolate individual objects within an external reference by opening the external reference, isolating and hiding objects as needed, saving the external reference drawing, and then reloading the external reference.

- You cannot isolate or hide objects in an external reference while editing it with REFEDIT in the host drawing. You need to use XOPEN and save the desired Hide/Isolate settings within the external reference.

- You cannot display hidden objects in an external reference while editing it with REFEDIT in the host drawing. You need to use XOPEN and save the desired Hide/Isolate settings within the external reference.

# Dragging Items Within or Between Drawings

Copy styles, description keys, and pipe rules using the Settings tree drag-and-drop capability.

You can drag items from the Settings tree into the drawing window to copy them, or you can drag them onto a drawing icon in the Settings tree.

### Dragging Items between Drawings or Templates

You can copy the following items by dragging them from one drawing or drawing template to another:

- Styles, including label and table styles

- Description keys

- Pipe rules

Both the item you want to copy and the name of the destination drawing must be visible in the Settings tree before you begin the drag-and-drop operation.

To drag an item from one drawing to another, click the item or collection you want to copy, hold down the left mouse button, and drag the item to the name of destination drawing in the Settings tree. When the cursor changes to     , release the mouse button to copy the item into the drawing. The item is automatically added to the correct collection in the drawing.

If the drawing already contains an item with the name of the item being copied, the Duplicate Item Name Dialog Box (page 1812) is displayed which allows you to decide how to handle the conflict.

If you drag a label style with one or more child styles from one drawing to another, only the selected style is copied into the drawing; the child styles are not copied. If you copy a child style into another drawing, the parent style is also copied.

### Dragging Items within a Drawing

You can copy label styles by dragging them from one level in a label style collection to another within a drawing, as follows:

You can drag and drop multiple styles from one drawing to another at the same time.

- Drag a child label style (and its children) up to a higher level in the style collection to sever the parent/child relationship.

- Return the child label style to its original location in the tree to reinstate the parent/child relationship.

- Drag a child label style to another label style collection. The child label style inherits the properties of the new parent.

Both the label style you want to copy and the destination location of the style must be visible in the Settings tree before you begin the drag-and-drop operation.

To drag a label style within a drawing, click the label style you want to copy, hold down the left mouse button, and drag the label style to the destination collection. When the cursor changes to ![cursor], release the mouse button to drop the style into the collection located at the tip of the cursor arrow.

When you copy a label style within a drawing, all child styles are copied with the parent style.

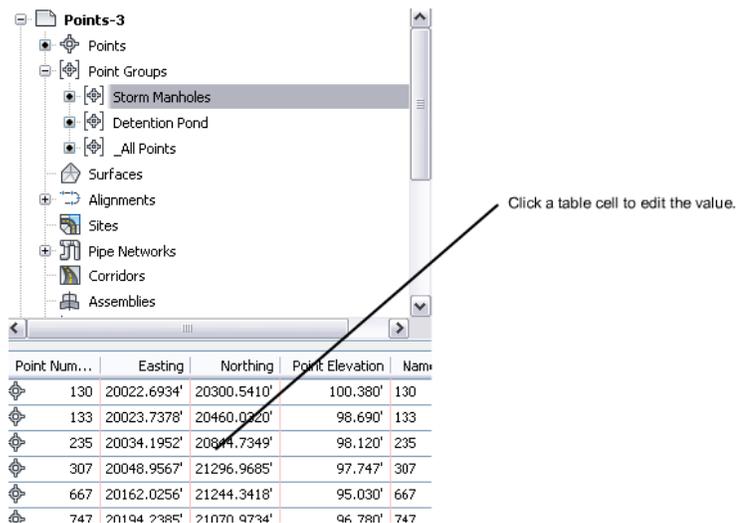
# Consistent Editing Methods

Object editing in CEV_ProdName_CEV uses an approach that is consistent for all objects. The main editing tools are described here.

## Item View

When you click an object or an object collection on the Prospector tab, for example, Points or Alignments, an item view appears. An item view can be either a list view or a graphical view, depending on the object selected.

The item view presents a table in which you can review and edit data for each object in the selected collection. For example, if you select a point group, the item view table includes a row for each point in the group.

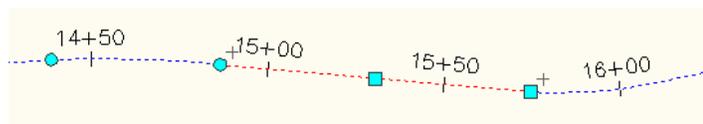


**Item view showing a group of points**

## Grips

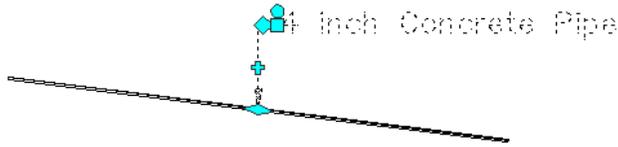
When you select an object in the drawing, grips appear on the object. You can use these grips to click and drag the object to a new location.

For example, when editing alignments, you can use grips to move points of intersection or points of line-arc tangency.



**Alignment grips for manual editing**

When you use a grip to drag a label object to a new location, a round reset grip appears. You can click this round grip to return the label to its original location. If there are multiple leader lines, click the round grip once to restore the leader to its orignal state. Click the round grip twice to restore a dragged label to its undragged state.

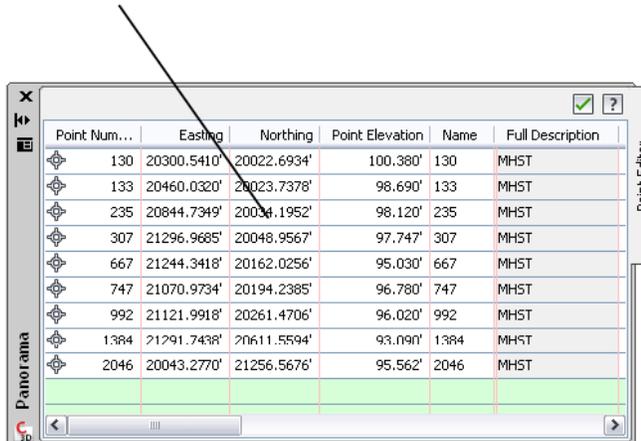


**Use round grip to to restore label leader or to reset label**

## Panorama Window

Some object types, such as alignments and profiles, use the Panorama window to display a table of entities that make up that object.

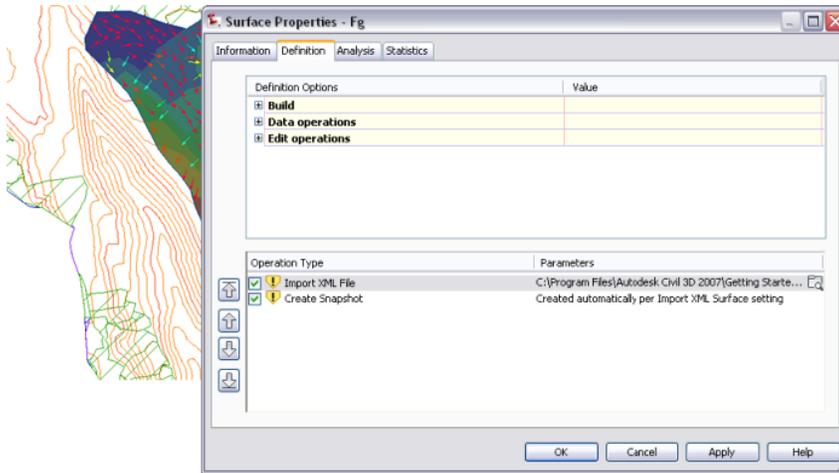
The Panorama window is a floating, dockable window that you can keep open as you work. It can include several tables, called vistas, on different tabs. Panorama data shown in black text can be edited; data shown in gray text cannot be edited.



**Panorama window showing an alignment**

## Property Editors

When you right-click any object on the Prospector tab, and then click Properties, you can view all the AutoCAD Civil properties of that object, and edit some of them.

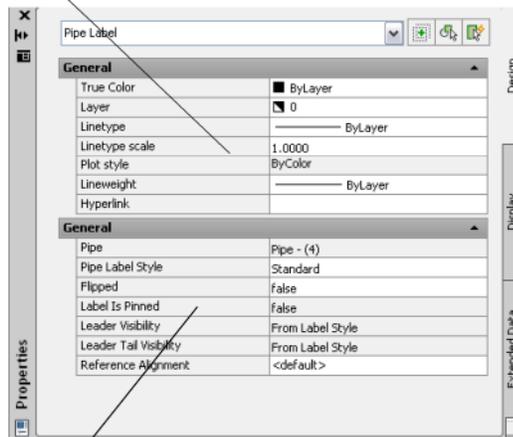
These properties typically include the styles, labels, related objects, and some structural details of the current object.


**Properties editor showing surface properties**

# AutoCAD Properties Editor

When you right-click an object in the drawing, and then click Properties, the AutoCAD Properties dialog box is displayed.

You can use this dialog box to review and edit AutoCAD properties, such as the layer on which the object is drawn. You can view the style assigned to the object, and can also change it here. You can also edit an object style on the Settings tab of Toolspace. Right-click the object style. Click Edit to open the <feature> Style dialog box.



**Editing AutoCAD properties for a pipe label**

# Tracking Stations in Alignments, Profiles, and Sections

The Station Tracker provides visual cues to help you locate the stations that match your cursor position when working with alignments, profiles and sections.

■ When the cursor is above a horizontal alignment, and one or more profile views for the same horizontal alignment are in the drawing, a temporary line is drawn in each profile view at the station defined by the orthogonal projection of the cursor onto the horizontal alignment. The temporary line is drawn to the full height of the profile view, and moves as the cursor moves.

■ When the cursor is within a profile view, a temporary line is drawn orthogonal to the horizontal alignment at the cursor's station. The line extends 200 world distance units to the left and right sides of the horizontal alignment. As the cursor's position changes in the profile view, the temporary line's position is redrawn at the new station location.

■ When the cursor is within a section view, a temporary line is drawn orthogonal to the horizontal alignment at the station of the cross-section view. The line extends 200 world distance units to the left and right sides of the horizontal alignment. Additionally, a vertical line is drawn in each associated profile view. The vertical line is drawn at the station of the section view.

This setting is controlled per drawing.

For information on the use of the similar station tracker utility in corridor section views, see Tracking Corridor Sections at Stations (page 1364).

**To display the Station Tracker in the current viewport**

➤ Click Analyze tab ➤ Inquiry panel ➤ Station Tracker drop-down ➤ Current Viewport  .

**To display the Station Tracker in all viewports**

➤ Click Analyze tab ➤ Inquiry panel ➤ Station Tracker drop-down ➤ All Viewports  .

**To turn off the display of the Station Tracker**

➤ Click Analyze tab ➤ Inquiry panel ➤ Station Tracker drop-down ➤ Off  .

## Quick Reference

Ribbon

HideDrawingTips

# Drawing Command Reference

You can use commands to quickly access drawing functionality.

The following table lists the drawing-related AutoCAD Civil commands and briefly describes their functionality.

| Command | Description |
| --- | --- |
| HideObjects | Selects objects to hide in a drawing (page 117) |
| IsolateObjects | Selects objects to display in a drawing (page 116) |
| New | Creates a new drawing (page 114) |
| Open | Opens an existing drawing (page 114) |
| SelectSimilar | Selects all objects that have the same style and that are on the same layer (page 115) |
| UnisolateObjects | Ends object isolation in a drawing and displays all hidden objects (page 118) |
| ShowDrawingTips | Displays the Station Tracker in the current viewport (page 123) |
| ShowDrawingTipsFull | Displays the Station Tracker in all viewports (page 123) |
| HideDrawingTips | Turns off the display of the Station Tracker (page 123) |

# Project Management

# 7

AutoCAD Civil offers a range of options for managing engineering projects. Once you understand these options, you can determine the best data structure for your projects.

For information on recommended workflows for project management, see the *AutoCAD Civil Workflow Guide*.

## Understanding Project Management

Depending on project complexity, your project management system can range from a few drawings in a folder to large database with shared objects and security controls.

When deciding on a structure to use for managing your projects, consider these factors:

■  The number and complexity of drawings

■  The size of the project team and number of people requiring access to the files

■  The relative need for ease of use versus data security

For more information on project management options and the decision-making process, see Project Management in the *AutoCAD Civil Best Practices Guide*.

## Object Sharing

Sharing design objects such as surfaces and alignments across drawings can provide major savings in project time lines, if done correctly.

Three main methods are available for sharing data within a project. These are also known as data reference types:

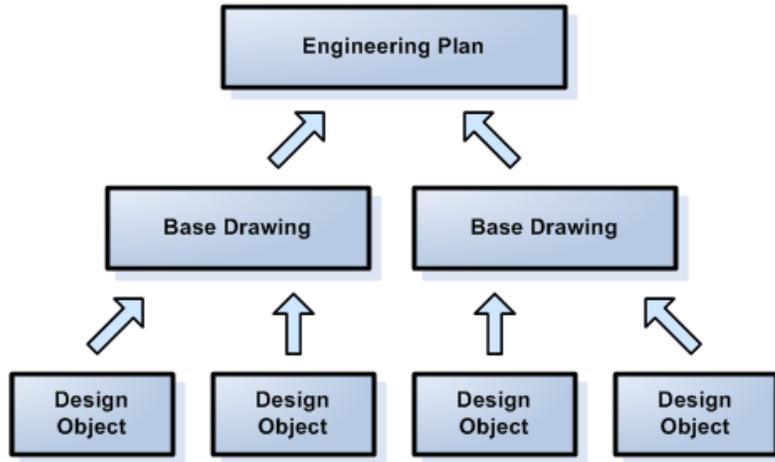
■  External references (xrefs), in which the contents of one drawing (DWG) is imported into another.

■  Data shortcuts between DWGs

■  Object references in Autodesk Vault

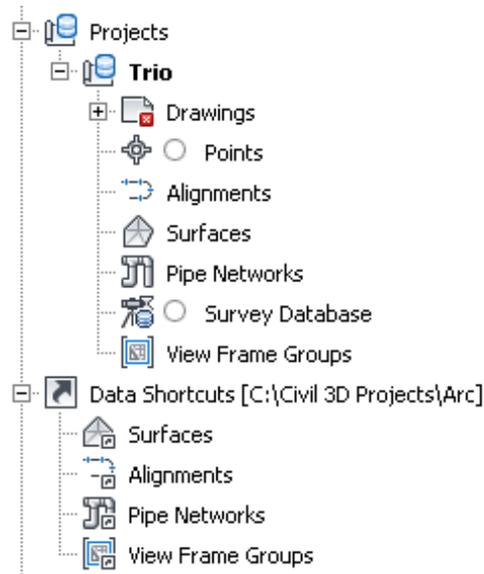
For a detailed description of each method, including advantages, limitations, and best practices, see Project Management in the *AutoCAD Civil Best Practices Guide*.

A best practice common to all project structures is to organize individual design objects such as alignments and surfaces in separate drawings. These objects are referenced into base drawings during the design process. Complete engineering plans and final production drawings are prepared with a combination of object references and drawing references.



## Project Management on the Prospector Tree

Projects can be displayed and managed from collections on the Prospector tree.



**Prospector collections for projects**

The figure shows the collections for a Vault project named Trio and a data shortcut project named Arc. Both project types are created from the default project template. As a result, they have identical collections of surfaces, alignments and other objects that can be referenced into multiple drawings.

You can store multiple projects in the same working folder. The default location of the working folder for data shortcuts projects is C:\Civil Projects, and for Vault projects is My Documents\Vault (Microsoft Windows XP), or Documents\Vault (Microsoft Vista).

Several Vault projects can be displayed in the Projects collection. In the figure, you see two projects, Trio and Vast. For data shortcut projects, you switch from one to another by changing the data shortcuts folder.

Most commands for managing projects are accessible by right-clicking specific objects in the project collections on the Prospector tree.

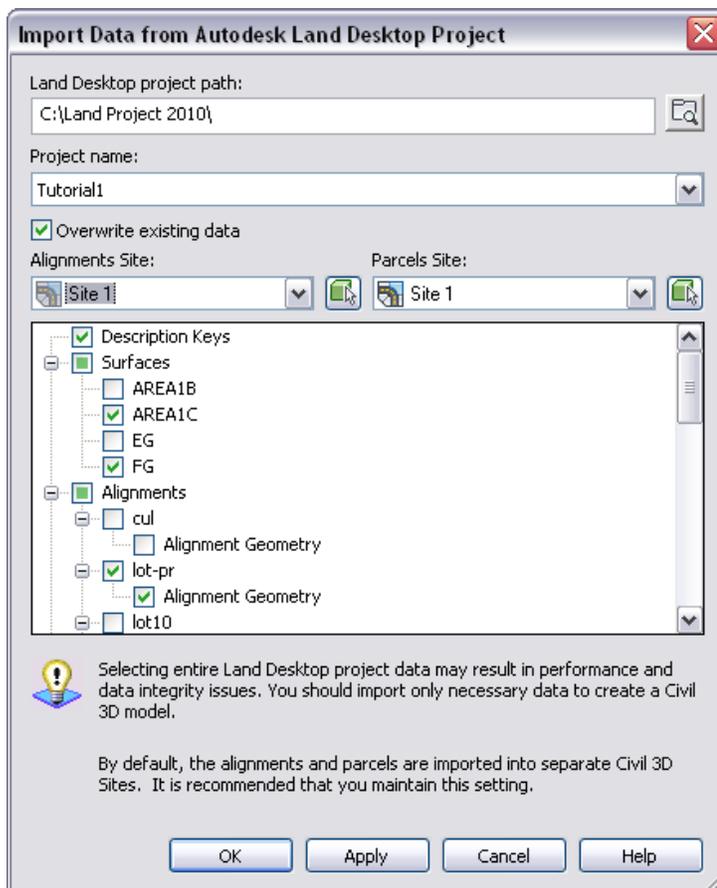
**See also:**

- Using Data Shortcuts (page 127)
- Using Vault (page 138)

# Transition from Land Desktop

Compared to the standard format used in AutoCAD Land Desktop, project structure within AutoCAD Civil can be customized to suit your requirements.

AutoCAD Civil includes an Import Data From Land Desktop command. This command makes use of the following dialog box, which enables you to selectively bring objects into new drawings for use in AutoCAD Civil. For more information, see Using the Import Data From Land Desktop Command.



The recommended use of this Import function is to bring individual surfaces, alignments, or pipe runs into new drawings, one object per drawing, for use in AutoCAD Civil projects.

# Using Data Shortcuts

This section explains the concepts and procedures for managing data shortcuts.

Using data shortcuts involves two main processes:

■ Create data shortcuts from their source drawings.

■ Create data references in consumer drawings to source objects in source drawings.

Data shortcuts can be used for surfaces, alignments, profiles, pipe networks, and view frame groups.

If you create a reference to a profile data shortcut, a data shortcut to the parent alignment is also created.

### Relationship Between Shortcuts and Data References

A data shortcut provides a direct path to the location of a shareable source object, either a surface, alignment, profile, pipe network, or view frame group. In a single operation, you can create data shortcuts for multiple objects in a source drawing. The data shortcut is used only for the creation of data references.

A data reference is a read-only copy of a source object, inserted into another drawing, often called a consumer drawing. From the Prospector tab, you can select a shortcut for an object and create a reference to that object in the active drawing. The data reference maintains an active link to the source object in the source drawing, without relying on the data shortcut.

**NOTE** The term 'project' is used here for ease of reference, and to explain a sample data structure. Formal projects and particular folder structures are not required with data shortcuts and references, but some form of structure usually helps to keep related data organized.

On the Toolspace Prospector tab, the Data Shortcuts node displays the path to the active project, where data shortcuts are stored. These data shortcuts can be created from any drawings associated with the active project. The figure shows how the Data Shortcuts node appears if the active project is Arc.

**Shortcut folders on the Prospector tree for sample project Arc**

If you change the active project, the new project name appears on the Data Shortcuts node, and the subfolders contain only the shortcuts in the new active project. A particular consumer drawing can contain data references from multiple projects.

### Data Reference Attributes

The reference object has read-only geometry, but the user can apply a local object style, apply custom annotation, do limited analysis, and access the source object's properties. The reference object takes up less file space when the consumer drawing is saved. If the source object is edited, the synchronization process ensures that changes are reflected in the reference object. Synchronization occurs when the consumer drawing is opened, and can also be done manually by a user. You can promote a data reference to an independent object that can be edited; after promotion it is no longer updated from its original source object.

Data Shortcut Best Practices

# Project Setup

This section explains how to organize the data for a new project, including some configuration options to consider.

## Setting a New Working Folder

Set a new working folder as the location to store data shortcut projects.

The default working folder for data shortcut projects is C:\Civil Projects. The default working folder is also used for Autodesk Vault projects and Survey projects.

If you work with Autodesk Vault, Survey, and data shortcut projects, you should have separate working folders for each project type, for ease of management.

**To set a new working folder**

1    In Toolspace, on the Prospector tab, right-click Data Shortcuts ➤ Set Working Folder.

2    Navigate to the desired folder and select it.

### Quick Reference

Ribbon

Click Manage tab ➤ Data Shortcuts panel ➤ Set Working Folder 🗂

Command Line

SetWorkingFolder

## Creating a Data Shortcut Project Template

Create a new template if the sample template is not suitable.

To create your own project template, copy the default template, _Sample Project and save it with a new name. To maintain the automatic storage of new data shortcut XML files, do not change the _Shortcuts folder and its subfolders. Your new project template will appear on the list of templates when you create a new data shortcut folder.

**To create a new template for data shortcut projects**

1    Navigate to the folder C:\Civil Project Templates.

2    Copy the folder _Sample Project, then paste it in the same location and rename it. This is your new template.

3    Open your new template and review the structure of folders and subfolders.

4    Do not change the top-level folder, _Shortcuts, or any folders inside it, but feel free to change the names of other folders and their hierarchical structure.

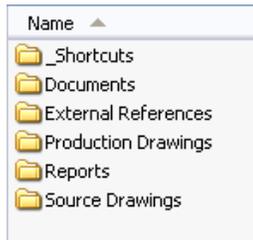
## Creating a New Shortcuts Folder

Create a new folder for storing a set of related project drawings and data shortcuts.

Create a folder name, which should reflect the project name, and specify whether to use a project template to organize your data.

The figures show the structure created by the default project template.

**Shortcut project template: the Prospector tree icons**



**Shortcut project template: the working folder**

Using a project template is a best practice that you will appreciate as your collection of projects and data expands.

**To create a new data shortcut folder**

1  In Toolspace, on the Prospector tab, right-click Data Shortcuts ➤ New Data Shortcuts Folder.

2  In the New Data Shortcut Folder dialog box, specify a name, and optionally a text description of the project folder.

3  Optionally, select Use Project Template, browse to another location for the project template folder, and click the name of a project template.

4  Click OK. The new project folder is created in the working folder.

### Quick Reference

Ribbon

Click Manage tab ➤ Data Shortcuts panel ➤ New Shortcuts Folder 

Command Line

NewShortcutsFolder

## Setting the Data Shortcuts Folder

Specify the project path for data shortcuts.

The path to the current data shortcuts folder (also known as the project folder) is specified on the Data Shortcuts node in Toolspace, on the Prospector tab.

The project folder typically contains both the data shortcuts and the source objects for data references.

Data references that you create in the active drawing come from the active project folder.

Setting or changing the data shortcuts folder reloads the shortcuts into all drawings in that folder. You can reload the shortcuts to apply changes made in the Data Shortcut Editor window. See Editing Data Shortcuts (page 137).

**To set the data shortcuts folder**

1  In Toolspace, on the Prospector tab, right-click Data Shortcuts and click Set Data Shortcuts Folder.

2  In the Set Data Shortcuts dialog box, click the name of the project you want to work with.

3  Check that the new project path is displayed on the Data Shortcuts node on the Prospector tab.

## Quick Reference

Set Data Shortcuts Folder (page 2208)

# Creating Data Shortcuts

Create data shortcuts from the active drawing.

Data shortcuts are stored in the _Shortcuts folder for the active project and used to create data references to the source objects in other drawings.

Each data shortcut is stored in a separate XML file.

**NOTE** The system will not allow you to create multiple shortcuts for a given object or to create a data shortcut to a reference object from another drawing.

**To create data shortcuts**

1  In Toolspace, on the Prospector tab, right-click Data Shortcuts ➤ Create Data Shortcuts.

2  In the Create Data Shortcuts dialog box, click any objects to be referenced in other drawings, and then click OK.

# Referencing a Project Object

Import a reference object into the active drawing.

A project object can be referenced into the active drawing, which is called the consumer drawing.

Before referencing a project object, the current drawing must be saved.

Only one copy of a reference object can be imported into a consumer drawing. If a reference copy exists, the referencing menu option is not available.

Objects can be referenced only from the active project, which is listed in Toolspace, on the Prospector tab.

**See also:**

■  Setting the Data Shortcuts Folder (page 130)

**To reference a data shortcut**

1   In Toolspace, on the Prospector tab, expand the Data Shortcuts collection to find the object you want to reference.

2   Right-click the object. Click Create Reference. A copy of the object is inserted into the active drawing.

### Quick Reference

Toolspace Data Shortcut Collection

Prospector tab ➤ Data Shortcuts, Right-click object name ➤ Create Reference

# Removing a Data Shortcut

Remove a data shortcut to make it unavailable for future data references.

You can remove a data shortcut from the Data Shortcuts collection in Toolspace, on the Prospector tab. Doing this does not remove any data references to the source object that exist in drawings, but it prevents anyone from creating more references to the object.

**To remove a data shortcut**

1   In Toolspace, on the Prospector tab, expand the Data Shortcuts collection to find the shortcut you want to remove.

2   Right-click the object and click Remove.

# Enabling and Disabling the Data Shortcuts Node

Control access to the use of data shortcuts.

You can remove the Data Shortcuts node from the Prospector tab of Toolspace. This can be useful if you want to prevent the use of data shortcuts.

Use the ShortCutNode command to either hide (disable) or show (enable) the Data Shortcuts node.

**To control access to the Data Shortcuts node**

1 On the command line, enter shortcutnode.

2 Set the value to 0 to disable the Data Shortcuts node, or 1 to enable the node.

# Synchronizing References

Synchronizing a data reference brings in any changes made to its source object.

When a drawing contains references to data shortcuts, the  icon is displayed at the bottom-right side of the window:

Data references are synchronized automatically when the drawing is opened. Otherwise, flags appear in the Prospector tree and the status bar of the drawing window when a reference object is out of date.

When references become out of date with the data shortcuts, the  icon displays a message prompting you to synchronize the references. Additionally, in the Prospector tree, the  icon is displayed next to reference objects that need to be synchronized.

**To synchronize a reference object**

1 In Toolspace, on the Prospector tab, expand the drawing node. Expand the object collection (for example, Surfaces).

2 Right-click the out-of-date reference object. Click Synchronize.

> **NOTE** The Synchronize menu item is displayed only for reference objects that are out of date.

**Quick Reference**

Drawing

Right-click 🖼 ➤ Synchronize

# Saving a Data Shortcut Project to Vault

Copy an entire project to a new project in Autodesk Vault, preserving all object references.

You can use the Add to New Vault Project command on the Data Shortcuts node of the Toolspace Prospector tab to copy a project to Vault. For an alternative method, see Importing a Project (page 154).

### Usage Guidelines

- Before using this command, you must be logged in to Vault, and the project you want to add to Vault must appear on the Prospector Data Shortcuts node as the current project.

- As a best practice, put all project drawings and files within a project folder, using a standard template. The structure of folders will be replicated in Vault, including the paths to all source drawings.

- The name you assign to the Vault project cannot be the same as the data shortcut project folder name.

- After being added to Vault, the data shortcut project remains in place and is usable.

### To copy a project to Autodesk Vault

1 On the Toolspace Prospector tab, right-click Data Shortcuts ➤ Add To New Vault Project.

2 In the New Project dialog box, enter a project name, and optionally a Description. This project name cannot be identical to the data shortcut project folder name.

3 Click OK. The Vault project is created, and appears on the Projects node on the Prospector tab.

### Quick Reference

Toolspace

Right-click Data Shortcuts ➤ Add To New Vault Project

# Promoting References

Promote references to independent objects.

A promoted reference becomes an independent object, and is no longer automatically updated if the original source is edited.

### To promote a reference

1 In Toolspace, on the Prospector tab, expand the Data Shortcuts collection to see the data shortcut of interest.

2 Right-click the reference object and then click Promote.

### To promote all references in a drawing

1 Manage tab ➤ Data Shortcuts panel ➤ Promote All Data References 🖼 .

2 In the Promote All Data References dialog box, click Promote All Referenced Objects Into The Current File.

### Quick Reference

Ribbon

Menu

Click General menu ➤ Data Shortcuts ➤ Promote All Data References

Command Line

PromoteAllReferences
PromoteReference (for surfaces, alignments, and profiles)
PromoteNetwork
PromoteViewFrameGroup

# Validating Data Shortcuts

Data shortcuts can become invalid if changes occur to the names or locations of drawings or reference objects.

When a data shortcut reference is broken, the  icon is displayed next to the invalid data reference in Toolspace, on the Prospector tab.

Validation reloads the data references if the drawing paths have not changed. Otherwise, you must repair broken references.

**To validate data shortcuts**

■   In Toolspace, on the Prospector tab, right-click Data Shortcuts ➤  Validate Data Shortcuts.
    The system checks data shortcut references. If any references are broken, the Event Viewer opens and displays details that you can use to fix the problem.

### Quick Reference

Ribbon

Click Manage tab ➤ Data Shortcuts panel ➤ Validate Data Shortcuts 

Command Line

ValidateShortcuts

# Repairing Broken References

You can recover from minor changes such as a moved or renamed drawing.

When a data shortcut reference is broken, the  icon is displayed next to the invalid data shortcut in Toolspace, on the Prospector tab for the host or consumer drawing.

Broken references typically occur if a source drawing has been renamed or moved to a different folder. If you can identify the new name or location, it is quite easy to repair the references. If the source drawing contains multiple data shortcuts, once you identify the drawing you are prompted to repair all of the references.

**To repair broken references**

**1** In Toolspace, on the Prospector tab, right-click the object name of the broken reference, and then click Repair Broken References.

**2** In the Choose the File dialog box, navigate to the source drawing for the referenced object, and then click Open.

If the source drawing contains other broken references, the Additional Broken References dialog is displayed. You can click the Repair All Broken References button, or click Cancel to repair only the broken reference you selected.

### Quick Reference

Toolspace

Right-click broken reference object ➤ Repair Broken References

Command Line

RepairBrokenReferences

## Accessing the Data Reference Source Drawing

Open the source drawing for a data reference.

This is useful if the source object requires editing.

**To access a data shortcut source drawing**

**1** In Toolspace, on the Prospector tab, expand the Data Shortcuts collection to see the data shortcut of interest.

**2** Right-click the data shortcut, and then click Open Source Drawing.

The source drawing for the data shortcuts is displayed in a new document window.

### Quick Reference

Menu

In Toolspace, on the Prospector tab, right-click Data Shortcut ➤ Open Source Drawing.

## Migrating Data Shortcuts

You can update data shortcuts to the current format or move them to a different folder.

Use the stand-alone Data Shortcuts Editor to save one or more data shortcuts to a specified folder. If the shortcuts were created with a previous version of AutoCAD Civil, they will be updated to the current format in this process.

**To migrate data shortcuts**

**1** From the Windows desktop, click the Start menu and navigate to your list of programs.

**2** Open the AutoCAD Civil 2010 folder and click Data Shortcuts Editor. The editor opens in a separate window.

**3** In the Data Shortcuts Editor window, click File menu ➤ Open Data Shortcuts Folder, and navigate to the shortcuts folder that contains the data shortcuts you want to edit. This folder is typically inside a named project folder.

**4** In the shortcut table, display the data shortcuts you want to migrate. Display all of them by clicking the data shortcut folder at the top of the tree, or display a subset by clicking an object type such as Surfaces or Alignments.

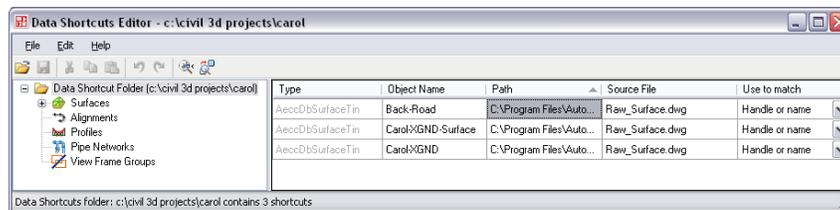
**5** Click File menu ➤ Save As, then specify the folder where you want to save the data shortcuts.

**6** Click OK to save and update the data shortcuts.

# Editing Data Shortcuts

Use the Data Shortcuts Editor for bulk operations on data shortcuts.

The Data Shortcuts Editor is a stand-alone application that you can use to edit multiple shortcut XML files safely and efficiently. For example, if you move an entire project from one working folder to another, you can use the Data Shortcuts Editor to update the paths to the data shortcut objects.



**The Data Shortcuts Editor window**

### Precautions

Before editing data shortcuts, ensure that no one else is currently creating or editing the same set of data shortcuts within AutoCAD Civil. Otherwise, one user can overwrite changes made by the other.

Changes made in the Data Shortcut Editor window do not take effect until shortcuts are reloaded. To reload the shortcuts, use the procedure Setting the Data Shortcuts Folder (page 130), or close AutoCAD Civil and restart it.

### Best Practices

On the Data Shortcut Editor's Edit menu, use the Find and Replace command to quickly change text strings in the names of data shortcuts, paths, or source drawings.

In the shortcut table, set the Use to Match column to associate data shortcuts with their source objects by means of the source object's name or handle, or both. The object's handle is its unique identifier used by the system. Users cannot change the handle, so it can be the most reliable matching attribute if an object's name has changed.

One situation in which you would match by name is if you delete an object, then re-create it and apply the same name. The new object has a different handle, but if you use the match-by-name option, the old data shortcuts will automatically reference the new object.

### See also:

■ Migrating Data Shortcuts (page 136)

### To access the Data Shortcuts Editor

**1** From the Windows desktop, click the Start menu and navigate to your list of programs.

**2** Open the AutoCAD Civil 2010 folder and click Data Shortcuts Editor. The editor opens in a separate window.

**3** In the Data Shortcuts Editor window, click File menu ➤ Open Data Shortcuts Folder, and navigate to the project folder that contains the data shortcuts you want to edit.

The data shortcuts are displayed in a table grid.

# Using Vault

Autodesk Vault is a complete document management system for drawings, project objects, and project-related files.

Autodesk Vault provides access control and version control for all project drawings. One master copy of each project drawing is maintained in the project database. Other team members can reference the master copy, and they are notified when the master copy is updated.

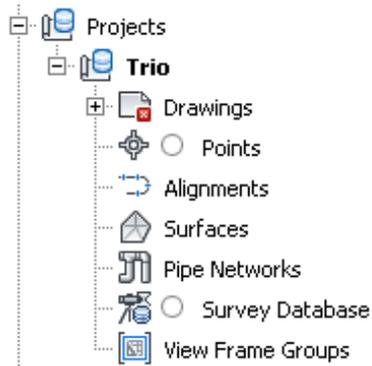
Most project team members can access all required Vault features using the Prospector tree. However, you will need a knowledgeable system administrator who installs the server and client Vault software, uses ADMS Console or the Autodesk Vault administration tool to customize Vault for your purposes, and regularly performs system administration tasks such as data backups. Most of the topics in this section are geared toward your system administrator.

**NOTE** Some tasks, such as managing user accounts, can be done with either the Autodesk Vault tool or ADMS Console. When Help suggests using the Vault tool to perform a task, you can often use ADMS Console instead.

For information about installing Autodesk Vault, see the Autodesk Data Management Server Installation Guide.

Autodesk Vault provides access control and file version control. AutoCAD Civil provides commands in the Prospector tree to create and access project drawings and shared project data.

After you have logged in to Vault, each project is displayed as a collection on the Projects node of the Prospector tree..



**Project Drawings**

A project contains a collection of project drawings. You can use folders to organize the drawings within a project. A master copy of a project drawing is maintained in a specified project within a Vault database, and only one person can edit the master copy at a time. When the edited project drawing is updated in the Vault database, a new version of the drawing is created. The icons displayed next to a drawing in the Prospector tree indicate the status of your local copy of the drawing in relation to the master copy of the drawing in the Vault database. For more information, see Project Item State Icons (page 140).

**Project Objects and References**

A project contains collections of project objects, including surfaces, alignments, profiles, pipe networks and view frame groups, that can be shared with others. All shared project objects are listed in the project object collections in the Prospector tree. Project members can create a read-only copy of a project object, called a *reference*, in a drawing. This read-only copy of the project object's geometry can be used to perform labeling, design, analysis, or what-if tasks.

Multiple project members can create references to the same shared project object.

**Project Points**

When using Vault, project management for AutoCAD Civil points is handled differently from project management for other objects. For more information, see Working with Vault Project Points (page 166).

**Project Management Commands**

The project management commands that are listed on Prospector shortcut menus can vary depending upon several factors, including the following:

■ Whether or not you have logged into Vault from the Prospector tree.

■ The state (for example, checked-in or checked-out) of the selected project item.

■ The location of the project item in the Prospector tree. For example, some drawing-related commands are available at the Open Drawings collection level, some are available at the Projects collection level, and some are available at both levels.

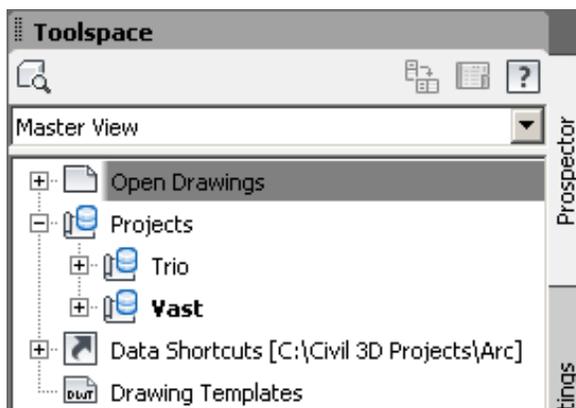
■ Whether or not the selected drawing has been saved.

■ Any circumstances that make the operation invalid for the selected item.

The user information that is defined for you on the current Vault server also affects the actions you are permitted to perform. For example, you might have permission to get copies of project drawings, but not create project drawings.

Vault Best Practices

# Project and Drawing Items in the Prospector Tree

The Master View of the Prospector tree contains three collections related to drawings and projects: Open Drawings, Projects, and Drawing Templates.


- **Open Drawings**. Lists open project and non-project drawings.

- **Projects**. Lists the projects available to you after you have logged in to a Vault server and a Vault database.

- **Drawing Templates**. Lists the available drawing templates. For more information, see Drawing Templates (page 109).

## Project Item State Icons

The project item state icons in the Prospector tree identify the state of a local project drawing in relation to the master copy in the Vault database.

NOTE To display the project item state icons, click  at the top of the Prospector tab.

The icons are displayed next to drawings that have been added to the project, indicating the state of the drawing on your system (your *local copy*) in relation to the latest version of the master copy of the drawing in the Vault database.

An icon that is displayed next to a project object (in a project object collection, such as Surfaces or Alignments) indicates the state of the project object's source drawing.

The project item state icons are shown in the following table:

| Icon | Meaning |
|---|---|
| | If no icon is displayed, then the drawing has been added to the project, but you do not have a local copy. |
| ○ | The drawing is available to be checked out, and the version of the master copy in the Vault database matches your local copy. |
| ● | The drawing is available to be checked out, but your local copy is newer than the latest version in the Vault database. This usually means that you changed the local copy without checking it out. |
| ● | The drawing is available to be checked out, and your local copy is older than the latest version in the Vault database. |
| ✔ | The drawing is checked out to you, but you do not have a local copy of the object. |
| ✔ | The drawing is checked out to you, and the version of the drawing in the Vault database matches your local copy. |
| ✔ | The drawing is checked out to you, and your local copy is newer than the latest version in the Vault database. This usually means that you have changed the drawing since you checked it out. |
| ✔ | The drawing is checked out to you, and your local copy is older than the latest version in the Vault database. |
| ✖ | The drawing is checked out to someone else, and you do not have a local copy. |

| Icon | Meaning |
|------|---------|
| ✖ | The drawing is checked out to someone else, and your local copy matches the latest version in the Vault database. |
| ✖ | The drawing is checked out to someone else, and your local copy is newer than the latest version in the Vault database. |
| ✖ | The drawing is checked out to someone else, and your local copy is older than the latest version in the Vault database. |

When your drawing contains a reference to a shared object, and the local copy of the source drawing becomes out of date, ⓘ is displayed next to the drawing name in the Prospector project tree. This generally occurs when someone adds a newer version of the project object's source drawing to the project.

## Drawing Item State Icons

The drawing item state icons in the Prospector and Settings trees identify whether an object is locked, is a reference, or is being referenced, as shown in the following table:

**NOTE** To display the drawing item state icons, click 🖾 at the top of the Prospector tab.

| Icon | Meaning |
|------|---------|
| 🖉 | Object is locked. |
| ◣ | Object is being referenced by another object. |
| ↗ | Object is a reference to an object in another drawing. |

## Drawing Item Modifier Icons

The drawing item modifier icons in the Prospector tree identify an object that is out of date or violates constraints, and also identifies the state of a local copy of a project object.

**NOTE** To display the drawing item modifier icons, click 🔰 at the top of the Prospector tab.

The following table explains the meaning of the three individual drawing item modifier icons:

| Icon | Meaning |
|------|---------|
| 🔰 | The object is out of date or violates constraints. |
| ◣ | The project object is more recent than the local copy. |
| ◢ | The local copy of the project object no longer matches the project version, which means that you have edited it. |

The following table lists all combinations of the drawing item modifier icons:

| Icon Displayed in Drawing | Object is Out of Date or Violates Constraints | Project Object is More Recent than Local Copy | Local Copy Has Been Edited Relative to Project Object |
|---|---|---|---|
| | No | No | No |
| ⚠ | Yes | No | No |
| ◣ | No | Yes | No |
| ⚠ | Yes | Yes | No |
| ◢ | No | No | Yes |
| ⚠ | Yes | No | Yes |
| ◡ | No | Yes | Yes |
| ⬟ | Yes | Yes | Yes |

**NOTE** Some of the above icons are displayed only in the Points list view.

## The Project Collection List Views

Use the list views displayed in the Projects collection to obtain information about the drawings and shared objects in the project.

**NOTE** To view the Projects collection in the Prospector tree, select Master View from the list at the top of the Prospector tab.

Click a collection in the Prospector tree Projects collection to display a list view.

If the selected item is a project, the following information is displayed in the list view:

- Project name
- Description
- User name of the person who created the project
- Date the project was created

If the selected item is a collection or folder containing drawing files, the following information is displayed in the list view:

- Name
- Version

- User name of the person who created this version

- Date checked in

- Comment

If the selected item is a collection containing shared objects, the following information is displayed in the list view:

- Object name

- Source drawing name

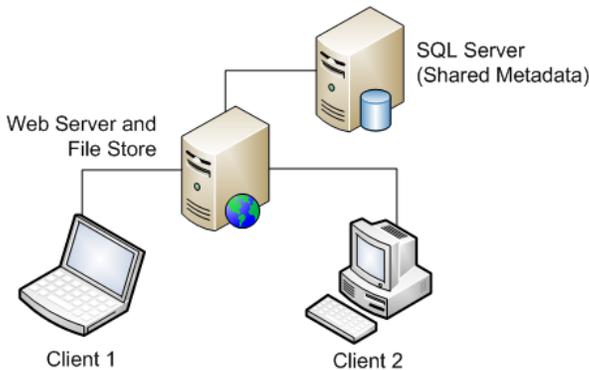
- Description

For more information about changing the list view display, see Customizing a List View (page 84).

# Installing and Configuring Vault

The Autodesk Data Management Server Installation Guide contains detailed recommendations for configuring your Vault installation.

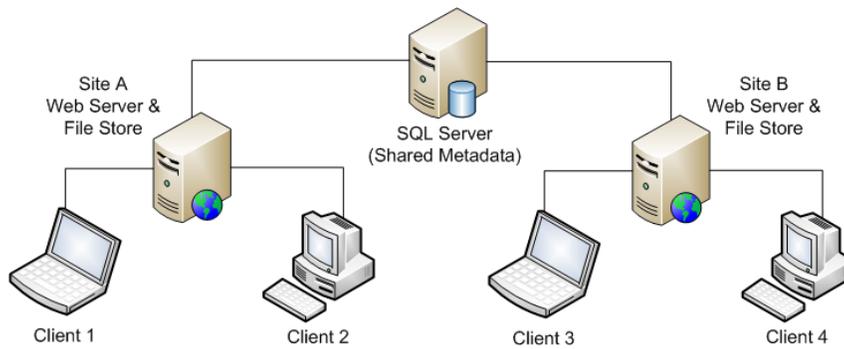
A single-site configuration is recommended for most teams. The Autodesk Data Management Server (ADMS) is installed on one system and the client component is installed on each computer that must communicate with that server. The server stores all master copies of data files, and the clients can access the files stored on the server. For best performance, a dedicated server is recommended.



**Vault single-site architecture**

You have flexibility within this model to choose a configuration that suits your requirements, based on criteria such as the number of users who must share data, how your users are divided into design teams, and the amount of project data you expect your users to generate. Refer to the Autodesk Data Management Server Installation Guide for more details.

After Vault is installed, you can decide to create a single vault (database) or multiple vaults on the server. User permissions apply within a single vault, and cannot be shared across vaults. For more information on the difference between a single vault configuration and a multiple vault configuration, see Autodesk Data Management Server Installation Guide.

Vault's optional multi-site feature is designed to support geographically dispersed workgroups sharing vaults. A single instance of remote SQL manages multiple servers, each with its own file store, at separate office sites. Depending on their level of permissions, all users can see all files at all sites as if the system was a single database.


**Vault multi-site architecture**

When a user checks out a file that is stored at another site, the system replicates that file at the user's site. As long as the file remains shared, the system remembers to update that copy with any changes. Vaults and individual files are replicated only where they are really in use. Backup and restore operations can be managed from any site that has all vaults enabled. For more information, see ADMS Console Help.

# Project Folders

Any file (drawing or not) that is associated with a project, especially any file that would benefit from version control, should be stored in the project. Temporary files, such as preliminary design drawings, do not need to be stored in the project.

For ease of use, all projects should use consistent folder structure and folder names. A practical structure is provided when you use the project template. You can easily create your own custom template if the default version is not suitable.

---

**NOTE** In general, a user who creates a folder or project data can delete it using the Autodesk Vault tool. For this reason, it is recommended that all new projects be created by a system administrator. This will prevent other users from advertently deleting a project and associated files.

---

You do not need to create a folder for point database files or survey data. These are automatically stored directly beneath the main project folder.

A project can also include files that are not drawings. Using the Autodesk Vault tool, create folders for such files directly under the project folder. Possible folder names might include: Proposals, Client Correspondence, and Contracts. You can store and access the files in non-drawing folders using the Vault tool.

**Working Folders**

When you work on objects, you check associated drawings out of a vault and work with them from working folders. The objects in a working folder are physically copied from a Vault file store. Other users can still get read-only copies of the files, but they cannot edit them until you have checked them back in. In this way, you maintain a single master version of each drawing.

When you check a file back into a vault, the revised version from your working folder is copied to the file store on the server. The Vault database marks the file with the appropriate revision data and makes it available to other users.

You can change your working folder without risk to the data in the Vault database, but you typically change the working folder only if you need to work with projects in different Vault databases. To avoid confusion, use a separate working folder for each Vault database.

The default working folder location is C:\Civil Projects.

For more information on best practices with working folders, see Working Folder Configurations in the *AutoCAD Civil Best Practices* guide.

# Controlling Access to Project Data

You can control who can access and edit project drawings and master copies of project objects.

To ensure a secure environment, define a separate Vault user account for each person who will be accessing project data on the project server. Each account requires a unique user name and password. For more information, see Creating Vault User Accounts (page 147).

Vault allows you to control access to project files at several levels: user names, groups, projects and folders. With careful planning, you can minimize the amount of configuration required and create a flexible security system. It is recommended that you control access to project files at the group level.

Create a different Vault group for each function performed by members of your organization. For example, you could create a set of groups including: Surveyors, whose members would create and edit master copies of data in a folder such as EG Surfaces; Civil Engineers, whose members would usually read (but not modify) data in the EG Surfaces folder, and would create and edit master data in a folder such as Alignments; and Drafters, whose members would generally read data but would not modify master copies of data. Access can then be further restricted to individual groups or users, at the folder level.

In general, each team member should belong to only one group. To change how someone accesses project files, move their user name from one group to another. For more information see Creating Vault Groups (page 147).

# Partitioning Project Data

You should divide your project data across multiple drawings using a strategy that both protects data integrity and supports ease of access.

In AutoCAD Civil, there is one master copy of each project object (such as a surface, alignment, profile, or pipe network), and that master copy is stored in a source drawing that is stored in the project's Vault database. There are virtually no restrictions on how many project objects you can store in the same drawing, but there are some factors you should consider.

A key determining factor in how you partition your project data is the ability of team members to create and modify project data when they need to. Because only one person can edit a drawing at a time, placing the master copy of every project object into the same drawing is too restrictive for a collaborative environment. In general, spreading your project objects across many drawings makes more sense than crowding many objects into fewer drawings.

For each project object, create a separate drawing that contains the geometry of the project object and, if needed, related project objects. Consider placing each surface in a separate drawing. At the very least, consider placing a key surface, such as an existing ground surface, in its own drawing. You should avoid placing all your project alignments in the same drawing.

The function of a drawing should match its content. If a drawing contains the master copy of a surface object, that drawing shouldn't also be a plan profile sheet. Keep project object geometry in its own drawing and create separate drawings for viewing and annotating read-only copies of the geometry.

It is important to understand that a single project must contain all the data that is required for that project. A drawing cannot contain references to more than one project at a time.

Adhering to a consistent naming convention will make the drawings that contain master copies of project objects easy to identify. Name a drawing that contains a project surface with the same name as the surface; name a drawing that contains a project alignment with the name of the alignment. Store project drawings in appropriately named folders. For more information see Project Folders (page 144).

Develop procedures that minimize the number of shared project objects. Make sure that team members understand that when adding or checking in a drawing, they should not share an object unless it is needed by others.

# Running the Autodesk Vault Tool from the Prospector Tree

You can access the Autodesk Vault tool from the Prospector tree.

You must log in to Vault from the Prospector tree before you can run the Vault tool from the Prospector tree.

**To run the Vault tool from the Prospector tree**

1  In Toolspace, on the Prospector tab, right-click the Projects collection.

2  Click Autodesk Vault.

3  If the Welcome dialog box is displayed, click Log In.

4  In the Log In dialog box, enter your Vault user name.

5  Enter your password.

6  Select a Vault server.

7  Select a Vault database. Click ⬚ to list available databases.

8  Click OK.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab (Master View): right-click Projects collection ➤ Autodesk Vault

# Running Vault from Microsoft Office Applications

The Microsoft Office add-in for Autodesk Vault enables direct access to Vault from Word, Excel or PowerPoint documents.

However, the Office add-in is not installed by default when you install Vault.

**To install the Office add-in after Vault is installed**

1  In Windows, from the Start menu, open the Control Panel. Depending on your system, the Control Panel may be on a Settings submenu.

2  Click Add or Remove Programs, or in Vista, click Uninstall a Program.

3  In the list of programs, click Autodesk Vault.

4  Click Change/Remove, or Uninstall/Change.

5  In the Autodesk Vault Installation Wizard dialog box, click Add or Remove Features.

6  In the Select Features to Install field, select the MS Office Add-In. Click Next.

7  Click Next.

8  Click Finish.

To use Vault with a Microsoft Office application, click File menu ➤ Autodesk Vault and select one of the Vault options.

# Project Files Created in a Project Database

When an AutoCAD Civil project is created, an initial set of empty or near-empty files is created in the project database.

Data is added to these files as you add drawings and data to the project.

### Project.xml

This file contains information about the project and the shared project objects. The presence of this file is what indicates to AutoCAD Civil that the folder containing this file is an AutoCAD Civil project folder. Do not delete, modify, or move this file.

### PointsGeometry.mdb

This file contains the project's point geometry. The points contained in the file are listed in the project's Points list in the Prospector tree. This file is not checked in and out directly as project drawing files are; it is checked in and out indirectly when users use point access control commands.

### PointsStatus.mdb

This file contains access control information about the points in *PointsGeometry.mdb*, including the status (checked-in, checked-out, or protected) of individual points.

### Survey.sdb

This file represents the project survey database. For more information, see Survey Database (page 196).

# Creating Vault User Accounts

Each team member must have a user account on the project Vault server before using project management commands.

To ensure a secure environment, define a separate Vault user account for each person who will be accessing project data on the project server. Each account requires a unique user name and password.

**NOTE** Each instance of a Vault Data Management server has a separate set of user accounts. If a user requires access to multiple servers, you must define an account for him on each server.

Only a user with administrator privileges can add a user. When you add a new user to a server, you can specify a *role* for the user, which defines how the user will access data on the server. AutoCAD Civil Vault project management supports *administrator, editor,* and *consumer* roles for user accounts.

In general, you will find managing access to project data easier to control at the group level, instead of at the individual user level. When you create a user account, specify a role for each user that gives them the highest level of access they require to any part of the database. For more information, see Creating Vault Groups (page 147).

**To add a new user in the Autodesk Vault administration tool**

■ Click Tools ➤ Administration and then use the Security tab to add a new user.

For more information, see Add/Edit Users in Autodesk Vault help.

# Creating Vault Groups

Use Vault groups to manage and control access to project files.

Use the Autodesk Vault tool to add a group to a Vault server. Only a user with administrator privileges can add a group.

When you create a group, you specify generally how the group's members should access project data by assigning the group the role of *data editor*, which means that members of the group can add or edit data, or *data consumer*, which means the group members can only read data, not edit it.

In general, a user should belong to only one group. To change someone's access to project files, move their user name from one group to another.

To add a group in the Vault tool, click Tools menu ➤ Administration and then use the Security tab to add the group. You can also add users to a group here. For more information, see Managing Groups in Autodesk Vault help.

# Folder Permissions

With Autodesk Vault in AutoCAD Civil, system administrators can extend permissions down to folders and sub-folders in a vault.

Before setting folder permissions, you may want to manage specific Vault users, groups, or roles from the Tools menu in the Autodesk Vault tool.

**To set folder permissions**

1 In the Vault tool window, expand the Vault Explorer ($) tree to the folder whose permissions you want to set.

2 Right-click the folder. Click Properties.

3 To add a user or group to the Access Control List, in the Properties dialog box, Security tab, click Add.

4 In the Add Members dialog box, select the member(s) to add to the Access Control List. Click Add.

5 Click OK.

6 In the Properties dialog box, click OK.

# Pack and Go

Use the Vault Pack and Go feature to hand off project data to someone else.

Pack and Go resolves file dependencies for a drawing. This feature can be used to supply copies of project files to someone. It is not intended for making copies of project files that you want to edit and then return to the project.

For example, if your firm begins a project by doing a survey, creating the base map, and completing the parcel layout, and then passes the drawing and associated data to a civil engineer who completes the job, you could use Pack and Go in Autodesk Vault to assemble the information related to the drawing before you hand it off.

For more information, see Packaging Files in Autodesk Vault help.

# Working with Vault Projects

An AutoCAD Civil project groups all the drawings and data for a single project in one place and controls access to all project files.

After you log in to a Vault server and a Vault database, the Projects collection in the Prospector tree lists all the projects that are available to you.

**NOTE** You must select Master View from the list at the top of the Prospector tab before you can view the Projects collection.

## Logging in to a Vault Server

Before you can create or access project data, you must log in to a Vault server and a Vault database from the Prospector tree.

You must be an authorized user on the server before you can log in. The server and the database that you select when you log in determines what projects you can access.

Before you log in, project management commands are not available on shortcut menus in the Prospector tree. After you log in, the projects available in the specified server and Vault database are listed in the Prospector tree, and applicable project management commands are displayed on the menus when you right-click a project item in the Prospector tree.

**To log in to Vault from Prospector**

1 In Toolspace, on the Prospector tab, select Master View from the list at the top of the Prospector tab.

2 Right-click the Projects collection.

3 Click Log In.

4 In the Log In (page 2205) dialog box, enter your Vault user name.

5 Enter your password.

6 Select a Vault server.

7 Select a Vault database. Click ⌶ to list available databases.

8 Optionally, select Automatically Log In Next Session.

9 Click OK.

### Quick Reference

Toolspace Shortcut Menu

  Prospector tab (Master View): right-click Projects collection ➤ Log In

Dialog Box

  Log In Dialog Box (page 2205)

## Logging Out of Vault

Logging out of Vault terminates your connection with the Vault server and the Vault database that you are logged in to.

After you log out, you can no longer view or access project data in Prospector. When you end an AutoCAD Civil session, you are automatically logged out.

**To log out of vault**

1 In Toolspace, on the Prospector tab, right-click the Projects collection.

2 Click Log Out.

**Quick Reference**

## Changing the Working Folder

The working folder maps your local copies of project files to the master copies of project files in the Vault database.

The default working folder for Autodesk Vault projects is C:\Civil Projects. This same default location is also used for data shortcut projects. For ease of management, it is a best practice in most cases to use different working folders for the two project types.

The working folder contains your local copies of files for all the projects stored in a Vault database. If all your projects are stored in the same Vault database, you will use the same working folder for all projects. If you work with projects that are stored in different Vault databases, you can prevent confusion by using a different working folder for each Vault database.

In general, you should not change your working folder while you have any objects referenced or files checked out from a Vault project. The working folder is used to determine the state of your local copies of files in relation to the master copies in the project database.

**To change the working folder**

1   In Toolspace, on the Prospector tab, right-click the Projects collection.

2   Click Properties.

3   In the Properties - AutoCAD Civil Projects (page 2207) dialog box, under Working Folder, click ⊡ .

4   In the Browse For Folder dialog box, browse to the folder and click OK.

## Quick Reference

## Creating Projects

If you are logged in to Vault, you can use the Prospector tree to create a new project in the project database.

You create the project using either the default Sample Project template, or another template you have saved. Project templates provide the capability to create a new project with a predetermined folder structure, where each folder can also contain files of any type. The template folders are found in the AutoCAD Civil Project Templates folder on your local disk.

**NOTE** In general, a user who creates a folder or project data can delete it using the Autodesk Vault tool. For this reason, it is recommended that all new projects be created by a system administrator. This will prevent other users from inadvertently deleting a project and associated files.

**To create a project**

1  In Toolspace, on the Prospector tab, right-click the Projects collection.

2  Click New.

3  In the New Project (page 2206) dialog box, enter a project name.

4  If you want to create your new project from a template, select Use Project Template.

5  On the Project Template list, click the template you want to use.

6  Click OK.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab (Master View): right-click Projects collection ➤ New

Dialog Box

New Project Dialog Box (page 2206)

# Project Administration

Your system administrator can use ADMS Console or the Autodesk Vault tool to customize Vault for your purposes and to regularly perform project administration tasks on an on-going basis.

These tasks include the following:

■  Creating, modifying, or deleting folders in a project

■  Deleting a project

■  Modifying the state of a file, for example, checking in a file that for some reason cannot be checked in by the person who originally checked it out

■  Restoring a file back to a prior version

■  Backing up project files

For more information, see the ADMS Console Help and Administrative Tasks in Autodesk Vault help.

# Changing the Active Project

The active project is displayed in bold type in the Prospector tree. It is the default project for the project dialog boxes.

**NOTE**  The active project is not displayed in the Select Projects To Display (page 2207) dialog box.

**To change the active project**

1  In Toolspace, on the Prospector tab, expand the Projects collection and right-click a project.

2  Click Set Active.

### Quick Reference

Prospector tab (Master View): Projects collection ➤ right-click &lt;project name&gt; ➤ Set Active

## Selecting Projects to Display

You can limit the number of projects that are listed in the Prospector tree.

The projects available to you are determined by the server and the database that you are logged in to. By default, all projects available in the database are listed in the Prospector tree under the Projects collection.

Reducing the number of projects that are listed in the Prospector tree will not only reduce the amount of data you will see, but also can reduce the time required to update the display of the tree.

You cannot turn off the display of the active project, and the name of the active project is not listed in the dialog box.

**To select projects to display**

1   In Toolspace, on the Prospector tab, right-click the Projects collection.

2   Click Select Projects To Display.

3   In the Select Projects To Display (page 2207) dialog box, select the check box next to the name of any project that you want listed in the Prospector Projects collection.

> **NOTE**  The name of the active project is not included in the list.

4   Click ![icon] to select all the projects in the list.

5   Click ![icon] to clear all the projects in the list.

6   Click OK.

### Quick Reference

Prospector tab (Master View): right-click Projects collection ➤ Select Projects To Display

Dialog Box

Select Projects To Display Dialog Box (page 2207)

## Working When Disconnected

You can work with project files while you are disconnected from Vault.

If you are not connected to the network, in general, you can work with your local copies of project drawings the way you normally do. However, you cannot perform project management functions (such as checking in and checking out files), you cannot get updated versions of any project files, and you cannot create new references to project objects while you are disconnected.

Before you disconnect, you should update your local copies of any project files by getting the latest versions of any project files that you are working with, including the source drawings for any project objects that your drawing references.

## Deleting a Project

Delete a project from the project database using the Autodesk Vault tool.

A project can be deleted by a system administrator or by the user that created it. It is recommended that all projects be created by a system administrator to protect projects from being inadvertently deleted by users who are not system administrators.

To delete a project from the project database, delete the top-level project folder. You cannot delete a file that is checked out.

After a project has been deleted from the Vault database, its name remains in the Projects collection in the Prospector tree until you refresh the display of the tree.

After the project has been deleted from the Vault database, use Windows Explorer to delete local copies of project files and folders from the working folder.

## Converting a Project to Data Shortcuts

Change all data references from the Vault format to data shortcuts.

After getting the latest version of all files from the Vault project, use the Data Shortcut Editor to convert the Vault project.xml file into a _Shortcuts folder. Doing this converts the Vault references into data shortcuts between drawings.

**To convert a Vault project**

1 On the Windows Start menu, click Programs ➤ Autodesk ➤ AutoCAD Civil 2010 ➤ Data Shortcuts Editor.

2 In the Data Shortcuts Editor, click File menu ➤ Open Data Shortcuts Folder. In the Browse for Folder dialog box, browse to the folder for the project that you want to convert. The default location is C:\Civil Projects.

   After you select the project folder, the Vault references are loaded into the table.

3 In the Data Shortcuts Editor, click Edit menu ➤ Find and Replace. Replace each instance of $ with the path to the local project folder (example: C:\Civil Projects).

4 In the Data Shortcuts Editor, click File menu ➤ Save As, and then save the new Shortcuts folder in its current location.

5 In the active project folder, delete the project.xml file.

## Labeling Project Milestones

You can use the Vault labeling feature to identify the status of a set of project files, such as the project milestone attained.

When a major project milestone is reached, you can label the files involved so they can be easily identified. When you create a label, the most recently checked-in version of every file in the project is assigned that label.

Labeling does more than just tag a set of files. If you later need to archive or retrieve the set of files, you can do so. Labels do not include folder information; only the project files are labeled.

To create a label, in the Autodesk Vault tool, right-click a project folder and click New Label. For more information on creating and viewing labels, see in the Autodesk Vault tool help.

## Exporting a Project

Export a project to a ZIP file for storage, or to move the project to another vault.

When a project is exported, copies of the latest versions of all drawings and other documents are compressed and saved in a ZIP archive. This archive can be reliably imported to a vault, retaining the data references between drawings.

The export operation does not affect the original project documents. They remain in place for ongoing use.

**TIP** Label your project files, then export them to archive a copy of the files at a specific milestone.

**See also:**

■ Importing a Project (page 154)

■ Labeling Project Milestones (page 153)

**To export a set of project files**

1 In Toolspace, on the Prospector tab, in Master View, expand the Projects node to see the list of projects.

2 Right-click the project to export and click Export to ZIP File.

3 In the Browse for Folder dialog box, navigate to and select the folder where you want to save the ZIP file, then click OK.

The system displays a progress bar while the files are compressed and saved.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab (Master View) ➤ right-click Project ➤ Export to ZIP File

## Importing a Project

You can import a Vault project or a project that uses data shortcuts.

Data shortcuts are converted to Vault references during import.

The project to be imported can be in a folder or a ZIP file. If you are importing a project that was previously exported from a vault, it is in a ZIP file.

You cannot import a project if it has the same name as an existing project in the vault.

**See also:**

■ Exporting a Project (page 154)

**To import a project**

1 In Toolspace, on the Prospector tab, in Master View, right-click the Projects node ➤ Import From, and click either ZIP File or Folder.

2 In the dialog box that opens (Import Project Archive or Browse for Folder, depending on project format), navigate to and select the project container, and then click OK.

The system displays a progress bar and status messages during the import operation.

### Quick Reference

## Managing File Status Prompts

You can control the use of prompts during file management events.

During file operations such as Check In, and Get Latest Version, prompts are available to advise you of unsaved changes, newer versions in the vault, and other details. You can specify whether these prompts are used always or never. You can also specify whether the default response to the prompt is Yes or No.

A new user can have all prompts displayed to guide them in file management. An experienced user can suppress some unnecessary prompts and work more efficiently.

**To manage file status prompts**

1   In Toolspace, on the Prospector tab, in Master View, right-click the Projects node ➤ Manage Prompts.

2   In the Manage Prompts dialog box, review the Response and Frequency settings for each prompt, making any required changes.

### Quick Reference

## Migrating Old Civil 3D Projects

You can easily migrate projects to AutoCAD Civil 2010 from AutoCAD Civil 3D 2006 and previous versions.

You must log in to Vault from the Prospector tree before the project migration command is available.

**To migrate an old Civil 3D project**

1   In Toolspace, on the Prospector tab, right-click the Projects collection.

2   Click Migrate Pre-Civil 3D 2007 Project.

3   In the Select Civil 3D Project Folder To Migrate dialog box, browse to the project folder to be migrated.

4   Select the folder that contains the project and click Open.

The new project is created on the Vault server in the database that you are logged in to.

### Quick Reference

# Working with Vault Project Drawings

Use drawings to create and access project data.

There is a tight association between a project object, such as a surface, and its *source drawing*, which is the drawing that contains the object. To create a project object, add the object's source drawing to a project and specify that you want to share the object with others. You can edit a project object by checking out the source drawing, making the change, and checking the source drawing back in.

You can store any project drawing in the project database. You will find it easier to keep your project organized if you use more than one folder to store your project drawings. For more information, see Project Folders (page 144).

The Drawings collection in the Prospector tree is not a folder and does not map to a folder in either the project database or the working folder. However, the folders under the Drawings collection map directly to folders in the project database and the working folder.

## Adding a Drawing to a Project

You can add a drawing to a project to make the drawing available to others, to place it under version control, and to create project objects from objects in the drawing.

**TIP** Before adding a drawing to a project, save the drawing in the most appropriate folder in the project working folder. Doing this ensures that Vault can determine where to save the drawing in the database.

While adding a drawing to a project, specify which objects (if any) in the drawing you want to share with others. Those objects are then added to the appropriate Prospector project object collection (such as Surfaces, Alignments, or Pipe Networks) and can be referenced by others.

**NOTE** You should only share objects that are required by others. If you are unsure whether an object should be shared, do not share it. You can share it later using the Check Out and Check In commands.

While adding a drawing to a project, you can specify that associated files, including surface data files, image files, and xrefs, are added to the project. You can also specify whether a *.dwf* file is created and added to the project for display in drawing item views and the Autodesk Vault tool.

If a drawing containing a surface is added to a project, and the surface references external data files, a folder is created under the drawing to hold those files. The files are placed in the folder, and the surface definition in the drawing is updated to reflect the new (relative) location of the files.

An open drawing must be saved before you can add it to a project. A copy of the drawing is created in your local working folder and the master copy is added to the project.

**To add a drawing to a project**

1   In Toolspace, on the Prospector tab, expand the Open Drawings collection.

2   Right-click the drawing you want to add to the project.

3   Click Add to Project.

4   On the Select A Project (page 2196) page of the Add To Project wizard, select the project to which you want to add the drawing.

5   Click Next.

6   On the Select A Drawing Location (page 2196) page of the Add To Project wizard, specify the location of the drawing within the project. Click [icon] to create a new folder.

7   Click Next.

**8** On the Drawing File Dependencies (page 2196) page of the Add To Project wizard, specify file dependencies and *.dwf* creation options.

**9** Click Next.

**10** In the Share Data (page 2196) page of the Add To Project wizard, specify which objects in the drawing you want to share with others.

---

**NOTE** If the drawing does not contain objects that can be shared, this page is not displayed.

---

**11** Click Finish.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Open Drawings collection ➤ right-click <drawing name> ➤ Add to Project

Add To Project Wizard

## Checking a Drawing out from a Project

You can check out a project drawing to edit it.

Checking out a drawing prevents others from changing the drawing while you are working on it. When you have completed your changes, check in the drawing.

Check out a drawing only if you intend to change it. If you do not need to change the drawing, get a read-only copy using Get Latest Version. For more information, see Getting the Latest Version of a Drawing (page 159).

You can check out files that the drawing is dependent on when you check out the drawing. However, you should only check out dependent files if you intend to change them.

When you check out a drawing, a local copy of the drawing is placed in your working folder, and the drawing is opened.

**To check a drawing out from a project**

**1** In Toolspace, on the Prospector tab, under the Projects collection, expand the project collection and the project Drawings collection that contains the drawing you want to check out.

---

**NOTE** If a drawing is open under the Open Drawings collection, all right-click functions are transferred to that location.

---

**2** Right-click the drawing and click Check Out.

**3** In the Check Out Drawing (page 2198) dialog box, specify whether dependent files should also be checked out.

**4** Specify whether you want the latest version of the file.

Getting the latest version overwrites your local copy of the file with the most recent version of the master copy of the file. Most of the time, you should get the latest version of the file. However, if you want to create a new version of the file from your existing local copy, do not get the latest version.

**5** If Include File Dependencies is selected, specify which project files should be checked out.

**6** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab (Master View): Projects collection ➤ project Drawings collection ➤ right-click <drawing name> ➤ Check Out

Dialog Box

Check Out Drawing Dialog Box (page 2198)

## Checking a Drawing in to a Project

After you check out a project drawing and change it, check in the drawing to make it available to others and to update the version in the project database.

You can only check in a drawing that you have checked out. Checking in the drawing returns the file to its original project database and folder, and updates the version. If the drawing is opened and has been changed, it is automatically saved before it is checked in.

When checking in a project drawing, you can specify which objects in the drawing (if any) you want to share with others. You can also specify whether a *.dwf* file is created for display in drawing item views and the Autodesk Vault tool.

**To check a drawing in to a project**

**1** In Toolspace, on the Prospector tab, under the Projects collection, expand the project collection and the project Drawings collection that contains the drawing you want to check in.

**NOTE** If a drawing is open under the Open Drawings collection, all right-click functions are transferred to that location.

**2** Right-click the drawing and click Check In.

**3** On the Drawing File Dependencies (page 2197) page of the Check In Drawing wizard, specify any file dependencies, *.dwf* creations options, and comments.

**4** Click Next.

**5** On the Share Data (page 2197) page of the Check In Drawing wizard, specify which objects in the drawing you want to share with others.

**NOTE** If the drawing does not contain objects that can be shared, this dialog box is not displayed. Objects that were shared during the Add to Project command or a previous Check In command are not listed.

**6** Click Finish.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab (Master view): Projects collection ➤ project Drawings collection ➤ right-click <drawing name> ➤ Check In

OR

Prospector tab: Open Drawings collection ➤ right-click <drawing name> ➤ Check In

Check In Drawing Wizard

## Opening a Project Drawing

After a drawing has been added to a project, open it from the Projects collection in the Prospector tree.

If you want to open a project drawing and edit it, you must first check it out. If you do not have the project drawing checked out, you can only open it in read-only mode.

You can tell whether the drawing is checked out to you by the icon displayed next to the drawing name in the Prospector tree. For more information, see Project Item State Icons (page 140).

If the drawing you want to check out is a source drawing for a project object, you can open it from the project object collection. For more information, see Viewing Project Object Source Drawings (page 164).

**To open a project drawing**

1   In Toolspace, on the Prospector tab, under the Projects collection, navigate to the folder that contains the drawing you want to open.

2   Right-click the drawing.

3   Click Check Out or Open (read-only).

The command that is listed on the menu depends on whether or not you have the drawing checked out.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab (Master View): Projects collection ➤ project Drawings collection ➤ right-click <drawing name> ➤ Open

## Getting the Latest Version of a Drawing

You can obtain a read-only copy of the latest version of any project drawing.

Use the Get Latest Version command to update your copy of a source drawing for a project object, a drawing that contains a reference to shared project objects, or any other project drawing.

You can tell whether your local copy of a drawing is the latest version available in Vault by the icon displayed next to it in the Prospector tree. For more information, see Project Item State Icons (page 140).

The Get Latest Version command is displayed in the shortcut menu of a Prospector tree item only when the local copy of the file is out of date or does not exist. The command is not available for an open drawing.

When applicable, the Get Latest Version command is available at every level within the Projects collection on the Prospector tab. If you select the command at a level that contains folders beneath it, you can choose which folders you want to update.

**To get the latest version of a drawing**

**1** In Toolspace, on the Prospector tab, under the Projects collection, right-click the drawing, collection, or folder you want to update.

**2** Click Get Latest Version.

**3** In the Get Latest Version (page 2204) dialog box, select Include File Dependencies to display any dependent files in the Project Files list.

**4** Clear the check boxes next to files and folders that you do not want updated.

**5** Click OK.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab (Master View): Projects collection ➤ right-click collection, folder, or item ➤ Get Latest Version

Dialog Box

Get Latest Version Dialog Box (page 2204)

## Resetting a Checked out Drawing

If you have a project drawing checked out, you can reset it to a checked-in state without making any changes to it.

A drawing must be checked out to you before you can reset its state. The Undo Check Out command resets your local copy of the drawing back to the latest version of the file in the project database, which means that any changes you made to the drawing are lost. You can preserve the changes you made to the drawing by saving and renaming the drawing (using Save As) before using the Undo Check Out command.

The status of the drawing in the project database is reset to checked-in, and the file version is not updated.

**To undo the checkout of a drawing**

**1** In Toolspace, on the Prospector tab, under the Projects collection, expand the project collection and the project Drawings collection that contains the drawing you want to reset.

> **NOTE** If a drawing is open under the Open Drawings collection, all right-click functions are transferred to that location.

**2** Right-click the checked-out drawing.

**3** Click Undo Check Out.

**4** In the Undo Check Out (page 2209) dialog box, select Include File Dependencies to display dependent files.

**5** If dependent files are displayed, clear the check boxes next to files that should remain checked-out.

**6** Click OK.

### Quick Reference

Toolspace Shortcut Menu

OR
Prospector tab: Open Drawings collection ➤ right-click <drawing name> ➤ Undo Check Out

Dialog Box

Undo Check Out Dialog Box (page 2209)

## Synchronizing Drawing Data with Project Data

You can update an open drawing with the latest versions of all project objects and point data.

The Sync To Project command updates out-of-date drawings that reference project objects. It also updates any out-of-date project points contained in the drawing. The out-of-date condition can occur when someone checks in a project object's source drawing or checks in project points.

Local copies of out-of-date source drawings and project points are replaced with the latest version from the project database.

**To synchronize a drawing**

1  In Toolspace, on the Prospector tab, under the Open Drawings collection, right-click the drawing you want to synchronize.

2  Click Sync To Project.

3  In the Sync To Project (page 2208) dialog box, select the out-of-date project objects you want synchronized.

4  Click OK.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Open Drawings collection ➤ right-click <drawing name> ➤ Sync to Project

Dialog Box

Sync To Project Dialog Box (page 2208)

## Detaching a Drawing from a Project

You can detach a drawing from a project to sever the connection between the drawing and all project data.

**WARNING** When you detach a drawing from a project, all links to project source drawings and project data are severed and cannot be re-established.

A drawing must be open to be detached from a project. When you detach a drawing from a project, all references in the drawing to shared project objects are replaced with object data that can be edited.

When a drawing contains a project object, such as a reference to a project surface, the project object is promoted to a surface object that has no reference back to the original source drawing that its geometry it based on. You can edit the promoted surface, but you cannot rebuild it based on the original source data.

**To detach a drawing from a project**

1   In Toolspace, on the Prospector tab, in the Open Drawings collection, right-click the drawing you want to detach.

2   Click Detach Project.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Open Drawings collection ➤ right-click <drawing name> ➤ Detach Project

# Working with Vault Project Objects

You can create, manage, and reference project objects through their source drawings.

A project object is an object that is intended to be shared with others working on a project. A project object is managed through its *source drawing*, which is the drawing that contains the object.

A project object becomes available to others when the source drawing containing the object is added to or checked in to the project database and the object is selected to be shared.

To include a project object in another drawing, you create a *reference* to the object. A reference is a read-only copy of the object that you can refer to as if it were the object itself.

## Creating Project Objects

Create a project object by adding a source drawing to a project.

When you add or check in a drawing to a project, you can specify which objects (such as surfaces) in the drawing are to be shared. For more information, see Adding a Drawing to a Project (page 156) and Checking a Drawing in to a Project (page 158).

After a project object has been shared, it is listed in the project's object collection (such as Surfaces, Alignments, or Pipe Networks) in the Prospector tree.

You can access a project object's data in another drawing by creating a read-only copy called a reference. For more information, see Creating References to Project Objects (page 162).

## Creating References to Project Objects

Include a read-only copy of a project object in a drawing by creating a reference to it.

All the available project objects in a project are listed in the project's object collections, including Surfaces, Alignments, and Pipe Networks, in the Prospector tree.

You access a project object's data in a drawing by creating a reference to it. A reference is a read-only copy of an object. When you create a reference to an object, you cannot modify the object's geometry, but you can access its properties and data, apply styles and annotation, and perform some types of analysis.

Creating a reference creates a local copy of the object's source drawing in your working folder. If you already have a local copy of the object's source drawing, it is updated to the latest version, if necessary.

**To create a reference to a project object**

1   Open the drawing to which you want to add the reference, and make it the active drawing.

2   In Toolspace, on the Prospector tab, expand the Projects collection.

**3** Expand the project and object collections that contain the project object.

**4** Right-click the project object.

**5** Click Create Reference.

**6** In the Create Reference dialog box for the object, specify how the object's geometry will be displayed in the drawing.

**7** Click OK.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab (Master View): Projects collection ➤ <project> collection ➤ <object> collection ➤ right-click <object> ➤ Create Reference

# Removing a Project Object

Make an object unavailable for referencing in other project drawings.

You can delete an object from the list of reference objects for a project. Any existing references to the object remain intact, and continue to be updated from the source object.

**To delete a project object**

**1** In Toolspace, on the Prospector tab, expand the Projects collection.

**2** Expand the project and object collections that contain the project object.

**3** Right-click the project object to be deleted.

**4** Click Remove.

## Quick Reference

Toolspace Shortcut Menu

# Getting the Latest Version of Project Objects

If someone makes a change to a project object, you can easily update your local copy of the object's source drawing.

When someone creates a new version of a project object's source drawing in the project database, your local copy becomes out of date. You can determine the state of your local copy by the icon displayed next to either the source drawing or the project object in the Prospector tree. For more information, see Project Item State Icons (page 140).

**NOTE** The Get Latest Version command is available at all levels of a project in the Prospector tree, when applicable.

**To get the latest version of a project object**

**1** In Toolspace, on the Prospector tab, expand the Projects collection.

**2** Expand the project collection that contains the project object.

**3** Expand the object collection that contains the project object.

**4** Right-click the project object and click Get Latest Version.

**5** In the Get Latest Version (page 2204) dialog box, select Include File Dependencies to display dependent files in the Project Files list.

**6** Clear the check boxes next to files and folders that you do not want updated.

**7** Click OK.

## Quick Reference

Dialog Box

Get Latest Version Dialog Box (page 2204)

# Viewing Project Object Source Drawings

You can quickly open or switch to a project object's source drawing.

You can open a project object's source drawing from the project object level in the Prospector tree. If the drawing is already open, you can make it the active drawing.

**NOTE** If you do not have the drawing checked out, you can only open the drawing in read-only mode.

**To access a source drawing for a project object**

**1** In Toolspace, on the Prospector tab, expand the Projects collection.

**2** Expand the project collection that contains the project object.

**3** Expand the object collection that contains the project object.

**4** Right-click the project object and do one of the following:

■ If you have the source drawing checked out, click Open Source Drawing to open it.

■ If you do not have the source drawing checked out, click Open Source Drawing (Read-only) to open it.

■ If the drawing is open, click Switch To Source Drawing to make it the active drawing.

## Quick Reference

Toolspace Shortcut Menu

OR
Prospector tab (Master View): Projects collection ➤ <project> collection ➤ <object> collection ➤ right-click <object> ➤ Open Source Drawing (Read-only)

OR

Prospector tab (Master View): Projects collection ➤ <project> collection ➤ <object> collection ➤ right-click <object> ➤ Switch To Source Drawing

## Checking Out Project Object Source Drawings

You can check out a project object's source drawing at the project object level in the Prospector tree.

When you check out a drawing, a local copy of the drawing is placed in your working folder, and the drawing is opened.

**To check out a project object's source drawing**

1   In Toolspace, on the Prospector tab, expand the Projects collection.

2   Expand the project collection that contains the project object.

3   Expand the object collection that contains the project object.

4   Right-click the project object and click Check Out Source Drawing.

5   In the Check Out Drawing (page 2198) dialog box, specify whether file dependencies should be included.

6   Specify whether the latest version of the file is desired.

7   If Include File Dependencies is selected, specify which project files should be checked out with the drawing file by selecting the check boxes next to them.

8   Click OK.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab (Master View): Projects collection ➤ <project> collection ➤ <object> collection ➤ right-click <object> ➤ Check Out Source Drawing

Dialog Box

Check Out Drawing Dialog Box (page 2198)

## Resetting a Checked Out Source Drawing

You can undo the checkout of a project object's source drawing at the project object level in the Prospector tree.

**To undo the checkout of a project object's source drawing**

1   In Toolspace, on the Prospector tab, expand the Projects collection.

2   Expand the project collection that contains the project object.

3   Expand the object collection that contains the project object.

4   Right-click the project object and click Undo Check Out Source Drawing.

5   In the Undo Check Out (page 2209) dialog box, select Include File Dependencies to display dependent files.

6   If dependent files are displayed, clear the check boxes next to files that should remain checked out.

**7** Click OK.

### Quick Reference

## Promoting Project Objects

You can replace a read-only object reference with an editable copy of the project object by promoting the object reference.

**WARNING** Promoting an object reference severs all connections to project object source data. The connection cannot be re-established.

You should promote an object reference only when you have no need to maintain the project object's link to its source drawing or data.

**To promote a project object**

**1** In Toolspace, on the Prospector tab, under the Open Drawings collection, expand the drawing that contains the project reference object you want to promote.

**2** Expand the drawing object collection that contains the object reference you want to promote.

**3** Right-click the object and click Promote.

### Quick Reference

# Working with Vault Project Points

Project management for AutoCAD Civil points differs from project management for other project objects.

Master copies of points are stored in a point database, not a source drawing, and points are checked out or copied directly to a drawing. The project points in a drawing are usually a subset of the project database. Individual points are not displayed in the project database, and they cannot be viewed using the Autodesk Vault tool.

Project points are accessed and managed through two files that are stored in the project database with other project files: *PointsGeometry.mdb*, which is the project point database, and *PointsStatus.mdb*, which contains information about the status (for example, checked-in or checked-out) of individual points. You do not explicitly check out or check in the project point database. Instead, you check out, modify, and check in individual project points and the project point database is updated automatically.

The status of your local project points in relation to the latest version of the project point database in the project's Vault database is shown by the icon displayed next to the project Points node under the project collection. The icons that can be displayed are shown in the following table:

| Icon | Meaning |
|---|---|
| | If no icon is displayed, the project point database exists in the project's Vault database, and you have not accessed it. |
| ○ | The local project point database matches the latest version of the project point database in the project's Vault database. |
| ● (green) | The local project point database is newer than the latest version of the project point database in the project's Vault database. |
| ● (red) | The local project point database is older than the latest version of the project point database in the project's Vault database. |

Many of the project management operations (such as check-in and check-out) that can be performed on points in a drawing can also be performed using point groups.

## Project Point State Icons

Because Vault is not used for managing individual points, the icons indicating the state of individual points (for example, checked-in or checked-out) are different from the icons used for other project objects.

The following table shows the project point state icons, which are displayed in the Points list view.:

| Icon | Meaning |
|---|---|
| 🔓 | The point is checked in. |
| ☑ | The point is checked out to your active drawing. |
| ☑ | The point is checked out to a drawing other than your active drawing. This could be a drawing that belongs to you or to someone else. |
| 🔒 | The point is protected and cannot be changed. |

## The Project Points List View

You can use the project points list view to obtain information about the state of project points.

**NOTE** To view project points in the Prospector tree, select Master View from the list at the top of the Prospector tab.

In Prospector ➤ Projects, click the project Points collection to display a list view that lists all of the project points. Project management information is listed, including:

■ Most recent version number

■ User who last modified the point and the date it was modified

■ Current state of the point (checked-in, checked-out, or protected) and the date the state was last changed

- User who set the current state of the point

- If checked-out, the drawing and host computer that the point is checked out to

Project point state icons are displayed next to each point. For more information, see Project Point State Icons (page 167).

For more information about changing the list view display, see Customizing a List View (page 84).

## Working with Point-related Project Management Commands

You can perform point access control operations, such as checking in and checking out points, in several locations in the Prospector tree.

When you select multiple points and perform a project management operation on them, the operation is performed only on those points to which it applies. For example, if you select a list of points in the Points list view and use the Check In command to check them in, only the points you checked out are checked in.

In addition, Survey points that are created using the Prospector Survey tab are not included in project management commands even if they are selected. For example, any Survey points included in the selection list during the Add to Project command are not added to the project.

You can access point-related project commands using list view shortcut menus or using point groups, as described below:

- If you already have a copy of a project point in a drawing, use the shortcut menu in the Prospector drawing Points list view to check in, check out, protect, or get a copy of the point.

- If you do not have a copy of the point in a drawing, use the shortcut menu in the Prospector project Points list view to check in, check out, protect, or get a copy of a point.

- If you have point groups defined in the drawing, right-click a point group in the Prospector tree and use the point group shortcut menu to check in, check out, protect, or get copies of project points.

In some cases, only valid project management commands are displayed on a shortcut menu. For example, if a set of points are not available for check out, the Check Out command might not be displayed, but the Get From Project command would be displayed so that you can get a read-only copy of the point. In some cases, a drawing must be saved before project management commands are available.

## Adding Points to a Project

You can use the Add To Project command to add points to a project so they can be accessed by others.

You can add some or all of the points in a drawing to a project. Before you can add drawing points to a project, you must save the drawing. If the drawing has not been saved, the Add to Project command is not available.

If the drawing contains one or more project objects, the points are added to the project that the existing project objects belong to. If the drawing does not contain project objects, you are prompted to select a project.

You can access the Add To Project command not only from the drawing's Points list view, but also from a drawing point group's shortcut menu.

**To add points to a project**

1  In Toolspace, on the Prospector tab, under the Open Drawings collection, expand the drawing that contains the points you want to add to the project.

**2** Click the Points collection to display the Points list view.

**3** In the list view, select the points, right-click, and click Add To Project.

Any Survey points included in the selection are not added to the project. Survey points are stored only in the project's Survey Point database.

**4** If you are prompted, select a project to add the points to.

**5** In the Add To Project (page 2195) dialog box, enter a comment.

**6** From the Check In Options list, select an option to specify the state of the points after you add them to the project.

**7** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Open Drawings collection ➤ click Points collection ➤ right-click selected points in list view ➤ Add To Project
OR
Prospector tab: Open Drawings collection ➤ Point Groups collection ➤ right-click <point group> ➤ Add Points To Project

Dialog Box

Add Points To Project Dialog Box (page 2195)

## Checking Out Points

You can use the Check Out command to prevent others from making changes to project points while you are editing them.

To edit a project point, check it out to a drawing, edit it in the drawing, and then check it back into the project.

---

**NOTE** When working with project points, the term *local copy* refers to the copy of the point in your drawing.

---

Checking out a project point creates a local copy of the point in the drawing. The Check Out command gives you exclusive access to the project point; no one else can check it out while you are working on it.

If the Check Out command is not available, you can use the Get From Project command to a read-only local copy of the point. For more information, see Copying Project Points into a Drawing (page 171).

**To check out project points**

**1** Verify that the drawing you want to bring the points into is the active drawing. If it is not, right-click the drawing name in the Open Drawings collection in the Prospector tree and click Switch To.

**2** In Toolspace, on the Prospector tab, expand the Projects collection and then expand the project that contains the points you want to check out.

**3** Click the project Points collection to display a list view.

**4** In the list view, select the project points you want to check out, right-click, and click Check Out.

**5** In the Check Out (page 2199) dialog box, click OK.

Local copies of the points are created in the active drawing.

### Quick Reference

Prospector tab (Master View): Projects collection ➤ project Points collection ➤ right-click selected points in list view ➤ Check Out
OR
Prospector tab: Open Drawings collection ➤ Point Groups collection ➤ right-click <point group> ➤ Check Out Points

Dialog Box

Check Out Points Dialog Box (page 2199)

## Checking In Points

You can use the Check In command to check in checked-out project points.

**NOTE** When working with project points, the term *local copy* refers to the copy of the point in your drawing.

After you edit one or more project points, use the Check In command to replace the existing project point with your local copy of the project point, and increase the project point's version number.

The Check In command always updates the project point from the drawing that the point was checked out to.

**To check in project points**

1   Verify that the drawing that you want to check the points in from is the active drawing. If it is not, right-click the drawing name in the Open Drawings collection in the Prospector tree and click Switch To.

2   Click the drawing's Points collection to display a list view.

3   In the list view, select the points to check in and right-click.

4   Click Check In.

5   In the Check In (page 2198) dialog box, enter a comment.

6   From the Check In Options list, select an option to specify the state of the points after you check them in.

7   Click OK.

### Quick Reference

OR
Prospector tab: Open Drawings collection ➤ Point Groups collection ➤ right-click <point group> ➤ Check In Points

Dialog Box

Check In Points Dialog Box (page 2198)

## Copying Project Points into a Drawing

You can use the Get From Project command to make a read-only copy of project points in a drawing.

**To copy project points into a drawing**

1   Verify that the drawing to which you want to copy is the active drawing. If it is not, right-click the drawing name in the Prospector tree and click Switch To.

2   In Toolspace, on the Prospector tab, expand the Projects collection and then expand the project collection that contains the points you want to copy.

3   Click the project Points collection to display the list view.

4   In the list view, select the points to copy, right-click, and click Get From Project.

5   In the Get From Project (page 2204) dialog box, click OK.

## Quick Reference

Toolspace Shortcut Menu

OR
Prospector tab: Open Drawings collection ➤ Point Groups collection ➤ right-click <point group> ➤ Get Points From Project

Dialog Box

Get Points From Project Dialog Box (page 2204)

## Protecting Project Points

You can use the Protect command to prevent project points from being checked out and edited.

You cannot protect a project point that is checked-out.

**To protect project points**

1   In Toolspace, on the Prospector tab, expand the Projects collection and then expand the project collection that contains the points you want to protect.

2   Click the project Points collection to display the list view.

3   In the list view, select the points to protect, right-click, and click Protect.

4   In the Protect (page 2207) dialog box, click OK.

A lock icon 🔒 is displayed next to a protected project point in the Points list view.

### Quick Reference

Toolspace Shortcut Menu

OR
Prospector tab: Open Drawings collection ➤ Point Groups collection ➤ right-click <point group> ➤ Protect Points

Dialog Box

Protect Points Dialog Box (page 2207)

## Unprotecting Project Points

You can use the Unprotect command to allow protected project points to be checked out and edited.

Only the person who protected a project point can unprotect it.

A lock icon 🔒 is displayed next to a protected point in the Points list view.

**To unprotect project points**

1   In Toolspace, on the Prospector tab, expand the Projects collection and then expand the project collection that contains the points you want to unprotect.

2   Click the Points collection to display the list view.

3   In the list view, select the protected points, right-click, and click Unprotect.

4   In the Unprotect (page 2209) dialog box, click OK.

### Quick Reference

OR
Prospector tab: Open Drawings collection ➤ Point Groups collection ➤ right-click <point group> ➤ Unprotect Points

Dialog Box

Unprotect Points Dialog Box (page 2209)

## Deleting Project Points

You can use the Delete From Project command to delete project points.

When you delete a project point, it is permanently removed from the project, and is no longer listed in the Prospector tree.

Before you can delete a project point, you must check it out. For more information, see Checking Out Points (page 169).

**To delete project points**

1   In Toolspace, on the Prospector tab, expand the Projects collection and then expand the project collection that contains the points you want to delete.

2   Click the Points collection to display the list view.

3   In the list view, select the points to delete, right-click, and click Delete From Project.

4   In the Delete From Project  (page 2204)dialog box, click OK.

## Quick Reference

Toolspace Shortcut Menu

OR
Prospector tab: Open Drawings collection ➤ Point Groups collection ➤ right-click <point group> ➤ Delete Points From Project

Dialog Box

Delete Points From Project Dialog Box (page 2204)

## Resetting Points You Checked Out

You can use the Undo Check Out command to reset checked-out project points back to a checked-in state.

Use this command if you checked out one or more points but do not want to update the project with any changes you have made.

You can use this command only on project points that are checked out to you.

**To reset your checked out project points**

1   In Toolspace, on the Prospector tab, expand the Projects collection and then expand the project collection that contains the points you want to reset.

2   Click the Points collection to display the list view.

3   In the list view, select the points to reset, right-click, and click Undo Check Out.

4   In the Undo Check Out (page 2209) dialog box, click OK.

### Quick Reference

OR
Prospector tab: Open Drawings collection ➤ right-click <point group> ➤ Undo Check Out

Dialog Box

Undo Check Out Points Dialog Box (page 2209)

## Resetting Project Points Set by Others

If you are a system administrator, you can use the Reset To Checked In command to reset to a checked-in state a project point checked-out or protected by someone else.

Use this command if a point is checked out or protected and for some reason the person who originally checked it out or protected it cannot undo the operation or check in the point.

**NOTE** The Reset to Checked In command is available only to a system administrator.

**To reset points checked out to someone else**

1 In Toolspace, on the Prospector tab, expand the Projects collection, and then expand the project collection that contains the points you want to reset.

2 Click the Points collection to display the list view.

3 Select the checked-out or protected points, right-click, and click Reset To Checked In.

4 In the Reset To Checked In (page 2207) dialog box, click OK.

**NOTE** The Project Points item list can be sorted to assist selecting the project points to be reset to a checked in state.

# Error Codes

Errors encountered during Vault project management commands are reported in two ways.

If a single error is encountered during a project management operation, it is displayed in a message box. If multiple errors occur during a single operation, the resulting Vault error codes are displayed in the Event

Viewer. For example, if a drawing check-in operation fails, and then subsequent check-ins of dependent files also fail, the error codes for the related multiple failures are displayed in the Event Viewer.

The following table lists the Vault error codes that can be displayed if a project management command fails:

| Group Code/Error Code | Error Description |
| --- | --- |
| SysErrCodes | |
| 0 | Error code is not valid or is unspecified. |
| CoreErrCodes | |
| 100 | Error creating the knowledge vault in database. |
| 101 | Script to prime the database with its schema failed. |
| 102 | Knowledge vault already exists in database. |
| 103 | Attempt to create user in database failed. |
| 104 | Error adding user role in database. |
| 105 | Error removing user role in database. |
| 106 | Error validating the principal as being a secure principal (i.e. authenticated). |
| 107 | Principle requirement does not match. Should be anonymous. |
| 108 | Requires new transaction, but transaction was not created. |
| 109 | Error initializing knowledge vault in database. |
| 110 | Stored procedure cannot be found. |
| 111 | Error getting relative resource path. |
| 112 | File stream is null, so the crc code can't be calculated |
| 113 | File is not readable, so the crc code can't be calculated |
| 114 | Could not create (Knowledge)VaultMaster Database |
| 115 | Could not create (Knowledge)VaultMaster Database schema |
| 116 | Could not initialize (Knowledge)VaultMaster Database tables |

| Group Code/Error Code | Error Description |
| --- | --- |
| 117 | Failure during migrate of a KnowledgeVault |
| 118 | Failure creating VultSys user for the DB |
| 119 | Failure during migrate of KnowledgeVault-Master |
| 120 | Failure updating the KnowledgeVaultMaster stored procedures |
| 121 | Failure deleting the KnowledgeVaultMaster |
| 122 | Failure updating user information |
| 123 | Could not update ElDatabase table |
| 124 | Failure moving the file store |
| 125 | Failure attaching a database |
| 126 | Failure detaching a database |
| 127 | Failure deleting a Vault |
| 128 | Failure backing up |
| 129 | Failure restoring |
| 130 | Unable to determine the version of a KnowledgeVault or Master |
| 131 | The database master login is invalid |
| 132 | The directory is not empty |
| 133 | The Knowledge Vault referenced doesn't exist |
| 134 | There are Knowledge Vaults still attached. |
| 135 | Failure activating a vault |
| 136 | Failure deactivating vault. DB is probably in use |
| 137 | One of the inputs to the service call is incorrect. |
| 138 | Vault name is not allowed, most likely due to illegal characters. |
| 139 | Specified folder is illegal. |
| 140 | Specified folder is already in use. |

| Group Code/Error Code | Error Description |
| --- | --- |
| 141 | Could not find global option. |
| 142 | Could not find local option. |
| 143 | Duplicate User Name |
| 144 | Database error because an MDF or LDF file with that name already exists. |
| 145 | Database is in use |
| 146 | Cannot determine the migration steps. |
| 147 | The specified path is too long. |
| 148 | Incorrect vault category Id entered |
| 149 | The vault's category does not support the operation. |
| 150 | The KnowledgeVaultMaster referenced doesn't exist |
| 151 | Not enough disk space to perform Backup/Restore operation. |
| 152 | Cannot restore db files to a remote location |
| 153 | Selected directory does not contain a valid backup structure. |
| SecurityErrCodes | |
| 300 | Authentication Token is invalid. |
| 301 | User name and/or Password is invalid, so user cannot be authenticated. |
| 302 | User is not a member of the vault |
| 303 | Invalid permissions for transaction |
| 304 | User is disabled |
| 305 | Vault database does not exist |
| DocServiceErrCodes | |
| 1000 | Folder id is invalid. |
| 1001 | Cannot get the latest version of file. |

| Group Code/Error Code | Error Description |
| --- | --- |
| 1002 | Cannot get file version. |
| 1003 | File id is invalid. |
| 1004 | Checkout latest file version failed. |
| 1005 | Error checking in file version into database. |
| 1006 | Error undoing check out of file version. |
| 1007 | Bad version id when getting file version dependents or dependencies by version id. |
| 1008 | Cannot add file because file exists. |
| 1009 | Cannot add file (unspecified failure) |
| 1011 | Cannot add folder because folder exists. |
| 1012 | Cannot add folder (unable to create/make new folder). |
| 1013 | Cannot get file (file id is invalid). |
| 1014 | Cannot create/make version in database. |
| 1015 | Cannot delete file version because of dependencies. |
| 1016 | Cannot undo checkout because user is not the same as user who checked out file. |
| 1017 | Cannot undo checkout because passed in folder id is not the same folder that the file was checked out from. |
| 1018 | Cannot check in file because the file is not currently checked out |
| 1019 | Cannot check in file because the file is not currently checked out by the same user. |
| 1020 | Cannot check in file because passed in folder id is not the same folder that the file was checked out from. |
| 1021 | Cannot check out the file because it is already checked out. |
| 1022 | Circular dependency check failed. |
| 1023 | Cannot create folder in database. |

| Group Code/Error Code | Error Description |
| --- | --- |
| 1024 | Cannot get folder. |
| 1025 | Cannot get root folder from the database. |
| 1026 | File belongs to a library folder. |
| 1027 | Folder is a library folder. |
| 1028 | Cannot move file. |
| 1029 | A file exists in the destination folder that has the same name as the file that is being moved from its source folder. |
| 1030 | Cannot share because a file already exists in the destination folder with the same name. |
| 1034 | Cannot rename the file because there was some other unexpected error. |
| 1035 | Could not create property definition in database. |
| 1036 | Cannot get all property definitions. |
| 1037 | Cannot get all extended property definitions. |
| 1039 | Property could not be added in database. |
| 1040 | Big property could not be added in database |
| 1041 | Cannot get properties |
| 1042 | Create folder rule-check failed: parent must exist, for all but root |
| 1043 | Create folder rule-check failed: libs can only have non lib parent if that parent is root. Libs cannot have non-lib children. |
| 1044 | Request to share a file to a folder fails because of a concurrent request to share the file to the same folder. |
| 1045 | Request to move a file to a folder fails because of a concurrent request to move the file to the same folder or because of a concurrent request to move the file to another folder |

| Group Code/Error Code | Error Description |
| --- | --- |
| 1046 | Request to create a folder fails because the folder name is longer that 80 characters. |
| 1050 | Request to conditionally delete a file fails because there are delete restrictions (file has dependent parent files, file is checked out, or file is linked or attached to an item) |
| 1051 | Request to unconditionally delete a file fails because the are delete restrictions that cannot be overridden (file is linked or attached to an item) |
| 1052 | Request to delete a file failed for an unspecified reason. |
| 1053 | Request to conditionally delete a folder fails because there are delete restrictions on one or more child files (file has dependent parent files, file is checked out, or file is linked or attached to an item) |
| 1054 | Request to unconditionally delete a folder fails because the are delete restrictions that cannot be overridden on one or more child files (file is linked or attached to an item) |
| 1055 | Request to delete a folder fails due to an unspecified reason |
| 1056 | Occurs when either no parameters have been set and a purge is attempted or when an attempt is made set invalid parameter values. |
| 1057 | Occurs when something goes wrong while purging file iterations from the database, or while deleting files from the file store |
| 1058 | If the Unique File Name Required Vault option is ON, a request to Add or Check in a file with the same name as a file already existing in the Vault will fail with this error. |
| 1059 | Occurs when an attempt to update a Folder fails for an unspecified reason. |
| 1060 | Occurs when an attempt to update a Folder Name fails because another Folder with that name exists in the parent. |
| 1061 | Label ID is invalid |

| Group Code/Error Code | Error Description |
| --- | --- |
| 1062 | Label Name contains invalid characters |
| 1063 | Label Name already exists in vault |
| 1064 | Cannot create label in database. |
| 1065 | |
| 1066 | No PropertyGroup with the given Id exists |
| 1067 | A PropertyGroup with the specified name already exists. |
| 1068 | The PropertyDefinitions to be assigned to the PropertyGroup do not share the same DataType. |
| 1069 | The PropertyGroup must be assigned PropertyDefinitions |
| 1070 | Request to add a PropertyGroup failed for an unspecified reason |
| 1071 | Request to update a PropertyGroup failed for an unspecified reason. |
| 1072 | Request to delete a PropertyGroup failed for an unspecified reason. |
| 1073 | An unknown error occurred. |
| 1074 | Folder with the same name already exists in the destination folder |
| 1075 | Folder being moved has descendent files that are checked out. |
| 1076 | Move folder rule-check failed: parent must exist, for all but root |
| 1077 | Move folder rule-check failed: libs can only have non lib parent if that parent is root. Libs cannot have non-lib children. |
| 1078 | A null path or path with illegal characters has been passed in. |
| 1079 | The full path of the folder is greater than 256 characters |
| 1080 | A null value has been passed in where null values are not allowed. |

| Group Code/Error Code | Error Description |
|---|---|
| 1081 | The date is out of range for the DB. The date should be between 1-1-1753 and 12-31-9999 |
| SerializeErrCodes | |
| 1200 | Exception passed to Encodable Exception saying the object is null |

# Project Management Command Reference

Use these commands to access reference functionality for data shortcuts or Vault.

The following table lists AutoCAD Civil commands related to project management and briefly describes their functionality.

| Command | Description |
|---|---|
| CreateAlignmentReference | Creates a Vault alignment reference (page 893) |
| CreateNetworkReference | Creates a Vault pipe network reference (page 1199) |
| CreateProfileReference | Creates a Vault profile reference (page 1055) |
| CreateSurfaceReference | Creates a Vault surface reference (page 609) |
| CreateViewFrameGroupReference | Creates a Vault view frame group reference (page 1709) |
| CreateDataShortcuts | Creates a data shortcut for each eligible object in the active drawing (page 131) |
| NewShortcutsFolder | Creates a new project folder for use with data shortcuts (page 129) |
| PromoteAllReferences | Promotes all reference objects in the drawing, whether they are Vault or data shortcut references (page 134) |
| PromoteNetwork | Promotes a data shortcut reference pipe network (page 134) |
| PromoteReference | Promotes a data shortcut reference surface, alignment, or profile (page 134) |
| PromoteViewFrameGroup | Promotes a data shortcut reference view frame group (page 134) |
| RepairBrokenReferences | Repairs one or more data shortcut references in a consumer drawing (page 135) |
| SetShortcutsFolder | Changes the active project folder for use of data shortcuts (page 130) |

| Command | Description |
| --- | --- |
| SetWorkingFolder | Points to a different working folder for data short-cuts projects (page 129) |
| ShortcutNode | Hides or shows the Data Shortcuts node on the Prospector tab (page 133) |
| SynchronizeReferences | In data shortcuts projects, updates data references with current versions of their source objects (page 133) |
| ValidateShortcuts | Ensures that all data references are up to date and reloads any outdated ones from their source objects (page 135) |

# Survey

# Understanding Survey

<div style="text-align: right; font-size: large;">**8**</div>

You can use the AutoCAD Civil survey features to download, create, analyze, and adjust survey data. The survey features extend the functionality of AutoCAD Civil by streamlining the process of transferring field-captured survey data to and from the office.

Survey Best Practices

## Survey Overview

You can use the complete set of tools in AutoCAD Civil to import survey data, perform surveying calculations, and automate symbol placement and line work.

AutoCAD Civil survey data and figures persist in a survey database, and can be accessed using multiple drawings attached to the same AutoCAD Civil survey database.

The survey database stores angle values in Radians and distance values in Meters. Survey data is transformed according to the database units for the purposes of display and input. AutoCAD Civil drawing units can be independent of the survey database units. If drawing objects are imported from the survey database and the AutoCAD Civil drawing units and coordinate zone differ, the objects are transformed.

Survey objects and their components are displayed based on their styles. Before creating survey components, you should be familiar with creating and managing styles (page 53).

### Establish Survey Settings

Define and manage the following survey settings:

| | |
|---|---|
| Figure Prefix Database | Determine the display and properties of figures. |
| Survey Equipment Database | Establish an error model for a specific survey instrument when analyzing survey data using least squares. |
| Survey Database Settings | Control the default settings for all database components. |
| User Settings | Control the default settings for survey specific components. |

| Linework Code Set | Define the codes used to determine the connectivity of linework from point descriptions. |
| --- | --- |
| Survey Feature Settings | Control the default styles for figures and networks. |

For more information about settings, see Survey Settings (page 205).

**Import and Edit Survey Data**

You can import and modify survey data in the AutoCAD Civil environment and use the AutoCAD Civil drawing session to graphically display the survey data. Use the AutoCAD Civil survey data to affect other AutoCAD Civil data, such as points and surfaces.

| Survey Data Collection Link | Convert raw survey observation data to a field book file (*.fbk*) that can be imported into an AutoCAD Civil survey database. |
| --- | --- |
| Import Survey Data Wizard | Use the Import Survey Data wizard to import field book files, point files, and LandXML files or to select points in the drawing. |
| Import Commands | Use the commands available from a network to import a field book, point file, or points in a drawing. |
| Import Survey Land XML | Import Survey LandXML data into the survey database. |
| Import Events | An import event is created each time a data source is imported into the survey database. Use import events to process linework and re-import data with existing settings, also to delete only the data created from the import event. |
| Add survey data to a network | Use the commands from within a network collection to create or edit control points, non-control points, directions and observations from a network. |
| Survey Command Window | Perform coordinate geometry operations using specific survey commands, along with the options to record input and output, and to re-run the input from a batch file. |

For more information about input and figures, see Adding and Editing Survey Data (page 253) and Survey Figures (page 321).

**Perform Analysis Adjustments**

Using traverse and least squares adjustments, you can reduce field data for analysis.

| | |
|---|---|
| Define a traverse | Perform Compass, Crandall, Transit, and Least Squares analysis. |
| Least Squares analysis | Perform 2D or 3D network least squares analysis. Update points in the survey database and the linework input. |
| Mapcheck Analysis | Check the closure of values from label objects based on the precision of the annotation of the label object, or enter mapcheck data manually. |

For more information, see Survey Analysis and Output (page 361).

**Export Survey Data**

You can output and export survey data:

| | |
|---|---|
| Export survey data | Export data as a field book or Survey LandXML file. |
| Define surface breaklines | Use survey figures as breaklines when you create a surface model. |
| Update the survey objects in the drawing | Select a survey object in the drawing and use short-cut menus to update the drawing object on the Prospector tab. |

# Survey Project Phases

Organize survey data by creating networks within the survey database for the various stages of a project.

Throughout a survey project it may be necessary to perform several types of survey tasks such as a site analysis, a boundary analysis, and a topographic survey.

In AutoCAD Civil you can create multiple networks within a survey database and append survey data to the survey database to maintain the integrity of existing survey data. The benefits of multiple networks are:

■ Each network can represent a specific purpose.

■ Each network can be analyzed and adjusted separately, but can reference data from another network.

■ When you create figures by importing data into a network, that network contains information as to which figures will need to be updated if the network is modified.

# Site Analysis Phase Workflow

In the first phase of a project, a preliminary analysis of a site is necessary to determine if the project is feasible.

As an example of this phase, a survey crew would go to the site with a mapping grade GPS data collector to map wetlands that have been delineated on the site. This information is imported into a survey network of the project's survey database and overlaid onto a map of the area along with other relevant information, such as a steep slope analysis of the site's topography.

To accomplish this phase in AutoCAD Civil:

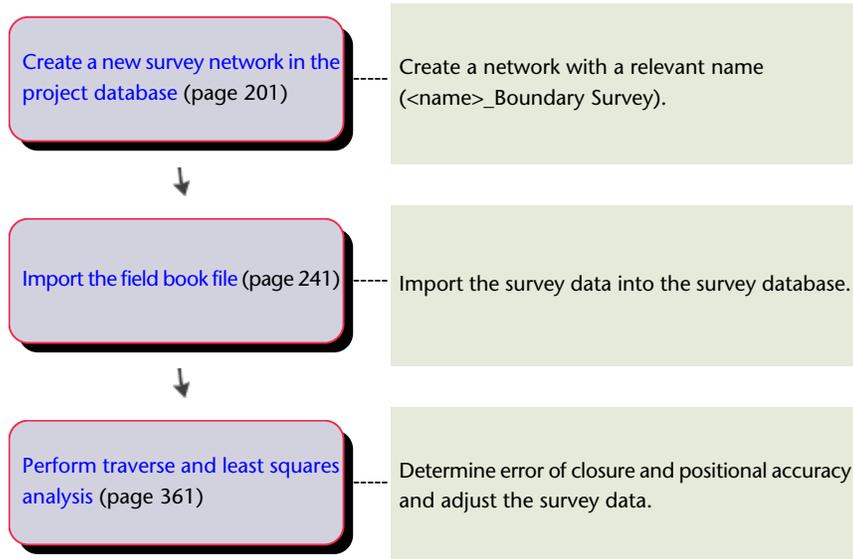
| | |
|---|---|
| **Create a new project** (page 128) | In Toolspace on the Prospector tab choose Master View and create a new project or create a local survey database. |
| **Check out the Survey Database** (page 125) | If you are working with the project management tools, check out the Survey database and import the wetland mapping points and line features. |
| **Create a new survey network** (page 201) | Create a network with a relevant name to the site (<name>_Site Analysis) and import the points and line work into the survey database. |

## Boundary Survey Phase Workflow

In the second phase, a boundary survey is performed to locate physical evidence and establish horizontal and vertical control on the site.

After determining that a site development is feasible and deed research is completed, a survey crew performs a boundary survey. Survey grade GPS control is established on the site to provide a tie onto the State Plane coordinate system. When the boundary survey is completed, the data (survey observations and linework) is imported into another survey network in the same project survey database. The data is analyzed to determine positional error and the network is adjusted.

To accomplish this phase in AutoCAD Civil:

| | |
|---|---|
| **Create a new survey network in the project database** (page 201) | Create a network with a relevant name (<name>_Boundary Survey). |
| **Import the field book file** (page 241) | Import the survey data into the survey database. |
| **Perform traverse and least squares analysis** (page 361) | Determine error of closure and positional accuracy and adjust the survey data. |


# Boundary Analysis Phase Workflow

In the third phase, the boundary is closed and a survey figure is created.

To maintain the integrity of the boundary survey network, you can create a new network and perform iterative coordinate geometry calculations. The parcel can be closed by creating a survey figure from the coordinate geometry calculations in conjunction with the points located in the field. You can query the survey figure to report the figure inverse and area. The figure can then be inserted into a drawing as the basis of a new subdivision.

To accomplish this phase in AutoCAD Civil:

| | |
|---|---|
| Create a new survey network in the project survey database (page 201) | Create a new network with a relevant name (<name>_Boundary Analysis). |
| ↓ | |
| Perform coordinate geometry calculations on the network (page 2419) | In the Survey Command Window, use the Survey Command Language, commands to close the parcel and create a survey figure by performing coordinate geometry calculations. |
| ↓ | |
| Mapcheck (page 356) and Figure Inverse (page 357) | Query the figure to report mapcheck and figure inverse. |
| ↓ | |
| Insert the figure into a drawing (page 324) | The new figure can be used a basis in creating a subdivision layout. |

# Topographic Survey Phase Workflow

In the last phase, a topographic survey of the proposed road locations is performed.

The topographic survey supports the engineering of the street grades, upgrade of the access from existing streets, site drainage, and driveway access to the proposed building sites. The topographic survey is based on the horizontal and vertical control established from the boundary survey network. After completing the topographic survey, the data is imported into a new survey network. This survey network references control from the boundary survey, and creates additional survey points and linework that can be used to create a terrain model for the site engineering.

To accomplish this phase in AutoCAD Civil:

| | |
|---|---|
| Create a new survey network (page 201) | In the survey database, create a new network with a relevant name (<name>_Topo). |
| ↓ | |

| | |
|---|---|
| **Import the topographic survey data** (page 241) | Import topographic survey data into the survey network using the Import Field Book command. |
| ↓ | |
| **Create a new drawing** (page 114) | Create a new drawing that contains the surface for the site engineering. |
| ↓ | |
| **Create a point group and add the survey points** (page 529) | Create a new point group and add the survey points. |
| ↓ | |
| **Create a new surface** (page 601) | Create a new surface and add the point group to the surface. |
| ↓ | |
| **Add the survey figures as breaklines** (page 324) | Add the survey figures (located in the topographic survey) to the surface as breaklines. |
| ↓ | |
| **Edit the surface** (page 611) | Perform additional edits on the surface, such as editing the surface boundary. |
| ↓ | |
| **Working with Vault Project Drawings** (page 156)**Adding a Drawing to a Project** (page 156) | Add the drawing with the new surface to the project if you are using project management. |

## Example: Using Networks with Import Events and Survey Data

The following descriptions of survey phases show an example of using networks and import events with survey data.

**Phase One**

■ A survey is being done on a parcel of land by multiple survey crews. The survey will be analyzed within a single survey network, for example a least squares network analysis.

- The data from each survey crew is downloaded into separate *.fbk* files and each *.fbk* file is imported into each network, creating a seperate import event. During each import, potential point identifier (point name or point number)conflicts can be resolved by applying a point identifier offset, and linework can be processed using the specified linework code set.

- The network is analyzed creating adjusted control points for each setup and updated coordinates for each sideshot within each setup. The coordinates for each figure are updated in each import event.

**Phase Two**

- In a later stage of the civil engineering process, an additional survey has to be performed to establish control for construction stakeout of proposed roads and parcel corners.

- This additional survey ties into the network that was adjusted in phase one and also requires a least squares analysis.

- A new network is created, and for each survey data file that is imported into this network an import event is created.

# Survey User Interface

Manage, analyze, and edit survey data using the Toolspace Survey tab, the Survey collection in the Prospector tab, the Survey collection in the Settings tab, the Survey Command Window, and various panorama vistas.

## Survey Tab

Use the Survey tab in Toolspace to access and manage survey settings, survey-related databases, and survey project data.

For more information about the Survey tab, see The Toolspace Survey Tab (page 97).

## Survey Collection (Prospector Tab)

Use the Survey collection on the Prospector tab in Toolspace to access survey data contained in the drawing. As you insert survey network and figure objects into the drawing, they are displayed in the Prospector Survey collection.

Expand the Survey collection to view the names of the survey components and display a tabular list of the components in the Prospector list view. For more information, see The Toolspace Item View (page 82).

Since the Prospector tab displays only the drawing representations of survey data, you manipulate and edit the data in the Survey tab.

**To browse to survey data from the Prospector tab**

- In Toolspace, on the Prospector tab, right-click a network object or a figure object ➤ Browse To Survey Data.
  On the Survey tab, the survey tree expanded, displaying the selected network or figure.

**To update a network or figure drawing object from survey data**

- In Toolspace, on the Prospector tab, right-click a network object or a figure object ➤ Update From Survey Data.
  The drawing object is updated with the data in the survey database.

**To update survey data from the drawing**

■ In Toolspace, on the Prospector tab, right-click a figure object ➤ Update Survey Data From Drawing. The survey database is updated with changes made to the selected figure object.

## Survey Collection (Settings Tab)

Use the Survey collection in the Settings tree to manage survey drawing settings and survey styles.

Right-click the Survey collection to edit survey feature settings. For information about survey feature settings, see Edit Feature Settings - Survey Dialog Box (page 2373).

Expand the Survey collection to display and edit the styles that are available for survey objects. For information, see Survey Styles and Display (page 195).

## Survey Command Input

Use the Survey Command Window to access survey input and analysis functionality with menu choices, or you can enter survey commands directly.

For more information about the Survey Command Window layout and options, see Survey Command Window (page 2419).

### Survey Command Language

The survey command language (which is also used in field book files) is one way to enter survey data into AutoCAD Civil.

Commands entered at the survey command line use a specific syntax. For information about the syntax and available commands, see Survey Command Reference (page 391).

**To display the Survey Command Window**

■ In Toolspace, on the Survey tab, expand the Network collection. Right-click a network item. Click Survey Command Window.

### Quick Reference

Toolspace

  Survey tab: ➤ right-click <named network> ➤ Survey Command Window

Dialog Box

  Survey Command Window (page 2419)

## Survey Objects

Survey networks and figures persist in AutoCAD Civil drawings as objects with the names AeccSvNetwork, AeccSvFigure, AeccDbSvNetwork, and AeccDbSvFigure.

■ Network object. Represents a survey network or traverse in the drawing. The network object is a read-only object that cannot be edited in the drawing. If the network is modified in the database, the survey network displayed on the Survey tab in Toolspace indicates that it needs to be updated.

■ Figure object. Represents a survey figure in a drawing.

The figure object can be edited in the drawing (depending on how the figure is defined), but it displays as out-of-sync with the survey database. The survey database can be updated from the figure drawing object. If other drawings have the same figure in a drawing and the survey database has been updated, their drawing figures are shown as out-of-date and can be updated from the survey database.

When a figure with a Lot Line property is inserted into the drawing, an AutoCAD Civil site is created in the drawing (if it does not exist) and Aecc_Parcel_Segment objects are created in the site that is specified for the figure. If the figure is closed, a parcel object of the same geometry is added. If not, then parcel segments are added to the site for the figure geometry.

■ **Survey Point**. A special type of COGO Point that is read-only in a drawing session. However, the display properties of a Survey Point can be modified in the Survey points collection on the Survey tab in Toolspace, or using the Edit Survey Point Properties command. A survey point is read-only in the drawing, because a survey point has dependent data, such as an Angle, Distance, Vertical Angle, Prism Height, from a specific instrument setup.

Survey drawing objects are displayed in the Toolspace Prospector tab under the Survey collection.

For general information about AutoCAD Civil objects, see Understanding Objects and Styles (page 51).

# Survey Styles and Display

Use the survey styles to control the way that survey networks and figures are displayed in a drawing.

The survey styles are accessed and managed on the Settings tab in Toolspace, where you can create, edit, copy, and delete them. For more information, see The Object Style Collection (Settings Tree) (page 94).

There are two survey-related styles:

■ Network styles. Include display control for survey network components, including known and unknown control points, non-control points, sideshot lines and sideshot points, direction lines, network lines, error ellipses, and tolerance error points. You can also control the network marker styles and 3D geometry display. For more information, see Survey Network Style Dialog Box (page 2388).

■ Figure styles. Include display control for survey figure components, including plan and model markers, and 3D display. For more information, see Survey Figure Style Dialog Box (page 2390).

For more general information about styles, see Object Styles (page 53).

**To create a network style**

1  In Toolspace, on the Settings tab, expand the Survey collection. Right-click the Network Styles collection. Click New.

2  In the Network Style dialog box, click the Information tab and enter a name and description for the style.

3  To specify the styles for markers and the error ellipse scale factor in the network, click the Components tab. For information on the components about this tab, see Components Tab (Survey Network Style Dialog Box) (page 2389).

4  To specify the 3D geometry display of the network, click the 3D Geometry tab and specify the settings.

5  To define the display of the various network components, including network lines, points, and error ellipses, click the Display tab.

6  To view summary information about the style, click the Summary tab.

7  Click OK.

**To create a figure style**

1 In Toolspace, on the Settings tab, expand the Survey collection, right-click the Figure Styles collection, and click New.

2 In the Figure Style dialog box, click the Information tab and enter a name and description for the style.

3 To define figure marker placement and styles, click the Markers tab and specify the options. For information about the components on this tab, see Plan and Model Tab (Survey Figure Style Dialog Box) (page 2391).

4 To specify the 3D geometry display of the figure, click the 3D Geometry tab and specify the settings.

5 To define the display of the various figure components, including figure lines, and markers, click the Display tab.

6 To view summary information about the style, click the Summary tab.

7 Click Apply.

**To edit a survey style**

1 In Toolspace, on the Settings tab, right-click the name of the network or figure style that you want to edit and click Edit.

2 In the Style dialog box, change the properties of the style as required.

# Survey Databases

In AutoCAD Civil, survey data is not drawing dependent and is stored in an external database. For display and visualization, survey data can be manually and automatically inserted into a drawing when the survey database is updated or when data is imported into the survey database.

The Survey *.sdb* file is the main survey database and it contains all the data in the survey database collections except for the Extended Properties definitions and values. The Survey *.sdx* file contains the Extended Properties definitions and values.

# Survey Database

Use the Toolspace Survey tab to create local survey databases. You can subsequently create a new AutoCAD Civil Project from the existing local survey database.

A survey database contains all the control points, known directions, observation measurements, traverse definitions, figures, and standard deviations based on equipment data for the survey database. This includes observations imported from data collector files, entered from the Toolspace Survey tab, the survey editors (for example, Traverse Editor and Observation Editor), and Survey Command Window.

A survey database is displayed on the Toolspace Survey tab under the Survey Databases collection.

By default, survey databases are local and do not use the AutoCAD Civil project management functionality. You can subsequently create a new AutoCAD Civil Project from the existing local database. When a new AutoCAD Civil project is created from Prospector, a new Survey database is automatically created and must be checked out to add or modify data.

**NOTE** AutoCAD Civil project management determines the working folder, therefore the databases that are displayed in the working folder may vary depending on whether you are logged in or logged out.

For more information about AutoCAD Civil project management, see Project Management (page 125).

## Using a Local Survey Database

Use the Toolspace Survey tab to create local survey databases.

Each local survey database is stored in the project working folder, for example: *Civil Projects\<project name>*. You can set the current working folder from either the Survey Databases collection on the Survey tab or in the Projects folder on the Prospector tab if you have Vault Explorer installed.

A survey database is displayed on the Toolspace Survey tab as a named survey database item under the Survey Databases collection.

**To create a local survey database**

1   In Toolspace, on the Survey tab, right-click the Survey Databases collection.

2   Click New Local Survey Database.

3   In the New Local Survey Database dialog box, enter the name for the database.

   The database is created and displayed in bold text under the Survey Databases collection.

**To change the location for local survey databases**

1   In Toolspace, on the Survey tab, right-click the Survey Databases collection.

2   Click Set Working Folder.

   **NOTE** If you have Vault Explorer installed you can also set the working folder on the Prospector tab in the Projects collection.

3   In the Browse For Folder dialog box, browse to the working folder location.

   Survey databases in the working folder are displayed in the Survey Databases collection and all local survey databases that you subsequently create are stored in this location.

**NOTE** By default, to save on resource usage, when you start AutoCAD Civil, all survey databases are displayed in a closed state.

**To open or close a survey database**

1   In Toolspace, on the Survey tab, right-click the named survey database. Click Open Survey Database or double click the database in the collection.

   The named survey database is displayed in bold text and it is expanded to display the Networks, Network Groups, Figures, Figure Groups, Survey Points, and Survey Point Groups collections.

   **NOTE** Only one survey database can be open at a time.

2   To close an open database, in Toolspace, on the Survey tab, right-click the named database. Click Close Survey Database.

## Quick Reference

Ribbon

Click Home tab ➤ Palettes panel ➤ Open Survey Toolspace 🛰

Toolspace

Survey tab: expand Survey Databases ➤ right-click <database name> ➤ Open Survey Database

or

Survey tab: expand Survey Databases ➤ right-click <database name> ➤ Close Survey Database

## Adding a Survey Database to a New Project

Create a new AutoCAD Civil project from an existing survey database to take advantage of the standard project management functionality when accessing survey databases.

After you add a survey database to a project, you must check it out to make changes to the survey data.

For more information about AutoCAD Civil project management, see Project Management (page 125).

**To create a new AutoCAD Civil project from an existing survey database**

1   In Toolspace, on the Survey tab, right-click the survey database. Click Add To New Project.

   **NOTE** The Add To New Project menu item is displayed if you have logged into Vault. For information, see Logging in to a Vault Server (page 149).

2   In the Add To New Project dialog box, the database name is displayed. The project icon is displayed next to the survey database name to indicate that the survey database is contained in an existing AutoCAD Civil project.

3   In Toolspace, click the Prospector tab, expand the Projects collection and right-click the newly created project to access the standard project management functions. See Working with Vault Projects (page 148).

   **NOTE**   If the Projects collection is not visible, click Master View from the list.

### Quick Reference

Toolspace

Survey tab: expand Survey Databases ➤ right-click <database name> ➤ Add To New Project

## Translating a Survey Database

Use this command to perform a simple translation of a selected survey database.

This command is useful when you need to move all the data in the survey database from an assumed location to a known location, subsequent to importing the survey data into AutoCAD Civil.

Translate the selected database by specifying a base point, rotation angle, destination point, and optional elevation.

**To translate a survey database**

1   Click Survey tab ➤ Modify panel ➤ 🔻 ➤ Translate Database.

2   On the Translate Survey Database Base Point page, enter a point number from the open database or click Pick In Drawing and select a point in the drawing. Click Next.

   **NOTE** If the base point exists as a survey point within the survey database, the Name, Easting, Northing, Elevation, Description, Latitude, and Longitude property values are displayed.

**3** On the Translate Survey Database Rotation Angle page, click the value cell and enter a rotation angle. Click Next.

**4** On the Translate Survey Database Destination page, click the value cell and enter Easting, Northing, and optional Elevation Change values. Click Next.

**5** On the Translate Survey Database Summary page, review the values for Base Point, Destination Point, and Translation. Click Finish.

Command Line

TranslateSvDatabase

## Survey Equipment Database

The survey equipment database contains one or more equipment definitions.

Equipment definitions specify the values associated with a specific surveying instrument, such as the standard deviations associated with the measuring capabilities.

For information on equipment definition settings, see New Equipment/Equipment Properties Dialog Box (page 2384).

**To create an equipment database and definition**

**1** In Toolspace, on the Survey tab, right-click the Equipment Databases collection. Click New.

**2** In the New Equipment Database dialog box, enter a name for the new equipment database. The database is created with the default equipment definition named 'Sample,' which is displayed in the Equipment Databases collection.

**NOTE** A best practice is to enter the model number or the name of the equipment manufacturer in the Name field.

**3** To create a new equipment definition, right-click the equipment database and click New.

**4** In the Equipment Properties dialog box, enter a name for the equipment definition and modify other properties as required. For more information about the equipment properties, see New Equipment/Equipment Properties Dialog Box (page 2384).

**To make an equipment definition current**

■ In Toolspace, on the Survey tab, expand the Equipment Databases collection. Expand the named equipment database. Right-click the equipment definition. Click Make Current.

**To edit an equipment definition**

**1** In Toolspace, on the Survey tab, expand the Equipment Databases collection. Expand the named equipment database. Right-click the equipment definition. Click Edit.

**2** In the Equipment Properties dialog box, modify the properties as required. For more information about the equipment properties, see New Equipment/Equipment Properties Dialog Box (page 2384).

**To copy an equipment definition**

**1** In Toolspace, on the Survey tab, expand the Equipment Databases collection. Expand the named equipment database. Right-click the equipment definition. Click Copy.

**2** In the Equipment Properties dialog box, enter a name for the new definition.

**To delete an equipment definition**

**1** In Toolspace, on the Survey tab, expand the Equipment Databases collection.

**2** Expand the named equipment database. Right-click the definition. Click Delete.

## Quick Reference

Toolspace

Survey tab: right-click Equipment Databases

# Survey Figure Prefix Database

The survey figure prefix database contains information to determine the layer that a figure is drawn on, how a figure is stylized, and whether figures are created as breaklines and lot lines.

When figures are imported or created, they are matched based on their names and the prefix names. When a figure is created and its name is matched with a figure prefix, the figure prefix properties are assigned to the new figure, such as a layer name.

Figure prefixes are also used to determine linework connectivity when you use the Process Linework command. Any point that is coded with a name that matches a figure prefix is treated as an active feature. The Process Linework command begins a figure when it encounters a prefix match if there is not an active figure with the same name.

For information about specifying the default path and location for figure prefix database, see Setting the Figure Prefix Database (page 208).

**To create a figure prefix database and definition**

**1** In Toolspace, on the Survey tab, right-click the Figure Prefix Databases collection. Click New.

**2** In the New Figure Prefix Database dialog box, enter a name for the new figure prefix database.

**3** To create a figure prefix definition, right-click the figure prefix database. Click New.

**4** In the Figure Prefix Properties dialog box, enter a name for the figure prefix definition and modify other properties as required. For more information about the figure properties, see New Figure Prefix/Figure Prefix Properties Dialog Box (page 2394).

**To make a figure prefix database current**

■ In Toolspace, on the Survey tab, expand the Figure Prefix Databases collection. Right-click the figure prefix database. Click Make Current.

**To edit a figure prefix definition**

1 In Toolspace, on the Survey tab, expand the Figure Prefix Databases collection. Click the named figure prefix database.

2 In the Survey list view, modify the properties of the figure prefix definition as required. For more information about the figure prefix properties, see New Figure Prefix/Figure Prefix Properties Dialog Box (page 2394).

**To copy a figure prefix database**

1 In Toolspace, on the Survey tab, expand the Figure Prefix Databases collection. Right-click the named figure prefix database. Click Copy.

2 In the Figure Prefix Databases dialog box, enter a name for the new database.

**To delete a figure prefix definition**

1 In Toolspace, on the Survey tab, expand the Figure Prefix Databases collection.

2 Click the named figure prefix database.

3 Right-click the definition in the Survey list view. Click Delete. Click 🖫 to save the delete operation.

### Quick Reference

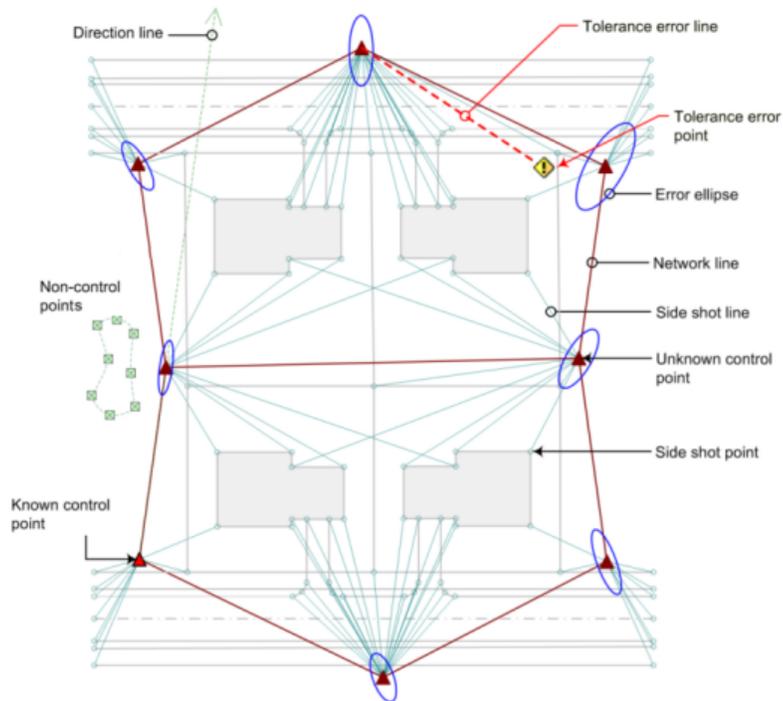
# Survey Networks

A survey network is a series of interconnected lines that represent the observed instrument setups, or stations. It contains all associated known control points, known directions, setups, and observations.

**TIP** Use the Import Survey Data command to create a network and import data using the wizard interface. For more information, see Import Survey Data Wizard (page 239).

After you have imported or created data in the survey network you can insert the network into your AutoCAD Civil drawing as a network object. For information about survey objects, see Survey Objects (page 194).

The following illustration shows the network components:


**Tips for working with Networks**

■ In a drawing you can hover your mouse over any network component to display a tooltip with component information.

■ In the drawing, select a network component and right-click for options to browse to the survey data on the Survey tab, edit, or update the data.

■ In Survey Toolspace, you can change the network display order using drag and drop functionality. When you drag and drop a network it is inserted after the network on to which it is dropped. Drag a network and drop it on the Networks collection to have it display first in the list.

■ You can drag and drop a Network from the Survey tab in Toolspace into the drawing.

■ Create a new network for each phase of a surveying project.

■ Create a new survey network to use the Survey Command Window to perform calculations involving points from other existing survey networks. Data that you input is captured in the batch file, where you can make edits and run the file again with the corrections, if necessary, without affecting the integrity of the other survey networks.

**To create a survey network**

■ In Toolspace, on the Survey tab, expand the survey project. Right-click the Networks collection. Click New.

**To insert a survey network into the drawing**

■ In Toolspace, on the Survey tab, expand the survey project, expand the Networks collection, right-click the named network, and click Insert Into Drawing.

■ In Toolspace, on the Survey tab, select the network and drag and drop the selection onto an open drawing in the AutoCAD Civil.

A survey network object is created in the drawing. Browse to the Survey collection in the Toolspace Prospector tab to view and modify the network object.

**To view survey network data in the drawing**

■ In the drawing, hover your cursor over a network object component to display a tooltip with relevant data.

**To browse to survey network data from the drawing to the Survey tab in Toolspace**

■ In the drawing, use CTRL + Select to select a network object sub-component, such as a sideshot point, and right-click to display commands for browsing to the survey data. The Survey tab is displayed (if hidden) and the survey database item is highlighted.

## Quick Reference

# Survey Settings

# 9

Before using the AutoCAD Civil survey features, review and modify the settings that define survey user defaults, drawing settings, database settings, and equipment settings.

## User Settings

Survey user settings are specific to a Windows user login account and affect only the survey features, not project or drawing data.

Specify the default settings for importing and exporting survey data and the display of interactive graphic components.

**Tips for working with Settings**

- Default Survey Database settings can be set up and can then be used each time you create a new survey database.

- Survey database settings can be exported to file with a *.*sdb_set* extension.

- Survey User Settings can be exported to a *.*usr_set* file.

- You can create a .sdb_set for imperial or metric survey database settings, or for use with for specific coordinate zone.

- Have everyone in your organization use the same path for the Survey User Settings.

## Setting the Survey Database Defaults

Specify the settings for survey database features.

**To specify the survey database defaults**

1 Click Survey tab ➤ Modify panel ➤ ⚊ ➤ Edit User Settings 🖼 .

2 In the Survey User Settings dialog box, expand the Survey Database Defaults property group.

3 Under Survey database settings path, specify the path to where survey database settings files are located. This path should be in a common location within an organization.

**4** Under Survey database settings, select a survey database settings file from the drop list. All files with a *.sdb_set extension are listed. The settings in this file are used whenever a new survey database is created by AutoCAD Civil.

**5** Under, Extended properties definition path, specify the path to where Extended Properties definitions are located. This path should be a common location within an organization.

**6** Under Extended properties definition, specify an extended properties definition file from the list. All files in the extended properties definition path that has a *.sdx_def extension is listed.

For information about the setting equipment properties, see New Equipment/Equipment Properties Dialog Box (page 2384).

### Quick Reference

Menu

Click Survey  menu ➤ Edit User Settings.

Toolspace

Survey tab: 🀫

Dialog Box

Survey User Settings Dialog Box (page 2374)

## Setting the Current Equipment Database

Specify the current equipment, equipment database, and equipment database path.

The current equipment sets the values associated with a specific surveying instrument, such the standard deviations associated with the measuring capabilities for the equipment. This information is used in various calculations including Least Squares.

**To specify the current equipment database**

**1** Click Survey tab ➤ Modify panel ➤ 🔻 ➤ Edit User Settings 🀫.

**2** In the Survey User Settings dialog box, expand the Equipment Defaults property group.

**3** Under Equipment Database Path, enter the path for the survey equipment databases or click 🔍 to browse to the folder. This is the path where all new equipment databases are stored.

**4** Under Current Equipment Database, select the current database from the drop-down list.
The list of available databases is determined from the databases contained in the Equipment Databases collection in the Toolspace Survey tab.

**5** Under Current Equipment, select the current equipment from the drop-down list.

For information about the setting equipment properties, see New Equipment/Equipment Properties Dialog Box (page 2384).

## Setting the Linework Processing Defaults

Specify the default path for the linework code set.

A linework code set interprets the syntax of the field codes that are entered into the data collector by the survey field crew.

**To specify the linework processing defaults**

1   Click Survey tab ➤ Modify panel ➤ ▼ ➤ Edit User Settings 🖼️.

2   In the Survey User Settings dialog box, expand the Linework Processing Defaults property group.

3   For Linework Code Sets Path, enter the path for the linework code or click 🔍 to browse to the folder. This is the path where all linework code set files are stored.

4   For Process Linework During Import, select the check box to process linework during the import. Linework can also be processed after the import is completed.

   **TIP** If you make adjustments to the associated network after importing data, update the linework using the Process Linework command when the adjustments are completed.

5   For the Current Linework Code Set, select a linework code set from the list.

6   For the Process Linework Sequence, select one of the following from the list:
   - By Import Order - processes points in the order which they are imported. Point names are always processed by import order.

   - By Point Number - processes points sequentially by point number (ascending order only).

For more information about linework processing settings, see Survey User Settings Dialog Box (page 2374).

Dialog Box

Survey User Settings Dialog Box (page 2374)

## Setting the Figure Prefix Database

Specify the current and default figure prefix database and database path.

Figure prefixes enable you to determine the layer that a figure is drawn on, how a figure is stylized, and whether figures are created as breaklines and lot lines. When figures are imported or created, they are matched based on their names and the prefix names. All figures with a specific prefix are assigned the properties of the prefix.

**To specify the figure prefix database**

1  Click Survey tab ➤ Modify panel ➤ 📷 ➤ Edit User Settings 📷.

2  In the Survey User Settings dialog box, expand the Figure Defaults property group.

3  For Figure Prefix Database Path, enter the path for the figure prefix databases or click 🔍 to browse to the folder. This is the path where all new figure prefix databases are stored.

4  For Current Figure Prefix Database, select the current database from the drop-down list.

The list of available databases is determined from the databases contained in the Figure Prefix Databases collection on the Toolspace Survey tab.

For more information about figure prefix settings, see Survey User Settings Dialog Box (page 2374).

## Specifying External Editor Settings

Specify whether to use an external editor for displaying analysis input and output and for editing field book and batch files.

**To specify the external editor settings**

1   Click Survey tab ➤ Modify panel ➤ ▼ ➤ Edit User Settings 🖼.

2   In the Survey User Settings dialog box, expand the Miscellaneous property group.

3   For Use External Editor, select the check box to use an external editor.

> **NOTE** If you do not specify to use an external editor, the default editor, specified in the AutoCAD Options dialog box, is used.

4   For External Editor, enter the path and name for the editor or click 🔍 to browse to the editor.

# Setting Import Defaults

Specify the Import Defaults properties for importing a field book or batch files into the selected project network.

**To specify import defaults**

1 Click Survey tab ➤ Modify panel ➤ <img> ➤ Edit User Settings <img>.

2 In the Survey User Settings dialog box, expand the Import Defaults property group.

3 Select the check boxes for the defaults that you want to enable.

For descriptions of the import defaults, see Survey User Settings Dialog Box (page 2374).

4 Optionally, for Default Figure Site property, enter a site name.

If the site does exists in the current drawing, it is created, or if it exists, it is used.

**NOTE** The site is used if the Lot Line property for the figure is true and the Site property for the figure is not specified.

Survey User Settings Dialog Box (page 2374)

# Reporting Tolerance Errors

Display tolerance errors in the Event Viewer at the completion of survey data import or run the command from the network collection or an individual network on the Survey tab.

Tolerance errors are based on the values you specify in the Survey Database Settings (page 2378). At the completion of importing survey data into the survey database, tolerance errors (in the network) that exceed these values can be displayed as events in the Event Viewer. In the Survey User Settings dialog box (page 2374) - Import Defaults, specify Yes for Display Tolerance Errors In Event Viewer.

The Report Tolerance Error command can be run at anytime from the right-click shortcut menu on the Networks collection or an individual network.

You can override the default settings in the Import Survey LandXML (page 2420), Import Field Book (page 2406), and Batch File (page 2413) dialog boxes.

**To report tolerance errors at the completion of importing survey data**

■ In the Survey User Settings - Import Defaults, specify Yes for Display Tolerance Errors In Event Viewer. The event viewer is displayed at the completion of any import function if the data contains tolerance errors.

**To report tolerance errors**

■ On the Survey tab in Toolspace right-click the Networks collection or a <named> network ➤ Report Tolerance Errors.

## Quick Reference

Toolspace

Survey tab: expand Survey Databases ➤ right-click Networks collection or right-click <named> Network ➤ Report Tolerance Errors

## Tolerance Errors Display in the Event Viewer

Use the event viewer to review and edit tolerance errors.

If you have specified Display Tolerance Errors In Event Viewer in the Survey User Settings (page 2374) and if the network contains tolerance errors, the following items are displayed the Event Viewer at the completion of a survey import command.

**NOTE** You can also run the Report Tolerance Error command from the right-click shortcut menu on the Networks collection or an individual network.

| Column | Description |
| --- | --- |
| Tree tab | Displays the tolerance error and the associated network. |
| Type | Displays the tolerance error as a warning using the warning icon. |
| Date | Displays the system date of the event. |
| Time | Displays the system time of the event. |
| Source | Displays the name of the network that contains the tolerance error. |
| User | Displays the Windows user log in. |
| Description | Displays the Point ID and the tolerance error type. |
| More information | Click Zoom To to zoom to the tolerance error in the drawing. |
| Action | Click Browse To to display the Observations Editor. The observation with the tolerance error is highlighted. |

| Column | Description |
| --- | --- |
| | **NOTE** The Survey Database must be open to use the Browse To link. |

**See also:**

■ Event Viewer Vista (page 2455)

# Setting Export Defaults

Use the Export Defaults to specify the properties for exporting survey data to a field book file.

### Figure Export Conditions and Formats

When you select the Export Figures With Network property, the format of the figure data exported to the field book is dependent on the conditions of the survey data as shown in the following.

**NOTE** For more information about the syntax in the following section, see the Figure Commands (page 397).

■ If the figure vertex has a point number, then the figure vertex is defined by referencing the point in the field book file:
BEG <figure name>

PT <point ID>

■ Then the following lines are added to the field book file:
NE SS <point ID> <north> <east> <elevation> <description>

BEG <figure name>

PT <point ID>

■ Then the following line is added to the field book file defining the figure vertex:
FIG NE <north> <east>

■ If the figure segment is a curve, then the curve segment is defined using the XC ZD (BULB) command. The BULB parameter is used when the delta angle for the curve is greater than 180 degrees.

■ If both ends of the curve segment reference point IDs, then the following format is output:
XC ZD (AZ <point ID> <point ID>) (D <point ID> <point ID>)

■ Otherwise the following format is output:
XC ZD <Azimuth> <Distance>

### Point Export Conditions and Format

If you select the Export Point Identifiers property, for each figure vertex, the following formats are output to the field book file.

**NOTE** For more information about the syntax in the following section, see the Figure Commands (page 397).

■ If the figure vertex has a point ID, then the following lines are added to the field book file:
BEG <Figure name>

PT <point ID>

■ If the vertex does not reference a point ID, then the following lines are added to the field book file:
BEG <figure name>

FIG NE <north> <east>

- If Export Point Identifiers property is not selected, the following lines are added to the field book file:
  BEG <figure name>
  FIG NE <north> <east>

- If the figure segment is a curve, then the curve segment is defined using the XC ZD (BULB) command. The BULB parameter is used when the delta angle for the curve is greater than 180 degrees.

- If both ends of the curve segment reference point numbers (and if this check box is selected), then the following format is output:
  XC ZD (AZ <point ID> <point ID>) (D <point ID> <point ID>)

- Otherwise the following format is output:
  XC ZD <azimuth> <distance>

When the Export Point Data is enabled, for each figure vertex that references a point ID, the following format is output to the field book file prior to the section defining the figures:

NE SS <point ID> <north> <east> <elevation> <description>

**To specify export defaults**

1   Click Survey tab ➤ Modify panel ➤ ⌄ ➤ Edit User Settings 🖼.

2   In the Survey User Settings dialog box, expand the Export Defaults property group.

3   Select the check boxes for the defaults that you want to enable.
    For descriptions of the properties, see Survey User Settings Dialog Box (page 2374).

## Importing and Exporting User Settings

Import and export existing user settings.

User settings can be exported to a user settings (.usr_*set*) file and subsequently imported.

**To export user settings**

**1** Click Survey tab ➤ Modify panel ➤ ▼ ➤ Edit User Settings 🖼 .

**2** In the Survey User Settings dialog box, click 🖼 .

**3** In the Save As dialog box, browse to the path where you want to save the settings file and enter a name.

**4** Click Save.

**To import user settings**

**1** Click Survey tab ➤ Modify panel ➤ ▼ ➤ Edit User Settings 🖼 .

**2** In the Survey User Settings dialog box, click 🖼 .

**3** In the Open dialog box, browse to the path where the settings file is located and select it.

**4** Click Open.
The Survey User Settings dialog box is populated with the settings from the file.

### Quick Reference

# Database Settings

Survey database settings are specific to the survey features of an AutoCAD Civil survey database.

By default, the survey database settings are stored in the *C:\Civil Projects\<database name>\Survey.sdb* file.

To edit survey database settings, the survey database must be open.

# Setting Measurement Units

Use the Units settings to specify project units including coordinate zone, distance, angle, direction, temperature, and pressure.

**NOTE** The survey database units are independent from the drawing units. If the survey database units and drawing units are different, the survey data is transformed when it is inserted into the drawing.

**To specify survey database measurement units**

1  In Toolspace, on the Survey tab, expand the Survey Databases collection, right-click on the database name, and click Edit Survey Database Settings.

2  In the Survey Database Settings dialog box, expand the Units property group.

3  For the Coordinate Zone property, click ⊡ and select the zone in the Select Coordinate Zone dialog box.

4  For the other unit settings, click the drop-down list and select the value for the unit type that you want to modify.

   For more information about the settings, see the Units section of the Survey Database Settings Dialog Box (page 2378).

### Quick Reference

Toolspace

Dialog Box

Survey Database Settings Dialog Box (page 2378)

## Setting Unit Display Precision

Use the Precision settings to specify the survey database display precision for units, including angle, distance, elevation, coordinates, and latitude and longitude.

The precision value specifies the number of digits to display to the right of the decimal.

**To specify display precision**

1  In Toolspace, on the Survey tab, expand the Survey Databases collection, right-click the project name, and click Edit Survey Database Settings.

2  In the Survey Database Settings dialog box, expand the Precision property group.

3  Click the value for the unit, and enter the precision value.

   For more information about the settings, see the Precision section of the Survey Database Settings Dialog Box (page 2378).

Dialog Box

Survey Database Settings Dialog Box (page 2378)

## Setting Measurement Type Defaults

Use the Measurement Type Defaults to specify the default measurement types for the database when adding new survey data, including angle type, distance type, vertical type, and target type.

For example, the defaults are used for adding new observations in the Observations Editor.

**To specify the measurement type defaults**

1  In Toolspace, on the Survey tab, expand the Survey Databases collection, right-click on the database name, and click Edit Survey Database Settings.

2  In the Survey Database Settings dialog box, expand the Measurement Type Defaults property group.

3  Click the drop-down list and select the value for the measurement type that you want to modify.

For more information about the measurement type defaults, see Survey Database Settings Dialog Box (page 2378).

Dialog Box

Survey Database Settings Dialog Box (page 2378)

# Measurement Correction Formulas

The survey corrections are calculated using the following formulas.

### Curvature and Refraction Formula

The following formula calculates the vertical angle (in radians):

$$VA = OVA - \left\{ \frac{(1-k) \times SD}{2 \times R} \right\}$$

where:

- OVA: Old vertical angle (in radians)
- VA: Vertical angle (in radians)
- SD: Slope distance
- R: Spheroid radius (if a coordinate system zone is set, this value is obtained from the zone)
- k: Coefficient of refraction

### Atmospheric Conditions Formula

The following formula determines the slope distance:

$$SD = OSD + OSD \times \left[ RI - \left( \frac{C \times P}{273.2 + t} \right) \right] \times 0.000001$$

where:

- OSD: Old slope distance
- SD: Slope distance
- C: Constant for the EDM carrier (for example, Sokkia Lietz 0.86)
- P: Atmospheric pressure in mm Hg
- RI: Group refractive index for EDM carrier (for example, Sokkia Lietz 287.96)
- T: Dry air temperature in degrees Celsius

### Sea Level Formula

The following formula calculates the horizontal distance at sea level:

$$HD = OHD - \frac{(SE \times OHD)}{R}$$

where:

- OHD: Old horizontal distance
- HD: Horizontal distance
- SE: Station elevation
- R: Spheroid radius (if a coordinate system zone is set, this value is obtained from the zone)

**Collimation Formulas**

The following formulas determine the collimation:

Horizontal collimation:

■ For FACE 1: Horizontal Angle = Measured Horizontal Angle + Horizontal Collimation Error

■ For FACE 2: Horizontal Angle = Measured Horizontal Angle - Horizontal Collimation Error

Vertical collimation (all vertical angles are converted to zenith):

■ For FACE 1: Vertical Angle = Measured Vertical Angle + Vertical Collimation Error

■ For FACE 2: Vertical Angle = Measured Vertical Angle - Vertical Collimation Error

# Setting Traverse Analysis Defaults

Use the Traverse Analysis Defaults to specify the database setting defaults for performing a traverse analysis on survey data.

**To specify traverse analysis defaults**

1  In Toolspace, on the Survey tab, expand the Survey Databases collection, right-click on the project name, and click Edit Survey Database Settings.

2  In the Survey Database Settings dialog box, expand the Traverse Analysis Defaults property group.

3  Edit the defaults as required.

For more information about the settings, see the Traverse Analysis section of the Survey Database Settings Dialog Box (page 2378).

## Quick Reference

# Setting Extended Properties

Use Extended Properties to specify if new extended property definitions are to be automatically created during a Survey LandXML import, or to display warnings in the Event Viewer if required extended properties have not been assigned during an export of Survey LandXML data.

**To specify extended properties settings**

1   In Toolspace, on the Survey tab, expand the Survey Databases collection, right-click on the database, and click Edit Survey Database Settings.

2   In the Survey Database Settings dialog box, expand the Extended Properties property group.

3   Specify Yes to create new definitions automatically when you are importing a LandXML file.

4   Specify Yes to display warnings for required properties that are missing when you export a LandXML file.

### Quick Reference

## Importing and Exporting Survey Database Settings

Import or export existing survey database settings.

Database settings can be exported to a database settings (*.set*) file and subsequently imported.

**To export survey database settings**

1  In Toolspace, on the Survey tab, expand the Survey Databases collection, right-click on the database name, and click Edit Survey Database Settings.

2  In the Survey Database Settings dialog box, click 🗊 .

3  In the Save As dialog box, browse to the path where you want to save the settings file and enter a name.

4  Click Save.

**To import survey database settings**

1  In Toolspace, on the Survey tab, expand the Survey Databases collection

2  Right-click the database name, and click Edit Survey Database Settings.

3  In the Survey Database Settings dialog box, click 🗊 .

4  In the Open dialog box, browse to the path where the settings file is located and select it.

5  Click Save.
   The Survey Database Settings dialog box is populated with the settings from the file.

# Equipment Properties

The survey equipment properties specify the values associated with a specific surveying instrument, such as the standard deviations associated with the measuring capabilities for the equipment. This information is used in the Least Squares calculations.

The equipment property groups are:

■ Miscellaneous. Specifies the name and description of the equipment that is displayed in the equipment database.

■ Angle. Determines how an instrument measures angles.

■ Units. Determines the unit types for angle and distance.

■ Electronic Distance Meter (EDM). Determines the Electronic Distance Measuring settings.

■ Prism. Sets the Prism accuracy, offset, and constant.

■ Standard deviations. Specifies the accuracy of the surveying equipment. These values are used in calculating the standard errors that are displayed in the Least Squares input file.

---

**NOTE** For detailed descriptions of the equipment properties, see New Equipment/Equipment Properties Dialog Box (page 2384).

---

**To set the equipment properties**

1 In Toolspace, on the Survey tab, expand the Equipment Databases collection, and expand the database name.

2 Right-click on the equipment name and click Properties.

---

**NOTE** For information about creating equipment databases, see Survey Equipment Database (page 199).

---

3 Edit the properties as required.

For more information about the settings, see the New Equipment/Equipment Properties Dialog Box (page 2384).

### Quick Reference

# Survey Drawing Settings

You can use survey drawing settings to specify the default behavior for drawing-related survey commands.

Drawing settings are handled in a standard way throughout AutoCAD Civil. You access drawing settings using the Toolspace Settings tab. You can control these settings at three levels: the drawing level, the object collection (feature) level, and the command level. It is important to understand how the different levels of settings work together. For more information, see Understanding Settings (page 61).

Use the Survey collection in the Settings tab to establish defaults for survey-related commands. You can change either survey-specific settings at this level or override the drawing ambient settings.

**NOTE** Overrides to the drawing ambient settings at the Survey collection level affect only the specified level. The drawing level settings are not changed.

The topics in this section describe only those settings that affect survey-related commands, and do not cover the drawing ambient settings that you can change at the survey collection level, even though those settings are displayed in the Survey Settings dialog box. For more information, see Specifying Ambient Settings (page 68).

**To change the survey feature settings**

1  In Toolspace, on the Settings tab, right-click Survey ➤ Edit Feature Settings.

2  In the Edit Feature Settings dialog box (page 2373), make changes to the existing settings.

3  Click OK to save the changed settings in the drawing.

## Quick Reference

Toolspace

Dialog Box

Edit Feature Settings - Survey Dialog Box (page 2373)

# Survey Field to Finish

# 10

Refer to this section for a description of the commands you can use to import and process survey data in AutoCAD Civil.

Field to Finish Field to Finish (page 2474) is a general term used to describe the surveying process that determines the connectivity and symbology of points surveyed in the field that match the feature name and field code field code (page 2474) that is defined in a AutoCAD Civil linework code set linework code set (page 2477), and the description keys that are defined for the current drawing. A field code is contained within the description of a survey point, and typically contains both the name of the point feature or line feature, and a special line segment or curve segment code to indicate connectivity between survey points of the same feature. During the processing of linework, the linework code set interprets the syntax of the field code within a survey point description. When you insert points into the drawing from the survey database, the display of the survey points is determined by a raw description match with the description keys in the drawing.

For more information, see Description Keys (page 537).

## Preparing to Import Survey Data

To successfully bring data from the field into AutoCAD Civil, it is important to understand the interaction between field codes, the linework code set, description keys, and the figure prefix database.

Perform the following setup tasks before importing survey data:

- Establish consistent point coding and linework connectivity. For more information, see Field Codes, Figure Prefixes, and Description Keys (page 228).

- Create a Linework Code Set based on the point coding and linework connectivity. For more information, see Linework Code Sets (page 230).

- Define the Survey User Settings. For more information, see User Settings (page 205).

- Define the Survey Database Settings. For more information, see Database Settings (page 216).

- Create a Survey Equipment Database. For more information, see Survey Equipment Database (page 199).

- Create a Figure Prefix Database and figure prefixes. For more information, see Survey Figure Prefix Database (page 200).

- Create Description Key Sets and description keys. For more information, see Creating Description Keys (page 550).

- Import survey data based on a drawing template (*.dwt*) that contains established styles and layers. For more information, see Drawing Templates (page 109).

Perform the following tasks after importing survey data:

■ View data in an import event and re-import the data if necessary. For more information, see Import Events (page 249).

■ Edit survey point properties and reprocess linework. For more information, see Editing Survey Point Properties (page 251) and Processing Survey Linework (page 251).

■ Create a traverse and perform traverse analysis. For more information, see Survey Analysis and Output (page 361).

■ Use the Survey Command Window and survey command language to batch process and record coordinate geometry operations. For more information, see Survey Command Reference (page 391).

## Field Codes, Figure Prefixes, and Description Keys

Surveyors locate existing features on the ground using systems, such as a total station or a GPS unit, that are configured with data collectors. For each surveyed point, the surveyor assigns a field code that describes the point feature or line feature and that is then saved in the data collector. Line features contain a line command code that indicates whether the line is a beginning, a continuation, an end, a curve segment, or a line segment. In AutoCAD Civil, the syntax of the field code corresponds to a previously defined linework code set. The correspondence between the field codes and the linework code set allows for the following:

■ Automatic assignment of COGO point properties such as Layer, Symbol, and Label when inserted into the drawing

■ Automatic assignment of line feature properties, such as Layer, Color, Linetype, and Lineweight when inserted into the drawing

■ Line connectivity between the COGO points

An example of a field code is EP1 B, where:

■ EP = the standard abbreviation that a company uses to represent an edge of pavement

■ 1 = the first edge of pavement that is located

■ B = the code in the linework code set to begin a figure

**NOTE** NOTE: When you import survey data, you can omit the Begin code if the feature name matches a figure prefix that is defined in the current figure prefix database. If the feature name does not match a figure prefix, you must specify a Begin code.

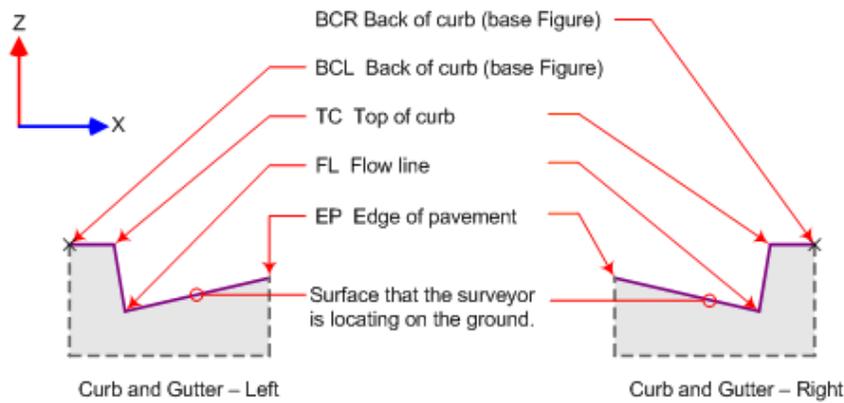
Field codes are associated with both the figure prefix database and the description keys in the current drawing. If EP has been defined in the figure prefix database, then EP1 matches EP and is assigned the properties of the EP figure prefix, such as layer, figure style, breakline. If the survey point with the description EP1 B is placed in a drawing that has a description key of EP*, then EP1 B matches description key EP* and is assigned the point properties defined in the EP* description key, such layer, point style, point label style.

The following table lists examples of features coded in the field and the field code assigned to the feature, and the description keys and Figure prefixes created in AutoCAD Civil to support the field codes:

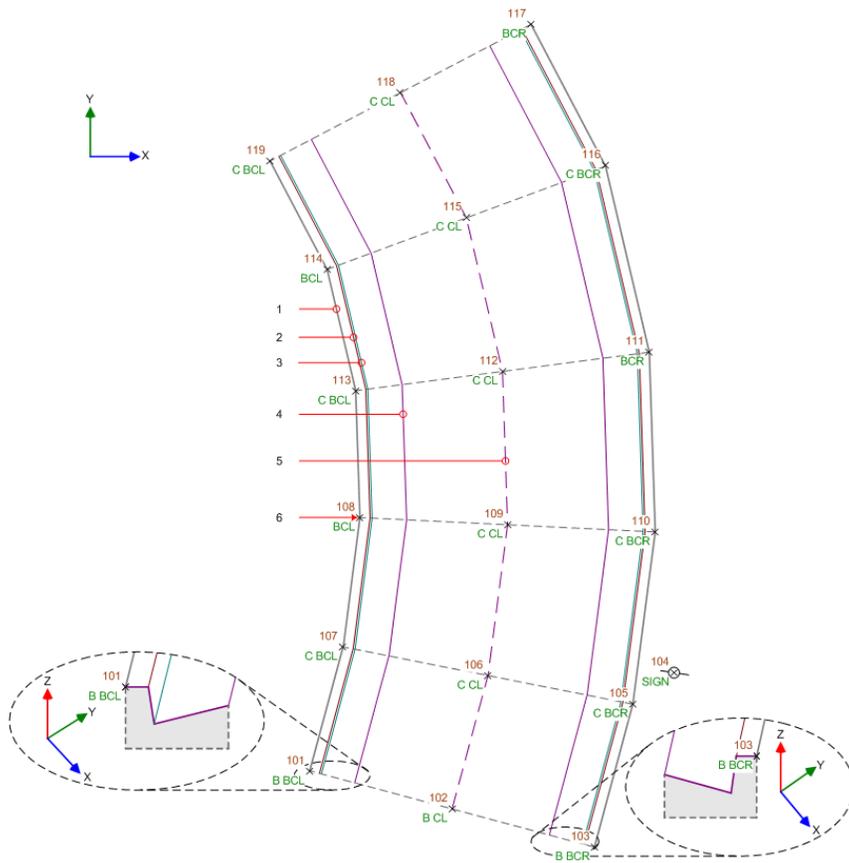
| Feature | Field Code | Description Key | Figure Prefix |
| --- | --- | --- | --- |
| Edge of pavement | EP<ID> | EP* | EP |
| Utility Pole | UP<ID> | UP* | |

| Feature | Field Code | Description Key | Figure Prefix |
|---|---|---|---|
| Fence Line | FCE<ID> | FCE* | FCE |
| Centerline | CL<ID> | CL* | CL |
| Ditch Line | DL<ID> | DL* | DL |
| Edge of Gravel | EG<ID> | EG* | EG |
| Sewer Manhole | SMH<ID> | SMH* | |
| Storm Manhole | DMH<ID> | DMH<ID> | |

The following illustration shows an example of feature definitions:



The following illustration shows these feature codes:

- 1: BC (back of curb)
- 2: TC (top of curve)
- 3: FL (flow line)
- 4: EP (edge of pavement)
- 5: CL (centerline of existing roadway)
- 6: Point located in the field by a surveyor


## Linework Code Sets

A linework code set interprets the syntax of the field codes that are entered into the data collector by the survey field crew. Linework Code sets are displayed on the Toolspace Survey tab. Specify the default linework code set in the Survey User Settings. An import event  import event (page 2476) stores the linework code set that was last used to process linework for that event.

**To create a new linework code set**

1   On the Survey tab in Toolspace, right-click the Linework Code Sets collection ➤ New.

2   In the New Linework Code Set dialog box, enter a unique file name.

3   In the Edit Linework Code Set dialog box, specify values for the following:

- Information

- Coding Methods

- Special Codes

- Line Segment Codes

- Curve Segment Codes

For more information, see Examples - Linework Codes (page 231).

4   Click OK.

For more information, see Edit Linework Code Set Dialog Box (page 2433).

**To copy or edit an existing linework code set**

1 On the Survey tab in Toolspace, expand the Linework Code Sets collection.

2 Right-click the existing linework code set and click Copy or Edit.

3 In the Edit Linework Code Set dialog box, enter a unique file name.

  By default, the Edit Linework Code Set dialog box displays the values of the copied file.

4 Edit the values and click OK.

### Quick Reference

Toolspace

Survey tab: right-click Linework Code Sets ➤ New, Edit, or Copy

# Examples - Linework Codes

The following tables provide examples of linework code set properties.

## Coding Methods

**WARNING** It is recommended that you use <space> as the Field/Code Delimiter Property Value. Using decimal characters as the Field/Code Delimiter Property Value may cause certain codes to fail. For example the (decimal). character is valid for a right-turn value and the (minus sign) - character is valid for a negative right-turn value.

| Property | Example | Description |
| --- | --- | --- |
| Feature/Code Delimiter: code that indicates the separation of the feature name from the code. | **EP1 B SW1 B** | A " " (space) is the recommended delimiter. |
| Field Code Escape: code that indicates that anything entered after the escape indicator is a comment. | **EP1 SW1 B/Start of sidewalk** | A / (forward slash) is the recommended escape. **Start of sidewalk** is a comment. You can enter and exit comment mode using multiple slashes. In the following example, /parking space line/is a comment and ignored. EP1 B/parking space line/LN CPN211. |

## Special Codes

| Property | Example | Description |
| --- | --- | --- |
| Begin: code that indicates the start of a new figure at the specified point. | **EP1 B SW1 B** or **B EP1 B SW1** | **EP1** and **SW1** are figure names. The letter **B** is the special code used to begin new figures named **EP1** and **SW1**. |

| Property | Example | Description |
|---|---|---|
| If a figure prefix exists that matches the figure name, you can omit the Begin code. This works best with unique figure names. | | |
| Continue: code that indicates a figure is continued from its last vertex. | EP1 C SW1 | The figure is continued with an explicit \<Continue code\>. **EP1** is a figure name, **C** continues the active figure named **EP1** If the field code does not contain an explicit \<Continue\> code and the figure name within the field code matches an active figure, the figure is continued. |
| End: code that indicates the figure is terminated. | EP1 E SW1 B | **EP1** is the figure name, " " (space) is the Field/Code Delimiter, **E** is the End code and continues an active figure with the name **EP1** to this point and then it is terminated (it is no longer an active figure). **SW1** is a figure name, " " (space) is the Field/Code Delimiter, and **B** is the Begin code and starts a new figure named **SW1**. In this example, if there is an existing figure named **SW1** it is terminated at its last vertex, and a new figure named **SW1** is started at this point. |
| Close: code that indicates that an active figure is continued from its last vertex to the current point and closes the figure with a line segment back to the starting vertex for that figure. | EP1 SW1 CLS | **EP1** is a figure name and if it matches an active figure it is continued to this point. **SW1** is a figure name and if it matches an active figure it is continued from its last vertex to this point, **CLS** is the Close code and a line segment is closed back to the starting vertex for the figure SW1. |
| Horizontal Offset: code used to specify a relative horizontal offset for creating a parallel figure starting at the current point, or transitioning to another offset if the active figure has a previous horizontal offset. | 101,500,490,100.01,BC1 B H-4 V.1 H.5 H.75 V-.7 H2.25 V-.35 ... 112,500,500,100.02,BC1 ... 123,500,510,100.03,BC1 ... 134,500,520,100.04,BC1 ... 145,500,530,100.05,BC1 ... 156,500,540,100.06,BC1 ... 167,500,550,100.07,BC1 SO ... 178,500,560,100.08,BC1 | Point 101: **BC1** is the line feature name, " " (Space) is the Feature/Code delimiter, **B** is the \<Begin\> code, **H** is the \<Horizontal offset\> code, -4 is the value for the first horizontal offset value, **V** is the \<Vertical offset\> code, .1 is the first vertical offset value, and so on for each of the remaining 3 offsets. Points 112, 123, 134, 145, and 156: BC1 figure with current offsets are continued. Point 167: **BC1** is continued, but the offset figures are stopped by the **SO** \<Stop offsets\> code. Point 178: **BC1** is continued. A value must follow the Horizontal offset code. A negative value offsets the active figure to the left and a positive value offsets the active figure to the right. Multiple offsets can be used, but if subsequent horizontal or vertical transitions are made, all previous horizontal offset or vertical offset codes must be specified for each offset. |

| Property | Example | Description |
|---|---|---|
| Vertical Offset: code used to specify a relative vertical offset starting at the current point. A value must follow the Vertical offset code. | (Shown in the following illustration) | A positive value is added to the elevation of the current vertex for the active figure and a negative value is subtracted from the current vertex for the active figure. If a Vertical offset is specified with no previous Horizontal offset, the Horizontal offset value is assumed to be zero. If a Horizontal offset is specified with no Vertical offset or no previous Vertical offset, the Vertical offset value is assumed to be zero. |
| | | **NOTE** If a previous horizontal or vertical offset was specified in the current point code, and if a subsequent horizontal or vertical offset is omitted within the current field code, the previous horizontal or vertical offset value is used. For example: |
| | | V1 H1 H2 = H0 V1 H1 V1 H2 V1<br>H1 H2 V1 H3 = H1 V0 H2 V1 H3 V1 |
| Stop Offsets: code used to specify the termination of all offsets on the active figure. Only the active figure can be continued. | (Shown in the following illustration) | |

The following illustration shows an example using the codes for Horizontal Offsets, Vertical Offsets, and Stop Offsets:

1,500,490,100.01,BC1 B H-4 V.1 H.5 H.75 V-.7 H2.25 V-.35

2,500,500,100.02,BC1

3,500,510,100.03,BC1

4,500,520,100.04,BC1

5,500,530,100.05,BC1

6,500,540,100.06,BC1

7,500,550,100.07,BC1 SO

8,500,560,100.08,BC1

## Line Segment Codes

| Property | Example | Description |
| --- | --- | --- |
| Recall Point: code used to connect the active figure with a segment from the last point, or a specified pointID. | **EP1 RPN**<br>**EP1 RPN101** | **EP1** is the figure name and continues an active figure if the name matches. **RPN** is the Recall Point code and if there is no point it connects from the previous point to the current point and inserts a segment before the current point. The code EP1 RPN101 connects from the current point to the indicated point. |
| Connect Point: code used to indicate the creation of a new figure (of the same feature) with a single line segment from the current point to the specified point ID. The specified point ID follows the Connect Point code. | **EP1 B CPN101** | In this example, a new figure is created at the current point, and also another new figure with a single line segment is drawn to point 101, called EP1.CPN101. The figure name can be modified using the Figure Properties command. |

The Connect Point code always creates a figure composed of a single line segment. The following illustration shows an example of the Connect Point code:

| Property | Example | Description |
| --- | --- | --- |
| Rectangle: code used to offset the segment coming into the current point by the specified number. | **BLD1 <Rectangle>40** | A positive number indicates an offset to the right, a negative number indicates an offset to the left, which is relative to the direction of the line segment coming in to the current point. If no number follows the Rectangle code, this code closes the figure by performing a perpendicular/perpendicular line intersection between the previous segment coming into the current point and the first segment of the figure. |
| | | **NOTE** A Rectangle code without a number requires at least three points previously located on the current figure. |

The following illustration shows the Rectangle code with a specified value of 40:

| Property | Example | Description |
| --- | --- | --- |
| Right Turn: code used with a line segment code to allow for additional vertices to be inserted perpendicular into the figure, or as extensions (straight offsets). | **BLD1 RT X10.1 5 -12.2 -5 -12.2** | Continues an active figure **BLD1** to the current point, extends the current segment **10.1** units, and then draws perpendicular segments for each value. Offset values, <Extend>, or <Rectangle> codes follow the <Right turn> code. Positive numbers indicate a jog to the right and negative numbers indicate a jog to the left. |
| | | **NOTE** Use <Extend><Value> to make an extension straight ahead by using a positive # or behind by using a negative #. |
| | | **NOTE** Use the <Rectangle> code to complete the <Right turn> code, closing back to the starting segment as a perpendicular/perpendicular line intersection from the current figure line segment. |

The following illustration shows examples of the Right Turn code and the Rectangle code:

| Property | Example | Description |
|---|---|---|

| Extend: code that is used to make an extension of a line segment ahead through the current point by using a positive value or a line segment that is short of the current point by using a negative value. | **BLD1 X15.5** | **BLD1** continues an active figure, X is the Extend code, and **15.5** is the value that the figure line segment is extended through the current point. |

The following illustrations show examples of the Extend code, Right Turn code, and Rectangle code:

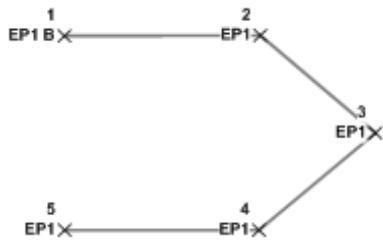
# Curve Segment Codes

| Property | Example | Description |
|---|---|---|
| Begin Curve: code used to specify that the current point is the beginning of a single curve (arc) segment or multiple curve segments. | **EP1 BC** | **EP1** is the active figure name and is continued to the current point, " " (space) is the Feature/Code Delimiter, **BC** indicates that the current point is the beginning of curve segments.<br>The current point with this code is the first point on the curve. The next point with the same figure name is considered a point on the curve, and the third point with the same figure name is the curve endpoint if no <End curve> code is used to correspond with the <Begin curve> code. |
| End Curve: code used with the <Begin curve> code to define curve segments with more than three points. Points on a curve do not have to be located sequentially. | **101 … EP1 BC**<br>**112 … EP1**<br>**123 … EP1**<br>**134 … EP1**<br>**145 … EP1 EC** | **EP1** is the active figure name and is continued to the current point, " " (space) is the Feature/Code Delimiter, **EC** indicates that the current point is the end of curve segments. |

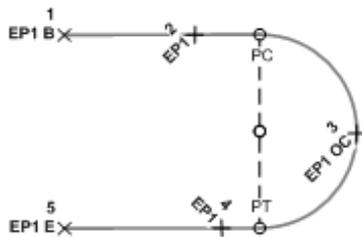
| Property | Example | Description |
|---|---|---|
| | | Starting at the point with the <Begin curve> code, the linework processor will look for an <End curve> code. If the <End curve> code is found, all the points between the <Begin curve> code and <End curve> code are used to fit arc segments of the figure. The curves pass through each of the points (similar to the PEDIT/Fit [curve] option). If no <End curve> is found following a <Begin curve> code, then a three-point arc is applied to the figure. |
| Circle: code that indicates the beginning of the circle feature. This code stops the linework on the previous point if it is a two or three-point circle.<br>A one point circle with a radius value is similar to the connect point command. It escapes out and creates a new circle feature using the point as the center point and the radius. The two and three-point circles behave like begin commands to create a new figure and end an active feature with the same name. | **POOL CIR5.0** | **POOL** is the figure name, " " (space) is the Feature/Code Delimiter, **CIR** is the <Circle> code, and creates a new circular figure where the current point is the radius point, and **5.0** is the circle radius value. The elevation of the figure is the elevation of the current point. This example uses only the current point as the center point, with the <Circle> code followed immediately by the radius.<br>Method 1 uses only the current point as the center point, with the <Circle> code followed immediately by the radius.<br>Method 2 uses two consecutive points to define the circular figure. The first point defines the center location and the second point defines the elevation and the radius.<br>Method 3 uses three points to define a circular figure. The elevation of all three points is used and continues the closure with an arc instead of a line. |
| Point On Curve: code to indicate that the current point resides on a curve segment. | **EP1 OC** | **EP1** matches the name of an active figure, " " (space) is the Field/Code Delimiter, and **OC** is the Point On Curve code. The figure is continued and the point is evaluated as a point residing on a curve. If there is no match to an active figure, **EP1 OC** may be a point coding error. |

| Property | Example | Description |
|---|---|---|

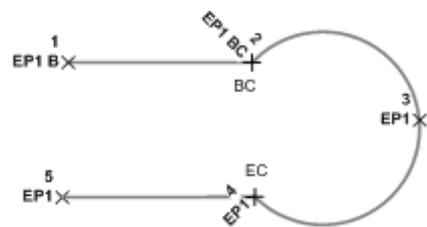
Curve Fit - No curve: In the following illustration, each survey point has the same EP1 figure name and are line points (no <Point on curve> code indicating a curve point, or <Begin curve> code). The resulting figure is a series of connected line segments.

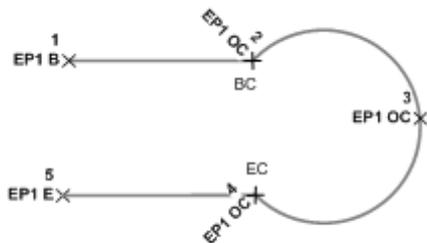


Curve Fit - One point on curve: In the following illustration each point has the same EP1 figure name, and one survey point is a coded as a curve point (OC <Point on curve> code). The resulting figure will have a calculated point of curvature (PC) and point of tangency (PT), and the curve will pass through the point.



Curve Fit - Three-point curve: In the following illustration, each point has the same EP1 figure name, and there is three consecutive curve points (OC <Point on curve> code, or BC <Begin curve> code at the beginning of the curve). The resulting figure will have a begin curve (BC) at the first EP1 point, an end curve (EC) at the third EP1 point, and the curve will pass through the second EP1 point.

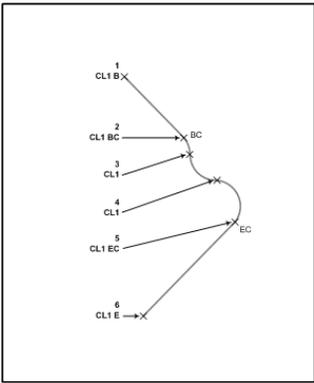




Curve Fit - Multi-point curves: In the following illustration, each point has the same CL1 figure name, and there are more than three consecutive points with an OC <Point on curve> code, or the first point on the curve segments has a BC <Begin curve> code and the ending point of the curve segments has an EC <End curve> code. The resulting figure will have a beginning of curve (BC) at the first CL1 point, and an end of curve (EC)

| Property | Example | Description |
|---|---|---|

at the last CL1 point. Compound and reverse curves will pass through each point between the BC figure vertex and the EC figure vertex.



# Importing Survey Data

Import data using the wizard or import commands in the survey network.

## Import Survey Data Wizard

Use the wizard to easily import survey data.

In the Import Survey Data wizard you have options for importing field book files, point files, points from the drawing, or Survey LandXML files. Importing data using this method creates an Import Event. For more information, see Import Events (page 249).

**To import survey data using the wizard**

1  Click Home tab ➤ Create Ground Data panel ➤ Import Survey Data .

2  On the Specify Database page, select an existing database or click Create New Survey Database.

3  On the Specify Data Source page, select one of the following options:
   ■  Field Book File

   ■  LandXML file

   ■  Point File

   ■  Points From Drawing

4  On the Specify Network page, specify a network or click Create New Network.

5  On the Import Options page, specify the import settings.

6  Click Finish.

An import event is created in the Import Events collection for the survey database.

**Quick Reference**

Ribbon

Click Home tab ➤ Create Ground Data panel ➤ Import Survey Data 

Toolspace

Survey tab: expand Survey Databases ➤ expand <named> database ➤ right-click Import Events ➤ Import Survey Data

Command Line

ImportSurveyData

# Field Book Files

Import field book files to enter data into the survey database and drawings.

Field book files (*.fbk*) are text files containing observed point data and figure definitions, which you can import into a drawing and database. Use the Survey Data Collection Link command to transfer and convert raw survey data to a field book file (*.fbk*) that you can import into AutoCAD Civil. For more information, see Survey Data Collection Link (page 240).

## Survey Data Collection Link

Use the Survey Data Collection Link command to transfer data from data collectors and convert the raw data files and coordinate data files into field book (*.fbk*) files.

Then you can import the *.fbk* files using the Import Survey Data Wizard or the import command in the survey network.

**NOTE** If you are using Windows Vista, you cannot display the Survey Data Collection Link Help files (Link32.hlp and Survey Attribute Manager.hlp) by default. To display the Survey Data Collection Link Help files in Windows Vista, download and install the Windows Help program (WinHlp32.exe) from the Microsoft Download Center.

## Transferring and Converting Data Using Survey Data Collection Link

Transfer and convert raw data files and coordinate data files into field book (*.fbk*) files that you can import into AutoCAD Civil.

**To transfer data**

1 Click Home tab ➤ Create Ground Data panel ➤  ➤ Survey Data Collection Link  to display Survey Link DC.

2 Click Transfer menu ➤ Send/Receive.

**To convert data files**

1 Click Home tab ➤ Create Ground Data panel ➤  ➤ Survey Data Collection Link  to display Survey Link DC.

2 Click Conversions menu ➤ Convert File Format.

**NOTE** For more information, use the Survey Link DC Help.

## Quick Reference

Ribbon

  Click Home tab ➤ Create Ground Data panel ➤ ⌷ ➤ Survey Data Collection Link 🖳

Menu

  Click Survey menu ➤ Survey Data Collection Link

Command Line

  StartSurveyLink

## Supported Input Types

The Survey Data Collection Link Extension supports the following input types.

| | |
|---|---|
| AutoCAD DXF | User Defined ASCII |
| AutoCogo | WILDSoft |
| ASCII (N,E,Z,Note) | Surv CAD |
| CLM | ASCII 2 |
| Autodesk-Softdesk | PacSoft Coordinates |
| ASCII | Maptech |
| Sierra Cybernetics | MTI |
| Drafix | Lewis & Lewis |
| TDS Coordinates | C & G |
| TDS Raw Data (*.rw5*) | TDS Raw Data (.raw) |
| Sokkia SDR Numeric 4 | Sokkia SDR Alpha 14 |
| Topcon FC-4 | Leica GRE3 |
| SMI | Nikon AP800,700,DTM500,400,300,DR48 |
| Topcon GTS210/220/310 Raw Data | Topcon DL-100 Digital Level |
| Leica GSI Raw Data | |

## Importing a Field Book File

Enter data into your drawing and survey database by importing an existing field book file.

**NOTE** In the Import Settings, clear the Process Linework check box when you are importing . *fbk* files created from the Survey Data Collection Link application because Linework Codes Set definitions may not be recognized. However, the figure commands created using the Survey Data Collection Link are recognized.

**TIP** You can also use the Import Survey Data wizard to import field book files. For more information, see Import Survey Data Wizard (page 239).

**To import a field book file from a network**

1  In Toolspace, on the Survey tab, expand the Networks collection and right-click the network to which you want to import the field book.

2  Click Import ➤ Import Field Book.

3  In the Field Book Filename (.FBK) dialog box browse to the field book that you want to import. Click Open.

4  In the Import Field Book dialog box, modify settings as required. For information about the settings, see Import / Re-import Field Book Dialog Box (page 2406).

## Quick Reference

Ribbon

Click Home tab ➤ Create Ground Data panel ➤ Import Survey Data 🗊

Toolspace

Survey tab: Survey Databases ➤ <database-name> ➤ Networks ➤ right-click <network-name> ➤ Import ➤  Import Field Book

# Editing a Field Book File

Use AutoCAD Civil to view and edit an existing field book file.

Load a field book file into a text editor so that you can view or edit it.

**NOTE** Notepad is the text editor unless you specify another editor in the External Editor in the Survey User Settings dialog box. For more information, see Specifying External Editor Settings (page 208).

**WARNING** To work correctly, a field book file must be in an ASCII format.

**To edit a field book file**

1  In Toolspace, on the Survey tab, expand the Networks collection and right-click on a network name.

2  Click Edit Field Book.

3  In the Field Book Filename (.FBK) dialog box, browse to the field book that you want to edit. Click Open.

4  The field book contents are displayed in the text editor.

5  Make any necessary changes and save the file.

## Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <database-name> ➤ Networks ➤ right-click <network-name> ➤ Edit Field Book

## Exporting a Field Book File

Export survey data from an individual network, individual figure, or collection of figures to a field book file.

**To export a field book file**

**NOTE** A field book can be exported from networks and figures.

1. In Toolspace, on the Survey tab, do one of the following:
   - Expand the Networks collection and right-click the network from which you want to export data to a field book.
   - Right-click the Figures collection that you want to export to a field book.
   - Expand the Figures collection and right-click a figure name to export it to a field book.

2. Click Export Field Book.

3. In the Save As dialog box, browse to the location where you want to save the field book and enter a file name. Click Save.

4. If you are exporting a network to a field book, in the Export Field Book dialog box, modify the settings as required. For information about the settings, see Export Field Book Dialog Box (page 2413).

### Quick Reference

Toolspace

## Survey LandXML Data

You can import and export survey LandXML data directly into or from the survey database.

Use the AutoCAD Civil Import Survey LandXML command to import LandXML survey data directly into the survey database. You can subsequently insert the data into the drawing, using the Insert Into Drawing commands.

The following table illustrates the results of importing LandXML data using the Import Survey LandXML command.

| LandXML Data | Results Using Import Survey LandXML |
|---|---|
| Parcels | Figures in the survey database |
| PlanFeatures | Figures in the survey database |
| COGO points, survey monuments | Survey points in the survey database |
| Reduced observations | Setups and Observations, control points, or non-control points in the survey database |

| LandXML Data | Results Using Import Survey LandXML |
| --- | --- |
| Raw observations | Setups and Observations in the survey database |

**NOTE** You can import reduced survey data directly into a AutoCAD Civil drawing. For more information about the different types of LandXML import functionality for survey data, see Importing Survey XML Data.

You can also export LandXML data from the survey database.

You specify both the LandXML import settings and data selection using the Import Survey LandXML command.

The LandXML import and export functionality is based on the LandXML schema. For more information about the LandXML schema, go to *http://www.landxml.org*.

## Importing Survey LandXML Data

Enter data into the survey database and the drawing by importing an existing LandXML.

**TIP** You can also use the Import Survey Data wizard to import Survey LandXML files. For more information, see Import Survey Data Wizard (page 239).

**NOTE** You can only import a LandXML file into an open survey database. For information about creating and opening a survey database, see Survey Database (page 196).

**To import a LandXML file**

1  On the Survey tab in Toolspace, right-click a survey database ➤ Import Survey LandXML.

2  In the Select LandXML File dialog box, browse to the LandXML file that you want to import. Click Open.

3  In the Import Survey LandXML dialog box, modify the import settings and select the survey data that you want to import. For information about the import settings, see Import / Re-import Survey LandXML Data Dialog Box (page 2420).

## Quick Reference

Ribbon

Click Home tab ➤ Create Ground Data panel ➤ Import Survey Data 🗄

Toolspace

Survey tab: Survey Databases ➤ right-click <database-name> ➤ Import Survey LandXML

## Exporting Survey Data to LandXML

Export survey data to a LandXML file using AutoCAD Civil.

**To export survey data to a LandXML file**

1  In Toolspace, on the Survey tab, expand the Survey Databases collection and right-click a database name.

**2** Click Export Survey LandXML.

**3** In the Export Survey LandXML dialog box, modify the export settings and select the survey data that you want to export. For information about the settings, see Export Survey LandXML Data Dialog Box (page 2423).

### Quick Reference

Toolspace

Survey tab: expand Survey Databases ➤ right-click <database-name> ➤ Export Survey LandXML

## Managing Survey Extended Properties

Use extended properties to import and export Survey LandXML attributes and to create, assign, and view user-defined attributes.

Using the extended properties command, you can do the following:

■ Import Survey LandXML data and attributes into the survey database.

■ View Survey LandXML attributes and modify user-defined attributes using the AutoCAD Civil Survey user interface.

■ Export Survey LandXML data (with attributes) to a specified LandXML file.

■ Insert Survey Points into a drawing with the Survey LandXML and user-defined attributes assigned.

■ Complete round-tripping of Survey LandXML and user-defined data using the Import Survey LandXML and Export Survey LandXML commands on the Survey tab in Toolspace.

## Extended Properties User Interface

By default there are no extended properties defined in the *sdx_def* file.

To display extended properties, you must specify an *sdx_def* file that contains definitions, or import a LandXML file with the Create New Definitions Automatically option selected in the Survey Database Settings.

For more information, see Survey Database Settings dialog box. (page 2378)

**To display the survey extended properties**

**1** In the Survey Database Defaults specify the path and the extended properties definition file.

**2** In Toolspace, on the Survey tab, expand the Survey Databases collection and right-click a database name ➤ Manage Extended Properties.

**3** In the Manage Extended Properties dialog box, select the check boxes for collections or individual properties.
For more information, see the Manage Extended Properties dialog box. (page 2425)

### Quick Reference

## Creating and Editing User-defined Properties

Use the options in the Manage Extended Properties dialog box to create or edit a user-defined property.

**To create or edit a user-defined extended property**

1 In Toolspace, on the Survey tab, expand the Survey Databases collection and right-click a database name.

2 Click Manage Extended Properties. In the Manage Extended Properties dialog box, collections are displayed for each of the <SurveyFeatureClasses>.

3 In the Manage Extended Properties dialog box, click ⫶▾ to expand the <SurveyFeatureClasses>in the tree. Each feature class has a collection for LandXML and User-defined.

4 Select a User-defined check box under a feature class, right-click ➤ New or Edit.

5 In the Edit Extended Property dialog box, enter the following:

■ XML Name

■ Display Name

■ Description

6 Select a type in the Property Field Type list. For more information on the display of property fields, see Property Field Type Table (page 246).

7 Select the Required Value check box to display a warning icon for properties that have not been assigned to an instance of a <SurveyFeatureClass>. The Event Viewer will also post a warning when you export the LandXML file using the Export Survey LandXML command.

8 Select the Display check box to have the extended property display on the object.

9 If you specified String as the Property Field Type, enter values for String.

### Quick Reference

## Property Field Types Table

Use this table to determine the display of the various Property Field types both in the Survey user interface and the display of extended properties that are assigned to Survey points in the drawing.

| Property Field Types | Stored in Survey Database As | Survey User-interface Display | DWG Formatting |
|---|---|---|---|
| Angle | Angle in radians | SDB Angle | Angle |

| Property Field Types | Stored in Survey Database As | Survey User-interface Display | DWG Formatting |
|---|---|---|---|
| Area | Square Units in Meters | SDB Square Distance | Area |
| Azimuth | Direction in Radians | SDB Direction | Direction |
| Boolean | Boolean | Boolean | Boolean |
| Coordinate | Distance in Meters | SDB Distance | Coordinate |
| Dimension | Distance in Meters | SDB Distance | Dimension |
| Direction | Direction in Radians | SDB Direction and Angle | Direction |
| Distance | Distance in Meters | SDB Distance | Distance |
| Double | Double | Double | Unitless |
| Elevation | Elevation in Meters | SDB Distance | Elevation |
| Grade | Double | Double | Grade |
| Slope | Double | Double | Slope |
| Integer | Integer | Integer | Unitless |
| Latitude | Angle in Radians | Signed Angle | Latitude |
| Longitude | Angle in Radians | Signed Angle | Longitude |
| Percent | Percent | Percent | Percent |
| Station | Distance in Meters | SDB Distance | Station |
| String | String | String | String |
| Volume | Cubic Meters | Cubic Yards if Foot or Cubic Meters if Meters | Volume |

## Extended Property Definition Files

You can edit default *.sdx_def* files or specify a pre-defined schema with specialized LandXML and User-defined properties contained in an existing *.sdx_def file.

By default, AutoCAD Civil Survey installs the LandXML - Standard *.sdx_def* and Sample *.sdx_def* files at the following location:

C:\ Documents and Settings\All Users\Application Data\Autodesk\C3D2010\enu\Survey.

For example, the LandXML - Standard *.sdx_def* file contains numerous SurveyFeatureClass items. You can open this file in a text editor and make any necessary edits to streamline this file to meet your needs. Use the Save As command and then save the file with a new name.

## Using Groups to Manage Survey Data

Use Network Groups, Figure Groups, and Survey Point Groups to organize and manage survey data.

Organize LandXML collections of elements, such as CgPoints or PlanFeature collections, using Network Groups, Figure Groups, and Survey Point Groups. These groups are located at the root collection within a Survey database item on the Survey tab in Toolspace.

**To create a new Network Group, Figure Group, and Survey Point Group**

1  In Toolspace, on the Survey tab, expand the Survey Databases collection and expand a database name.

2  Right-click ➤ New for the group you want to create.

3  In the New <type> Group dialog box enter a name and description.

4  In the lower pane of the dialog box, check the items you want to add to the group.

**NOTE** If you are using the extended properties feature, and have created User-defined properties, they are displayed. Click the cell in the Value column to assign an attribute.

### Quick Reference

Toolspace

Survey tab: Survey Databases ➤ right-click <group-name> ➤ New

# Importing Point Files

Use the Import Point File command to import points into the Survey database and network as control points or non-control points.

In the import settings, you have an option for linework processing. The selected point file format determines the column order, (P,N,E,Z,D), the delimiter, and coordinate zone of the file being imported. If you select the Process Linework option, the point file format must contain a Raw Description column. A point file format with a coordinate system zone that is different from the coordinate zone assigned to the Survey Database will require a transformation.

Each time you import a point file, a point group is created on the Prospector tab in Toolspace. The file name for the file you import is the default point group name.

**TIP** You can also use the Import Survey Data wizard to import point files. For more information, see Import Survey Data Wizard (page 239).

**To import a point file**

1  In Toolspace, on the Survey tab, right-click a <named> network.

2  Click Import ➤ Import Point File.

3  Browse to the file you want to import and click Open.

4  Make any necessary changes to the Import Point File settings and click OK.

### Quick Reference

Ribbon

Click Home tab ➤ Create Ground Data panel ➤ Import Survey Data 

Toolspace

&lt;named&gt; network ➤ Import ➤ Import Point File

## Importing Points From a Drawing

Use this command to import points from a drawing into the Survey database and network as control points or non-control points.

---

**TIP** You can also use the Import Survey Data wizard to import points from a drawing. For more information, see Import Survey Data Wizard (page 239).

---

**To import points from a drawing**

1 In Toolspace, on the Survey tab, right-click a &lt;named&gt; network.

2 Click Import ➤ Import Points From Drawing.

---

**NOTE** COGO points are imported from the current drawing.

---

3 At the command line, enter one of the following:

■ All: imports all points in the drawing.

■ Numbers: enter the point numbers you want to import.

■ Group: select the point group you want to import.

■ Selection: select points in the drawing.

4 Make any necessary changes in the Import Points From Drawing settings and click OK.

### Quick Reference

Ribbon

Click Home tab ➤ Create Ground Data panel ➤ Import Survey Data 

Toolspace

&lt;named&gt; network ➤ Import ➤ Import Points From Drawing

## Import Events

The import event provides a framework that you can use to view and edit specific survey data that is referenced within the import event.

An import event is created each time you import data using either the Import Survey Data wizard, the import commands on the survey network shortcut menu, or the import Survey LandXML command.

Import Events are displayed as a collection within a database on the Toolspace Survey tab. The default name for the import event is the same as the imported file name "&lt;File name&gt;.&lt;ext&gt;".

The Import Event collection contains the Networks, Figures, and Survey Points that are referenced from the specific import command, and provides a convenient way to remove, re-import, and reprocess linework, and insert survey data into the current drawing.

---

**TIP** Commands entered in the Survey Command Window or from using the Run Batch File command do not create an import event. To maintain the integrity of existing networks, you should create a separate network when you use the Survey Command Window.

---

**To edit an import event**

1 In Toolspace, on the Survey tab, expand a named survey database, and then expand the Import Events collection.

2 In the Import Events Editor vista, select an import event, right-click ➤ Edit.

**To delete an import event**

1 In Toolspace, on the Survey tab, expand a named survey database, and then expand the Import Events collection.

2 Select an import event, right-click ➤ Delete.

**To change the order of import events**

1 In Toolspace, on the Survey tab, expand a named survey database, and then expand the Import Events collection.

2 Select the import event and drag it to a new location in the collection.

## Quick Reference

Toolspace

  Survey tab: expand Survey Databases ➤ <named> survey database ➤ Import Events ➤ <named> event

# Import Event Commands

Use the following right-click commands to view and edit data in the Import Event collection and in individual import events.

**Import Event Collection**

■ Import Survey Data: Displays the Import Survey Data wizard.

■ Edit: Displays the Import Events Editor in the panorama vista.

■ Process Linework: Displays the Process Linework dialog box where you can edit settings if necessary and then process the linework for all import events using the specified settings.

■ Insert Into Drawing: Inserts data from all import events into the current drawing.

■ Remove From Drawing: Removes data from the import events created in the current drawing.

**Import Event**

■ Properties: Displays the properties for a selected event, such as name, description, and linework code set.

■ Edit: Displays the Import Events Editor in the panorama vista.

- Re-import: Displays the import settings for the event. Edit settings if needed and click OK to re-import the event data.

- Process Linework: Displays the Process Linework dialog box where you can edit settings if necessary and then process the linework for the selected import events using the specified settings.

# Editing Survey Point Properties

After importing survey data, you can edit survey point descriptions to correct field coding errors.

A survey point is a COGO point that is created by the Survey feature. When the survey point description is changed and the field coding errors are corrected you can re-process the linework. For more information, see Processing Survey Linework (page 251).

**To edit survey point properties**

1 Do one of the following:

- In the drawing, right-click a survey point ➤ Edit Survey Point Properties.

- From any survey point list view right-click a point ➤ Properties.

2 In the Survey Point Properties dialog box, edit the point name and the point description.

3 Click OK. At the command line, you are prompted to select another point. Continue to edit the points as necessary.

4 Press Enter to end the edit command and update the linework.

To process linework at anytime, right-click the Survey Points collection on the Survey tab in Toolspace ➤ Process Linework.

## Quick Reference

Ribbon

Click Survey tab ➤ Modify panel ➤ Survey Point Properties 

Toolspace

Expand Survey Point Collection ➤ right-click a survey point in a point list ➤ Properties

Command Line

EditSvPointProperties

# Processing Survey Linework

Process Linework during the import of survey data or as a post import process.

**IMPORTANT** Figures that are created using a Linework Code Set do not automatically update when you modify survey data by updating figures, changing survey point descriptions, editing point coordinates through changes in observations, or network and traverse adjustment. In order to obtain the most accurate results, it is recommended that you process the linework each time you make modifications to the survey data.

**To process or re-process linework**

1  In Toolspace, on the Survey tab, do one of the following:

   ■ Right-click the Import Events collection ➤ Process Linework. Linework for all import events in the collection is processed in the order that the import events are displayed in the Import Events collection. Use this command in situations where a figure spans across multiple import events. For example, in the first import event EP1 was created, but in a subsequent import event an attempt is made to continue the same EP1.

   ■ Right-click a named import event ➤ Process Linework. Linework for the event you selected is processed.

   ■ Right-click the Survey Points collection ➤ Process Linework. Linework for all points, including points from previous versions and manually entered points.

2  In the Process Linework dialog box, verify the settings and click OK.

## Quick Reference

Toolspace

Right-click Import Event Collection or <named> Import Event ➤ Process Linework

# Adding and Editing Survey Data

<div style="text-align: right; font-size: 3em; font-weight: bold;">11</div>

You can use AutoCAD Civil to add and edit survey data.

To add survey data to your drawing, you can:

- Use the AutoCAD Civil Toolspace Survey tab to define and manage survey data such as point, setups, directions, traverses, and figures.

- Use the AutoCAD Civil Survey Command Window to define survey data such as baselines, centerlines, and intersections, and to view and manage survey command input and output history.

In AutoCAD Civil, a survey database holds all the observed angles and distances for each point.

## Control Points

You can use several methods to create control points.

Control points are points you create at a known location. Control points are not affected by any adjustments or corrections you make. When you create a control point, it is added to survey database.

The Control Points collection on the Toolspace Survey tab expands to display individual control points.

## Creating Control Points

Use the Toolspace Survey tab to create a control point using known northing and easting, or latitude and longitude (if the survey database references a coordinate zone), and elevation coordinates, to be used for traverse and least squares adjustments.

**To create a control point**

1 In Toolspace, on the Survey tab, right-click the Control Points collection. Click New to open the New Control Point dialog box.

2 Enter the point number.

**IMPORTANT** If there is a Survey Point (Non-Control point) with a matching number then the data for that point displays in the New Control Point dialog box. If there is no Survey Point defined in the Survey database that has a matching name, the program checks the active drawing to see if there is an AutoCAD Civil point with a matching number. If there is an AutoCAD Civil point with a matching number, then the point information displays in the New Control Point dialog box.

**3** Optionally, enter the point name.

**IMPORTANT** You can define a point by Name, by deleting the number in the Number field and leaving it blank. Enter a Name in the Name field. If there is already a control point with that name an error message is displayed. If there is a Survey point with a matching name then the data for that point displays in the New Control Point dialog box. If there is no Survey Point or Control point defined in the Survey database that has a matching name, the program checks the active drawing to see if there is an AutoCAD Civil point with a matching name. If there is an AutoCAD Civil point with a matching name, then the point information displays in the New Control Point dialog box.

**4** Enter the easting (X-coordinate) of the new control point.

**5** Enter the northing (Y-coordinate) of the new control point.

**6** Optionally, enter the elevation (Z-coordinate) of the new control point.

**7** Enter a description for the control point.

**8** Optionally, enter the latitude of the point. The Northing property value is calculated from the value entered in this field.

**NOTE** This property is not available if the survey database does not have an assigned coordinate system zone.

**9** Optionally, enter the longitude of the point. The Easting property value is calculated from the value entered in this field.

**NOTE** This property is not available if the survey database does not have an assigned coordinate system zone.

**10** Click OK to create the new control point. The new control point is displayed in the control points list view in Toolspace.

**To create a new control point using the survey command language**

**1** In Toolspace, on the Survey tab, right-click on the network that you want to add the control point to. Click Survey Command Window.

**2** To create a control point by northing and easting, at the Command line, enter:

NE (point) [north] [east] (description)

To create a control point by northing, easting, and elevation, at the Command line, enter:

NEZ (point) [northing] [easting] (elevation) (description)

**3** To create a control point by latitude and longitude (if the survey database settings reference a coordinate zone), enter:

LAT LONG (point) [latitude] [longitude] (description)

**NOTE** For parameter descriptions, see the Quick Reference tab.

**Examples**

The following example sets point 2 at northing 2000, easting 2000 with an elevation of 100, and a description of TP.

*NEZ 2 2000 2000 100 TP*

The following example sets point number 55 at latitude 45°16'17" and longitude 36°55'55".

*LAT LONG 55 45.1617 36.5555*

## Quick Reference

Toolspace

  Survey tab: right-click Control Points ➤ New

Survey Command Window Syntax

  NE (point) [northing] [easting] (description)
  or
  NEZ (point) [northing] [easting] (elevation) (description)
  or
  LAT LONG (point) [latitude] [longitude] (description)

| Parameter | Definition |
| --- | --- |
| point | The point identifier of the new point. You do not need to assign a point number if auto point numbering is on. |
| northing | The northing of the point. |
| easting | The easting of the point. |
| elevation | The elevation of the point. |
| latitude | The latitude of the point. Enter this value using the current survey database Angle unit. Use a positive value to indicate a location above the equator, or a negative value for one below it. |
| longitude | The longitude of the point. Enter this value using the current survey database Angle unit. Use a positive value to indicate a location east of the prime meridian, or a negative value for a location west of the prime meridian. |
| description | An optional description associated with the point. |

# Editing Control Points

Use the Control Points Editor to view and edit control point data for individual or multiple control points.

For individual control points, the Control Points Editor provides the same functionality as the Control Points properties list view in the Toolspace Survey tab, but it is more suited for horizontal viewing of a tabulation of this type of data. The benefit of editing control points in the Control Points Editor is that you can easily switch to the Survey tab and browse through the data and then return back to the Control Points Editor to continue with your edits.

**To edit control points**

**1** Do one of the following:

- To view and edit all control points, in Toolspace, on the Survey tab, right-click the Control Points collection and click Edit to open the Control Points Editor.

- To view and edit a single control point, in Toolspace on the Survey tab, right-click the control point and click Edit to display the Control Points Editor.

**NOTE** You can also edit a single control point in the Toolspace properties list view, which is displayed when you select a control point in the tree view on the Survey tab.

**2** Modify the applicable fields as required.

**NOTE** When you make a change to any control point data, the entire row is displayed in bold until you save the changes to the survey database.

**3** To edit the values in multiple rows, select the rows, right-click the column heading, click Edit, and enter the new value.

**4** The selected row values for the column are updated with the new value.

**NOTE** If no rows are selected, then all rows are updated. Press the ESC key to clear the selection.

**5** To undo the changes for a single row or multiple rows, select the row(s), right-click, and click Reload. Alternatively, to undo all the changes in the vista, click 🔄 .

**6** To apply the changes for a single row or for multiple rows, select the row(s), right-click, and click Apply. Alternatively, to apply all changes in the vista, click 💾 .

**7** For information about the standard panorama vista functions, see The Panorama Window (page 102).

### Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <database name> ➤ Networks ➤ <network name> ➤ right-click Control Points ➤ Edit

# Non-Control Points

Use the Survey tab to create non-control points.

Non-control points are created with a northing, easting, and optional elevation.

Non-control points can be promoted to control points if you reference the point as a control point for creating a traverse, or reference the point as a setup to make observations to other points that may affect locations during an analysis.

The Non-Control Points collection on the Toolspace Survey tab expands to display individual non- control points.

# Creating a Non-Control Point

Create a point using known northing, easting, optional latitude and longitude, and optional elevation.

**To create a non-control point**

**1** In Toolspace, on the Survey tab, right-click the Non-Control Points collection and click New to open the New Non-Control Point dialog box.

**2** Enter the point number. You do not need to assign a point number if auto point numbering is on.

> **IMPORTANT** If there is an AutoCAD Civil point with a matching number, then the point information displays in the New Non-Control Point dialog box.

**3** Optionally, enter the point name.

> **IMPORTANT** You can define a point by Name, by deleting the number in the Number field and leaving it blank. Enter a Name in the Name field. If there is already a Control point or Non-control with that name an error message is displayed. If there is a point Survey point with a matching name then the data for that point displays in the New Non-Control Point dialog box. If there is no Survey Point or Non-Control point defined in the Survey database that has a matching name, the program checks the active drawing to see if there is an AutoCAD Civil point with a matching name. If there is an AutoCAD Civil point with a matching name, then the point information displays in the New Non-Control Point dialog box.

**4** Enter the easting (X-coordinate) of the new non-control point.

**5** Enter the northing (Y-coordinate) of the new non-control point.

**6** Optionally, enter the elevation (Z-coordinate) of the new non-control point.

**7** Enter a description for the non-control point.

**8** Enter the latitude of the point. The Northing property value is calculated from the value entered in this field.

> **NOTE** This property is not available if the survey database does not have an assigned coordinate system zone.

**9** Enter the longitude of the point. The Easting property value is calculated from the value entered in this field.

> **NOTE** This property is not available if the survey database does not have an assigned coordinate system zone.

**10** Click OK to create the new non-control point. The new control point is displayed in the non-control points list view in Toolspace.

**To create a non-control point using the survey command language**

**1** In Toolspace, on the Survey tab, right-click the network that you want to add control points to. Click Survey Command Window.

**2** At the Command line, enter:

NE SS (point) [north] [east] (elevation) (description)

> **NOTE** For parameter descriptions, see the Quick Reference tab.

### Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <database name> ➤ Networks ➤ <network name> ➤ right-click Non-Control Points ➤ New

Survey Command Window Syntax

NE SS (point) [North] [East] (elevation) (description)

| Parameter | Definition |
| --- | --- |
| point | The point identifier of the new point. You do not need to assign a point number if auto point numbering is on. |
| north | The northing of the point. |
| east | The easting of the point. |
| elevation | The elevation of the point. |
| description | An optional description associated with the point. |

## Editing Non-Control Points

Use the Non-Control Points Editor to view and edit point data for individual or multiple non-control points.

For individual points, the Non-Control Points Editor provides the same functionality as the properties list view in Survey tab, but is more suited for horizontal viewing of a tabulation of this type of data. The benefit of editing non-control points in the Non-Control Points Editor is that you can switch to the Survey tab and browse through the data and then return to the Non-Control Points Editor to continue with your edits.

**To edit non-control points**

1  Do one of the following:
  ■  To view and edit all non-control points, on the Survey tab, right-click the Non-control Points collection and click Edit to display the Non-Control Points Editor.

  ■  To view and edit a single non-control point, in the Survey tab, click the Non-Control Points collection. In the item list view, click the point you want to edit.

2  Modify the applicable fields as required.

   **NOTE** When you make a change to any point data, the entire row is displayed in bold until you save the change to the survey database.

3  To edit the values in multiple rows, select the rows, right-click the column heading, click Edit, and enter the new value.

4  The selected row values for the column are updated with the new value.

   **NOTE** If no rows are selected, then all rows are updated.

5  To undo the changes for a single row or multiple rows, select the row(s), right-click, and click Reload. Alternatively, to undo all the changes in the vista, click  .

**6** To apply the changes for a single row or for multiple rows, select the row(s), right-click, and click Apply. Alternatively, to apply all changes in the vista, click ![save icon] .

**7** For information on the standard panorama vista functions, see The Panorama Window (page 102).

# Setups

Setups are the instrument setups that are defined in the survey database. The Setups collection on the Toolspace Survey tab expands to display individual setups.

# Creating a New Setup

Use the Toolspace Survey tab to create new instrument setups.

You can create a point using an angle turned from either a specified reference line or a previously determined backsight point. Additionally, you can also use a vertical angle or vertical distance to locate the point.

**To create a new setup**

**1** In the Survey Toolspace tab, right-click on the Setups collection and click New to display the New Setup dialog box.

**2** Enter the station point for the setup.

> **NOTE** If you enter a non-existent station point, you are prompted to create a point and the New Control Point dialog box is displayed where you can create a new station point.

**3** Enter the backsight point for the setup. When this column contains a valid entry, the Backsight Direction column displays the calculated backsight direction value and is read-only.

> **NOTE** If you enter a non-existent backsight point, you are prompted to create a point and the New Control Point dialog box is displayed from which you can create a new backsight point.

> **NOTE** Setups can be created using the names of Survey Points that exist in the Survey Database. Enter the point names in the Station Point and Backsight Point fields.

**4** Enter a backsight direction. This field is read-only if the Backsight Point column contains a valid point number.

**5** Enter the backsight orientation angle for the setup.

> **NOTE** This is the reference angle for all angle observations except Face1 and Face2 angles.

**6** Enter the direct angle reference on the backsight for Face1 angles.

**7** Enter the reverse angle reference on the backsight for Face2 angles.

**8** Enter the measured instrument (theodolite) height. This is typically measured from the center of the theodolite optics to the setup point on the ground.

**9** Click OK to create the new setup.

**To create a setup using the survey command language**

**1** In Toolspace, on the Survey tab, right-click on the network that you want to add control points to. Click Survey Command Window.

**2** At the Command line, enter:

STA [point] (instrument height) (description)

> **NOTE** For parameter descriptions, see the Quick Reference tab.

**Example**

This example sets the instrument on point 1. It is 5.1 feet above ground elevation. Therefore, the instrument elevation is 105.1 feet.

NEZ 1 1000 1000 100

AZ 1 2 90

*STA 1 5.1*

!STATION h.i.: 105.10

!POINT: 1 NORTH: 1000.0000 EAST: 1000.0000 ELEV: 100.0000

## Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <database name> ➤ Networks ➤ <network name> ➤ right-click Setups ➤ New

Survey Command Window Syntax

STA [point] (instrument height) (description)

| Parameter | Definition |
| --- | --- |
| point | The point identifier of the traverse station. |
| instrument height | The height of the instrument above ground elevation. |
| description | An optional description associated with the point. |

# Defining New Station and Backsight Points

When creating a new setup, you can specify station and backsight points. If you enter a point identifier that does not exist in the survey database, you are prompted to create a new point in the New Control Point dialog box.

**To define new station or backsight points**

**1** In the New Setup dialog box, enter the new station or backsight point in the respective fields.

**2** Click Yes when you are prompted with the message asking you if you want to create the point.

**3** In the New Control Point dialog box, enter the easting, northing, elevation, and description for the new point. Click OK.

**4** The point is added to the Control Points collection and the survey database.

# Viewing and Editing Setups

Use the Toolspace Survey tab to view and edit setup data for multiple setups or for an individual setup.

For individual setups, the Setups Editor vista provides the same functionality as the setup properties list view in the Toolspace Survey tab, but is more suited for horizontal viewing of a tabulation of this type of data. The benefit of editing setups in the Setups Editor is that you can easily switch to the Survey tab and browse through the data and then return to the Setups Editor to continue with your edits.

**To edit setups**

**1** Do one of the following:
- To view and edit all setups, on the Survey tab, right-click the Setups collection and click Edit to display the Setups Editor.

- To view and edit a single setup, on the Survey tab, right-click an individual setup and click Edit to display the Setups Editor.

**NOTE** You can also edit a single setup in the Toolspace item view, which is displayed when you select a setup in the tree view on the Survey tab.

**2** Modify the applicable fields as required.

**NOTE** When you make a change to any setup data, the entire row is displayed in bold until you save the change to the survey database.

**3** To edit the values in multiple rows, select the rows, right-click the column heading, click Edit, and enter the new value.
The selected row values for the column are updated with the new value.

**NOTE** If no rows are selected, then all rows are updated.

**4** To undo the changes for a single row or for multiple rows, select the row(s), right-click, and click Reload. Alternatively, to undo all the changes in the vista, click ⟳ .

**5** To apply the changes for a single row or multiple rows, select the row(s), right-click, and click Apply. Alternatively, to apply all changes in the vista, click 💾 .

**6** For information about the standard panorama vista functions, see The Panorama Window (page 102).

**To edit setups that observe a point**

**1** On the Toolspace Survey tab, expand the network name and click Survey Points.

**2** In the Toolspace list view, right-click the point for which you want to edit the setups that observe. Click Edit Setups That Observe to open the Setups Editor.

**3** In the Setups Editor, optionally, right-click a setup and click Edit Observations.

**4**  Modify the applicable fields as required.

> **NOTE** When you make a change to any setup data, the entire row is displayed in bold until you save the change to the survey database.

**5**  To edit the values in multiple rows, select the rows, right-click the column heading, click Edit, and enter the new value.

**6**  The selected row values for the column are updated with the new value.

> **NOTE** If no rows are selected, then all rows are updated.

**7**  To undo the changes for a single row or multiple rows, select the row(s), right-click, and click Reload. Alternatively, to undo all the changes in the vista, click ⟳ .

**8**  To apply the changes for a single row or for multiple rows, select the row(s), right-click, and click Apply. Alternatively, to apply all changes in the vista, click 💾 .

**9**  For information about the standard panorama vista functions, see The Panorama Window (page 102).

Toolspace

Survey tab: Survey Databases ➤ <database name> ➤ Networks ➤ <network name> ➤ right-click Setups ➤ Edit

## Deleting Setups

Delete setups from the Toolspace Survey tab list view or from the Setups Editor vista.

Use the Setups Editor vista to mark setups for deletion, and then accept or roll back the deletions.

> **NOTE** When a setup is deleted, only the setup is deleted, not the points that were created by the setup.

**To delete a setup from the Toolspace Survey tree**

**1**  In Toolspace, on the Survey tab, expand the Setups collection.

**2**  Right-click a setup and click Delete.

**To delete a setup from the Setups Editor**

**1**  In Toolspace, on the Survey tab, right-click the Setups collection and click Edit to open the Setups Editor.

**2**  Select the setup(s) to delete, right-click, and click Delete.

The setup icon is replaced with a ✖ and the row is set to read-only.

**3**  To undo the changes for a single row or for multiple rows, select the row(s), right-click, and click Undelete. Alternatively, to undo all the changes in the vista, click ⟳ .

**4**  To apply the changes for a single row or multiple rows, select the row(s), right-click, and click Apply. Alternatively, to apply all deletions and changes in the vista, click 💾 .

# Observations

Observations are measured to survey points in relation to a setup.

You use the Toolspace Survey tab and the Observations Editor to add, edit, and manage observations at a specific setup.

In addition to creating and editing observation at a specific setup in the Observations Editor, you can create observations using the Survey Command Window.

Observations are used to measure locations on the Earth's surface that have been determined by surveying (geometric) methods. You can locate points by known coordinates, or in reference to some other known location, such as an angle and distance from an existing point.

When automatic point numbering is off, you must specify the point numbers. If automatic point numbering is on, the points are automatically numbered. Subsequent points are assigned the next available number in sequential order. For information about setting automatic point numbering, see Setting Survey Command Window Options (page 221).

It is helpful to establish a point numbering system for all your projects. A recommended point numbering method might be to number traverse points sequentially, starting with 1. If the job contains fewer than 100 traverse points, then number all sideshots observed from point 1 with numbers 101 to 199, and sideshots taken at point 2 with numbers 201 to 299. This method makes it easy to determine where any given point was observed from.

## Browsing to an Observation

Browse to an observation in the Observation Editor.

In the Observations Editor you have the options to view, create, and edit survey data.

**To browse to an observation**

1  Click Survey tab ➤ Modify panel ➤ Browse To Survey Data Drop-down ➤ Browse To Observation 🛱 .

2  In the Edit Setups That Observe dialog box, enter the point identifier for the observation you wish to find.
The specified observation is displayed in the Observation Editor.

# Enabling Point Numbering

When automatic point numbering is on, new points are automatically assigned the next available point number. When automatic point numbering is off, you must specify new point numbers as they are needed.

**To turn point numbering on or off**

1 In the Toolspace Survey tab, right-click the survey database name and click Edit Survey Database Settings.

2 In the Survey Database Settings dialog box, expand the Survey Command Window property group.

3 Do one of the following:

■ To enable automatic point numbering, select the Auto Point Numbering check box.

■ To turn off automatic point numbering, clear the Auto Point Numbering check box.

4 Click OK.

---

**NOTE** For parameter descriptions, see the Quick Reference tab.

---

**To turn point numbering on or off using the survey command language**

1 In Toolspace, on the Survey tab, right-click the network name for which you want to turn automatic point numbering on or off. Click Survey Command Window.

2 To turn automatic point numbering on, at the Command line, enter:
AUTO ON [point]

3 To turn automatic point numbering off, at the Command line, enter:
AUTO OFF

## Example

The following example shows a valid entry using the Automatic Point Numbering On command with 1001 as the starting point number:

*AP ON 1001*

If you do not enter a point number, then the program assigns the next available point number.

# Creating Observations

Use the Observations Editor to add observations to an existing setup.

Add points using one of the following methods:

■ Angle: Creates an observation using an angle turned from either a specified reference line or a previously determined backsight point. For an example and illustration of this method, see Creating an Observation by Angle and Distance (page 266).

■ Deflection: Creates an observation using a deflection angle and distance from an established line. For an example and illustration of this method, see Creating an Observation by Deflection Angle and Distance (page 270).

■ Face1/Face2 angle: Creates an observation from a traverse station using a horizontal angle measured on Face1 or Face2 of your instrument. For an example and illustration of this method, see Creating an Observation Using a Face1 or Face2 Angle (page 272).

■ Azimuth: Creates an observation from an occupied traverse station by entering a recorded azimuth and distance. For an example and illustration of this method, see Creating an Observation Using an Azimuth (page 275).

■ Bearing: Creates an observation in reference to the occupied point using bearing and distance. For an example and illustration of this method, see Creating an Observation by Bearing and Distance (page 268).

**To add an observation to a setup**

1 In Toolspace, on the Survey tab, right-click the setup name and click Edit Observations.

2 In the Observations Editor, right-click either an existing observation or an empty row and click New.

A new row is added to the Observations Editor.

> **NOTE** If you select an existing row and add a new observation, the new observation uses the settings of the selected row. If you select an empty row, the new observation's settings are based on the Database Settings (page 216).

3 Modify the fields by selecting the field and entering the new value as needed.

4 To edit the Angle Type, Distance Type, Vertical Type, and Target Type fields, click the field and select a new value from the drop-down lists. For information about these types, see Survey Database Settings Dialog Box (page 2378).

> **NOTE** If no rows are selected, then all rows are updated.

5 To create an observation using a point name, delete the value in the point number field and then specify the Angle and Distance values, and then enter a point name. The Angle and Distance values must be entered before you enter the Name. If there is a point Survey point with a matching name then the data for that point is displayed.

6 To undo the changes for a single row or multiple rows, select the row(s), right-click, and click Reload. Alternatively, to undo all the changes in the vista, click ⟳ .

> **NOTE** If you have new observations and have not applied them, clicking the Reload button will discard the new observations.

7 To apply the changes for a single row or multiple rows, select the row(s), right-click, and click Apply. Alternatively, to apply all changes in the vista, click 💾 .

**8** For information about the standard panorama vista functions, see The Panorama Window (page 102).

# Creating Observations Using the Survey Command Language

In addition to adding observations using the Observations Editor, you can add observations using the survey command language.

## Creating an Observation by Angle and Distance

Use the angle distance (AD) command to quickly create a point by angle and distance.

Create a point using an angle turned from either a specified reference line or a previously determined backsight point. You can also use a vertical angle or vertical distance to locate the point.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To create an observation by angle and distance, using the command language**

**1** In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

**2** At the Command line, enter:

AD (point) [angle] [distance] (description)

**To create an observation by angle, distance, and vertical angle, using the command language**

**1** In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

**2** At the Command line, enter:

AD VA (point) [angle] [distance] [vertical angle] (description)

**To create an observation by angle, distance, and vertical distance, using the command language**

**1** In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

**2** At the Command line, enter:

AD VD (point) [angle] [distance] [vertical distance] (description)

**Examples**

This example creates point 103, which is located by turning a horizontal angle of 80°20'40" right at a distance of 100 units from the instrument point with the description WELL. Because no method of vertical difference determination was given, the elevation is <Null>.

AD 103 80.2040 100 WELL

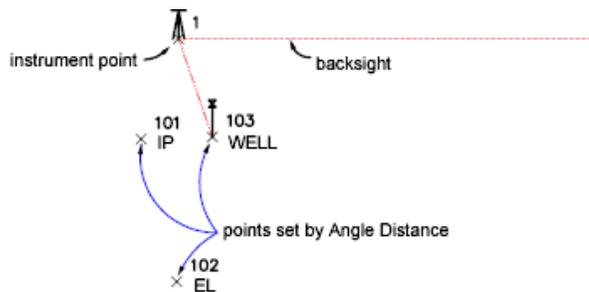
This example creates point 101, which is located by turning a horizontal angle of 100°20'45" right from the backsight and using a vertical angle of 91°15'15" at a distance of 100 units from the instrument point with the description IP.

AD VA 101 100.2045 100 91.1515 IP

This example creates point 102, which is located by turning a horizontal angle of 90°30'30" right from the backsight and using a vertical distance of -1.5 units at a distance of 200 units from the instrument point with the description EL.

AD VD 102 90.3030 200 -1.5 EL

**Points created with the angle distance command:**



Point 101 is located by turning a horizontal angle of 100°20'45" right from the backsight and using a vertical angle of 91°15'15" at a distance of 100 units from the instrument point with the description IP.

Point 102 is located by turning a horizontal angle of 90°30'30" right from the backsight and using a vertical distance of -1.5 units at a distance of 200 units from the instrument point with the description EL.

Point 103 is located by turning a horizontal angle of 80°20'40" right at a distance of 100 units from the instrument point with the description WELL. Because no method of vertical difference determination was given, the elevation is <Null>.

## Quick Reference

Survey Command Window Syntax

AD (point) [angle] [distance] (description)
or
AD VA (point) [angle] [distance] [vertical angle] (description)
or
AD VD (point) [angle] [distance] [vertical distance] (description)

| Parameter | Definition |
|-----------|-----------|
| point | The assigned point identifier. You do not need to assign a point number if auto point numbering is on. |
| angle | The measured horizontal angle. It is assumed to be clockwise (right). Use a negative number (-) to turn counter-clockwise (left). Express in the current units (Degrees Minutes Seconds (D.MS), grads, decimal degrees (D.DD), radians, or mils). |
| distance | The distance from the instrument point to the point being located. It is measured in the current units unless otherwise specified. Distance is assumed to be a horizontal distance unless VA is used. When VA is used, the distance is recognized as slope distance. |

| Parameter | Definition |
|-----------|------------|
| vertical angle | The direction of the vertical angle (zenith, horizontal, or nadir). Specify the vertical angle in the current angular units. |
| vertical distance | The elevation difference from the instrument to the prism. If the prism is higher than the instrument, then this is a positive value. |
| description | An optional description associated with the point. |

## Creating an Observation by Bearing and Distance

Use the bearing and distance command (BD) to create an observation in reference to the occupied point using bearing and distance.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To create an observation using bearing and distance, using the command language**

1  In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2  At the Command line, enter:

   BD (point) [bearing] [quadrant] [distance] (description)

**To create an observation using bearing, distance, and vertical angle, using the command language**

1  In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2  At the Command line, enter:

   BD VA (point) [bearing] [quadrant] [distance] [vertical angle] (description)

**To create an observation using bearing, distance, vertical distance, using the command language**

1  In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2  At the Command line, enter:

   BD VD (point) [bearing] [quadrant] [distance] [vertical distance] (description)

**Examples**

The following example illustrates using the BD command when the units are set to feet:

NE 1 100 100

STN 1

*BD 2 45 1 100 PT*

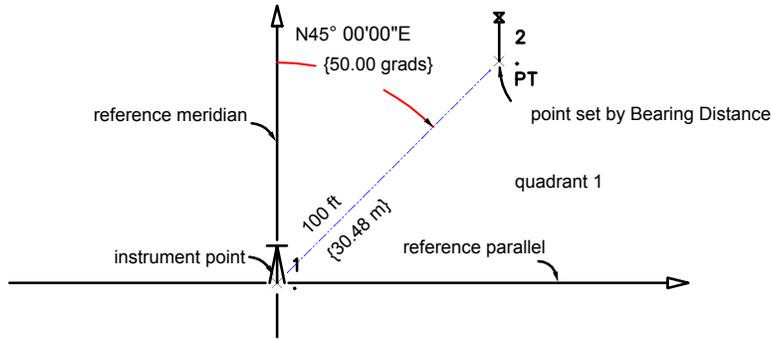
! BEARING: N 45-00-00 E DISTANCE: 100.0000

! POINT 2 NORTH: 170.7107 EAST: 170.7107

! ELEV: <Null>

This creates point 2 at the bearing and distance specified.

**Point created with the BD command:**



Point 2 is located by turning a bearing of 45°0'0" (50 grads) in Quadrant 1 (NE) at a distance of 100 feet from the instrument point with the description PT.

## Quick Reference

Survey Command Window Syntax

BD (point) [bearing] [quadrant] [distance] (description)
or
BD VA (point) [bearing] [quadrant] [distance] [vertical angle] (description)
or
BD VD (point) [bearing] [quadrant] [distance] [vertical distance] (description)

| Parameter | Definition |
| --- | --- |
| point | The point identifier of the new point. You do not need to assign a point number if auto point numbering is on. |
| bearing | The bearing. Enter this value in the current angular units (DMS, grads, decimal degrees, mils, or radians). |
| quadrant | The quadrant for the bearing. Specify the quadrant using one of the following numbers: 1 (for NE), 2 (for SE), 3 (for SW), or 4 (for NW). |
| distance | The distance from the instrument point to the point being located. It is measured in the current distance units. The distance is assumed to be a horizontal distance unless VA is used. When VA is used, the distance is recognized as a slope distance. |
| vertical angle | The direction of the vertical angle (zenith, horizontal, or nadir). Type this value in the current angular units (DMS, grads, decimal degrees, mils, or radians). |
| vertical distance | The elevation difference from the instrument to the prism. If the prism is higher than the instrument, then this is a positive value. |
| description | An optional description associated with the point. |

# Creating an Observation by Deflection Angle and Distance

Use the deflection distance (DD) command to quickly create a point using a deflection angle and distance from an established line.

The term deflection angle refers to the angular direction turned from the extension of the previous course. Additionally, you can also use a vertical angle or vertical distance to locate the point.

---

**NOTE** For parameter descriptions, see the Quick Reference tab.

---

**To create an observation using deflection angle and distance, using the command language**

1. In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2. At the Command line, enter:

    DD (point) [angle] [distance] (description)

**To create an observation using deflection angle, distance, and vertical angle, using the command language**

1. In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2. At the Command line, enter:

    DD VA (point) [angle] [distance] [vertical angle] (description)

**To create an observation using deflection angle, distance, and vertical distance, using the command language**

1. In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2. At the Command line, enter:

    DD VD (point) [angle] [distance] [vertical distance] (description)

**Examples**

The following example illustrates using the deflection distance command.

NE 1 100 100

STN 1

AZ 1 2 100

BS 2

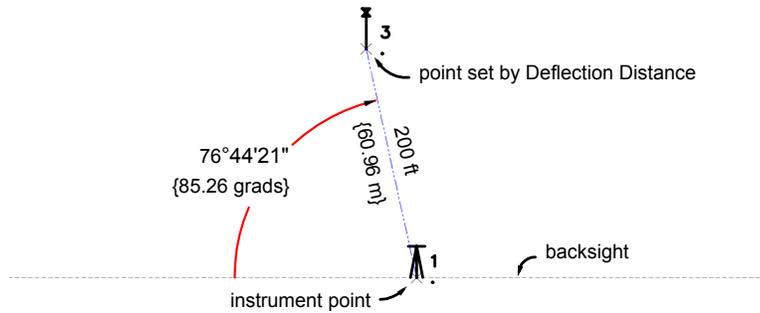
*DD 3 85.2657 60.960*

! AZIMUTH: 385.2657 DISTANCE: 60.9600

! POINT 3 NORTH: 159.3345 EAST: 86.0167

! ELEV: <Null>

**Points created using the DD command:**



Point 3 is located by turning a deflected angle of 85.2657 right from the extension of the backsight line at a distance of 200. Angles and distances are in the current units, unless you type a qualifying suffix.

## Quick Reference

Survey Command Window Syntax

DD (point) [angle] [distance] (description)
or
DD VA (point) [angle] [distance] [vertical angle] (description)
or
DD VD (point) [angle] [distance] [vertical distance] (description)

| Parameter | Definition |
|-----------|------------|
| point | The point identifier of the new point. You do not need to assign a point number if auto point numbering is on. |
| angle | The deflection angle as measured to the point. Type this value in the current angular units (DMS, grads, decimal degrees, radians, or mils). |
| distance | The distance from the instrument point to the point being located. It is measured in the current units unless otherwise specified. The distance is assumed to be a horizontal distance unless VA is used. When VA is used, the distance is recognized as a slope distance. |
| vertical angle | The direction of the vertical angle (zenith, horizontal, or nadir). Type this value in the current angular units (DMS, grads, decimal degrees, mils, or radians). |
| vertical distance | The elevation difference from the instrument to the prism. If the prism is higher than the instrument, then this is a positive value. |
| description | An optional description associated with the point. |

## Creating an Observation Using a Face1 or Face2 Angle

Create an observation from a traverse station using a horizontal angle measured on Face1 or Face2 of your instrument.

You can then input the measurements, using the Face1 (direct) and Face2 commands. These commands apply collimation (if set), and automatically average the sightings after you input observations.

Face1/Face2 angles can be collected in any order. The only requirement is that the Face1 backsight be recorded first. If Face2 observations are recorded, then a corresponding Face2 backsight should also be recorded. In the case where Face2 foresight observations are recorded previous to the Face2 backsight, the Face2 backsight is assumed to be the Face1 backsight plus 180°.

AutoCAD Civil uses all reciprocal observations to a point (both foresight and backsight) by calculating an average horizontal and vertical distance of all the observations as long as the distance is a non-zero value to calculate the average horizontal and vertical position of a point.

The correct average for all Face1/Face2 and reciprocal observations is applied when the [adjust] command is used. An adjustment may be done to get the correct average values whether there is a closed traverse or not.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To create an observation using a Face1 or Face2 angle, using the command language**

1  In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2  At the Command line, enter:

F1(point) [angle] [distance] (description)

or

F2 (point) [angle] [distance] (description)

**To create an observation using a Face1 or Face2 angle and vertical angle, using the command language**

1  In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2  At the Command line, enter:

F1 VA (point) [angle] [distance] [vertical angle] (description)

or

F2 VA (point) [angle] [distance] [vertical angle] (description)

**To create an observation using a Face1 or Face2 angle and vertical distance, using the command language**

1  In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2  At the Command line, enter:

F1VD (point) [angle] [distance] [vertical distance] (description)

or

F2 VD (point) [angle] [distance] [vertical distance] (description)

**Example: Face1**

NE 2 200 200

AZ 2 1 100

STN 2 1.585

BS 1

*F1 VA 101 0 30.480 100 BS*

! AZIMUTH: 101.6126 DISTANCE: 30.4800

! POINT 101 NORTH: 199.2280 EAST: 230.4702

! ELEV: <Null>

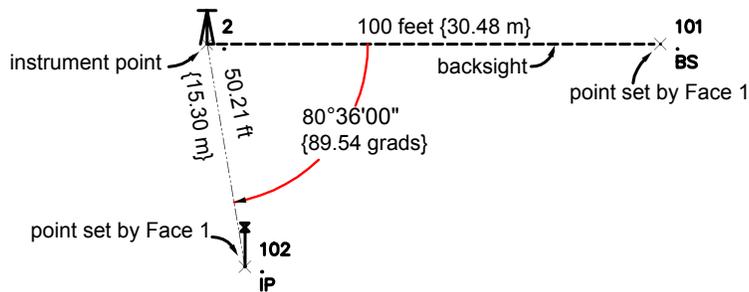
*F1 VA 102 89.5370 15.304 101.2052 IP*

! AZIMUTH: 191.1682 DISTANCE: 15.3013

! POINT 102 NORTH: 184.8457 EAST: 202.1159

! ELEV: <Null>

**Points created Face1 command:**



Point 101 is located by turning a horizontal angle of 0 right from Face1, and a vertical angle of 100 at a distance of 30.480 from the instrument point with the description BS.

Point 102 is located by turning a horizontal angle of 89.5370 right from Face1, and a vertical angle of 101.2052 at a distance of 15.304 from the instrument point with the description IP. Angles and distances are in the current units, unless you type a qualifying suffix.

**Example: Face2**

NE 2 200 200

AZ 2 1 100

STN 2 1.585

*F2 1 200*

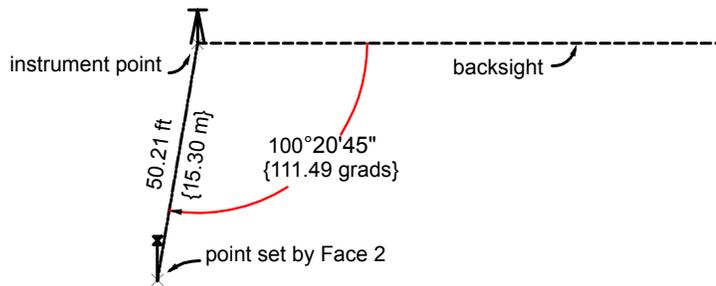
*F2 VA 101 311.4954 15.30 301.0355 IP*

! AZIMUTH: 213.1080 DISTANCE: 15.300

! POINT 101 NORTH: 198.2901 EAST: 199.6429

! ELEV: <Null>

**Points created Face2 command:**



Point 101 is located a distance of 15.30 from the instrument setup at an observed angle right from the backsight of 311.4954. The actual physical angle turned is 111.49, with a vertical angle of 301.03. The description for the point is IP. Angles and distances are in the current units, unless you type a qualifying suffix.

**NOTE** This is an angle turned with the scope inverted. Normally, the backsight is set at a 180° angle, so that the difference between it and the angle is the amount of the angle turned right (100°20'45").

## Quick Reference

Survey Command Window Syntax

F1 (point) [angle] [distance] (description)
F2 (point) [angle] [distance] (description)
or
F1 VA (point) [angle] [distance] [vertical angle] (description]
F2 VA (point) [angle] [distance] [vertical angle] (description]
or
F1 VD (point) [angle] [distance] [vertical distance] (description)
F2 VD (point) [angle] [distance] [vertical distance] (description)

| Parameter | Definition |
|---|---|
| point | The point identifier of the new point. You do not need to assign a point number if auto point numbering is on. |
| angle | The measured horizontal angle. It is assumed to be clockwise (right). Use a negative number (-) to turn counter-clockwise (left). Type the horizontal angle in the current angular units (DMS, grads, decimal degrees, radians, or mils). |
| distance | The distance from the instrument point to the point being located. It is measured in the current units unless otherwise specified. The distance is assumed to be a horizontal distance unless VA is used. When VA is used, the distance is recognized as a slope distance. |
| vertical angle | The direction of the vertical angle (zenith, horizontal, or nadir). Type this value in the current angular units (DMS, grads, decimal degrees, mils, or radians). |

| Parameter | Definition |
|---|---|
| vertical distance | The elevation difference from the instrument to the prism. If the prism is higher than the instrument, then this is a positive value. |
| description | An optional description associated with the point. If you use a description key, then specific information is assigned to the point. |

## Creating an Observation Using an Azimuth

Create an observation from an occupied traverse station by entering a recorded azimuth and distance.

Additionally, you can also use a vertical angle or vertical distance to locate the point.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To create an observation using an azimuth and distance, using the command language**

1   In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2   At the Command line, enter:

ZD (point) [azimuth] [distance] (description)

**To create an observation using an azimuth, distance, and vertical angle, using the command language**

1   In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2   At the Command line, enter:

ZD VA (point) [azimuth] [distance] [vertical angle] (description)

**To create an observation using an azimuth, distance, and vertical distance, using the command language**

1   In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2   At the Command line, enter:

ZD VD (point) [azimuth] [distance] [vertical distance] (description)

## Quick Reference

Survey Command Window Syntax

ZD (point) [azimuth] [distance] (description)
or
ZD VA (point) [azimuth] [distance] [vertical angle] (description)
or

ZD VD (point) [azimuth] [distance] [vertical distance] (description)

| Parameter | Definition |
| --- | --- |
| point | The new point identifier. You do not need to assign a point number if auto point numbering is on. |
| azimuth | The measured azimuth from the traverse station to the point being located. Type this value in the current angular units (DMS, grads, decimal degrees, mils, or radians). |
| distance | The distance from the instrument point to the point being located. It is measured in the current distance units. The distance is assumed to be a horizontal distance unless VA is used. When VA is used, the distance is recognized as a slope distance. |
| vertical angle | The direction of the vertical angle (zenith, horizontal, or nadir). Type this angle in the current angular units. |
| vertical distance | The elevation difference from the instrument to the prism. If the prism is higher than the instrument, then this is a positive value. |
| description | An optional description associated with the point. |

## Creating a Point By Offset

Create a new point by offsetting the last point you created by a given distance.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To create a point by offset, using the command language**

1  In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2  At the Command line, enter:
   PT OFFSET (point) [offset] [ahead] (description)

**Example**

NEZ 1 1000 1000 30.480

AZ 1 2 100

STN 1 1.585

BS 2

AD 3 100 30.480

*PT OFFSET 4 15.240 7.620*

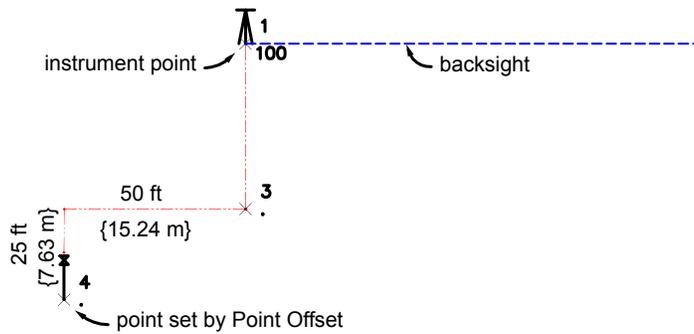
! AZIMUTH: 224.2238 DISTANCE: 41.0350

! POINT 4 NORTH: 961.9000 EAST: 984.7600

! ELEV: <Null>

Point 4 is located at an offset distance of 15.240, and an ahead distance of 7.620, from point 3.

**Point created by offset:**



## Quick Reference

Survey Command Window Syntax

PT OFFSET (point) [offset] (ahead) (description)

| Parameter | Definition |
| --- | --- |
| point | The point identifier of the new point. You do not need to assign a point number if auto point numbering is on. |
| offset | The offset distance from the last point created. |
| ahead | The distance added to the line between the station and the last point created to locate the position of the new point (optional). |
| description | An optional description associated with the point. |

## Creating an Observation Point Using the Stadia Rod

Use the stadia rod intercept method to reduce a distance that has been measured.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To create an observation using the stadia rod method, using the command language**

1  In Toolspace, on the Survey tab, right-click the network that you want to add points to, and click Survey Command Window.

2  At the Command line, enter:
    STADIA (point) [angle] [distance] [rod] (vertical angle) (description)

### Quick Reference

Survey Command Window Syntax

STADIA (point) [angle] [distance] [rod] (vertical angle) (description)

| Parameter | Definition |
| --- | --- |
| point | The point identifier of the new point. You do not need to assign a point number if auto point numbering is on. |
| angle | The measured horizontal angle. It is assumed to be clockwise (right). Use a negative number (-) to turn counter-clockwise (left). Type the angle in the current units (DMS, grads, decimal degrees, radians, or mils). |
| distance | The distance from the instrument point to the point being located. It is measured in the current units unless otherwise specified. The distance is assumed to be a horizontal distance unless a vertical angle is specified. When a vertical angle is specified, the distance is recognized as a slope distance. The distance required here is actually the rod intercept multiplied by the stadia constant. For example, if 1.37 is intercepted on the stadia board, and the stadia constant is 100, then you should type 137 as the distance. |
| rod | The rod reading taken by the central hairline of the instrument. This is, in effect, the height above ground of the sighted target point. |
| vertical angle | The direction of the vertical angle to the rod (zenith, horizontal, or nadir) and must be specified in the current angular units. |
| description | An optional description associated with the point. |

## Editing Observations

Use the Observations Editor panorama vista to edit the observations of a selected setup item in the Survey tree view.

**NOTE** When changes made in the Observations Editor are saved back to the survey database, the affected points in the drawing are updated from the survey database.

**To edit observations for a setup**

1 In the Toolspace Survey tab, right-click the named setup and click Edit Observations.

2 Modify the fields by selecting the field and entering the new value.

**NOTE** If an observation is marked with a ⚠ , the observation has been modified outside of the Observations Editor and must be reloaded (by right-clicking and clicking Reload) before you can make any edits to the observation.

**3** To edit the Angle Type, Distance Type, Vertical Type, and Target Type fields, click the field and select a new value from the drop-down lists. For information about these types, see Database Settings (page 216).

**4** To edit the values in multiple rows, select the rows, right-click the column heading, click Edit, and enter the new value.

The selected row values for the column are updated with the new value. If no rows are selected, then all rows are updated.

**NOTE** When you make a change to any observation data, the entire row is displayed in bold until you save the change to the survey database.

**5** To delete observations, click the observation(s) to delete, right-click, and click Delete. The observation icon is replaced with a ✖ and the row is set to read-only.

**6** To undo the changes for a single row or multiple rows, select the row(s), right-click, and click Reload or Undelete. Alternatively, to undo all the changes in the vista, click ♻ .

**7** To apply the changes for a single row or multiple rows, select the row(s), right-click, and click Apply. Alternatively, to apply all changes in the vista, click 🖫 .

**8** For information about the standard panorama vista functions, see The Panorama Window (page 102).

### Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <database name> ➤ Networks ➤ <network name> ➤ right-click Setups ➤ Edit Observations

## Modifying the Description of a Point at the Survey Command Line

You can assign or edit the description of a point.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To modify the description for a point, using the survey command language**

**1** In Toolspace, on the Survey tab, right-click the network that you to edit, and click Survey Command Window.

**2** At the Command line, enter:

MOD DESC [point 1] [description]

**Example**

NE 1 1000 1000 FENCE

*MOD DESC 1 HOUSE*

! POINT 1 DESC: HOUSE

This example changes the description of point 1 from FENCE to HOUSE.

### Quick Reference

Survey Command Window Syntax

MOD DESC [point 1] [description]

| Parameter | Definition |
|-----------|------------|
| point 1 | The point number which has the description you want to modify. |
| description | An optional description associated with the point. |

## Modifying the Elevation of Points at the Survey Command Line

Use the Survey Command Window to modify the elevation of points.

The elevation modification commands are intended to work only with control and non-control points.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To modify the elevation of a single point**

1 In Toolspace, on the Survey tab, right-click the network that you want to edit, and click Survey Command Window.

2 At the Command line, enter:

MOD ELEV [point 1] (elevation)

**To modify the elevation of a multiple points**

1 In Toolspace, on the Survey tab, right-click the network that you want to edit, and click Survey Command Window.

2 At the Command line, enter:

MOD ELEVS [point 1] [point 2] [elevation]

**To modify point elevation by an increment**

1 In Toolspace, on the Survey tab, right-click the network that you want to edit, and click Survey Command Window.

2 At the Command line, enter:

MOD ELEV BY [point 1] (amount)

or

MOD ELEVS BY [point 1] [point 2] (amount)

**Example**

This example modifies the elevation of point 2 from 33.528 to 32.004 and then increases the elevation of point 2 by an increment of 10.0. Elevations are in the current units, unless you type a qualifying suffix:

NEZ 1 100 100 30.480

NEZ 2 200 200 33.528

*MOD ELEV 2 32.004*

! POINT 2 ELEVATION: 32.004

MOD ELEV BY 2 10.0

! POINT 2 ELEVATION ADDED: 42.004

## Quick Reference

Survey Command Window Syntax

MOD ELEV [point 1] (elevation)
or
MOD ELEVS [point 1] [point 2] [elevation]
or
MOD ELEV BY [point 1] (amount)
or
MOD ELEVS BY [point 1] [point 2] (amount)

| Parameter | Definition |
| --- | --- |
| point 1 | The point number to assign an elevation to. |
| point 2 | Used with point 1 to specify the range of points affected. |
| elevation | The new elevation value. |
| amount | The amount to increment or decrement the height of point 1. To decrement the height, type a negative value. |

# Inserting, Removing, and Updating Points

You can access a standard set point manipulation commands from the Toolspace Survey tab collections and items.

The point manipulation commands are available via a right-click menu and are applicable to the points relative to where the commands are accessed. For example, if you use the Insert into Drawing command on an individual control point, it only inserts that control point.

| Select this... | If you want to do this... |
| --- | --- |
| Update | Update the points in the drawing to the values in the survey database. |
| Insert Into Drawing | Insert points referenced in the survey database into the drawing. |
| Remove From Drawing | Remove points referenced in the survey database from the drawing. |

# Updating the Drawing Points with the Survey Points

If the points in the drawing are out-of-sync with the survey database, you can update them to the values in the survey database.

**To update the drawing points with the survey database points**

**1** In Toolspace, on the Survey tab, right-click the collection or item for which you want to update the points with the survey database.

**2** Click Points ➤ Update.

The points in the drawing and point database are updated with the values from the survey database. Points that are not referenced in the survey database are not affected by the Update command.

The points will not be updated if the points reside on a locked layer.

## Quick Reference

Toolspace

Survey tab: right-click <collection or item> ➤ Points ➤ Update

## Inserting Points into a Drawing

You can insert points into a drawing from the point database. The drawing points, which are referenced by the points in the survey database for the applicable collection or item, are inserted.

**To insert survey points into the drawing**

**1** In the Survey tab, right-click the collection or item for which you want the points (referenced in the survey database) inserted, and click Points ➤ Insert Into Drawing. If you select points that are already in the drawing, then the Duplicate Point Number dialog box is displayed.

**2** Click one of the following options:
   - Click Skip to leave the existing point in the drawing.
   - Click Replace to replace the existing point in the drawing with the selected point in the point database.
   - Click Skip All to leave all existing points in the drawing.
   - Click Replace All to replace the existing points in the drawing with the selected points in the point database.
   - Click Cancel to cancel the command.

## Quick Reference

Toolspace

Survey tab: right-click a collection or item ➤ Points ➤ Insert Into Drawing

## Removing Points from a Drawing

You can remove points that are referenced by the survey database from the drawing.

**To remove points from the drawing**

➤ In the Survey tab, right-click the collection or item for which you want the points (referenced in the survey database) removed from the drawing, and click Points ➤ Remove From Drawing.

## Quick Reference

Toolspace

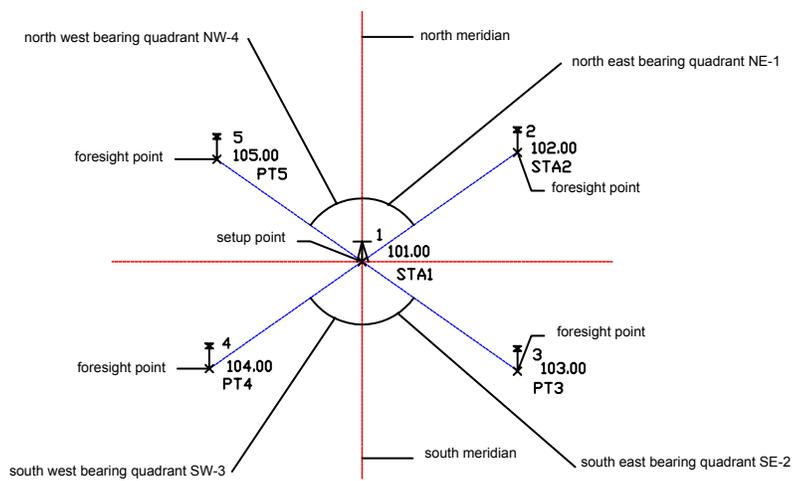
Survey tab: right-click a collection or item ➤ Points ➤ Remove From Drawing

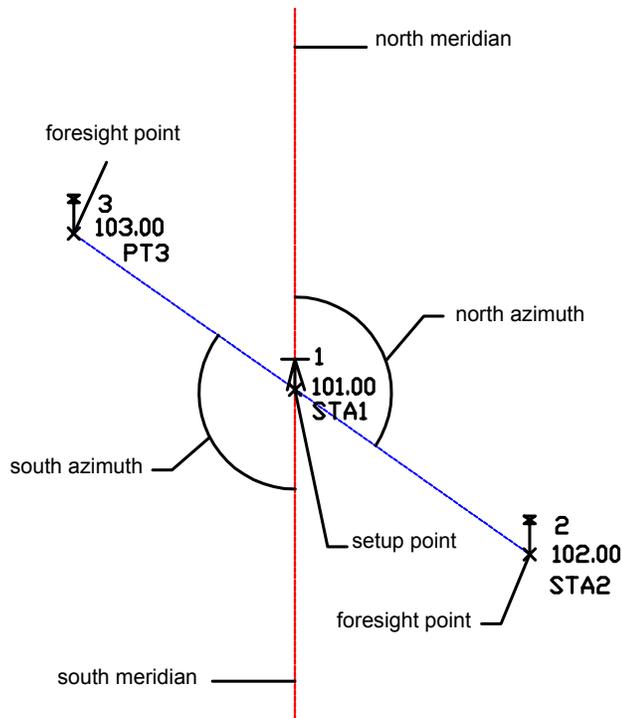
# Directions

A direction is an angle measured from the north or south meridian.

A direction can be formatted as either a bearing or azimuth and must be defined from an existing control point to another point (either a false point or another control point).

A bearing is less than 90 degrees (PI/2 radians or 100 grads), and is measured clockwise in the NE quadrant, counter-clockwise in the SE quadrant, clockwise in the SW quadrant, and counter-clockwise in the NW quadrant.



An azimuth is measured clockwise from either the north or south meridian and is always less than or equal to 2PI.


## Creating a Direction

Use the Toolspace Survey tab to create directions.

**To create a direction**

1  In the Toolspace Survey tab, right-click the Directions collection and click New.

2  In the New Direction dialog box, specify the point and direction information. For information about the direction properties, see New Direction/Direction Properties Dialog Box (page 2417).

3  Click OK to create the direction.

### Quick Reference

Toolspace

Survey tab: Expand Survey Databases ➤ <database name> ➤ Networks ➤ <network name> ➤ right-click Directions ➤ New

## Editing a Direction

Use the Toolspace Survey tab item view to edit directions.

You can change the direction value and type.

**To edit a direction**

**1** In the Toolspace Survey tab, click the Directions collection.

**2** In the Survey tab item view, click the field for the direction that you want to edit. Editable fields are colored white.

For information about common functions available in the list view, see Survey Tab Item View (page 2383).

### Quick Reference

Toolspace

Survey tab: expand Survey Databases ➤ expand <named project> ➤ click Directions ➤ edit in the item view

# Baselines

You can create baselines, which are reference lines from a baseline start point and a baseline end point.

You can create or list points in respect to the defined baseline. The Inverse Point command determines the station and offset distance of an existing point, or group of points, from an existing baseline. The Station/Offset command creates a new point using a station and an offset distance in reference to an existing baseline. Before you can use the Inverse Point, or the Station/Offset commands, you must define the current baseline. If you haven't defined the baseline and you select one of these commands, you are prompted to define the baseline.

# Defining a Baseline

Use the Survey Command Window to define a baseline.

You can create a baseline as a reference line, and then create or list points in relation to the line.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To define a baseline from the Survey Command Window menu**

**1** In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

**2** Click Baseline menu ➤ Define Baseline.

**3** Enter the point identifier for the origin of the baseline.

**4** Enter the point identifier for the end point of the baseline.

**5** Enter the point identifier for the starting station of the baseline.

**To define a baseline, using the survey command language**

**1** In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

**2** At the Command line, enter:

BL IS [point 1] [point 2] [station]

**Command Line Example**

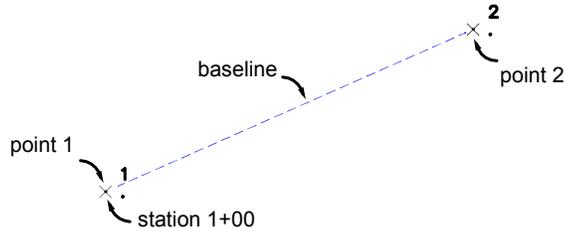
NEZ 1 1000 1000 30.48

NEZ 2 1500 1500 32.004

*BL IS 1 2 100*

The baseline runs from point 1 to point 2. Point 1 is set as station 1+00. Direction and distances are in the current units, unless you type a qualifying suffix.

**Baseline from point 1 to point 2:**



## Quick Reference

Survey Command Window

  Baseline ➤ Define Baseline

Survey Command Window Syntax

  BL IS [point 1] [point 2] [station]

| Parameter | Definition |
|-----------|------------|
| point 1 | The existing point identifier for the beginning point of the baseline. This point is assigned the station number given for the station component. |
| point 2 | The existing point identifier for the end point on the baseline. When you assign this point, you define the direction and length of the baseline. |
| station | The station for the assigned point number. Type the station in the current distance units. Some examples of station entries are 0, 50, and 100. For example, station 150 indicates that the station is 150 feet or meters along the baseline. |

# Listing a Baseline Direction Using Inverse Point

You can determine the station and offset distance of an existing point, or group of points, from an existing baseline with the Inverse Point command.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To inverse a point from the Survey Command Window**

1  In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2  Click Baseline menu ➤ Inverse Point.

**3** Type the start and end of the point range for which you want the station and offset information.

> **NOTE** You must define the baseline as a prerequisite.

**To inverse a point, using the survey command language**

**1** In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

**2** At the Command line, enter:
BL INV [point 1] (point 2)

**Command Line Example**

NE 1 1000 1000

STN 1

ZD 2 90 400

BL IS 1 2 100

BL PT 3 220 50

BL PT 4 270 -50

*BL INV 1 4*

This station and offset of points 1, 2, 3, and 4 are listed:

! Point Station Offset Elevation. Northing Easting

! 1 100.00 0.00 <Null> 1000.00 1000.00

! 2 500.00 0.00 <Null> 1000.00 1400.00

! 3 220.00 50.00 <Null> 950.00 1120.00

! 4 270.00 -50.00 <Null> 1050.00 1170.00

## Quick Reference

Survey Command Window

  Baseline ➤ Inverse Point

Survey Command Window Syntax

  BL INV [point 1] (point 2)

| Parameter | Definition |
| --- | --- |
| point 1 | An existing point in the drawing. It does not need to be adjacent to the baseline since the baseline is infinite in length. |
| point 2 | Used with point 1 to specify a range of points that you want to list. If you do not specify point 2, then only point 1 is listed. |

# Creating a New Point from a Baseline Using a Station and Offset

You can create a new point by specifying a station on a baseline, and an offset distance in reference to an existing baseline, with the Station/Offset command.

**To create a point by station and offset from the Survey Command Window**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   Click Baseline menu ➤ Station/Offset.

3   Enter the point identifier of the point you want to create.

**NOTE** If Auto point numbering is on, then the next point number is displayed.

4   Enter the station of the new point. The station can be a positive or a negative value.

5   Enter the offset of the new point. The offset can be a positive or a negative value.

6   Optionally, enter a description of the new point.

**To create a point at an offset from a baseline, using the survey command language**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   At the Command line, enter:
    BL PT (point 1) [station] (offset) (description)

**Command Line Example**

NE 1 1000 1000

STN 1

ZD 2 100 121.92

BL IS 1 2 0

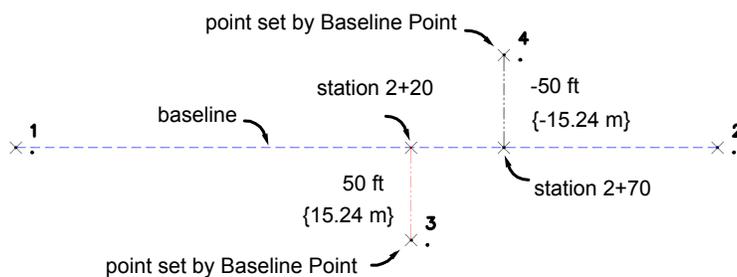
*BL PT 3 220 15.24*

! POINT 3 NORTH: 946.7889 EAST: 1214.0113 ELEV:<Null>

*BL PT 4 270 -15.24*

! POINT 4 NORTH: 968.1235 EAST: 1268.5445 ELEV: <Null>

Point 3 is offset a distance of 15.24 to the right of the baseline at Station 2+20 and Point 4 is offset a distance of 15.24 to the left of the baseline at Station 2+70. Distances are in the current units, unless you type a qualifying suffix.

**Baseline created at an offset distance:**


### Quick Reference

Survey Command Window

　Baseline ➤ Station/Offset

Survey Command Window Syntax

　BL PT (point 1) [station] (offset) (description)

| Parameter | Definition |
| --- | --- |
| point 1 | The point identifier for the new point. You do not need to assign a point number if auto point numbering is on. |
| station | The station location of the assigned point. Type the station in the current distance units. Some examples of station entries are 0, 50, and 100. For example, station 150 indicates that the station is 150 feet or meters along the baseline. |
| offset | An optional distance offset from the baseline. |
| description | An optional description associated with the point. |

# Centerlines

A centerline is defined from a figure. After you define the current centerline and current cross section, you can create new points in relation to them.

Before using the Inverse Point command, you must define the current centerline. If you haven't defined the centerline, you are prompted to define the centerline.

The cross section commands operate in a similar manner; if you have not set the current cross section, then you are prompted to set the cross section.

If you have not set the height of instrument and you use either the Station/ Offset Vertical Distance or the Station/Offset Rod command, then the Set Height of Instrument command is automatically invoked. Likewise, the Offset Rod or Offset Vertical Distance commands invoke the Prism command the first time you select them.

# Defining a Centerline

Use the Survey Command Window to quickly define a centerline.

To define a centerline, you specify a figure name, starting station, and starting point number.

If you use a point off the centerline to determine the beginning station, then a perpendicular line is established and that intersection is the starting station. Therefore, any point you use to establish the beginning station must be adjacent to some leg of the centerline.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To define a centerline from the Survey Command Window menu**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2 Click Centerline menu ➤ Define Figure Centerline.

3 Enter a figure name for the centerline.

**4** Enter the starting station value.

**5** Enter the starting station point identifier. This is the location to start stationing from. The starting station is the perpendicular intersection of the starting station point identifier and the centerline.

**To define a centerline, using the survey command language**

**1** In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

**2** At the Command line, enter:

CL IS [figure] (station) (point)

**Command Line Example**

In the following example, the beginning of this command sequence describes how to draw the centerline figure.

BEGIN CL1

NE 1 1000 1000

NE 2 1000 1500

NE 3 1300 1700

END

NE 4 1100 1100

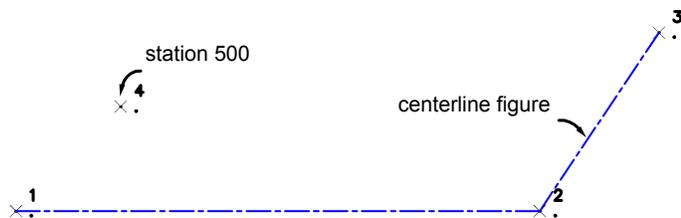
*CL IS CL1 500 4*

! Figure CL1 is the current centerline.

! Start Station: 400.00 End Station: 1260.56

Figure CL1 is the current centerline. Assigning Point 4 a station of 5+00 results in the centerline starting at station 4+00.

**Centerline figure:**



## Quick Reference

Survey Command Window

Centerline ➤ Define Figure Centerline

Survey Command Window Syntax

CL IS [figure] (station) (point)

| Parameter | Definition |
|-----------|------------|
| figure | The figure that you want to use as the centerline. |
| station | The defining station of the centerline. If you do not type a point number, then this is the station at the beginning of the figure. If you type a point number, then the station is at the point you specify. When you don't specify a station, the default 0+00 is used. |
| point | An optional reference point for the station. The point specified need not be on the centerline, but it must be adjacent to the centerline (not beyond the end points). |

# Listing Centerline Data Using Inverse Point

You can display the station, offset, and elevation of an existing point(s) in reference to the current centerline.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To display point data in reference to the current centerline from the Survey Command Window**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   Click Centerline menu ➤ Inverse Point.

3   Enter the point number range you want the station, offset, and elevation information for.

**To display point data in reference to the current centerline, using the survey command language**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   At the Command line, enter:
    CL INV [point 1] (point 2)

**Command Line Example**

BEGIN CL1

NE 1 1000 1000

NE 2 1000 1500

NE 3 1300 1700

END

CL IS CL1

CL PT 4 200 60.96

CL PT 5 625 -45.72

*CL INV 1 5*

! Point Station Offset Elevation Northing Easting

! 1 0.00 0.00 <Null> 1000.0000 1000.0000

! 2 500.00 0.00 <Null> 1000.0000 1500.0000

! 3 860.56 0.00 <Null> 1300.0000 1700.0000

! 4 200.00 60.96 <Null> 939.0400 1200.0000

! 5 625.00 -45.72 <Null> 1129.3672 1531.2962

These examples return station information along the centerline. Distances are in the current units, unless you type a qualifying suffix.

### Quick Reference

Survey Command Window

  Centerline ➤ Inverse Point

Survey Command Window Syntax

  CL INV [point 1] (point 2)

| Parameter | Definition |
|-----------|------------|
| point 1 | The point to inverse. |
| point 2 | Used with point 1 to specify the range of points affected. This point is optional. If you do not specify point 2, then only data for point 1 displays. |

## Setting the Height of the Instrument

You can establish the instrument height to use with the Station/Offset Rod or Offset Rod commands by using the Set Height of Instrument command.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To set the instrument height from the Survey Command Window**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   Click Centerline menu ➤ Set Height of Instrument.

3   Enter the instrument height.

   **NOTE** The Set Height of Instrument command does not affect the height of the traverse station. It lets you process level data.

**To set the instrument height, using the survey command language**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   At the Command line, enter:
    HI [elevation]

**Command Line Example**

BEGIN CL1

NE 1 1000 1000

NE 2 1000 1500

NE 3 1300 1700

END

CL IS CL1

*HI 200*

! Current HI: 200.000

The height of instrument is set to 200.00.

### Quick Reference

Survey Command Window Menu

Centerline ➤ Set Height of Instrument

Survey Command Window Syntax

HI PT [elevation]

| Parameter | Definition |
| --- | --- |
| elevation | The elevation of the optical axis of the instrument above datum (not the height above ground). |

## Creating a New Point by Station Offset

You can create a new point using an offset from a station on the current centerline.

NOTE For parameter descriptions, see the Quick Reference tab.

**To create a point by station offset in the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2 Click Centerline menu ➤ Station/Offset.

3 Enter the point identifier of the point you want to create.

NOTE If Auto point numbering is on, then the next point number is displayed.

4 Enter the station of the new point. The station can be a positive or a negative value.

5 Enter the offset of the new point. The offset can be a positive or a negative value.

6 Optionally, enter a description for the point.

**To create a point at an offset, using the survey command language**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2 At the Command line, enter:
CL PT (point 1) [station] (offset) (skew angle) (description)

**Command Line Example**

BEGIN CL1

NE 1 1000 1000

NE 2 1000 1500

NE 3 1300 1700

END

CL IS CL1

*CL PT 100 200*

! POINT 100 NORTH: 1000.0000 EAST: 1200.0000 ELEV: <Null>

*CL PT 101 450 -91.44*

! POINT 101 NORTH: 1091.4400 EAST: 1450.0000 ELEV: <Null>

102 600 152.4 50

! POINT 102 NORTH: 931.7283 EAST: 1572.2198 ELEV: <Null>

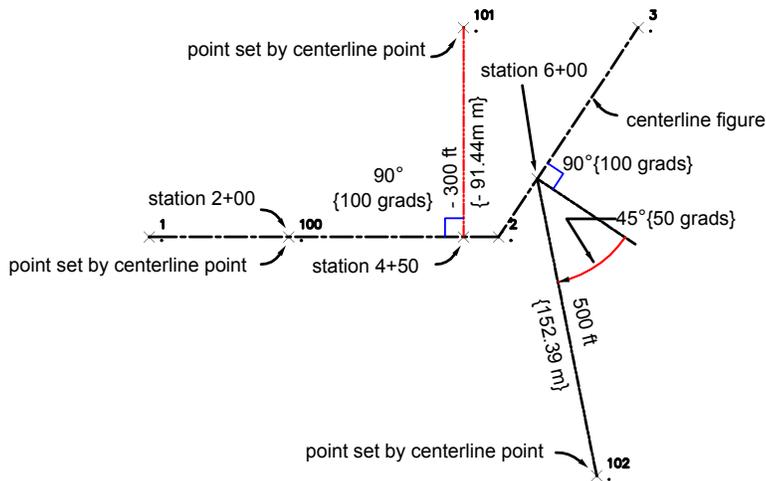
Point 100 is located at station 200 with a zero offset. Point 101 is located at station 450 with a left offset distance of 91.44. Point 102 is located at station 600 with a right offset distance of 152.4 and a skew angle of 50.

---

**NOTE** The point 102 input uses the Ditto command. Angles and distances are in the current units, unless you type a qualifying suffix.

---

**Centerline point created by a station offset:**



## Quick Reference

Survey Command Window Menu

Centerline ➤ Station/Offset

Survey Command Window Syntax

CL PT (point 1) [station] (offset) (skew angle) (description)

| Parameter | Definition |
|---|---|
| point 1 | The point identifier for the new point. You do not need to assign a point number if auto point numbering is on. |
| station | The station at which to set the point. |
| offset | An optional component that specifies the distance from the centerline to the new point. A negative offset sets the point to left of the centerline, and a positive offset sets it to the right. |
| skew angle | An optional component that specifies the clockwise angle to skew the point from the centerline to create non-perpendicular offsets. Type this value in the current angular units (DMS, grads, decimal degrees, radians, or mils). |
| description | An optional description associated with the point. |

# Creating a Point Using a Station, Offset, and Elevation

You can create a point at a given station, offset, and elevation with respect to the current centerline.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To create a point by station, offset, and elevation from the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2 Click Centerline menu ➤ Station/Offset Elevation.

3 Enter the point number of the point you want to create.

**NOTE** If Auto point numbering is on, then the next point number is displayed.

4 Enter the station of the new point. The station can be a positive or a negative value.

5 Enter the offset of the new point. The offset can be a positive or a negative value.

6 Enter the elevation for the point.

7 Optionally, enter a description for the point.

**To create a point by station, offset, and elevation, using the survey command language**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2 At the Command line, enter:
CL EL (point) [station] [offset] [elevation] (description)

**Command Line Example**

BEGIN CL1

NE 1 1000 1000

NE 2 1000 1500

NE 3 1300 1700

END

CL IS CL1

*CL EL 100 350 45.72 58.7502*

! POINT 100 NORTH: 954.2800 EAST: 1350.0000 ELEV: 58.7502

## Quick Reference

Survey Command Window Menu

Centerline ➤ Station/Offset Elevation

Survey Command Window Syntax

CL EL (point) [station] [offset] [elevation] (description)

| Parameter | Definition |
| --- | --- |
| point | The identifier of the new point that you want to create. You do not need to assign a point number if auto point numbering is on |
| station | The station of the new point. |
| offset | The perpendicular distance from the centerline to the new point. |
| elevation | The elevation of the new point. Elevations are in the current units, unless you type a qualifying suffix. |
| description | An optional description associated with the point. |

## Creating a New Point by Station, Offset, and Rod Height

You can create a point by specifying a station, offset, and rod height from the current centerline. The elevation is computed by algebraically adding the rod reading to the current value set with the Set Height of Instrument command.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To create a point along a centerline using a rod reading from the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2 Click Centerline menu ➤ Station/Offset Rod.

3 Enter the station.

4 Enter the offset.

5 Enter the rod reading.

6 Optionally, enter a description for the point.

**To create a point along a centerline using a rod reading, using the survey command language**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2 At the Command line, enter:
CL ROD (point) [station] [offset] [rod] (description)

**Command Line Example**

BEGIN CL1

NE 1 1000 1000

NE 2 1000 1500

NE 3 1300 1700

END

CL IS CL1

HI 60.96

*CL ROD 100 350 45.72 4.2098*

! POINT 100 NORTH: 954.2800 EAST: 1350.0000 ELEV: 56.7502

## Quick Reference

Survey Command Window Menu

Centerline ➤ Station/Offset Rod

Survey Command Window Syntax

CL ROD (point) [station] [offset] [rod] (description)

| Parameter | Definition |
| --- | --- |
| point | The point identifier for the new point. You do not need to assign a point number if auto point numbering is on. |
| station | The station of the new point. |
| offset | The perpendicular distance from the centerline to the new point. |
| rod | The rod height. This value is subtracted from the height of instrument elevation to determine the elevation of the new point. |
| description | An optional description associated with the point. |

## Creating a New Point by Station, Offset, and Vertical Distance

You can create a point given a vertical distance, with respect to the current centerline, height of instrument, and prism height.

The elevation is computed by subtracting the prism height from the instrument height, then algebraically adding the vertical distance.

**To create a point along a centerline using a vertical distance from the Survey Command Window**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   Click Centerline menu ➤ Station/Offset Vertical Distance.

3   Enter the point number of the point you want to create.

   **NOTE** If auto point numbering is on, then the next point is displayed.

4   Enter the station of the new point. The station can be a positive or a negative value.

5   Enter the offset of the new point. The offset can be a positive or a negative value.

6   Enter the vertical distance.

7   Optionally, enter a description for the point.

**To create a point along a centerline using a vertical distance, using the survey command language**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   At the Command line, enter:
   CL VD (point) [station] [offset] [vertical distance]

**Command Line Example**

BEGIN CL1

NE 1 1000 1000

NE 2 1000 1500

NE 3 1300 1700

END

CL IS CL1

HI 200

PRISM 5

*CL VD 10 350 150 7.25*

! POINT 10 NORTH: 850.0000 EAST: 1350.0000 ELEV: 202.2500

## Quick Reference

Survey Command Window Menu

   Centerline ➤ Station/Offset Vertical Distance

Survey Command Window Syntax

CL VD (point) [station] [offset] [vertical distance]

| Parameter | Definition |
| --- | --- |
| point | The identifier of the new point that you want to create. You do not need to assign a point number if auto point numbering is on. |
| station | The station of the new point. |
| offset | The perpendicular distance from the centerline to the new point. |
| vertical distance | The elevation difference from the instrument to the prism. If the prism is higher than the instrument, then this is a positive value. |

# Setting the Current Cross Section

You can set the current cross section by station value. When the current cross section is set, you can create new points from this occupied point by supplying the offset and elevation information.

To use the Offset Rod, Offset Elevation, and Offset Vertical Distance commands, you must set the current cross section station.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To set the current cross section from the Survey Command Window**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   Click Centerline menu ➤ Set Cross Section.

3   Type the station of the current cross section.

**To set the current cross section, using the survey command language**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   At the Command line, enter:
    XS [station]

**Command Line Example**

BEGIN CL1

NE 1 1000 1000

NE 2 1000 1500

NE 3 1300 1700

END

CL IS CL1

*XS 350*

Current Cross-section Station: 350.00

### Quick Reference

Survey Command Window Menu

Centerline ➤ Set Cross Section

Survey Command Window Syntax

XS [station]

| Parameter | Definition |
|-----------|------------|
| station | The station to use for subsequent cross section commands. |

## Creating a New Point on the Cross Section by Offset and Elevation

You can create a new point by giving an offset and elevation, with respect to the current cross section located on the current centerline.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To create a point with offset and elevation from the current cross section from the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click on the network to edit, and click Survey Command Window.

2 Click Centerline menu ➤ Offset Elevation.

3 Type the point number of the point you want to set.

4 Enter the offset.

5 Enter the elevation.

**To create a point with offset and elevation from the current cross section using the survey command language**

1 In Toolspace, on the Survey tab, right-click on the network to edit, and click Survey Command Window.

2 At the Command line, enter:
XS EL (point) [offset] [elevation] (description)

**Command Line Example**

BEGIN CL1

NE 1 1000 1000

NE 2 1000 1500

NE 3 1300 1700

END

CL IS CL1

XS 350

*XS EL 100 45.72 58.7502*

! POINT 100 NORTH: 954.2800 EAST: 1350.0000 ELEV: 58.7502

Point 100 is offset from cross section 350 by a distance of 45.72 with an elevation of 58.7502. Distance and elevations are in the current units unless you type a qualifying suffix.

### Quick Reference

Survey Command Window Menu

  Centerline ➤ Offset Elevation

Survey Command Window Syntax

  XS EL (point) [offset] [elevation] (description)

| Parameter | Definition |
|---|---|
| point | The identifier of the new point that you want to create. You do not need to assign a point number if auto point numbering is on. |
| offset | The perpendicular distance from the centerline to the new point. |
| elevation | The elevation of the new point |
| description | An optional description associated with the point. |

## Creating a New Point on the Cross Section by Offset and Rod Height

You can create a point by giving an offset and rod height with respect to the current cross section, height of instrument, and centerline.

The elevation is computed by subtracting the rod from the current value you set with the Set Height of Instrument command.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To create a point by offset and rod height from the current cross section in the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click on the network to edit, and click Survey Command Window.

2 Click Centerline menu ➤ Offset Rod.

3 Enter the point number of the point you want to set.

4 Enter the offset of the new point. The offset can be a positive or a negative value.

5 Enter the rod height.

**To create a point by offset and rod height from the current cross section, using the survey command language**

1 In Toolspace, on the Survey tab, right-click on the network to edit, and click Survey Command Window.

2 At the Command line, enter:

  XS ROD (point) [offset] [rod] (description)

**Command Line Example**

BEGIN CL1

NE 1 1000 1000

NE 2 1000 1500

NE 3 1300 1700

END

CL IS CL1

XS 350

HI 200

*XS ROD 100 150 7.25*

! POINT 100 NORTH: 850.000 EAST: 1350.000 ELEV: 192.750

Point 100 is offset from cross section 350 a distance of 150 with an elevation of 192.75 (height of instrument - rod).

## Quick Reference

Survey Command Window Menu

Centerline ➤ Offset Rod

Survey Command Window Syntax

XS ROD (point) [offset] [rod] (description)

| Parameter | Definition |
|---|---|
| point | The identifier of the new point that you want to create. You do not need to assign a point number if auto point numbering is on. |
| offset | The distance from the cross section to the new point. |
| rod | The rod height. This value is subtracted from the height of instrument elevation to determine the elevation of the new point. |
| description | An optional description associated with the point. If you use a description key, then specific information is assigned to the point. |

## Creating a New Point on the Cross Section by Vertical Distance

You can create a point by specifying a vertical distance from the current cross section, height of instrument, prism height, and centerline.

The elevation is computed by subtracting the prism height from the value you specified with the Set Height Of Instrument command, and then adding the vertical distance.

NOTE For parameter descriptions, see the Quick Reference tab.

**To create a point by offset and vertical distance from the current cross section in the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click on the network to edit, and click Survey Command Window.

2 Click Centerline menu ➤ Offset Vertical Distance.

3 Enter the point number of the point you want to create.

**4** Enter the offset of the new point. The offset can be a positive or a negative value.

**5** Enter the vertical distance.

**To create a point by offset and vertical distance from the current cross section, using the survey command language**

**1** In Toolspace, on the Survey tab, right-click on the network to edit, and click Survey Command Window.

**2** At the Command line, enter:

XS VD (point) (offset) [vertical distance]

**Command Line Example**

BEGIN CL1

NE 1 1000 1000

NE 2 1000 1500

NE 3 1300 1700

END

Centerline ➤ Offset Vertical Distance

Survey Command Window Syntax

XS VD (point) (offset) [vertical distance]

| Parameter | Definition |
|---|---|
| point | The identifier of the new point that you want to create. You do not need to assign a point number if auto point numbering is on. |
| offset | The distance from the centerline to the new point. A positive distance indicates an offset to the right, and a negative distance indicates an offset to the left. |
| vertical distance | The elevation difference from the instrument to the prism. If the prism is higher than the instrument, then this is a positive value. |

# Intersections

You can use the intersection commands to locate intersection points between bearings, azimuths, lines, and arcs, and to calculate the square offset.

After you find an intersection, you can save the intersection point by specifying a new point identifier.

## Creating a Bearing/Bearing Intersection

You can find the point of intersection between two infinite lines from existing points.

After an intersection is found, you can save it by specifying a new point identifier.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To calculate a Bearing/Bearing intersection in the Survey Command Window**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   Click Intersections menu ➤ Bearing/Bearing.

3   Enter the starting point number of the first bearing.

4   Enter the bearing from that point.

5   Enter the quadrant for the first point.

6   Enter an offset for the first points.

7   Enter the starting point number of the second bearing.

8   Enter the bearing from that point.

9   Enter the quadrant for the second point.

10   Enter the offset for the second point.

**To calculate a Bearing/Bearing intersection, using the survey command language**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   At the Command line, enter:
    BB [point 1] [bearing 1] [quadrant 1] [offset 1] [point 2] [bearing 2] [quadrant 2] [offset 2]

**Command Line Example**

NE 1 100 100

NE 2 200 200

*BB 1 66.6667 1 50 2 33.3333 2 50*

! INTERSECTION # 1 NORTH:100.000000 EAST:200.000000

An intersection is located between a bearing of N66.6667"E drawn from point 1, with an offset distance of 50 feet to the right and a bearing of S33.3333"E drawn from point 2 with, an offset distance of 50 to the right.

Centerline ➤ Station/Offset

Survey Command Window Syntax

BB [point 1] [bearing 1] [quadrant 1] [offset 1] [point 2] [bearing 2] [quadrant 2] [offset 2]

| Parameter | Definition |
|---|---|
| point 1, point 2 | The existing point identifiers that establish the beginning of the bearings. |
| bearing 1, bearing 2 | The bearings for the lines from the existing points. Bearings establish a direction for each vector and are expressed in current angle units. |
| quadrant 1, quadrant 2 | The quadrants in which the bearings exist. The possible values are: 1 (for NE), 2 (for SE), 3 (for SW), and 4 (for NW). |
| offset 1, offset 2 | The offsets from the lines. This acts as if the lines are moved X feet or meters to the left or right. An offset to the right is a positive number, and an offset to the left is a negative number. If you do not want an offset, then use zero. |

# Creating an Azimuth/Azimuth Intersection

You can find the point of intersection between two infinite lines from existing points.

After an intersection is found, you can save it by specifying a new point number.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To calculate an azimuth/azimuth intersection in the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

**2** Click Intersections menu ➤ Azimuth/Azimuth.

**3** Enter the starting point number of the first azimuth.

**4** Enter the azimuth from that point.

**5** Enter an offset.

**6** Enter the starting point number of the second azimuth.

**7** Enter the azimuth from that point.

**8** Enter an offset.

**To calculate an azimuth/azimuth intersection, using the survey command language**

**1** In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

**2** At the Command line, enter:

AZAZ [point 1] [azimuth 1] [offset 1] [point 2] [azimuth 2] [offset 2]

**Command Line Example**

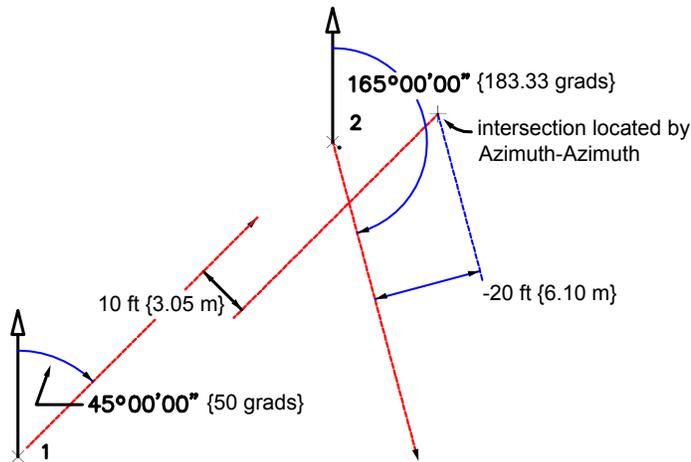
NE 1 100 100

NE 2 200 200

*AZAZ 1 50 10 2 183.3333 -20*

! INTERSECTION # 1 NORTH:186.991377 EAST:219.229524

An intersection is located between an azimuth of 50.000 drawn from point 1 with an offset distance of 10 to the right, and an azimuth of 183.3333 drawn from point 2 with an offset distance of 20 to the left.



## Quick Reference

Survey Command Window Menu

Intersections ➤ Azimuth/Azimuth

Survey Command Window Syntax

AZAZ [point 1] [azimuth 1] [offset 1] [point 2] [azimuth 2] [offset 2]

| Parameter | Definition |
|---|---|
| point 1, point 2 | The existing point identifiers defining the beginning of the azimuths |
| azimuth 1, azimuth 2 | The azimuths for the lines from the existing points (point 1 and point 2). Azimuths establish a direction for each vector and are expressed in current angle units. |
| offset 1, offset 2 | The offsets from the lines. This acts as if the lines are moved X feet or meters to the left or right. An offset to the right is a positive number, and an offset to the left is a negative number. If you do not want an offset, then use zero. |

# Creating a Line/Line Intersection

You can find the point of intersection between two lines defined from existing points. After an intersection is found, you can save it by specifying a new point number.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To create a Line/Line intersection in the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2 Click Intersections menu ➤ Line/Line.

3 Enter the starting point identifier of the first line.

4 Enter the second point identifier to define the first line.

5 Enter an offset.

6 Enter the starting point identifier of the second line.

7 Enter the second point identifier to define the second line.

8 Enter an offset.

**To create a Line/Line intersection, using the survey command language**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2 At the Command line, enter:
LNLN [point 1] [point 2] [offset 1] [point 3] [point 4] [offset 2]

**Command Line Example**

NE 1 100 100

NE 2 200 200

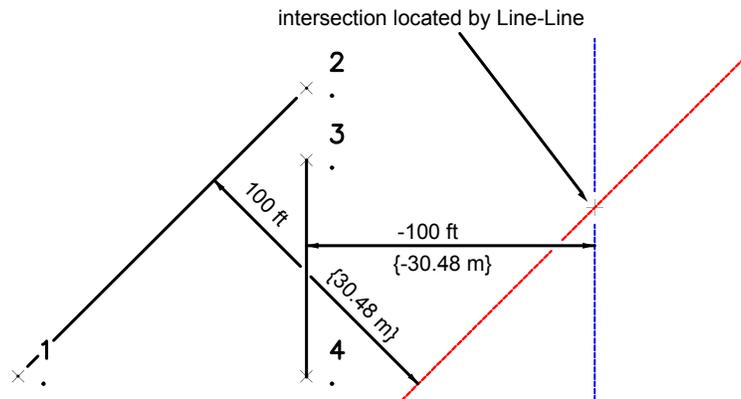
NE 3 175 200

NE 4 100 200

*LNLN 1 2 100 3 4 -100*

! INTERSECTION # 1 NORTH:158.578644 EAST:300.000000

An intersection is located between a line drawn between points 1 and 2 with an offset of 100 feet to the right and a line drawn between points 3 and 4 with an offset of 100 feet to the left.



## Quick Reference

Survey Command Window Menu

Intersections ➤ Line/Line

Survey Command Window Syntax

LNLN [point 1] [point 2] [offset 1] [point 3] [point 4] [offset 2]

| Parameter | Definition |
| --- | --- |
| point 1, point 2 | The point identifiers that establish the position and direction of vector 1. Point 1 is the end point and Point 2 is the start point. These points can be any points including figure points. |
| offset 1, offset 2 | The offsets from the lines. This acts as if the vectors are moved X feet or meters to the left or right. An offset to the right is a positive number, and an offset to the left is a negative number. If you do not want an offset, then use a zero for the offset. |
| point 3, point 4 | The point numbers that establish the position and direction of vector 2. Point 3 is the end point and point 4 is the start point. These points can be any points including figure points. |

# Creating a Square Offset Intersection

You can determine the offset, distance, and point of intersection where a right angle would be projected onto an infinite line (defined by two points). After an intersection is found, you can save it by specifying a new point identifier.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To create a square offset in the Survey Command Window**

1  In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2  Click Intersections menu ➤ Square Offset.

3  Enter the starting point identifier of the line.

4  Enter the second point identifier to define the line.

5  Enter the point identifier of the point offset from the line.

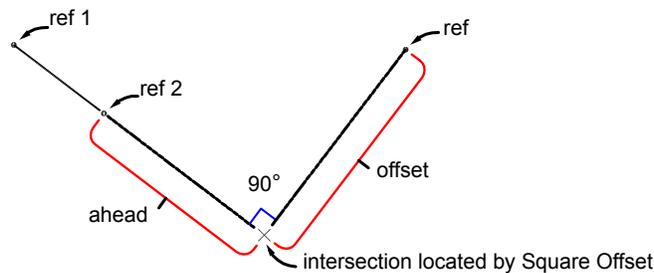
   AutoCAD Civil determines the offset distance of the point (entered in step 5) from the line established by the first two points. This establishes one known side distance and two known side directions. Using this information, AutoCAD Civil calculates the corners of a square and creates the corner of the square offset from the line (established in steps 3 and 4) at the same distance as defined by the point entered in step 5.

**To create a square offset, using the survey command language**

1  In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2  At the Command line, enter:

   SQ [reference 1] [reference 2] [reference]



**Command Line Examples**

The following example shows a valid entry using the Square Offset command:

SQ 302 303 501

This example finds the point that creates a right angle between the line from point 302 to point 303 and point 501.

SQ 13 14 501

This example finds the point that creates a right angle between the line from point 13 to point 14 and point 501.

The Square Offset command lists the ahead distance and offset distance to the point of intersection.

## Quick Reference

Survey Command Window Menu

Intersections ➤ Square Offset

Survey Command Window Syntax

SQ [reference 1] [reference 2] [reference]

| Parameter | Definition |
| --- | --- |
| reference 1 | The existing end point on the vector. It can be any type of point, including a figure point. |
| reference 2 | The existing start point on the vector. Ref 1 and Ref 2 establish a direction on the vector. |
| reference | The point off the vector. The intersection point creates a right angle between the vector and this point. |

# Creating an Arc/Bearing Intersection

You can calculate the intersection between a line and an arc. The line is established by a point, bearing, and offset.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To calculate the intersection of an arc and bearing line in the Survey Command Window**

1  In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2  Click Intersections menu ➤ Arc/Bearing.

3  Enter the point identifier of the arc center.

4  Enter the radius of the arc.

5  Enter the starting point identifier of the line.

6  Enter the bearing of the line.

7  Enter the quadrant of the line.

8  Enter an offset.

9  Enter one of the following options:

■ N: To select the northern-most intersection.

■ S: To select the southern-most intersection.

■ E: To select the eastern-most intersection.

■ W: To select the western-most intersection.

■ R: To select the solution nearest.

■ F: To select the solution farthest.

■ 1: To select intersection 1.

■ 2: To select intersection 2.

■ A: To select all the intersections.

■ P: To pick the intersection with your pointing device

**To calculate the intersection of an arc and bearing line, using the survey command language**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   At the Command line, enter:
    ARCB [point] [radius] [point 1] [bearing] [quadrant] [offset]

**Command Line Example**

NE 1 100 100

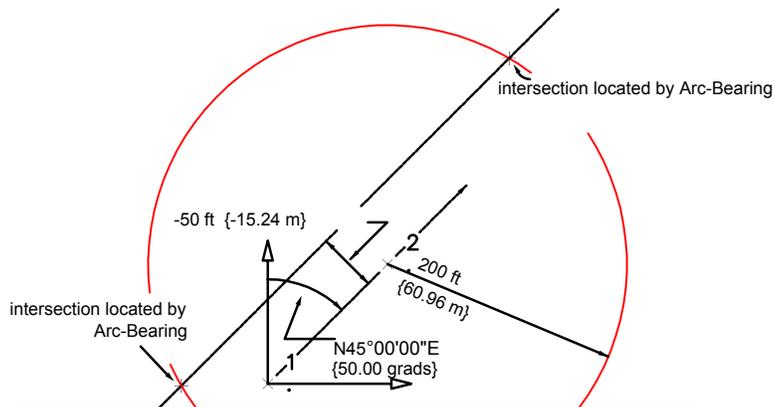
NE 2 200 200

*ARCB 2 200 1 50 1 -50*

! INTERSECTION # 1 NORTH:372.285978 EAST:301.575300

! INTERSECTION # 2 NORTH:98.424700 EAST:27.714022

Intersections are located between an arc radius of 200 with its center at point 2 and a bearing of 50.0000 drawn from point 1 with an offset distance of 50 to the left.



## Quick Reference

Survey Command Window Menu

  Intersections ➤ Arc/Bearing

Survey Command Window Syntax

  ARCB [point] [radius] [point 1] [bearing] [quadrant] [offset]

| Parameter | Definition |
|-----------|------------|
| point | The radial point. This is an existing point that is used as the center point for the arc. |
| radius | The radial distance. This is the distance in feet or meters from the radial point to the arc. |
| point 1 | The existing point from which a vector extends. It can be any type of point including a figure point. |

| Parameter | Definition |
|-----------|------------|
| bearing | The bearing of the line from the existing point. A bearing establishes a direction for the vector and is expressed in current angle units. |
| quadrant | The quadrant in which the bearing exists. The possible values are: 1 (NE), 2 (SE), 3 (SW), and 4 (NW). |
| offset | The offset left or right from the vector. This acts as if the line is moved X feet. An offset to the right is a positive number, and an offset to the left is a negative number. If you do not want an offset, then use zero for the offset. |

## Creating an Arc/Azimuth Intersection

You can find the points of intersection between an arc and a line that is established by a point, azimuth, and offset.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To calculate the intersection of an arc and a line determined by an azimuth in the Survey Command Window**

1  In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2  Click Intersection menu ➤ Arc/Azimuth.

3  Enter the point number of the arc center.

4  Enter the radius of the arc.

5  Enter the starting point number of the line.

6  Enter the azimuth of the line.

7  Enter an offset.

8  Enter one of the following options:

- N: To select the northern-most intersection.

- S: To select the southern-most intersection.

- E: To select the eastern-most intersection.

- W: To select the western-most intersection.

- R: To select the nearest intersection.

- F: To select the farthest intersection.

- 1: To select intersection 1.

- 2: To select intersection 2.

- A: To select all the intersections.

- P: To pick the intersection with your pointing device.

**To calculate the intersection of an arc and a line determined by an azimuth, using the survey command language**

**1** In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

**2** At the Command line, enter:

ARCAZ [point] [radius] [point 1] [azimuth] [offset]

**Command Line Example**

NE 1 100 100

NE 2 200 200

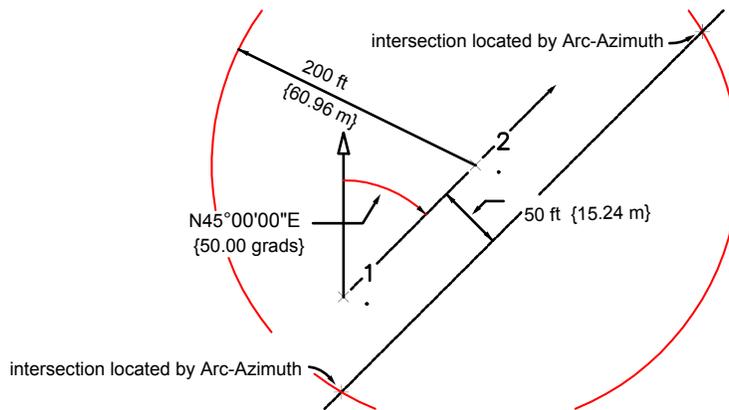
*ARCAZ 2 200 1 50 50*

! INTERSECTION # 1 NORTH:274.411634 EAST:385.641883

! INTERSECTION # 2 NORTH:30.099879 EAST:94.482471

Intersections are located between an arc radius of 200 with its center at point 2 and an azimuth of 50.0000 drawn from point 1 with an offset distance of 50 to the right.

**Intersection of arc and line determined by azimuth:**



## Quick Reference

Survey Command Window Menu

Intersections ➤ Arc/Azimuth

Survey Command Window Syntax

ARCAZ [point] [radius] [point 1] [azimuth] [offset]

| Parameter | Definition |
|-----------|------------|
| point | The radial point. This is an existing point that is used as the center point for the arc. |
| radius | The radial distance in feet or meters for the first arc. Radial distance is the length of a line from the radius point to the arc. |

| Parameter | Definition |
|-----------|------------|
| point 1 | The existing point from which a vector extends. It can be any type of point including a figure point. |
| azimuth | The azimuth of the line from the existing point. An azimuth establishes the direction for the vector and is expressed as current angle units. |
| offset | The distance to offset the intersection. |

## Creating an Arc/Line Intersection

You can calculate the intersection(s) of a line established by two points, and an arc established by a radial point and radius.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To calculate an Arc/Line intersection in the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2 Click Intersections menu ➤ Arc/Line.

3 Enter the point identifier of the arc center.

4 Enter the radius of the arc.

5 Enter the starting point identifier of the line.

6 Enter the ahead or the direction point for the line.

7 Enter an offset.

8 Enter one of the following options:
   ■ N: To select the northern-most intersection.

   ■ S: To select the southern-most intersection.

   ■ E: To select the eastern-most intersection.

   ■ W: To select the western-most intersection.

   ■ R: To select the nearest intersection.

   ■ F: To select the farthest intersection. 1: To select intersection 1.

   ■ 2: To select intersection 2.

   ■ A: To select all the intersections.

   ■ P: To pick the intersection with your pointing device.

**To calculate an Arc/Line intersection, using the survey command language**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2 At the Command line, enter:
   ARCLN [point] [radius] [point 1] [point 2] [offset]

**Command Line Example**

NE 1 100 100

NE 2 200 200

NE 3 250 100

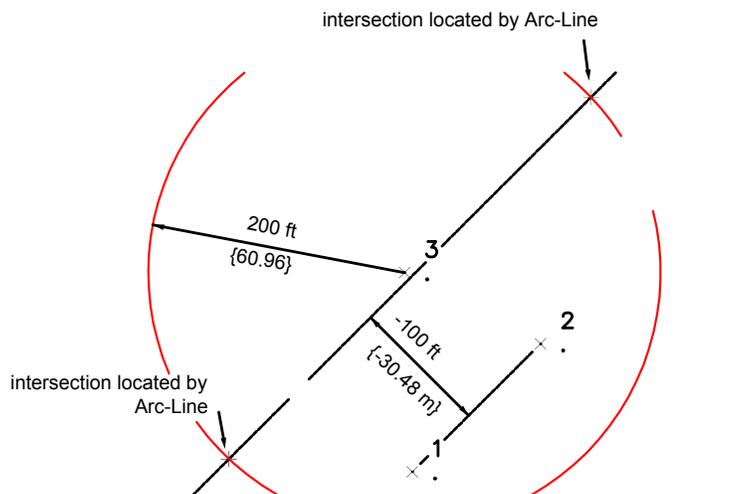
*ARCLN 3 200 1 2 -100*

! INTERSECTION # 1 NORTH:387.066972 EAST:245.645615

! INTERSECTION # 2 NORTH:104.354385 EAST:-37.066972

Intersections are located between an arc radius of 200 with the center at Point 3 and a line drawn between Points 1 and 2 with an offset distance of 100 to the left.

**Intersection of arc and line:**



## Quick Reference

Survey Command Window Menu

  Intersections ➤ Arc/Line

Survey Command Window Syntax

  ARCLN [point] [radius] [point 1] [point 2] [offset]

| Parameter | Definition |
| --- | --- |
| point | The point number of the radial (center) point. |
| radius | The radial distance in feet or meters. The radial distance is the length of a line from the radius point to the arc. |
| point 1, point 2 | The existing points that establish the position and direction of the line. Point 1 is the start point and point 2 is the end point. These points can be any points including figure points. |

| Parameter | Definition |
|-----------|------------|
| offset | The offset from the vector. This acts as if the line is moved a specified number of feet (or meters) to the left or right. An offset to the right is a positive number, and an offset to the left is a negative number. If you do not want any offset, then use zero. |

# Creating an Arc/Arc Intersection

You can calculate the intersection(s) of two arcs, each defined by an existing center point and a radius.

**NOTE** For parameter descriptions, see the Quick Reference tab.

**To calculate the intersection of two arcs in the Survey Command Window**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   Click Intersections menu ➤ Arc/Arc.

3   Enter the point identifier of the first arc center.

4   Enter the radius of the first arc.

5   Enter the point identifier of the second arc center.

6   Enter the radius of the second arc.

7   Enter one of the following options:

- ■ N: To select the northern-most intersection.

- ■ S: To select the southern-most intersection.

- ■ E: To select the eastern-most intersection.

- ■ W: To select the western-most intersection.

- ■ R: To select the nearest intersection.

- ■ F: To select the farthest intersection.

- ■ 1: To select intersection 1.

- ■ 2: To select intersection 2.

- ■ A: To select all the intersections.

- ■ P: To pick the intersection with your pointing device.

**To calculate the intersection of two arcs, using the survey command language**

1   In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2   At the Command line, enter:
ARCARC [point 1] [radius 1] [point 2] [radius 2]

**Command Line Example**

NE 1 100 100

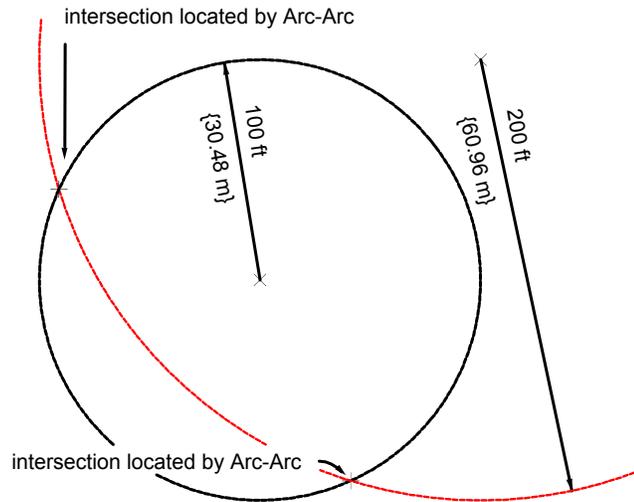
NE 2 200 200

*ARCARC 1 100 2 200*

! INTERSECTION # 1 NORTH:8.856217 EAST:141.143783

! INTERSECTION # 2 NORTH:141.143783 EAST:8.856217

Intersections are located between an arc radius of 100 with a center at Point 1 and an arc radius of 200 with its center at Point 2.



## Quick Reference

Survey Command Window Menu

 Intersections ➤ Arc/Arc

Survey Command Window Syntax

 ARCARC [point 1] [radius 1] [point 2] [radius 2]

| Parameter | Definition |
|-----------|------------|
| point 1 | The point number of radial (center) point 1. |
| radius 1 | The radial distance in feet or meters for the first arc. The radial distance is the length of a line from the radius point to the arc. |
| point 2 | The point number of radial (center) point 2. |
| radius 2 | The radial distance in feet or meters for the second arc. |

# Saving Intersection Points

After you find an intersection using the Intersection commands, you can save the new intersection point.

**To save the intersection point, using the survey command language**

1 In Toolspace, on the Survey tab, right-click the network to edit, and click Survey Command Window.

2 At the Command line, enter:

SAVE [NORTH, SOUTH, EAST, WEST, 1, 2, ALL] (point) (description)

---

**NOTE** For parameter descriptions, see the Quick Reference tab.

---

**Command Line Example**

SAVE NORTH 5

This saves the north intersection solution to point number 5.

## Quick Reference

Survey Command Window Syntax

SAVE [NORTH, SOUTH, EAST, WEST, 1, 2, ALL] (point) (description)

| Parameter | Definition |
| --- | --- |
| NORTH | Saves the northern most intersection. |
| SOUTH | Saves the southern most intersection. |
| EAST | Saves the eastern most intersection. |
| WEST | Saves the western most intersection. |
| 1 | Saves intersection 1. |
| 2 | Saves intersection 2. |
| ALL | Saves all intersections. |
| point | Saves the intersection nearest a point that you select. |
| description | An optional description associated with the point. If you use a description key, then specific information is assigned to the point. |

# Batch Files

Use batch files to record all survey commands that you use.

You can use the commands on the Batch file menu and the Output menu in the Survey Command Window to provide a historical record of a surveyor's decisions. A best practice is to create a new survey network to use in the Survey Command Window where you can perform calculations involving points from other existing survey networks. By using a new network, the data that is being input is captured in the batch file, where it can be edited and run with the corrections, and it will not affect the integrity of the other survey networks.

These commands are from data that is downloaded from a field book or entered from either the menus or at the Survey Command Window. You can open this file in your text editor to review and edit it.

After you make changes in the batch file, you can use the Run command to insert the data and draw the points in your drawing. The Run - Walk Through command downloads the data from the batch file and prompts you to press a key after each command in the batch file.

To use batch files, select the Use Batch File setting in the Survey Database Settings. For more information, see Database Settings (page 216).

## Setting the Batch File

Enable default batch file functionality in the Survey Database Settings.

You can also enable and change the batch file name in the Survey Command Window or by using the survey command language.

**To set the batch file**

1 In Toolspace, on the Survey tab, expand the Survey Databases collection, right-click the database, and click Edit Survey Database Settings.

2 Expand the Survey Command Window property group.

3 Ensure that Use Batch File is selected and enter the name for the batch file.

### Quick Reference

Toolspace

Survey tab: Survey Databases ➤ right-click <database-name> ➤ Edit Survey Database Settings

Survey Command Window

Use Batch File
and
Batch File ➤ Set File Name

## Editing a Batch File

Use the Edit command to load the current batch file into your text editor, where you can view and edit it.

AutoCAD Civil uses Notepad as the default text editor. You can specify another editor in the Survey User Settings dialog box.

**NOTE** Some text editors format files. The batch file must be saved in standard ASCII format to work correctly.

**To edit a batch file**

1 In Toolspace, on the Survey tab, expand the Networks collection and right-click a network item. Click Survey Command Window.

2 In the Survey Command Window, click Batch File menu ➤ Edit.

3 The batch file is opened in a text editor.

### Quick Reference

Survey Command Window

Batch File ➤ Edit

# Running a Batch File

Use the Run command to load the batch file into the current project.

Running a batch file updates your drawing with any points and line work specified in the file (if the Insert settings are enabled). For information, see Setting Import Defaults (page 211).

The Run - Slow Motion command loads the batch file at a slower rate. You can watch each command entry as it is added to and displayed in your drawing.

Use the Run - Walk Through command to stop the action at every file line as it is read into the drawing. This command is very helpful when you are looking for problems in the data.

**To run a batch file**

1   In Toolspace, on the Survey tab, expand the Networks collection and right-click a network item. Click Survey Command Window.

2   In the Survey Command Window, click Batch File menu ➤ Run.

**To run a batch file in slow motion**

1   In Toolspace, on the Survey tab, expand the Networks collection and right-click a network item. Click Survey Command Window.

2   In the Survey Command Window, click Batch File menu ➤ Run - Slow Motion.

**To walk through a batch file**

1   In Toolspace, on the Survey tab, expand the Networks collection and right-click a network item. Click Survey Command Window.

2   In the Survey Command Window, click Batch File menu ➤ Run - Walk Through.

3   Press Enter after each line is displayed to continue. You must repeat this until you import the whole file.

### Quick Reference

or
Batch File ➤ Run - Slow Motion
or
Batch File ➤ Run - Walk Through

# Survey Figures

# 12

You can use the Survey Toolspace and Survey Figure commands to create and edit survey figures, as well as to perform figure inquiries, identifying figures, and checking them for exact course and closure.

## Creating Figures

When you create a figure, it is stored in the survey database and may be also inserted into the active drawing depending on the Survey User Settings. Create a figure by either entering coordinates or referencing an existing point, and then giving a distance and direction to the next point.

Each figure consists of points or locations that have a relationship. You use figures to represent features such as fences, buildings, or roads. Figures are always referenced by name, and can consist of letters and numbers. For example: ROAD_1. One survey database may contain many figures. The AutoCAD Civil Survey feature has options to perform figure inquiries that identify a figure and determine exact courses and closure.

**NOTE**  Numeric figure names should not start with the number zero. For example, a figure name of 235 is acceptable but 0235 is not.

## Closing Figures

Close a figure by joining the last point of a figure to the first point of the same figure using the CLOSE command.

**NOTE**  For syntax descriptions, see the Quick Reference tab.

**To close a figure**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  At the Command line, enter:
   CLOSE [figure]

**To close a building figure**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  At the Command line, enter:
   CLOSE BUILDING

**To close a rectangle figure**

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 At the Command line, enter:

CLOSE RECTANGLE [offset].

The offset is the distance to the other side of the rectangle.

**Command Line Example of Closing a Figure**

BEG ROAD

NE SS 1000 1000

FIG BD 90 1 100

NE SS 1400 1400

CLOSE

END

CLOSE BUILD
CLOSE RECTANG [offset]

Command Synonyms

CLOSE BLDG
CLOSE BLD
CLOSE RECT

| Parameter | Definition |
| --- | --- |
| figure | The name of the figure you want to close. |
| offset | The distance to the other side of the rectangle when you are closing a rectangle figure. |

## Creating a Figure from an Object

Create a figure by selecting an object in the drawing.

When you create a figure, it is stored in the survey database and may be also inserted into the active drawing depending on the Survey User Settings.

You can create a survey figure from the following object types:

■ 2D Line

■ 3D Line

■ 2D Polyline

■ 3D Polyline

■ Feature Line

■ Lot Line

■ Parcel (select the parcel area label)

**To create a figure from an object**

1 In Toolspace, on the Survey tab, right-click the Figures collection ➤ Create Figure from Object.

2 Select an object in the drawing.

3 Specify settings in the Create Figure From Object dialog box.

4 Click OK. The figure is created and listed in the Figures collection.

**Quick Reference**

## Creating Breaklines from Figures

Use figures that you located in your survey as surface breaklines.

In the process of making a surface model, you can easily select the figures to use as breaklines.

**To create breaklines from figures using Toolspace**

1  In Toolspace, on the Survey tab, right-click Figures ➤ Create Breaklines.

2  In the Create Breaklines dialog box, click the Select Surface drop-down list and click a surface name or click ⬚ to open the New Surface dialog box, where you can create a new surface. Figures that have the Breaklines fields set to Yes are displayed in the list view part of the dialog box.

3  Optionally, to prevent a breakline from being created from a figure, in the list view, click the Breakline field and set the value to No.

4  Click OK to create the breaklines. The selected breaklines are inserted into to the drawing, or if necessary updated if they already exist in the drawing.

5  In the Add Breaklines dialog box (page 2360), enter a Description for the breakline operation, specify the Type of breaklines, or specify the Mid-ordinate distance for any breaklines that have curved segments.

**Quick Reference**

Toolspace

Survey tab: Survey Databases ➤ <survey database name> ➤ Figures collection ➤ right-click Create Breaklines

## Inserting Figures into Drawings

Insert survey figures into drawings.

**To insert a survey figure into a drawing**

➤  In Toolspace, on the Survey tab, expand the Figures collection and right-click a <figure name> ➤ Insert Into Drawing.

### Quick Reference

Toolspace

Survey tab: Figurescollection ➤ right-click <named figure> ➤ Insert Into Drawing

# Creating Points on a Figure

Add survey points to the vertices of an existing figure by selecting a figure and then setting a survey point at each figure vertex.

**To create points on a figure in the Survey Command Window**

1   In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2   Click Figures menu ➤ Create Points on Figures.

3   Select the figure that you want to create the points on.

4   At the Command line, enter the starting point number or accept the default. A survey point is created for each figure vertex.

### Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Network ➤ right-click <network name> ➤ Survey Command Window

# Creating a Point of Curvature on a Figure

Create a curve (on a figure) with three shots: the first at the beginning, the second on the arc between the beginning and end of the curve, and the third at the end of the curve.

**To draw a 3-point curve**

1   In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2   At the Command line, enter:
    C3

**Command Line Example**

BEG CURVE

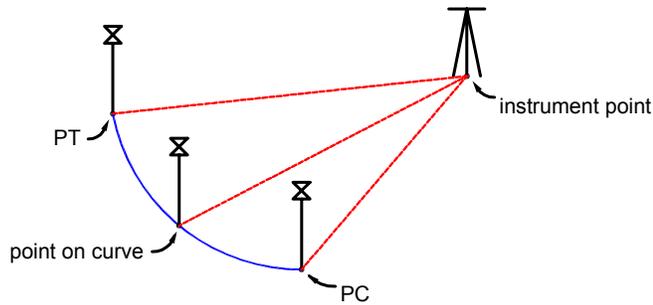
C3

AD VA 11 85 200 90

AD VA 12 82 200 90

AD VA 13 80 190 90

END

The following illustrates the Three Point Curve command:


### Quick Reference

Survey Command Window Syntax

C3

## Creating Multi-point Curves in a Figure

Within an active Figure, where (BEG <Figure name>) has been invoked, you can enter a figure command to specify subsequent points to define multiple points on a curve.

After the points on the curve have been defined, you can enter a command to end the multi-point curve and subsequent points will define line segments. The figure object created from the multi-point curve contains contiguous arc segments for each multi-point curve range.

**NOTE** For syntax descriptions, see the Quick Reference tab.

**To create a multi-point curve in a figure**

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 At the Command line, enter:
  BEGIN [figure]

3 With the BEGIN command active, enter:
  MCS

  The next points you enter will define the points on the curve.

4 Enter MCE to end the curve on the figure. Entering MCE does not end the figure. Enter END to end the active figure or enter BEGIN to start a new figure.

**Command Line Example**

NE 1000 1000

BEG EP1

PT1

NE SS 2 1100 1100

MCS

NE SS 3 1140 1120

NE SS 4 1800 1110

NE SS 5 1180 1070

MCE

NE SS 6 1160 1020

END

## Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Network ➤ right-click <named> Network ➤ Survey Command Window

Survey Command Window Syntax

BEGIN [figure] and then MCS

Command Synonyms

BEG and MCS to start curve
MCE to end the Multi-point Curve command

| Parameter | Definition |
|-----------|------------|
| figure | The name of the figure. |

# Creating a Curve on a Figure Using Point of Curvature

Specify that the next shot is a Point of Curvature (PC) in the current figure. The shot immediately following the next shot is on the Point of Tangency (PT). This command creates a tangential arc from the last leg in the figure.

**To specify that the next shot is a Point of Curvature (PC)**

1   In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2   At the Command line, enter:
    PC

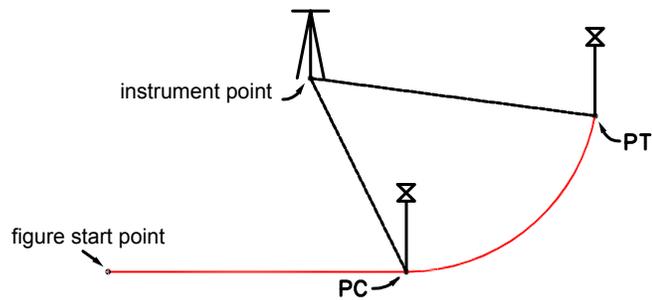
**Command Line Example**

PC

AD 13 30 25 ! Shot on PC

AD 14 33 24 ! Shot on PT

END

The following illustrates the Point of Curvature command:


## Quick Reference

Survey Command Window Syntax

PC

# Creating a Curve in the Current Figure

Create a curve in the current figure using two known variables.

**To create a curve**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  In the command window, enter any capitalized curve parameters, plus the radius and the curve parameter value:

- CURVE DELTA [radius] [value]

- CURVE LENGTH

- CURVE DEFL

- CURVE TANGENT

- CURVE CHORD

- CURVE MID

## Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Network ➤ right-click <named> Network ➤ Survey Command Window

Survey Command Window Syntax

CURVE DELTA [radius] [value]
CURVE LENGTH [radius] [value]

CURVE DEFL [radius] [value]
CURVE TANGENT [radius] [value]
CURVE CHORD [radius] [value]
CURVE MID [radius] [value]

Command Synonyms

CURVE TAN

| Parameter | Definition |
|---|---|
| DELTA | The value parameter indicates the angle of the circular curve. |
| LENGTH | The value parameter indicates the length of the circular curve. |
| DEFL | The value parameter indicates the deflection angle between the current figure direction and the chord. |
| TANGENT, TAN | The value parameter indicates the tangent distance of the curve. |
| CHORD | The value parameter indicates the chord length of the curve. |
| MID | The value parameter indicates the mid-ordinate distance of the desired curve. |
| radius | The distance from a center point to the curve. You must enter this value in the current survey database distance units. Use a negative radius to draw the curve in a counter-clockwise (left) direction. |
| value | A curve value that depends on the curve parameter that you specified. For example, if you specify CHORD, then the value is the chord length. You must enter all distances in the current survey database distance units, and angles in the current survey database angular units, either DMS, grads, decimal degrees, mils, or radians. If you enter a negative value, then the negative sign is ignored. The radius component described above is used to control the direction of the curve. |

## Creating a Figure Vertex Using an Angle Distance

Create a figure vertex using an angle turned from a previous backsight. Two or more vertices must exist in the figure to use this command.

**To create a figure vertex using an angle and distance**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  At the Command line, enter:
   FIGURE ANG-DIST [angle] [distance]

**Command Line Example**

FIG NE 1000 1000

FIG ZD 0 222.2222

FIG AD 55.5556 304.80

AZIMUTH: 255.5556 DISTANCE: 304.8000

NORTH: 1026.301 EAST: 766.510

FIG AD 83.3333 15.240

AZIMUTH: 138.8889 DISTANCE: 15.2400

NORTH: 1017.559 EAST: 778.993

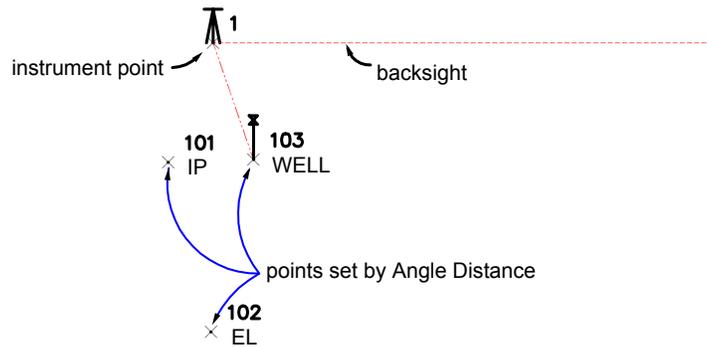
END

---

**NOTE** Distances are in the current survey database units, unless you enter a qualifying suffix.

---

The following illustrates the Figure Angle Distance command:



## Quick Reference

Toolspace

Survey Command Window Syntax

FIGURE ANG-DIST [angle] [distance]

Command Synonyms

FIG AD

| Parameter | Definition |
|-----------|------------|
| angle | The clockwise angle to turn from the last vertex in the figure. Enter this value in the current survey database angular units, either DMS, grads, decimal degrees, radians, or mils. |
| distance | The distance from the current vertex in the figure. Enter this value in the current survey database distance units. |

# Creating a Figure Using an Azimuth Distance

Create a new vertex from an existing vertex in the figure using an azimuth and distance. At least one vertex must exist in the figure for this command to work.

**To create a new vertex**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  At the Command line, enter:
   FIGURE AZ-DIST [azimuth] [distance]

**Command Line Example**

BEGIN 1_95

FIG NE 2000 2000

FIG ZD 50.5556 91.440

AZIMUTH: 50.5556 DISTANCE: 91.4400

NORTH: 2057.6291 EAST: 2070.9941

CRV DELTA 152.400 9.1440

CRV LENGTH -243.840 152.400

END

The following illustrates the Azimuth Distance command:

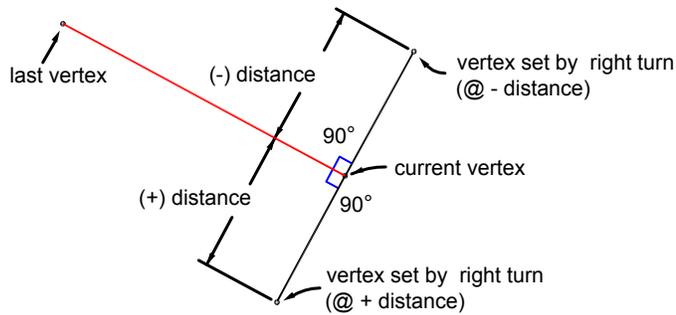
The following illustrates the Right Turn command:


## Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Network ➤ right-click <named> Network ➤ Survey Command Window

Survey Command Window Syntax

RT-TURN [distance]

Command Synonyms

RIGHT
RT

| Parameter | Definition |
|-----------|------------|
| distance | The distance from the current vertex to the new vertex. Enter this value in the current survey database distance units. |

# Creating a Point at the Current Location

Create a point at the current location as you create a figure.

**To create a point at the current location in a figure**

1. In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2. At the Command line, enter:
   SET (point)

**Command Line Example**

BEG FIG

FIG NE 1000 1000

FIG ZD 0 30.480

RT 60.960

FIG AD 50 60.960

SET 5

POINT 5 NORTH: 1077.1781 EAST: 1021.7757 ELEV: <Null>

END

### Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Network ➤ right-click <named> Network ➤ Survey Command Window

Survey Command Window Syntax

SET (point)

| Parameter | Definition |
| --- | --- |
| point | The assigned point identifier. You do not need to assign a point number if auto point numbering is on. |

# Creating Non-Tangential Curves in Figures

You can use the following commands to create non-tangential curves in the Survey Command Window.

## Creating a Non-Tangential Curve in the Current Figure

Create a non-tangential curve in the current figure.

**To create a non-tangential curve**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  At the Command line, enter:
   XC AD BULB [radius] [chord angle] [chord distance]

   **NOTE** Use the BULB parameter if the resulting curve is greater than 180 degrees.

**Command Line Example**

NE 1 1000 1000

NE 2 1000 1200

BEG ROADCL

PT 1

PT 2

XC ZD 100 45 120

SET 3

FIG DD 0 100

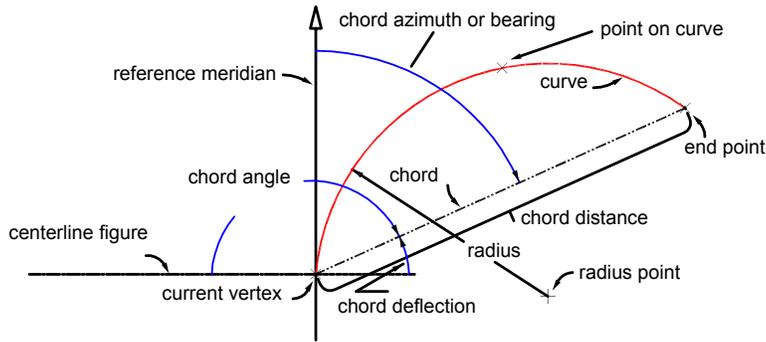
SET 4

XC AD 100 45 150

SET 5

END

The following illustrates a non-tangential curve:



## Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Network ➤ right-click <named> Network ➤ Survey Command Window

Survey Command Window Syntax

XC AD BULB [radius] [chord angle] [chord distance]

| Parameter | Definition |
| --- | --- |
| radius | The distance from a center point to the curve. Enter this value in current survey database distance units. Use a negative radius to draw the curve in a counter-clockwise (left) direction. |
| chord angle | The clockwise angle to turn from the last vertex in the figure. |
| chord distance | The distance from the current vertex in the figure. |

# Creating a Curve on a Figure Using a Point on the Curve

Create a non-tangent curve on a figure using three points.

---
**NOTE** For syntax descriptions, see the Quick Reference tab.

---

**To create a curve on a figure using a point on the curve**

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 At the Command line, enter:
   XC C3 [point on curve] [end point]

### Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Network ➤ right-click <named> Network ➤ Survey Command Window

Survey Command Window Syntax

XC C3 [point on curve] [end point]

| Parameter | Definition |
|---|---|
| point on curve | The point identifier of an existing point on the curve. |
| end point | The point identifier of the end point of the curve. |

## Creating a Curve Using a Radius Point

Create a non-tangential curve using a radius point and point at the end of the curve.

**NOTE** For syntax descriptions, see the Quick Reference tab.

**To create a non-tangential curve using a radius point and a point at the end of the curve**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  At the Command line, enter:
   XC PTS [radius] [radius point] [end point]

**Command Line Example**

NE 1 1000 1000

NE 2 1000 1200

NE 3 1084.8528 1284.8528

NE 6 985.8579 1298.9949

BEG ROADCL

PT 2

XC PTS 100 6 3

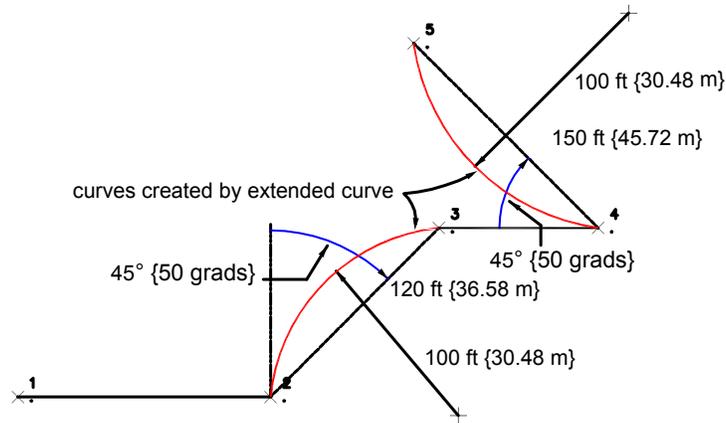
FIG DD 0 100

SET 4

XC AD 100 45 150

SET 5

END

The following illustrates two non-tangential curves:


## Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Network ➤ right-click <named> Network ➤ Survey Command Window

Survey Command Window Syntax

XC PTS [radius] [radius point] [end point]

| Parameter | Definition |
|---|---|
| radius | The distance from a center point to the curve. Enter this value in current survey database distance units. Use a negative radius to draw the curve in a counter-clockwise (left) direction. |
| radius point | The point identifier of an existing point that is used as the radial point for the arc. |
| end point | The point identifier of the end point of the curve. |

# Creating a Curve Using the Chord Bearing

Create a non-tangential curve using the chord bearing.

**NOTE** For syntax descriptions, see the Quick Reference tab.

**To create a non-tangential curve using the chord bearing**

1   In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2   At the Command line, enter:
    XC BD BULB [radius] [chord bearing] [quadrant] [chord distance]

### Quick Reference

Survey Command Window Syntax

XC BD BULB [radius] [chord bearing] [quadrant] [chord distance]

| Parameter | Definition |
| --- | --- |
| BULB | Creates a curve that is greater than 180°. |
| radius | The distance from a center point to the curve. Enter this value in the current survey database distance units. Use a negative radius to draw the curve in a counter-clockwise (left) direction. |
| chord bearing | The desired bearing. Enter this value in the current survey database angular units, either DMS, grads, decimal degrees, mils, or radians. |
| quadrant | Specify the quadrant using one of the following numbers: 1 (for NE), 2 (for SE), 3 (for SW), or 4 (for NW). |
| chord distance | The distance from the current vertex in the figure. Enter this value in the current survey database distance units. |

# Creating a Curve Using the Chord Deflection

Create a non-tangential curve using the chord deflection.

**NOTE** For syntax descriptions, see the Quick Reference tab.

**To create a non-tangential curve using the chord deflection**

1   In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2   At the Command line, enter:
    XC DD BULB [radius] [chord deflection] [chord distance]

### Quick Reference

Survey Command Window Syntax

XC ZD BULB [radius] [chord deflection] [chord distance]

| Parameter | Definition |
| --- | --- |
| BULB | Creates a curve that is greater than 180°. |

| Parameter | Definition |
|---|---|
| radius | The distance from a center point to the curve. Enter this value in the current survey database distance units. Use a negative radius to draw the curve in a counter-clockwise (left) direction. |
| chord bearing | The desired bearing. Enter this value in the current survey database angular units, either DMS, grads, decimal degrees, mils, or radians. |
| chord distance | The distance from the current vertex in the figure. Enter this value in the current survey database distance units. |

## Creating a Curve Using the Chord Azimuth

Create a non-tangential curve using the chord azimuth.

**NOTE** For syntax descriptions, see the Quick Reference tab.

**To create a non-tangential curve using the chord azimuth**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  At the Command line, enter:

XC ZD BULB [radius] [chord azimuth] [chord distance]

### Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Network ➤ right-click <named> Network ➤ Survey Command Window

Survey Command Window Syntax

XC ZD BULB [radius] [chord azimuth] [chord distance]

| Parameter | Definition |
|---|---|
| BULB | Creates a curve that is greater than 180°. |
| radius | The distance from a center point to the curve. Enter this value in the current survey database distance units. Use a negative radius to draw the curve in a counter-clockwise (left) direction. |
| chord bearing | The desired bearing. Enter this value in the current survey database angular units, either DMS, grads, decimal degrees, mils, or radians. |
| chord distance | The distance from the current vertex in the figure. Enter this value in the current survey database distance units. |

# Modifying Figures

Use the Modify Figure commands to add points, segments and vertices to existing figures.

# Beginning a New Figure

You can create a figure by either entering coordinates or referencing an existing point, and then giving a distance and direction to the next point.

Within an active Figure where (BEG <Figure name>) has been invoked, you can enter a figure command to specify that subsequent points define multiple points on a curve. After the points on the curve have been defined, you can enter a command to end the multi-point curve and subsequent points will define line segments. The Polyline object created from the multi-point curve contains contiguous arc segments for each multi-point curve range.

**NOTE** For syntax descriptions, see the Quick Reference tab.

**To begin a new figure**

1  In Toolspace, on the Survey tab, right-click a Figure collection ➤ Modify Figure ➤ Begin New Figure.

2  At the Command line, enter a figure name.

3  Pick the first point. You can pick a point on the screen with object snaps.

4  Select the next vertex by selecting a point on the screen, or entering one of the following options:

   ■  AD and then the angle and distance.

   ■  BD and then the bearing and distance.

   ■  ZD and then the azimuth and distance.

   ■  DD and then the deflection distance.

   ■  RT and then a negative or positive right distance, which is a right angle departure from the last leg of the figure.

   ■  CU to create a curve, type the radius, and select one of the following options for creating the curve: Select entry (Tan/Chord/Delta/Ext/Mid/Length)<Length>:

   ■  PT and then the point number.

   ■  CL to close the figure, linking the last vertex with the first point.

**Command Line Example**

1000 1000

BEG EP1

PT 1

NE 2 1100 1100

MCS

NE 3 1140 1120

NE 4 1800 1110

NE 5 1180 1070

MCE

NE 6 1160 1020

END

When you use the Begin command to start another figure, any figure currently being drawn is automatically ended.

## Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Network ➤ right-click <named> Network ➤ Modify Figure ➤ Begin New Figure

Command Line Syntax

BEGIN [figure]

Command Synonyms

BEG

| Parameter | Definition |
| --- | --- |
| figure | The name of the figure. |

# Extending a Figure from the Start Point

Add segments to the start point of an existing figure. The start point of the figure becomes the first point of the new segments.

**NOTE** For syntax descriptions, see the Quick Reference tab.

**To extend a figure from the start point in the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click a Figure collection or in individual figure ➤ Modify Figure ➤ Start Figure.

2 Enter the figure name.

3 Define the next vertex by selecting the points on screen or by entering one of the following options:

■ AD and then the angle and distance

■ BD and then the bearing and distance.

■ ZD and then the azimuth and distance.

■ DD and then the deflection distance.

■ RT and then a negative or positive right distance, which is a right angle departure from the last leg of the figure.

■ CU to create a curve, type the radius, and select one of the following options for creating the curve: Select entry (Tan/Chord/Delta/Ext/Mid/Length)<Length>:

■ PT and then the point identifier.

■ CL to close the figure, linking the last vertex with the first point.

**Command Line Example**

AP ON 1

BEG ROAD

NE SS 1000 1000

NE SS 1200 1200

NE SS 1400 1400

BEG EP

FIG NE 1300 1300

FIG ZD 180 200

START ROAD

This example starts figure ROAD, which proceeds from N 1000 E 1000 with a referenced azimuth away from N 1300 E 1300.

**NOTE** The Start command, like the Continue and Begin commands, ends the current figure.

### Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Network ➤ right-click <named> Network ➤ Modify FigureStart Figure

Command Line Syntax

START [figure]

| Parameter | Definition |
| --- | --- |
| figure | The name of the figure that you want to extend. |

## Continuing a Figure

Add additional vertices to an existing figure using the last vertex entered as the starting point.

**NOTE** For syntax descriptions, see the Quick Reference tab.

**To continue a figure in the Survey Command Window**

1   In Toolspace, on the Survey tab, right-click a Figure collection or in individual figure ➤ Modify Figure ➤ Continue Figure.

2   Enter the figure name.

3   Define the next vertex by selecting the points on screen or by entering one of the following options:

   ■ AD and then the angle and distance

   ■ BD and then the bearing and distance.

   ■ ZD and then the azimuth and distance.

   ■ DD and then the deflection distance.

   ■ RT and then a negative or positive right distance, which is a right angle departure from the last leg of the figure.

   ■ CU to create a curve, type the radius, and select one of the following options for creating the curve: Select entry (Tan/Chord/Delta/Ext/Mid/Length)<Length>:

- PT and then the point identifier.

- CL to close the figure, linking the last vertex with the first point.

**Command Line Example**

NE 1 1000 1000

NE 2 1000 2000

STN 1

BS 2

BEG CURBA

AD 4 50 60

BEG CURBB

AD 5 60 80

AD 6 90 40

CONT CURBA

!Figure CURBA has been continued.

AD 7 20 60

END

### Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Network ➤ right-click <named> Network ➤ Modify FigureContinue Figure

Command Line Syntax

Continue [figure]

Command Synonyms

CONT

| Parameter | Definition |
| --- | --- |
| figure | The name of the figure that you want to continue. |

# Editing Figures

Adjust the point data in a defined figure. After you enter the adjusted data, you can update and rename the figure.

The Figures Editor, which is accessible in the Survey Toolspace, provides a centralized way of editing and managing figure data.

**IMPORTANT** Figures that are created using a Linework Code Set do not automatically update when you modify survey data by updating figures, changing survey point descriptions, editing point coordinates through changes in observations, or network and traverse adjustment. In order to obtain the most accurate results, it is recommended that you process the linework each time you make modifications to the survey data. For more information, see Processing Survey Linework (page 251)

## Editing Figures from the Toolspace

Use the Survey Toolspace to view and edit figure data for either multiple figures or an individual figure.

The Figures Editor provides the same editing functionality as the Figure properties list view does in Toolspace, but is more suited for horizontal viewing of a tabulation of this type of data. The benefit of editing figures in the Figures Editor is that you can switch to the Survey Toolspace browse through the data, and then return to the Figures Editor and continue with your edits.

**NOTE** You can use the Survey Database Settings dialog box to set the Direction Type, Angle Unit, Distance/Coordinate Unit that is displayed for the Figures Editor vista.

**To view and edit figures**

1   In Toolspace, on the Survey tab, do one of the following:

   ■  To view and edit all figures, right-click the Figures collection ➤ Edit to display the Figures Editor.

   ■  To view and edit a single figure, expand the Figures collection and click the individual figure. Edit the figure data in the Toolspace properties list view.

2   Modify the fields as required by selecting the field and entering or selecting the new value.

   In the Breakline field, select the check box to indicate that the figure will be used as a surface breakline when you run the Create Breakline command.

   For more information, see Creating Breaklines from Figures (page 324). When you make a change to any figure data, the entire row is highlighted in bold until the change is saved to the survey database.

3   To edit the values in multiple rows, select the rows, right-click the column heading, click Edit. Enter the new value. The selected row values for the column are updated with the new value.

   **NOTE**  If no rows are selected, then all rows are updated.

4   To delete figures, click the figure(s) to delete, right-click, and click Delete.

   The figure icon 🖫 is replaced with ❌ and the row is set to read-only.

5   To undo the changes for a single row or multiple rows, select the row(s), right-click, and click Reload or Undelete. To undo all the changes in the vista, click 🔄 .

6   To apply the changes for a single row or multiple rows, select the row(s), right-click, and click Apply. To apply all changes in the vista, click 💾 .

7   Click ✅ to close the vista.

## Quick Reference

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Figures Collection

# Browsing to a Figure

Browse to a figure in the Figures collection on the Survey tab in Toolspace.

The figure is highlighted in the Figures collection on the Survey tab in Toolspace.

**To browse to a figure**

1  Click Survey tab ➤ Modify panel ➤ Browse To Survey Data Drop-down ➤ ⬛ Browse To Figure.

2  Select a figure in the drawing. The figure you select will be highlighted in the Figures collection on the Survey tab in Toolspace.

### Quick Reference

Ribbon

Survey tab ➤ Modify panel ➤ Browse To Survey Data Drop-down ➤ ⬛ Browse To Figure

UpdateSvFigureFromDwg

# Changing the Name of an Existing Figure

You can change the name of a figure.

**To change the name of a figure**

1 In Toolspace, on the Survey tab, do one of the following:
   - Right-click the Figures collection and click Edit to display the Figures Editor.
   - Click the figure to display its properties in the list view.

2 Do one of the following:
   - If you are working in the Figures Editor, select the figure you want to rename.
   - If you are working in the list view, click the figure name field.

3 Enter a new name for the figure.

**Quick Reference**

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Figures Collection

# Redrawing Adjusted Figures

You can redraw all the defined figures in your survey database based on the current point coordinates.

After you adjust and update survey points, you can update the figures based on adjusted coordinates.

**To update figures**

➤ In Toolspace, on the Survey tab, do one of the following:
   - To update all figures, right-click the Figures collection ➤ Update Figures.
   - To update a single figure, expand the Figures collection and right- click the individual figure ➤ Update Figure.

**Quick Reference**

Toolspace

Survey tab: Survey Databases ➤ <named survey database> ➤ Figures collection ➤ Update Figures

# Offsetting a Figure

You can offset an existing figure by a specified distance. A positive value indicates an offset to the right; a negative value indicates an offset to the left.

**To offset a figure**

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 At the Command line, enter:

OFFSET [figure] [distance]

---

**NOTE** Numeric figure names should not start with the number zero. For example, a figure name of 235 is acceptable but 0235 is not.

---

**Command Line Example**

NE 30 2000 2000

NE 31 2500 2500

BEGIN EASTERN_AVE

PT 30

PT 31

CRV LENGTH 60.960 91.440

FIG DD 0 91.440

CRV DELTA -121.920 6.096

END

OFFSET EASTERN_AVE 15.240

OFFSET EASTERN_AVE -6.096

# Deleting Figures

Delete figures from either the Toolspace list view or the Figure Editor vista, and also in the Survey Command Window.

Use the Figures Editor vista to mark figures for deletion and then accept or roll back the deletions.

**To delete figures from the Toolspace tree**

1   In Toolspace, on the Survey tab, expand the Figures collection to display the individual figures.

2   Right-click the figure and click Delete.

**To delete figures from the Toolspace list view**

1   In Toolspace, on the Survey tab, click the Figures collection to display the Figures list view.

2   Right-click the figure in the list view, and click Delete.

**To delete figures from the Figures Editor**

1   In Toolspace, on the Survey tab, right-click the Figures collection ➤ Edit to display the Figures Editor.

2   Select the figure(s) to delete, right-click, and click Delete. The figure icon  is replaced with a  and the row is set to read-only and cannot be edited.

3   To undo the deletion for a single row or multiple rows, select the row(s), right-click, and click Undelete. To undo all the deletions in the vista, click  .

4   To apply the deletion for a single row or multiple rows, select the row(s), right-click, and click Apply. To apply all deletions and changes in the vista, click  .

**To delete a figure in the Survey Command Window**

**1** In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

**2** At the Command line, enter:
DELETE FIGURE <name>.

### Quick Reference

Survey Command Window Syntax

DELETE FIGURE (name)

Command Synonyms

DEL FIG

| Parameter | Definition |
|-----------|-----------|
| name | The name of the figure that you want to delete. |

# Editing Figure Elevations and Figure Geometry

Use the feature line editing commands to edit survey figure elevations and figure geometry.

You can access these commands by clicking Modify tab ➤ Edit Geometry Panel or Modify tab ➤ Edit Elevations panel. For more information on these commands see Editing Feature Lines (page 751).

# Figure Inquiry Commands

Use either the Figure collection in the Survey Toolspace or the Survey Command window to access Figure Inquiry commands to identify figures, obtain closure information, and determine the area and perimeter for the figures in your drawing.

# Identifying a Figure

Identify and display the figure name for a selected figure.

**To identify a figure**

**1** In Toolspace, on the Survey tab, expand the Figures collection.

**2** Right-click a figure ➤ Show Properties. The properties for the figure are displayed in the list view.

**To identify a figure in the Survey Command Window**

**1** In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

**2** At the Command line, enter:
ID FIG

The following prompt is displayed:

Select figure:

After you select the figure, the figure name displays as shown below:

Name: {Figure Name}

## Quick Reference

DISPLAY FIGURES

Command Synonyms

DISP FIGS, LIST FIGS, DSP FIGS

## Listing Mapcheck Information for a Figure

Use the Mapcheck command to check your figure for length, course, perimeter, area, error of closure, or precision information.

Calculate closure, precision, perimeter, and area using the listed distances, courses, and units based on the current drawing unit precision set.

**NOTE** Use the Inverse command to return exact distances and courses, based on the current survey database distance units in the Survey Database Settings.

### Notes on Mapcheck Information

The Mapcheck report starts at the beginning of the figure. For each segment, based on the Linear and Angle precision (set in the Survey Database Settings) then the next figure vertex XY coordinates are computed based on the inversed direction and distance/curve data (rounded to the Linear and Angle precision values). For closed figures, due to the fact that error is introduced into the sequential computation of vertices of the mapcheck report, a closure error, closure direction, and precision can be calculated. The area is also based on the computed vertex XY coordinates.

### To do a Mapcheck in Toolspace

■ In Toolspace, on the Survey tab, expand the Figures collection, right-click a figure, and click Display Mapcheck. The Figure Display vista is displayed with the Mapcheck information for the selected figure.

### To Mapcheck a figure in the Survey Command Window

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 At the Command line, enter:

MAPCHECK [figure name]

For more information about performing mapcheck on labels, see Performing a Mapcheck Analysis (page 1608).

### Command Line Example

The following is a typical report generated by the Mapcheck command:

```
Line Length: 73.01          Course: N 00-00-00 E

Line Length: 92.99          Course: N 90-00-00 W

Line Length: 73.09          Course: S 02-36-16 E

Line Length: 89.67          Course: S 90-00-00 E

Perimeter: 328.76

Area: 6667.83                       0.15 acres

Mapcheck Closure - (Uses listed courses & COGO Units)

Error Closure: 0.005          Course: 285-27-17

# Listing Inverse Information for a Figure

Use the Inverse command to display the inverse information which includes the length, course, perimeter, area, closure error, and precision information for a given figure.

Closure, perimeter, precision, and area values are calculated using the exact XY coordinate data of each figure vertex.

### Notes on Inverse Information

The Inverse report starts at the beginning of the figure. For each segment, the inverse report lists the direction and distance, or curve data computed from the XY coordinates of the endpoints of the figure segments. The area is calculated from the XY coordinates of each segment.

### To display Inverse (exact closure) information using Toolspace

■ In Toolspace, on the Survey tab, expand the Figures collection. Right-click a figure ➤ Display Inverse. The Figure Display vista is displayed with the Inverse information for the selected figure.

> **NOTE** Figures that have vertices created using Point names will display the point name in the Point column.

### To calculate the mathematical closure of a figure using the Survey Command Window

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 At the Command line, enter:
INVERSE FIGURE [figure]

### Command Line Example

The following is a typical report generated by the Mapcheck command:

```
Figure Name: WALL

North: 5000.000            East: 5000.000

Line Length: 431.47           Course: 355-00-19

North: 5429.830           East: 4962.435
```

```
Line Length: 265.59          Course: 43-52-25

Line Length: 609.71          Course: 93-31-48

North: 5583.743        East: 5755.061

Line Length: 954.40          Course: 232-17-32

North: 5000.000        East: 5000.000

Perimeter: 2261.16

Area: 234948.16                    5.39 acres

Mathematical Closure - (Uses Survey Units)

Error Closure: 0.000          Course: 0-00-00

Error Closure: 0.000          Course: 0-00-00

Precision 1: 2261164601.60
```

# Listing the Area and Perimeter of a Figure

Determine and report the area and perimeter of an existing figure. Use the Toolspace list view to list the figure properties, or you can use the Area Perimeter command. The figure can be any shape, provided it is a closed figure.

**NOTE** The area and perimeter information is also listed at the top of the Figure Display vista when displaying Inverse information for the figure.

**To list the area of a figure**

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 At the Command line, enter:
AREA [figure]

**Command Line Example**

The following is a sample valid entry using the Area command:

BEG TRIANGLENE 1 0 0NE 2 10 10NE 3 0 10CloseAREA TRIANGLEArea = 50.000 Perimeter = 46.5028

# Labeling Figures

**To label survey figures**

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Figure ➤ Add Figure Labels 🏷 .

2  In the Add Labels dialog box, specify the label type and label style.

**To add labels to single or multiple segments**

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Figure ➤ Add Single Segment or Multiple Segments 🏷 .

2  If you select Single Segment you are prompted to select a point on an entity in the drawing. If you select Multiple Segment you are prompted to select an entity in the drawing.

**To add tables**

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Figure ➤ Add Line/Curve/Segment 🔲 .

2  Specify values in the Table Creation dialog box.

For more information, see Add Labels Dialog Box (page 1970) and Table Creation Dialog Box (page 2441).

# Survey Analysis and Output

# 13

You can use analysis tools, such as Least Squares, to make adjustments in Survey Networks as well as individual traverses. Use the menus on the Survey Command Window to input survey data using the command line.

## Least Squares Analysis

You can use Least Squares Analysis to make adjustments in Survey Networks.

A surveyor's fundamental job is making measurements, or observations, to determine the relative position of points. In doing this, many surveyors typically make more measurements than are minimally necessary to rule out the possibility of gross errors, or blunders, which might have occurred during the measurement process. As a result, redundant measurements, together with random measurement errors, create a model that is geometrically over-determined. This condition may also be referred to as an over-constrained problem.

You can calculate the most probable value for each observation by adjusting each of the observations simultaneously so that the sum of the squares of the residuals (the difference between measured and adjusted observations) is at a minimum. This is the origin of the term "least squares."

You use the AutoCAD Civil Survey Least Squares commands to perform least squares adjustments of surveys. Traverse loops and networks of distance and angle measurements are evaluated by the observation equation method.

## Using Least Squares with Networks

Use the Least Squares method to make adjustments to the survey observations database. These adjustments update points in the survey database and the line work input with your survey.

### Creating an Input File for a Network

The Create Input File command creates the Least Squares Network input file, *network.lsi*, which is generated from station-to-station observations in the current project survey database (sideshots are not considered).

**To create an input file for a network**

■ In Toolspace, on the Survey tab, expand the Networks collections. Right-click a named network ➤ Least Squares Analysis ➤ Create Input File.

---

**NOTE** The current equipment settings are used to compute the standard deviations for each observation, when the observation is created.

---

## Quick Reference

Toolspace

Survey tab: expand Survey Databases ➤ <named> survey database ➤ Networks ➤ right-click <named> network ➤ Least Squares Analysis ➤ Create Input File

## Editing the Input File for a Network

Use the Edit Input File command to add or make changes to the data using the text editor you specified in the External Editor Settings.

**To edit an input file**

1 In Toolspace, on the Survey tab, expand the Networks collection. Right-click a named network ➤ Least Squares Analysis ➤ Edit Input File.

2 In the text editor, enter your changes.

3 Click File menu ➤ Save. Click Exit to leave the text editor and return to the drawing.

## Quick Reference

Toolspace

Survey tab: expand Survey Databases ➤ <named> survey database ➤ Networks ➤ right-click <named> network ➤ Least Squares Analysis ➤ Edit Input File

## Processing the Input File for a Network

Use the Process Input File command to process and view the results of the Least Squares adjustment for the network.

The program reads the input file, *network.lsi*. The adjustment is calculated, and the program creates a least squares network adjustment file (*network.adj*) and a least squares network output file (*network.lso*).

**To process the input file for a network**

1 In Toolspace, on the Survey tab, expand the Networks collection. Right-click a named network ➤ Least Squares Analysis ➤ Process Input File.

2 Use the scroll bar to review the information in the file. You can also save the output file to a new filename, or print the file to your printer.

The least squares network output file initially displays the Survey Least Squares calculations data, based on the processed *network.lsi* input file.

3 Page down to display the observation data for the network.

The measured observations and standard deviations are the values that existed before the Least Squares adjustment. The adjusted observations and residuals are the results of the Least Squares adjustment.

4 Page down again to display the adjusted coordinates for the network. The point identifiers, northing, easting, northing standard deviation, and easting standard deviation for each unknown point are listed.

5 Page down to the end of the file to display the error analysis for the network. The values of the semi-major and semi-minor axes, as well as the axis azimuth of the error ellipse for each unknown point are listed.

## Quick Reference

Toolspace

Survey tab: expand Survey Databases ➤ <named> survey database ➤ Networks ➤ right-click <named> network ➤ Least Squares Analysis ➤ Process Input File

# Displaying the Output File for a Network

Use the Display Output File command to view information about a network. The least squares network output file, *network.lso*, is automatically loaded into the text editor.

**To display the output file for a network**

1 In Toolspace, on the Survey tab, expand the Networks collections. Right-click a <named> network ➤ Least Squares Analysis ➤ Display Output File.

2 Use the scroll bar to review the information in the file. Optionally, from the viewer, save the output file to a new file name, or print the file to your printer.

## Quick Reference

Toolspace

Survey tab: expand Survey Databases ➤ <named> survey database ➤ Networks ➤ right-click <named> network ➤ Least Squares Analysis ➤ Display Output File

# Updating the Survey Database with Adjusted Coordinates

Use the Update Survey Database command to import the adjusted network points in the survey database and their graphic information into the current drawing. The Least Squares network adjustment file, *network.adj*, is automatically selected.

**To update the database with the adjusted network coordinates**

1 In Toolspace, on the Survey tab, expand the Networks collections. Right-click a <named> network ➤ Least Squares Analysis ➤ Update Survey Database.

2 In the Least Squares Adjusted File Selection dialog box, select the *network.adj* file.

When you update the survey database and insert the network into the drawing, the network object can display error ellipses according to the Style properties for the network.

The following illustration shows the least squares network:

## Least Squares Formulas

You can use these formulas as a reference for Least Squares analysis.

## Least Squares Algorithm

The algorithm used by the AutoCAD Civil Survey Least Squares program uses a series of matrixes and formulas.

This algorithm is used to determine the probable position of points based on the least squares method.

The following matrix equation, based on a system of weighted observations, is solved iteratively:

$$X = (A^T P A)^{-1} A^T P L$$

where:

- X is a matrix that contains the difference between the current coordinates and the new coordinates of each unknown station, and that updates the current coordinates with each iteration (until X @ 0.0).

- A is a matrix that is created from the observations and coordinates of the points, based on a linearization by a Taylor series expansion of the specific observation type.

- P is a diagonal matrix with the standard deviations, or weights, of the observations.

- L is a matrix that contains the difference between measured observations and calculated observations.

# Horizontal Survey Adjustment

The first step in the adjustment of a horizontal survey is the calculation of C, the coordinate matrix, with the approximate coordinates for all stations.

$$C = \begin{array}{c} \\ \\ \\ \\ \\ \\ \\ m \end{array} \begin{vmatrix} x_1 & y_1 \\ x_2 & y_2 \\ x_3 & y_3 \\ . & . \\ . & . \\ . & . \\ x_m & y_m \end{vmatrix}^1$$

Next, the L matrix is calculated based on the calculated observations derived from the coordinate matrix, C, and the measured observations. The following formula is used to determine each Li observation value:

$$L_i = O_{meas} - O_{calc}$$

where:

- Omeas = the observation as measured

- Ocalc = the observation as calculated

The L matrix appears as follows:

$$L = \begin{array}{c} \\ \\ \\ \\ \\ \\ \\ m \end{array} \begin{vmatrix} L_1 \\ L_2 \\ L_3 \\ . \\ . \\ . \\ L_m \end{vmatrix}^1$$

Next, the diagonal weight matrix, P, is calculated based on the standard deviations of distances and angles.

The following formulas are used to solve for $P_{L_{ij}}$ , the weighted distance value, and $P_{\theta_{ijk}}$ , the weighted angular value:

$$P_{L_{ij}} = \frac{1}{(S_{L_{ij}})^2}$$

where:

$S_{L_{ij}}$ is the standard deviation of the length ij, and

$$P_{\theta_{jik}} = \frac{1}{(S_{\theta_{jik}})^2}$$

where:

$S_{\theta_{jik}}$ is the standard deviation of angle jik

$$P = \begin{array}{c}{}\\{}\\{}\\{}\\{}\\{}\\{}\\{}\\{m}\end{array}\left|\begin{array}{cccccc} p_1 & & & & 0 & 0 \\ & p_2 & & & & 0 \\ & & p_3 & & & \\ & & & . & & \\ & & & & . & \\ 0 & & & & . & \\ 0 & 0 & & & & p_m \end{array}\right|^{1}$$

The final step is to calculate the A matrix, which relates the changes in coordinates to each observation determined through the use of distance observation equations and angle or azimuth/bearing observation equations. These equations are initially nonlinear, so the Taylor series approximation is used to render them as linear equations.

## Distance Observation Equation Geometry

The change in coordinates for each observation is expressed in the following Taylor series approximations of the distance observation equation:

$$dx_i = \frac{X_i - X_j}{L_{ij}}$$

$$dy_i = \frac{Y_i - Y_j}{L_{ij}}$$

and

$$dy_i = \frac{Y_i - Y_j}{L_{ij}}$$

$$dy_j = \frac{Y_j - Y_i}{L_{ij}}$$

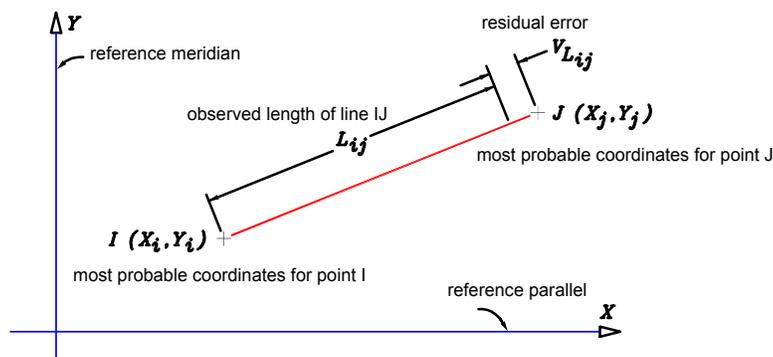
where

■ Lij = the observed length of line IJ

■ Xi, Yi = the most probable coordinates of point I

■ Xj, Yj = the most probable coordinates of point J

The following illustration shows the geometry of the distance observation equation:



## Angle Observation Equation Geometry

The change in coordinates for each observation is expressed in the following Taylor series approximations of the angle observation equation:

$$dx_i = -dx_j - dx_k$$

$$dy_i = -dy_j - dy_k$$

$$dx_j = \frac{Y_i - Y_j}{(L_{ij})^2}$$

$$dy_j = \frac{X_i - X_j}{(L_{ij})^2}$$

$$dx_k = \frac{Y_i - Y_k}{(L_{ik})^2}$$

$$dy_k = \frac{X_i - X_k}{(L_{ik})^2}$$

where

- Lij = the observed length of line IJ

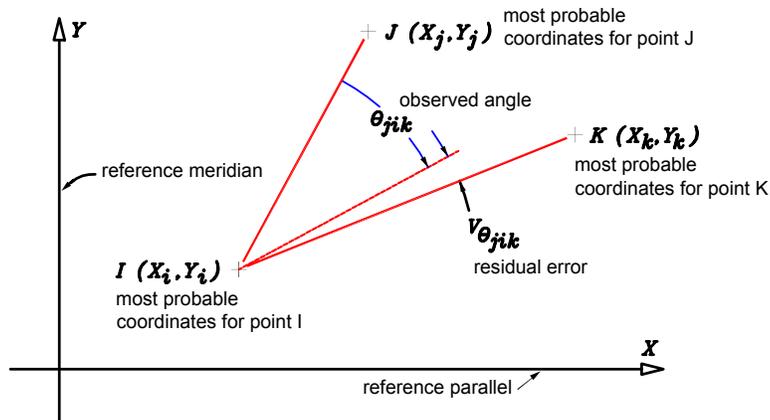
- Lik = the observed length of line IK

- Lik = the observed length of line IK

- Xi, Yi = the most probable coordinates of point I

- Xj, Yj = the most probable coordinates of point J

- Xk, Yk = the most probable coordinates of point K

The following illustration shows the geometry of the angle observation equation:


## Azimuth/Bearing Observation Equation Geometry

The change in coordinates for each observation is expressed in the following Taylor series approximations of the azimuth/bearing observation equation:

$$dx_i = \frac{X_i - X_j}{(L_{ij})^2}$$

$$dy_i = \frac{Y_i - Y_j}{(L_{ij})^2}$$

and

$$dx_j = \frac{X_j - X_i}{(L_{ij})^2}$$

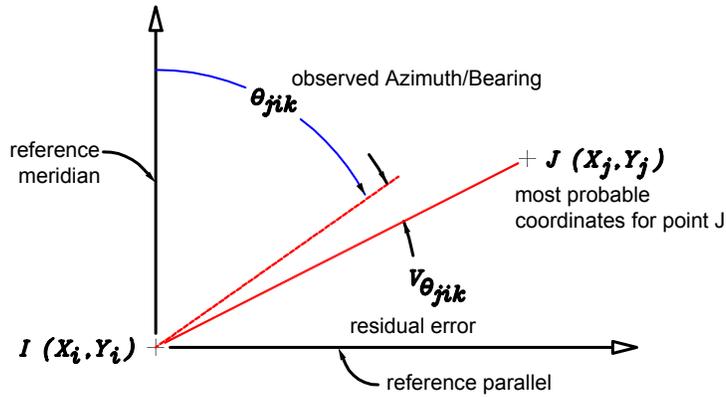
$$dy_j = \frac{Y_j - Y_i}{(L_{ij})^2}$$

where

- Lij = the observed length of line IJ

- Xi, Yi = the most probable coordinates of point I

- Xj, Yj = the most probable coordinates of point J

The following illustration shows the geometry of the azimuth/bearing observation equation:


## Weighted Observations

The following calculated values are used in the A matrix:

$$A = \begin{vmatrix} dx_1 \ dx_2 \ dy_1 \ dy_2 \ ... \\ dx_1 \ dx_2 \ dy_1 \ dy_2 \ ... \\ . \\ . \\ . \end{vmatrix}^{2}_{m}$$

The computed matrices A, P, and L are now plugged into the matrix formula for a system of weighted observations to solve for the X matrix, as stated previously:

$$X = (A^{T}PA)^{-1}A^{T}PL$$

This results in the X matrix, that consists of the difference between the current coordinates and the most probable values for the coordinates:

$$X = \begin{vmatrix} \Delta x_1 \\ \Delta x_2 \\ \Delta y_1 \\ \Delta y_2 \\ . \\ . \\ . \\ \Delta x_n \\ \Delta y_n \end{vmatrix}^{1}_{2n}$$

These values are used to revise the coordinate matrix, C. The iteration process continues, recalculating the A, P, and L matrices and solving for the X matrix until the values in the X matrix are negligible.

After the X matrix values have reached the desired limits, the V matrix is calculated. This matrix consists of the residuals after adjustment and is solved for by the following matrix equation:

$$V = AX - L$$

This results in the V matrix, which appears as follows:

$$V = \begin{array}{c} \\ \\ \\ \\ \\ \\ \\ \\ m \end{array} \begin{vmatrix} v_1 \\ v_2 \\ v_3 \\ . \\ . \\ . \\ v_m \end{vmatrix}^{1}$$

## Chi-Square Value and Goodness-of-Fit Test

Chi-square distribution is a probability tool used in hypothesis testing. In the case of least squares adjustment, original observations are compared to adjusted observations and evaluated in terms of how widely these observations vary with respect to each other.

The following formula is used to calculate X2, the chi-square value:

$$\chi^2 = \sum_{i=1}^{m} v_i^2 p_i^2$$

where

■  m = the number of observation equations

■  vi = the residual value from the V matrix

■  pi = the corresponding weight from the P matrix

The X2 value is small if the adjusted observations are close to the corresponding measured observations. This is referred to as a "good fit." A goodness-of-fit test is then conducted in which the X2 value is compared to those from a table of critical values of chi-square distribution at the 5% level. A X2 value below that listed in the table passes, while a larger X2 value than that listed fails, indicating possible blunders in the initial surveying measurements.

## Standard Deviation Computations

Calculation of the covariance matrix, Q, is next. The covariance matrix consists of the coefficients of the unknowns from the observation equations, and is used to compute standard deviations and error ellipses. The following matrix formula, using the previously solved A and P matrices, is used:

$$Q = (A^TPA)^{-1}$$

The Q matrix appears as follows:

$$Q = \begin{vmatrix} n \\ S_1^2 & S_1 S_2 & \cdots & S_1 S_n \\ S_2 S_1 & S_2^2 & \cdots & S_2 S_n \\ & & \cdot & \\ & & \cdot & \\ & & \cdot & \\ {}_n S_n S_1 & S_n S_2 & \cdots & S_n^2 \end{vmatrix}^n$$

Next, the calculation of the degrees of freedom in an adjustment, r, is accomplished through the use of the following formula:

$$r = m - n$$

where

- m = the number of observation equations

- n = the number of unknowns (or 2n in the case of coordinates, since both x and y are unknown)

The next procedure is the calculation of the standard deviation of unit weight for a weighted adjustment, So, which is done through the following matrix formula:

$$S_o = \sqrt{\frac{(V^T P V)}{r}}$$

where

- r = the degree of freedom in the adjustment

Calculation of the standard deviations of the individual adjusted quantities, $S_{x_i}$, is next. These are determined by the following formula:

$$S_{x_i} = S_o \sqrt{Q_{x_i x_i}}$$

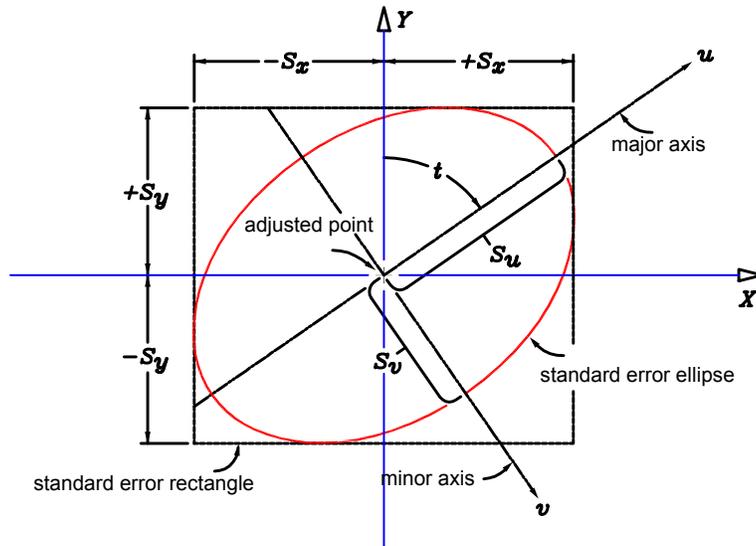
where

- So = the standard deviation of unit weight

- $S_{x_i}$ = the diagonal element in the ith row and ith column from the covariance matrix Q

## Error Rectangles and Ellipses

After the completing the Least Squares adjustment, the covariance matrix is used to calculate the positional standard deviations $S_{x_i}$ and $S_{y_i}$.

The following illustration shows that standard deviations represent half-dimensions of the standard 68% probability error rectangle around each point:


Where:

- t = the orientation of the error ellipse, the direction of the semi-major axis

- u = semi-major axis of the error ellipse

- v = the semi-minor axis error ellipse

- x = half-width dimension of the error rectangle

- y = half-height dimension of the error rectangle

- S = Positional standard deviation of a point

## Standard Error Rectangle and Ellipse Geometry

To further refine this process, a standard error ellipse can also be drawn. Using an F distribution from applied statistics, either a 95% or 99% probability error ellipse is created. This ellipse has arcs tangent to the sides of the error rectangle, with its orientation determined by an angle, t, and auxiliary orthogonal u-v axes. Again, values from the covariance matrix are used to calculate the t angle and the associated semi-major and semi-minor axes.

First solve three variables to use in equations that determine the semi-major and semi-minor axes: K, Quu and Qvv.

The following formulas are used:

$$K = \sqrt{[(Q_{yy} - Q_{xx})^2 + 4(Q_{xy})^2]}$$

$$Q_{uu} = \frac{(Q_{yy} + Q_{xx} + K)}{2}$$

and

$$Q_{vv} = \frac{(Q_{yy} + Q_{xx} - K)}{2}$$

where

■ Qxx, Qyy, and Qxy are values from the covariance matrix.

Then, these values are used to solve two equations to determine Su, the semi-major axis length and Sv, the semi-minor axis length:

$$S_u = S_o \sqrt{Q_{uu}}$$

and

$$S_v = S_o \sqrt{Q_{vv}}$$

where

■ So = standard deviation of unit weight

Finally, the angle t, which the u axis makes with the Y axis, is solved for by the following equation:

$$\tan 2t = \frac{2Q_{xy}}{Q_{yy} - Q_{xx}}$$

The adjusted point is most likely found within this ellipse with either a 95% or 99% degree of confidence.

# Traverses

Use the Traverses collection to manage the existing traverses defined within the network.

You can create a traverse from data in a field book file, or use the Traverse Editor to manually enter survey data, for example hand notes or data from a site plan. Using the Traverse Editor is an efficient way to view and edit all the setups in a traverse contained in a Network.

## Creating Traverses

Create traverses to perform traverse closure analysis such as Compass Rule, Crandall Rule, or Transit Rule. You can also perform a least squares analysis on a traverse.

You can create a traverse from data that you import from a field book file, or use the Traverse Editor to manually enter traverse observations.

**To create a traverse**

1 In Toolspace, on the Survey tab, expand the Networks collections. Expand a network ➤ right-click Traverses ➤ New.

2 In the New Traverse dialog box, click a cell in the Value column and enter values. Click OK.

**NOTE** Observations created using Point names will display in the Value column.

### Quick Reference

Toolspace

Survey tab: expand Survey Databases ➤ <named> survey database ➤ Networks ➤ <named network> ➤ Traverses ➤ New

Dialog Box

Traverse Editor (page 2403)

## Editing Traverse Properties

Change the initial properties for a traverse in the Traverse Properties dialog box.

**To edit traverse properties**

1  In Toolspace, on the Survey tab, expand the Networks collections. Expand a named network ➤ Traverses.

2  Right-click a named traverse ➤ Properties.

3  In the Traverse Properties dialog box, click a cell in the Value column and make any necessary changes.

4  Click OK.

### Quick Reference

Toolspace

Survey tab: expand Survey Databases ➤ <named> survey database ➤ Networks ➤ <named network> ➤ Traverses ➤ <named> traverse ➤ right-click Properties

Dialog Box

New Traverse (page 2419)

## Editing Traverses

Edit the properties of all traverses using the Traverses Editor panorama window, or edit an individual traverse in the Traverse Editor.

**To edit traverses**

1  In Toolspace, on the Survey tab, expand the Networks collections. Expand a named network ➤ Traverses ➤ Edit.

2  In the Traverses Editor Panorama window, click a cell and enter changes.

3  Right-click a cell and click New to create a traverse or click Delete to remove an existing traverse.

**To edit an individual traverse using the Traverse Editor**

1  In Toolspace, on the Survey tab, expand the Networks collections. Expand a named network ➤ Traverses ➤ right-click named traverse ➤ Edit.

2  In the Specify Initial Setup dialog box, enter the Initial Station and the Initial Backsight. Click OK.

**3** If you have defined the traverse, the current Setup property list is displayed on the left side of the panorama. In the current Setup property list you can edit the Backsight Orientation, Backsight Face1 and BacksightFace2 settings, and the Instrument Height.

> **NOTE** If the Setup you select is the initial setup for the traverse and the backsight point is not defined by a control point, you can enter the backsight direction. If the backsight direction is not assigned in the setup properties, you can enter it as a backsight observation.

**4** Expand each Station point. Enter or edit the observations for each Setup. A new blank observation row is added to the last setup observation where you can enter a new backsight or foresight observation.

> **NOTE** Observations created using Point names will display the name in the Name column.

**5** Specify a backsight observation in a new row by entering the point identifier for the setup.

**6** Specify a foresight observation to the next station point by entering a point identifier that has not been referenced in the current traverse.

When you specify the new foresight point identifier, the next Station point and setup are created.

> **NOTE** Once you have referenced a foresight point identifier, all new foresight observations must use the same point identifier.

**7** Click 💾 to apply the changes.

# Mapcheck Analysis

Perform a Mapcheck Analysis by selecting AutoCAD Civil line and curve labels to determine values from label objects based on the precision of the annotation of the label object, or enter mapcheck data manually.

For more information, see Mapcheck Analysis (page 1607).

# Displaying Point Information

You can use the Point Information commands to list angle, distance, and bearing information about the points that exist in the survey database.

# Listing the Horizontal Angle Between Points

Display the angle between any three points in the survey database. You must specify a backsight point, instrument point, and ahead point.

**To list the horizontal angle between three points in the Survey Command Window**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  In the Survey Command Window, click Point Information menu ➤ Angle.

3  Enter the point identifier of the backsight.

4  Enter the point identifier of the instrument point.

5  Enter the point identifier of the foresight point.

**To list the horizontal angle between three points in the Survey Command Window**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  At the command line, enter:
ANGLES [point 1] [point 2] [point 3]

**Command Line Example**

NE 1 1200 1200

NE 2 1000 1000

## Listing the Bearing Between Two Points

Use the Bearing command to list the bearing from one point to another.

**To list a bearing between two points in the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 In the Survey Command Window, click Point Information menu ➤ Bearing.

3 Enter the point identifier of the start point.

4 Enter the point identifier of the ahead point.

**To list a bearing between two points at the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 At the command line, enter:
 BEARINGS [point 1] [point 2] or
 B [point 1] [point 2]

**Command Line Example**

The following example shows a valid entry using the Bearing command:

NE 1 1000 1000

NE 2 2000 2000

B 1 2

Bearing: N 45-00-00 E

The bearing between point 1 and point 2 is listed.

The following example shows a valid entry using the Bearing command to define an observed bearing. Angles are in the current survey database units.

NE 1 1000 1000

NE 2 2000 2000

B 1 2 50 1

Observed direction: N 50-00-00 E

## Quick Reference

Survey Command Window Menu

  Point Information ➤ Bearing

Survey Command Window Syntax

  B [point 1] [point 2] [observed bearing] [quadrant]

Command Synonyms

  BEARINGS
  BRGS

| Parameter | Definition |
| --- | --- |
| point 1 | The point identifier of the origin of the bearing. |
| point 2 | The point identifier to which the bearing is measured. The bearing is measured from point 1 to point 2. |
| observed bearing | The observed bearing between point 1 and point 2. |
| quadrant | The quadrant for the bearing. Specify the quadrant using one of the following numbers: 1 (for NE), 2 (for SE), 3 (for SW), or 4 (for NW). |

# Listing the Azimuth Between Two Points

You can list the azimuth between two points in the survey database using the Azimuth command.

**To list the azimuth between two points in the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 In the Survey Command Window, click Point Information menu ➤ Azimuth.

3 Enter the point identifier of the start point.

4 Enter the point identifier of the ahead point.

**To list the azimuth between two points at the Command line in the Survey Command Window**

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 At the command line, enter:
AZIMUTH [point 1] [point 2] (observed azimuth)

**Command Line Example**

The following example shows a valid entry using the Azimuth command to list an azimuth. Angles are in the current survey database units.

NE 1 1000 1000

NE 2 2000 2000

AZ 1 2

Azimuth: 45-00-00

The following example shows a valid entry using the Azimuth command to define an observed azimuth.

NE 1 1000 1000

NE 2 2000 2000

AZ 1 2 50

Observed direction: 50-00-00

## Quick Reference

Survey Command Window Menu

   Point Information ➤ Azimuth

Survey Command Window Syntax

   AZIMUTH [point 1] [point 2] (observed azimuth)

Command Synonyms

   AZM
   AZ

| Parameter | Definition |
| --- | --- |
| point 1 | The point identifier of the origin of the azimuth. |
| point 2 | The point identifier to which the azimuth is measured. The azimuth is measured from point 1 to point 2. |
| observed azimuth | The observed azimuth between point 1 and point 2. |

# Listing the Distance Between Two Points

Use the Distance command to determine the horizontal distance between two points in the survey database.

**To determine the distance between two points in the Survey Command Window**

 1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

 2  In the Survey Command Window, click Point Information menu ➤ Distance.

 3  Enter the point identifier of the start point.

 4  Enter the point identifier of the ahead point.

**To determine the distance between two points at the Command line in the Survey Command Window**

**1** In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

**2** At the command line, enter:
DISTANCE [point 1] [point 2]

**Command Line Example**

The following example shows a valid entry using the Distance command:

NE 1 1000 1000

NE 2 2000 2000

D 1 2

Distance: 1414.21

## Quick Reference

| point 1 and point 2 | The two existing points between which the distance is determined. |

# Listing the Direction and Distance Between Points

Use the Inverse Points command to determine the direction and distance between two points.

**To inverse points in the Survey Command Window**

**1** In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

**2** In the Survey Command Window, click Point Information menu ➤ Inverse Points.

**3** Enter the point identifier of the start point.

**4** Enter the point identifier of the ahead point.

**To inverse points at the Command line in the Survey Command Window**

**1** In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

**2** At the command line, enter:

INVERSE POINTS [point 1] [point 2]

**Command Line Example**

The information is based on the current display setting and is calculated from the lines between points one and two, two and three, and from three to one. The command then computes and displays the area.

The following example shows a valid entry using the Inverse Points command when units are set to feet:

NE 1 100 100

NE 2 100 200

NE 3 50 150

INV PTS 1 2

POINT 1 NORTH: 100.0000 EAST: 100.0000 ELEV: <Null>

Distance: 100.000 Course: N 90-00-00 E

POINT 2 NORTH: 100.0000 EAST: 200.0000 ELEV: <Null> 3

Distance: 70.710 Course: S 45-00-00 W Perimeter: 170.7

POINT 3 NORTH: 50.0000 EAST: 150.0000 ELEV: <Null> 1

Distance: 70.710 Course: N 45-00-00 W Perimeter: 241.4

POINT 1 NORTH: 100.0000 EAST: 100.0000 ELEV: <Null>

Area: 2500.00 0.06 acres

The following is an example of a valid metric entry using the Inverse Points command:

NE 1 100 100

NE 2 100 200

NE 3 50 150

INV PTS 1 2

POINT 1 NORTH: 100.0000 EAST: 100.0000 ELEV: <Null>

Distance: 100.000 Course: 100.0000

POINT 2 NORTH: 100.0000 EAST: 200.0000 ELEV: <Null> 3

Distance: 70.710 Course: 250.0000 Perimeter: 170.7

POINT 3 NORTH: 50.0000 EAST: 150.0000 ELEV: <Null> 1

Distance: 70.710 Course: 350.0000 Perimeter: 241.4

POINT 1 NORTH: 100.0000 EAST: 100.0000 ELEV: <Null>

Area: 2500.00 0.25 hectares

# Listing an Angle and Distance Using the Inverse Radial

You can use the Inverse Radial command to determine the angle and distance from a setup in a radial direction from the backsight point. You must specify a backsight point identifier, an instrument point identifier, and a foresight point.

**To list angle and distance information using the Inverse Radial in the Survey Command Window**

**1** In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

**2** In the Survey Command Window, click Point Information menu ➤ Inverse Radial.

**3** Enter the point identifier of the backsight.

**4** Enter the point identifier of the instrument point.

**To list angle and distance information using the Inverse Radial at the Command line in the Survey Command Window**

**1** In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

**2** At the command line, enter:
INVERSE RADIAL [backsight] [station]

**Command Line Example**

The following example shows a valid entry using the Inverse Radial command:

NE 1 100 100

NE 2 200 200

NE 3 175 300

NE 4 300 200

NE 5 310 220

NE 6 200 250

INVERSE RADIAL 2 1

Inverses reference instrument at point 2 backsighting point 1 3

Angle: 24-26-38 Distance: 213.600

POINT 3 NORTH: 175.000 EAST: 300.000 ELEV: <Null> 4 6

Angle: 341-33-54 Distance: 223.610

POINT 4 NORTH: 300.000 EAST: 200.000 ELEV: <Null>

Angle: 344-44-42 Distance: 241.870

POINT 5 NORTH: 310.000 EAST: 220.000 ELEV: <Null>

Angle: 11-18-36 Distance: 180.280

POINT 6 NORTH: 200.000 EAST: 250.000 ELEV: <Null>

The instrument is set on point 2, backsights point 1, and gives the angle turned from line 2-1 to line 2-3. This command returns the distance from point 2 to point 3, then does the same for points 4 through 6.

### Quick Reference

Survey Command Window Menu

Point Information ➤ Inverse Radial

Survey Command Window Syntax

INVERSE RADIAL [backsight] [station]

Command Synonyms

INV RADIUS
INV RAD

| Parameter | Definition |
|-----------|------------|
| backsight | The known reference point or line. |
| station | The point where the instrument is located (the occupied point). |

## Listing the Elevation Distance Between Two Points

Use the Vertical Distance command to determine the elevation difference between two points in the survey database.

**To list the elevation distance in the Survey Command Window**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  In the Survey Command Window, click Point Information menu ➤ Vertical Distance.

3  Enter the point identifier of the start point.

4  Enter the point identifier of the ahead point.

**To list the elevation distance at the Command line in the Survey Command Window**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  At the command line, enter:
VDIST [point 1] [point 2]

**Command Line Example**

The following example shows a valid entry using the Vertical Distance command:

NEZ 1 100 100 30.480

NEZ 2 200 200 33.528

VD 1 2

Vertical distance 3.048

This example determines the vertical distance from point 1 to point 2. A positive value indicates that point 2 is higher than point 1.

## Listing the Slope Distance Between Two Points

Use the Slope Distance command to determine the slope distance between two points.

**To determine the slope distance between two points in the Survey Command Window**

1   In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2   In the Survey Command Window, click Point Information menu ➤ Slope Distance.

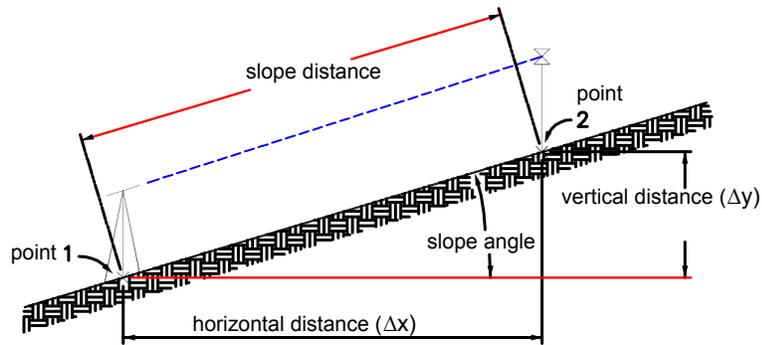
3   Enter the point identifier of the start point.

4   Enter the point identifier of the ahead point.

**To determine the slope distance between two points at the Command line in the Survey Command Window**

1   In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2   At the command line, enter:
SDIST [point 1] [point 2]

The following illustration shows the Slope Distance command:


**Command Line Example**

The following example shows a valid entry using the Slope Distance command:

NEZ 1 100 100 30.480

NEZ 2 200 200 33.528

SD 1 2

Slope distance: 141.45

This example determines the slope distance from point 1 to point 2. Distances are in the current survey database units.

## Quick Reference

| point 1 and point 2 | These are the two existing points between which an invisible line is established. This line is used to determine the slope distance between the two points. |

# Listing the Grade Between Points

Use the Grade command to determine the grade between two points. You must specify a starting point and an ahead point.

**To list the grade between two points in the Survey Command Window**

**1** In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

**2** In the Survey Command Window, click Point Information menu ➤ Grade.

**3** Enter the point identifier of the start point.

**4** Enter the point identifier of the ahead point.

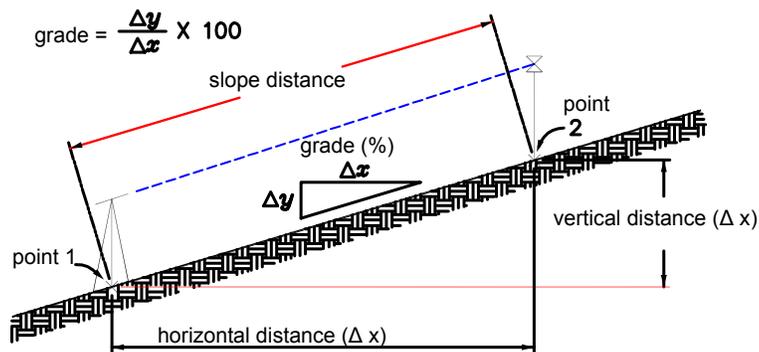
**To list the grade between two points at the Command line in the Survey Command Window**

**1** In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

**2** At the command line, enter:

GRADE [point 1] [point 2]

The following illustrates the Grade command:



**Command Line Example**

The following example shows a valid entry using the Grade command:

NEZ 1 100 100 30.480

NEZ 2 200 200 32.004

GRADE 1 2

Grade: 1.0776 Percent

This example displays the grade from point 1 to point 2 in percent. When used as a built-in function, this command supplies the vertical angle in the current vertical reference system (zenith, nadir, or horizontal).

## Quick Reference

Command Synonyms

G

| Parameter | Definition |
|---|---|
| point 1 and point 2 | The two existing points between which the grade is determined. |

# Listing the Slope Angle Between Existing Points

Use the Slope Angle command to determine the slope angle between two points.

**To list the slope angle between two points in the Survey Command Window**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  In the Survey Command Window, click Point Information menu ➤ Slope Angle.

3  Enter the point identifier of the start point.

4  Enter the point identifier of the ahead point.

**To list the slope angle between two points at the Command line in the Survey Command Window**

1  In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2  At the command line, enter:
   SLOPE [point 1] [point 2]

**Command Line Example**

The following example shows a valid entry using the Slope command:

NEZ 1 100 100 30.480

NEZ 2 200 200 33.528

SLOPE 1 2

Slope angle: 1.3719

This example determines the slope angle between point 1 and point 2. When used as a built-in function, this command supplies the vertical angle in the current vertical reference system (zenith, nadir, or horizontal).

## Quick Reference

| Parameter | Definition |
|---|---|
| point 1 and point 2 | The two existing points between which an invisible line is established. This line is used to determine the slope between the two points. |

# Outputting Survey Files

The Output file stores all the commands you enter at the Survey Command Line, including results from the query commands. The format of the output file is the same language or format as the Survey Command Language.

You can create, edit, or delete the output file using the commands in the Output menu. You can determine the name of the current output file using the Use Output File setting in the Survey User Settings dialog box.

The output file for each network in a survey database is saved to *Civil Projects\<named> Survey Database\<named> Network\Output.txt*.

**NOTE** For other options on outputting survey data see Exporting a Field Book File (page 243) and Exporting Survey Data to LandXML (page 244).

## Turning the Output File On or Off

Use the Output File menu to specify the settings that affect how the output file is used and updated during the Survey Command Window session.

**To turn the output file on or off**

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 In the Survey Command Window, click Output File menu ➤ Use Output File. A check mark next to the item indicates it is active. Click the menu item to clear the check mark. Specify the following settings:

- Use Output File: a check mark next to the menu item indicates the Output File is active.

- Set File Name: enter a name for the output file.

- Use Point Course Echo: reports the course taken to reach a point, including the direction and the distance.

- Use Figure Course Echo: reports the course taken to create a figure, including direction and distance.

- Use Point Coordinate Echo: displays the point coordinates, including northing, easting, and elevation information.

- Use Figure Coordinate Echo: displays figure point coordinates, including northing, easting, and elevation information.

### Quick Reference

Survey Command Window Menu

Output File

## Viewing the Contents of the Survey Output File

Use the Output File menu to specify the settings that affect how the output file is used and updated during the Survey Command Window session.

**To view the output file**

1 In Toolspace, on the Survey tab, right-click a named network ➤ Survey Command Window.

2 In the Survey Command Window, click Output File menu ➤ View.

The Output.txt file is displayed in the text editor.

**Quick Reference**

Survey Command Window Menu

Output File ➤ View

# Astronomic Direction Calculations

You can use the Astronomic Direction Calculator to calculate astronomic directions from Sun Shot and Star Shot observations.

In the Astronomic Direction Calculator you can specify the calculation type as either Sun Shot or Star Shot. A Sun Shot calculates the astronomic direction from solar observations by the hour angle method and uses a multiple foresight procedure. A Star Shot calculates the astronomic direction from Polaris or star observations by the hour angle method and uses a single foresight procedure.

Each method requires a source of UT1 time (radio) and a stopwatch to measure the observations accurately. Set the stopwatch to zero (0) at UT1 time. Start the stopwatch at a known interval of UT1 time and write down the value of UT1 time (adding any necessary DUT corrections). When measuring the horizontal angle to the sun or star, record the stopwatch reading (stop time) in the field book along with the angular data.

### Single Foresight

This procedure is recommended for Polaris observations, or any sightings that have a large vertical angle inherent in the observation. The single foresight procedure uses the following sequence: direct on the target, direct on Polaris, reverse on target, reverse on Polaris. A stopwatch time is recorded for each pointing on the Polaris. The two stopwatch times and the four horizontal circle readings correspond to one set of data. It is recommended that you perform a minimum of three sets.

### Multiple Foresight

This procedure is used as a solar observation method. It uses the following sequence: direct on the target, multiple direct on the sun, multiple reverse on the sun (same number of times as direct), reverse on the target. A stopwatch time is recorded for each pointing on the sun. Pair up each observation on the sun (and its stop time) with its related target observation, and enter it into the editor as a single direct or reverse pair. The editor computes an azimuth (or bearing) for each pair. You can average any number of these azimuths. Do not average the multiple observations themselves because they are time-dependent and not a linear function of time.

# Calculating Directions with Sun Shots and Star Shots

In the Astronomic Direction Calculator you can select Sun Shot or Star shot to calculate astronomic directions.

Sun shots calculate a direction using solar observations by the hour angle method and use a multiple foresight method. Star Shots calculate a direction from Polaris or a star observation by the hour angle method and use a single foresight method.

**To calculate an astronomic direction using the Sun Shot or Star Shot calculations**

1 Click Analyze tab ➤ Ground Data panel ➤ Survey drop-down ➤ Astronomic Direction ☀ .

2 In the Calculation Type list, select either Sun Shot Calculation, or Star Shot Calculation.

**3** Under Observation Station Data, specify the following:

- Station Point

- Backsight Point

- Station Latitude

- Station Longitude

- UT1 Time (Sun Shots only)

See Astronomic Direction Calculator Dialog Box (page 2424) for more information.

**4** Under Ephemeris Data, enter the following:

- GHA 00 Hours

- GHA 24 Hours

- Declination 00 Hours

- Declination 24 Hours

- Sun Semi-diameter (Sun Shots only)

---

**NOTE** Enter zero (0) if you are sighting either the center or both the trailing and leading edges of the sun. The left edge is always the leading edge at latitudes greater than 23.5 degrees north and greater than 23.5 degrees south. If only the left edge is being sighted (left when facing the sun), then the semi- diameter is positive; likewise, the semi-diameter is negative when only the right edge is sighted.

---

**5** Click ⬛ to create an observation set. Enter Direct and Reverse observations for the Backsight Observation, Sun Observationor Star Observation and the Stop Time.

The observations determine the true astronomic direction from the first setup to the backsight. When you enter the stop time for an observation, the observed and average directions are calculated automatically.

# Survey Command Reference

# 14

You can use commands to quickly access survey functionality.

## Survey Commands

The following table lists the survey-related AutoCAD Civil commands that can be entered at the command line.

| Command | Description |
| --- | --- |
| CST | Closes the Toolspace Survey tab (page 98) |
| BrowseToSvFigure | Synchronizes the Toolspace Survey tab to the specified figure in the drawing (page 349) |
| BrowseToSvNetwork | Synchronizes the Toolspace Survey tab to the specified network in the drawing (page 203) |
| BrowseToSvObservation | Synchronizes the Toolspace Survey tab to the specified observation in the drawing (page 263) |
| CreateFigureFromObject | Creates a survey figure from AutoCAD and AutoCAD Civil objects (page 323) |
| EditSvDatabaseSettings | Displays the Survey Database Settings dialog box (page 216) |
| EditSvUserSettings | Displays the Survey User Settings dialog box (page 205) |
| GradingElevEditor | Change elevations using the Grading Elevation Editor panarama vista (page 755) |
| EditFeatureElevs | Edits feature-line or lot-line elevations using the command line (page 757) |

| Command | Description |
|---|---|
| SetFeatureGrade | Specifies the grade or slope between selected points on a feature line (page 758) |
| InsertElevPoint | Inserts an elevation point (page 765) |
| DeleteElevPoint | Deletes feature line elevation points (page 767) |
| InsertFeatureHighLowPoint | Inserts high or low elevation points into feature lines (page 767) |
| SetFeatureRefElev | Sets the feature line elevation in relation to an existing elevation in the drawing (page 759) |
| RaiseLowerFeaturesByRef | Raise/lower a feature line based on a grade, slope, or relative elevation from a reference point (page 761) |
| AdjacentFeatureElevsByRef | Set the elevation based on a grade, slope, or elevation difference from another feature (page 762) |
| FeatureGradeExtensionByRef | Extends a grading by reference (page 763) |
| RaiseLowerFeatures | Raises or lowers feature lines by elevation (page 764) |
| FeatureElevsFromSurf | Creates feature line elevations from a surface (page 768) |
| InsertFeaturePI | Inserts points of intersection (page 769) |
| DeleteFeaturePI | Deletes points of intersection (page 771) |
| JoinFeatures | Joins multiple feature lines into a single object (page 771) |
| ReverseFeature | Reverses the direction of feature lines for stationing purposes (page 772) |
| EditFeatureCurve | Edit feature line curves (page 773) |
| FilletFeature | Rounds the corners of feature lines (page 776) |
| FitCurveFeature | Converts tessellated curves to true arcs for better grading results (page 777) |
| OffsetFeature | Offsets feature lines at an elevation difference (page 783) |
| AddFeatureLineLabels | Displays the Add Line labels dialog box (page 1970) |
| AddSegmentLabel | Add segment labels to figures (page 359) |
| FeatureLineSegmentLabels | Label feature line segments (page 787) |

| Command | Description |
|---|---|
| AddParcelLineTable | Inserts a parcel line table (page 1565) |
| AddParcelCurveTable | Inserts a parcel curve table (page 1565) |
| AddParcelSegmentTable | Inserts a parcel segment table (page 1565) |
| EditParcelTagNumbers | Activates the renumber label tags command (page 1544) |
| Mapcheck | Displays the Mapcheck Analysis Window (page 1607) |
| OST | Opens the Toolspace Survey tab (page 98) |
| SurveyCalculator | Displays the Astronomic Direction Calculator (page 389) |
| TranslateSvDatabase | Displays the Translate Survey Database dialog box (page 198) |
| ImportSurveyData | Displays the Import Survey Data Wizard (page 2435) |
| EditSvPointProperties | Displays the Survey Point Properties dialog box (page 2416) |
| EditSvFigureProperties | Displays the Survey Figure Properites dialog box (page 2411) |

# Survey Command Language Commands

You can use the survey command language to enter information directly at the Survey Command Window input line.

---

**TIP** In the Survey Command Window, enter HELP at the command line to display a text file that lists all the Survey Command Language commands.

---

For more information, see Survey Command Window (page 2419).

## Command Language Syntax Conventions

When using the survey command language, you enter the command name and data using a specific syntax.

The following conventions are used to present the survey command language syntax:

- Command name: Shown in uppercase.

- []: Square brackets enclose a required parameter, such as a coordinate or an angle measurement.

- ( ): Parentheses enclose an optional parameter, such as a description or point number.

---

**NOTE** Do not insert any brackets or parentheses when you type the command. The only exception to this rule is when you use mathematical operations.

---

**Example**

The following is an example of the syntax to create a point by angle, distance, and vertical angle.

AD VA (point) [angle] [distance] [vertical angle] (description)

The following is an example of the actual data you would enter:

AD VA 5 67.5757 100.63 91.1546 IPF

**NOTE** If you use numeric descriptions such as 100, or descriptions that include one or more spaces such as VERY LARGE MONUMENT, then you should enclose them in quotation marks.

# Point Creation Commands

The following table lists the point creation-related AutoCAD Civil survey commands and briefly describes their functionality.

**NOTE** These commands must be entered in the Survey Command Window. For more information, see Survey Command Window (page 2419).

| Command | Description |
|---|---|
| AD (point) [angle] [distance] (description) | Creates a point by angle and distance (page 266) |
| AD VA (point) [angle] [distance] [vertical angle] (description) | Creates a point by angle, distance, and vertical angle (page 266) |
| AD VD (point) [angle] [distance] [vertical distance] (description) | Creates a point by angle, distance, and vertical distance (page 266) |
| AP ON (point) | Turns automatic point numbering on (page 264) |
| AP OFF | Turns automatic point numbering off (page 264) |
| BD (point) [bearing] [quadrant] [distance] (description) | Creates a point by bearing and distance (page 268) |
| BD VA (point) [bearing] [quadrant] [distance] [vertical angle] (description) | Creates a point by bearing and distance (page 268) |
| BD VD (point) [bearing] [quadrant] [distance] [vertical distance] (description) | Creates a point by bearing, distance, and vertical distance (page 268) |
| DD (point) [angle] [distance] [vertical angle] (description) | Creates a point by deflection angle and distance (page 270) |
| DD VA (point) [angle] [distance] [vertical angle] (description) | Creates a point by deflection angle, distance, and vertical angle (page 270) |
| DD VD (point) [angle] [distance] [vertical distance] (description) | Creates a point by deflection angle, distance, and vertical distance (page 270) |

| Command | Description |
| --- | --- |
| F1 (point) [angle] [distance] (description) | Creates a point using a FACE 1 angle (page 272) |
| F1 VA (point) [angle] [distance] [vertical angle] (description) | Creates a point using a FACE 1 angle and a vertical angle (page 272) |
| F1 VD (point) [angle] [distance] [vertical distance] (description) | Creates a point using a FACE 1 angle and a vertical distance (page 272) |
| F2 (point) [angle] [distance] (description) | Creates a point using a FACE 2 angle (page 272) |
| F2 VA (point) [angle] [distance] [vertical angle] (description) | Creates a point using a FACE 2 angle and a vertical angle (page 272) |
| F2 VD (point) [angle] [distance] [vertical distance] (description) | Creates a point using a FACE 2 angle and a vertical distance (page 272) |
| LAT LONG (point) [latitude] [longitude] (description) | Creates a control point using a latitude and longitude (page 253) |
| NE (point) [northing] [easting] (description) | Creates a control point using a northing and easting (page 253) |
| NE SS (point) [northing] [easting] (elevation) (description) | Creates a non control point (page 256) |
| NEZ (point) [northing] [easting] (elevation) (description) | Creates a control point using a northing, easting, and elevation (page 253) |
| PRISM [height] | Changes the current prism height |
| PT OFFSET (point) [offset] (ahead) (description) | Createss a point by offsetting the last point (page 276) |
| SKIP | Skips over the next available point (when automatic point numbering is on) |
| STADIA (point) [angle] [distance] [rod] (vertical angle) (description) | Creates a point using the stadia method (page 277) |
| ZD (point) [azimuth] [distance] (description) | Creates a point using azimuth and distance (page 275) |
| ZD [VA] (point) [azimuth] [distance] [vertical angle] (description) | Creates a point using azimuth, distance, and vertical angle (page 275) |
| ZD [VD] (point) [azimuth] [distance] [vertical distance] (description) | Creates a point using azimuth, distance, and vertical distance (page 275) |

# Point Location Commands

The following table lists the point location-related AutoCAD Civil survey commands and briefly describes their functionality.

**NOTE** These commands must be entered in the Survey Command Window. For more information, see Survey Command Window (page 2419).

| Command | Description |
| --- | --- |
| AZ [point 1] [point 2] [azimuth] | Determines the azimuth between two points (page 378) |
| B [point1] [point2] [bearing] [quadrant] | Defines a bearing between two points (page 377) |
| BS [point] (orientation) | Locates a point by backsight |
| STN [point] (instrument. height) (description) | Creates a new setup station (page 259) |

# Point Information Commands

The following table lists the point information-related AutoCAD Civil survey commands and briefly describes their functionality.

**NOTE** These commands must be entered in the Survey Command Window. For more information, see Survey Command Window (page 2419).

| Command | Description |
| --- | --- |
| A [point 1] [point 2] [point 3] | Lists the horizontal angle between points (page 376) |
| AZ [point 1] [point 2] | Lists the azimuth between two points (page 378) |
| B [point 1] [point 2] | Lists a bearing between two points (page 377) |
| D [point 1] [point 2] | Determines the distance between two points (page 379) |
| DISP PTS (point 1) (point 2) | Displays point information (page 376) |
| GRADE [point 1] [point 2] | Lists the grade between two points (page 385) |
| INV PTS [point 1] [point 2] | Lists the direction and distance between points (page 380) |
| INVERSE RADIAL [backsight] [station] | Lists the angle and distance from a setup in a radial direction from the backsight point (page 382) |
| SLOPE [point 1] [point 2] | Lists the slope angle between two points (page 387) |

| Command | Description |
| --- | --- |
| SD [point 1] [point 2] | Lists the slope distance between two points (page 384) |
| VD [point 1] [point 2] | List the elevation distance between two points (page 383) |

## Point Editing Commands

The following table lists the point information-related AutoCAD Civil survey commands and briefly describes their functionality.

**NOTE** These commands must be entered in the Survey Command Window. For more information, see Survey Command Window (page 2419).

| Command | Description |
| --- | --- |
| DEL PTS [point 1] (point 2) | Deletes points from the survey databases (page 278) |
| MOD DESC [point 1] [description] | Modifies a point's description (page 279) |
| MOD ELEV [point 1] [elevation] | Modifies the elevation of a point (page 280) |
| MOD ELEV BY [point 1] [amount] | Modifies the elevation of a point by an increment (page 280) |
| MOD ELS [point 1] [point 2] [elevation] | Modifies the elevation of multiple points (page 280) |
| MOD ELS BY [point 1] [point 2] [amount] | Modifies the elevation of a group of points by an increment (page 280) |

## Figure Commands

The following table lists the figure-related AutoCAD Civil survey commands and briefly describes their functionality.

**NOTE** These commands must be entered in the Survey Command Window. For more information, see Survey Command Window (page 2419).

| Command | Description |
| --- | --- |
| AREA [figure] | Lists the area and perimeter of a figure (page 358) |
| BEG [figure] | Begins a new figure (page 344) |
| C3 | Draws a 3-point curve (page 325) |
| CLOSE | Closes a figure (page 321) |
| CLOSE BLD | Closes a figure (page 321) |

| Command | Description |
| --- | --- |
| CLOSE RECT [offset] | Closes a figure (page 321) |
| CONT [figure] | Continues a figure to add additional vertices to it (page 346) |
| CRV [DELTA, LENGTH, DEFL, MID, TAN, CHORD] [radius] [value] | Creates a curve in the current figure (page 328) |
| DEL FIG [figure] | Deletes a figure from the drawing (page 353) |
| DISP FIGS | Lists all the existing figure names in the current drawing (page 355) |
| END | Indicates the end of a figure (page 352) |
| FIG AD [angle] [distance] | Creates a figure vertex using an angle and distance (page 329) |
| FIG DD [deflection] [distance] | Creates a figure vertex using a deflection angle and distance (page 332) |
| FIG ZD [azimuth] [distance] | Creates a figure vertex using an azimuth and distance (page 331) |
| FIG BD [bearing] [quadrant] [distance] | Creates a figure vertex using a bearing and distance (page 333) |
| FIG NE [northing] [easting] | Creates a figure vertex using known coordinates (page 334) |
| ID FIG | Identifies a figure (page 354) |
| INVERSE FIG [figure] | Displays the exact closure (inverse) information for a figure (page 357) |
| MCS | Starts a multi-point curve within an active figure (page 326) |
| MCE | Ends a multi-point curve within an active figure (page 326) |
| MAPCHECK [figure] | Displays mapcheck information for a figure (page 356) |
| OFFSET [figure] [distance] | Offsets a figure (page 351) |
| PC | Specifies that the next shot is a point of curvature (page 327) |
| POINT [point] | Selects an existing point to be the next vertex in the figure (page 335) |
| RT [distance] | Defines a right turn in a figure (page 336) |

| Command | Description |
|---|---|
| SET (point) | Creates a point at the current location in a figure (page 337) |
| START [figure] | Extends a figure from the start point (page 345) |
| XC ZD (BULB) [radius] [chord azimuth] [chord distance] | Creates a curve using the chord azimuth (page 343) |
| XC BD (BULB) [radius] [chord bearing] [quadrant] [chord distance] | Creates a curve using the chord bearing (page 341) |
| XC AD (BULB) [radius] [chord angle] [chord distance] | Creates a non-tangential curve (page 338) |
| XC DD (BULB) [radius] [chord deflection] [chord distance] | Creates a curve using the chord deflection (page 342) |
| XC C3 [point on curve] [end point] | Creates a curve using a point on the curve (page 339) |
| XC PTS [radius] [radius point] [end point] | Creates the curve radius (page 340) |

## Intersection Commands

The following table lists the intersection-related AutoCAD Civil survey commands and briefly describes their functionality.

**NOTE** These commands must be entered in the Survey Command Window. For more information, see Survey Command Window (page 2419).

| Command | Description |
|---|---|
| AZAZ [point 1] [azimuth 1] [offset 1] [point 2] [azimuth 2] [offset 2] | Calculates an azimuth/azimuth intersection (page 305) |
| BB [point 1] [bearing 1] [quadrant 1] [offset 1] [point 2] [bearing 2] [quadrant 2] [offset 2] | Calculates a bearing/bearing intersection (page 304) |
| LNLN [point 1] [point 2] [offset 1] [point 3] [point 4] [offset 2] | Calculates a line/line intersection (page 307) |
| ARCAZ [point] [radius] [point 1] [azimuth] [offset] | Creates an arc/azimuth intersection (page 312) |
| ARCB [point] [radius] [point 1] [bearing] [quadrant] [offset] | Calculates an arc/bearing intersection (page 310) |
| ARCLN [point] [radius] [point 1] [point 2] [offset] | Calculates an arc/line intersection (page 314) |

| Command | Description |
| --- | --- |
| ARCARC [point 1] [radius 1] [point 2] [radius 2] | Calculates an arc/arc intersection (page 316) |
| SAVE [NORTH, SOUTH, EAST, WEST, 1, 2, ALL] (point) (description) | Saves the intersection point (page 317) |
| SAVE [NEAR, FAR] (point) [reference point number] (description) | Saves the intersection point (page 317) |
| SAVE PICK (point) (description) | Saves the intersection point (page 317) |
| SQ [reference 1] [reference 2] [reference] | Calculates a square offset (page 308) |

# Equipment Correction Commands

The following table lists the equipment correction-related AutoCAD Civil survey commands and briefly describes their functionality.

---

**NOTE** These commands must be entered in the Survey Command Window. For more information, see Survey Command Window (page 2419).

---

| Command | Description |
| --- | --- |
| ANGLES [RIGHT, LEFT] [ZENITH, NADIR, HORIZ] | Changes the horizontal angle type (right or left) and the vertical angle type |
| ATMOS [ON, OFF] | Turns atmospheric corrections on or off |
| COLL [ON, OFF] | Turns the collimation corrections for measurements on or off |
| CR [ON, OFF] | Turns curvature and refraction corrections on or off |
| EDM OFFSET [offset] | Sets the EDM (Electronic Distance Measuring) offset for an instrument |
| HORIZ ANGLE [RIGHT, LEFT] | Changes the horizontal angle type |
| PRESS [pressure] [INCH, MBAR, MM] | Specifies the atmospheric pressure |
| SF [factor] | Changes the scale factor |
| PRISM CONSTANT [constant] | Changes the prism constant |
| PRISM OFFSET [offset] | Changes the prism offset |
| TEMP [temperature] [F, C, K] | Sets the temperature for atmospheric corrections |

| Command | Description |
|---|---|
| UNITS [METER, FOOT] [DMS, DECDEG, GRAD, MILS, RADIANS] | Changes the distance or angle units for measurements |
| VERT ANGLE [ZENITH, NADIR, HORIZ] | Changes the vertical angle reference system |

# Baseline Commands

The following table lists the baseline-related AutoCAD Civil survey commands and briefly describes their functionality.

**NOTE** These commands must be entered in the Survey Command Window. For more information, see Survey Command Window (page 2419).

| Command | Description |
|---|---|
| BL IS [point 1] [point 2] [station] | Defines a baseline (page 285) |
| BL PT (point 1) [station] (offset) (description) | Creates a point at an offset from a baseline (page 287) |
| BL INV [point 1] (point 2) | Lists a baseline direction using inverse point (page 286) |

# Centerline Commands

The following table lists the centerline-related AutoCAD Civil survey commands and briefly describes their functionality.

**NOTE** These commands must be entered in the Survey Command Window. For more information, see Survey Command Window (page 2419).

| Command | Description |
|---|---|
| CL IS [figure] (station) (point) | Defines a centerline (page 289) |
| CL INV [point 1] (point 2) | Displays point data in reference to the current centerline (page 291) |
| CL PT (point) [station] (offset) (skew angle) (description) | Creates a new point by station offset (page 293) |
| CL PT BY [point] [station 1] [offset] [distance] (station 2) (description) | Creates points at an increment along the centerline (page 293) |
| CL ELEV (point) [station] [offset] [elevation] (description) | Creates a point by station, offset, and elevation (page 295) |
| CL ROD (point) [station] [offset] [rod] (description) | Creates a point using station, offset and rod height (page 296) |

| Command | Description |
| --- | --- |
| CL VD (point) [station] [offset] [vertical distance] (description) | Creates a point along a centerline using a vertical distance (page 297) |
| HI [elevation] | Defines the height of instrument (page 292) |
| XS [station] | Sets the current cross section station (page 299) |
| XS ELEV (point) [offset] [elevation] (description) | Creates a point with offset and elevation from the current cross section (page 300) |
| XS ROD (point) [offset] [rod] (description) | Creates a point by offset and rod height from the current cross section (page 301) |
| XS VD (point) [offset] [vertical distance] (description) | Creates a point by offset and vertical distance from the current cross section (page 302) |

## AutoCAD Related Commands

The following table lists the AutoCAD commands that you can use at the AutoCAD Civil survey command line and briefly describes their functionality.

The following table lists the corridor-related AutoCAD Civil commands and briefly describes their functionality.

**NOTE** These commands must be entered in the Survey Command Window. For more information, see Survey Command Window (page 2419).

| Command | Description |
| --- | --- |
| PAN | Shifts the location of the drawing |
| REDRAW | Refreshes the display in the current viewport |
| ZOOM PT [point] | Zooms to a point |
| ZOOM [WINDOW, EXTENTS, PREVIOUS, W, P, E, A] | Zooms according to one of the specified parameters |

## Miscellaneous Commands

You can use commands to quickly access survey functionality.

The following table lists the survey-related AutoCAD Civil commands and briefly describes their functionality.

**NOTE** These commands must be entered in the Survey Command Window. For more information, see Survey Command Window (page 2419).

| Command | Description |
| --- | --- |
| CALC [formula] | Performs mathematical calculations |
| DITTO [ON, OFF] | Turns the Ditto feature on or off |

| Command | Description |
| --- | --- |
| HELP (command) | Displays the syntax of the specified command |
| HISTORY | Displays all the commands you used during the current session |
| OUTPUT [ON, OFF] | Turns the use of an output file on or off |
| TRAV [ON, OFF] | Turns the traverse command on or off |

# Point Data

# Points

# 15

Points are basic building blocks in AutoCAD Civil. You can use points in land development projects to identify existing ground locations and design elements.

Points are numbered and named uniquely. Each point has properties that can include information such as northing, easting, elevation, and description. A point that is displayed in a drawing can have additional properties that control its appearance, such as a point style, a point label style, and a layer.

A point can be included in an AutoCAD Civil project so that it can be accessed by multiple users, or it can exist outside a project in a single drawing. For more information about the differences between project and drawing points, see Managing Points (page 423).

Points Workflow

## Understanding Points

In AutoCAD Civil, you can create, work with, and manage points using a variety of commands and tools.

The points created by AutoCAD Civil are called Coordinate Geometry (COGO) points, which are very different from AutoCAD point nodes. AutoCAD point nodes have only coordinate data (XYZ values) associated with them. However, COGO points, in addition to coordinate data, have a variety of properties associated with them, including point number, point name, raw (field) description, and full (expanded) description. Unlike AutoCAD point nodes, which exist in a single drawing, COGO points can be stored in a project outside a drawing and referenced by multiple users. In AutoCAD Civil, the term point refers to a COGO point, not to an AutoCAD point node.

### Displaying and Labeling Points

To control the appearance of a point symbol in a drawing, either select a default point symbol, or create a point symbol. For more information, see Point Styles (page 419).

You can automatically label points with predefined labeling criteria as you create points in a drawing. For more information, see Point Labels and Tables (page 421).

### Editing Points

Use the Point Editor to edit point properties. For more information, see Point Properties (page 408). You can also use AutoCAD commands to edit points graphically. For more information, see Editing Points in a Drawing (page 488).

**Creating Points**

Choose from many point creation commands to create points. For more information, see Creating Points (page 427). You can also create points by importing point data from a file. For more information, see Importing and Exporting Points (page 495).

When you create or import points, you can use description keys to automatically control the appearance of a point in the drawing based on its raw (field) description. For more information, see Description Keys (page 537).

**Managing and Organizing Points**

You can group related points into point groups using a variety of criteria. You can use point groups to control the appearance of points in a drawing, to create surfaces, or to export selected points to a file. For more information, see Point Groups (page 521).

Use a project to manage and protect the points needed for a design project. When you use a project as a central repository for your project points, the points can be viewed and copied by others, but not necessarily modified.

## The Point Object

Points are AutoCAD Civil objects that can be displayed in the drawing and manipulated graphically. Point appearance is controlled using point labels and point styles.

In the early releases of AutoCAD Civil points were a subcomponents of a point group. Now points in AutoCAD Civil are individual objects where you can perform the following:

■ You can select points individually in the drawing and graphically change the location and rotation using grips.

■ You can create a selection set of points to move their elevations to a surface.

■ You can modify point properties in the AutoCAD Properties dialog box which describes both the basic and specific AutoCAD Civil properties.

■ You can change the Next Point Number settings in the point creation commands.

**NOTE** To perform any of these functions, the point must be checked out, unlocked, and not a Survey Point.

Point Groups are still used as a way to organize points and to manage points for selection, overrides, and adding points to surfaces.

When creating points you specify the point layer in the Edit Command Settings-CreatePoints dialog box. For more information, see Edit Point Settings dialog box (page 2103).

You can use the AutoCAD LIST command to display point properties.

## Point Properties

Use the Prospector tree to access point properties.

Point properties specify all the information associated with a point, including its data, such as point number, northing, easting, and elevation. Properties for a drawing point include information about how the point is displayed in a drawing, and properties for a project point include information about its status with respect to the project.

Display the properties of a point, even a point that is not in the current drawing, by clicking either a drawing Points collection or a project Points collection in the Prospector tree to display a list view. For more information, see The Toolspace Item View (page 82).

For a description of all drawing and project point properties, see Point Editor (page 2130). Use the Point Editor to edit drawing point properties. View the properties of project points in the project Points collection list view.

Point group overrides affect how some point properties, including elevation and raw description, are displayed and are used in a drawing without changing the stored value of the point property. You can also use point group overrides to override point styles and point label styles. For more information, see Using Point Groups to Override Point Properties (page 523).

## Points Collection (Prospector Tab)

Use the Points collection in the Prospector tree to access the points in a drawing.

Right-click the drawing Points collection to:

- Create a new point. (page 427)

- Export the points in a drawing. (page 505)

- Transfer points in a file to another file format. (page 506)

- Edit the points in a drawing with the Point Editor. (page 488)

- Zoom or pan to the points in the drawing. (page 426)

- Lock or unlock the points in the drawing. (page 423)

- Refresh the Prospector tree.

**NOTE** The Points shortcut menu in the Prospector tree and in the Points list view can also contain project management access control menu items when they are available. The menu items that display can change depending on the status of the selected point relative to the project, such as whether it is checked out.

If one or more points have been added to the current drawing, you can view a list of the points in the list view next to or beneath the Prospector tree. For more information, see The Toolspace Item View (page 82).

## Point Collection (Settings Tab)

Use the Point collection in the Settings tree to manage point settings, point styles, point label styles, point file formats, description key sets, table styles, and point command settings.

Right-click the Point collection to:

- Edit the point feature settings. (page 410)

- Edit the point styles defaults. (page 419)

- Refresh the Settings tree.

Expand the Point collection to display and edit the styles, command settings, and other collections available for points, which are listed in the following table:

| For more information about... | Follow this link... |
|---|---|
| Point Styles | The Object Style Collection (Settings Tree) (page 94) |
| Label Styles | The Label Styles Collections (Settings Tree) (page 95) |
| Point File Formats | Point File Formats Collection (Settings Tab) (page 496) |
| Description Key Sets | Description Key Sets Collection (Settings Tree) (page 538) |
| External Data References | Using External Data References (page 508) |
| User-Defined Property Classifications | User-Defined Property Classifications (page 416) |
| Table Styles | The Table Styles Collections (Settings Tree) (page 96) |
| Commands | Point Settings (page 410) |

# Point Settings

Point settings control how point-related commands behave.

You work with point settings the same way you work with other object settings in AutoCAD Civil, using the Toolspace Settings tree. You can control point-related settings at both the object collection (feature) level and at the command level. For information about how the levels of settings work together, see Understanding Settings (page 61).

Use the Settings tree Point collection shortcut menu to establish defaults for all point-specific settings and to override the drawing ambient settings for all point-related commands. Use the Commands collection under the Settings tree Point collection to override point-specific settings or drawing ambient settings for a specific command.

**NOTE** Overrides to the drawing ambient settings at the Point collection level and the Point Commands collection level affect only the specified level. The drawing level settings are not affected. For more information, see Understanding Settings (page 61).

The topics in this section describe only those settings that affect point-related commands. They do not describe the drawing ambient settings that you can edit at the Point collection level and the Point Commands collection level, even though those settings are displayed. For more information about the drawing ambient settings, see Specifying Ambient Settings (page 68).

## Editing the Default Styles Settings

Before creating points, specify the default point style and point label style used to create the points if description keys are not used.

The styles you specify establish the default settings for the styles in the Create Points dialog box. When you select the Create Points command, you can expand the Create Points dialog box and edit these default settings.

---

**IMPORTANT** By default, in the Create Points dialog box - Points Creation section the Disable Description Keys value is set to false and the controls in the Default Styles section are not available. To enable the Default Styles controls, set the Disable Description Keys value to true.

---

**To edit the Default Style settings**

1 Open the Edit Point Settings (page 2103) dialog box using one of the following methods:
  - Edit settings for all point-related commands: In Toolspace, on the Settings tab, right-click Point ➤ Edit Feature Settings.
  - Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools ⊕. Expand the Create Points dialog box. Expand Points Creation.
  - Edit settings for a specific command: In Toolspace, on the Settings tab, expand the Commands collection under the Point collection. Right-click the desired command. Click Edit Command Settings.

2 If needed, scroll to Default Styles and expand the collection.

3 To specify a default point style, edit the Point Style setting.

4 To specify a default point label style, edit the Point Label Style setting.

5 Click OK.

## Quick Reference

Ribbon

Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools ⊕. Expand the Create Points dialog box. Expand Points Creation.

Toolspace Shortcut Menu

Settings tab: right-click Point collection ➤ Edit Feature Settings
OR
Settings tab: Point Commands collection ➤ right-click <command> ➤ Edit Command Settings

Command Line

ShowPointSettings

Dialog Box

Point Settings (page 2103)

# Editing the Default Name Format

Before creating points, specify the default name template for points and point groups.

**To edit the Default Name Format**

1 Open the Edit Point Settings (page 2103) dialog box using one of the following methods:
  - Edit settings for all point-related commands: In Toolspace, on the Settings tab, right-click Point ➤ Edit Feature Settings.

- Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools . Expand the Create Points dialog box. Expand Points Creation.

- Edit settings for a specific command: In Toolspace, on the Settings tab, expand the Commands collection under the Point collection. Right-click the desired command. Click Edit Command Settings.

2 If needed, scroll to Default Name Format and expand the collection.

3 To specify a default Point Group Name Template, click in the Point Group Name Templatevalue column and enter values in the Name Template dialog box.

4 To specify a default Point Name Template, click in the Point Name Template value column and enter values in the Name Template dialog box.

5 Click OK.

### Quick Reference

Ribbon

Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools . Expand the Create Points dialog box. Expand Points Creation.

Settings tab: right-click Point collection ➤ Edit Feature Settings
OR
Settings tab: Points ➤ Commands collection ➤ right-click <command> ➤ Edit Command Settings

Command Line

ShowPointSettings

Dialog Box

Point Settings (page 2103)

## Editing the Update Points Settings

Use the Update Points setting to control whether you can change project points without checking them out.

Normally, after you check a point in to a project, you cannot modify the point in the drawing. To modify it, you must first check it out of the project. In general, you should not modify a project point unless you first check it out of the project.

However, there may be times when you want to modify a point that you have not checked out. In that case, use the Update Points setting, Allow Checked-In Points To Be Modified.

**WARNING** If you edit points without checking them out, you cannot check the points in to the project. Your changes exist only in the drawing in which you made them.

**To edit the Update Points settings**

1 Open the Edit Point Settings (page 2103) dialog box using one of the following methods:

- Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools . Expand the Create Points dialog box. Expand Points Creation.

- Edit settings for all point-related commands: In Toolspace, on the Settings tab, right-click the Point ➤ Edit Feature Settings.

- Edit settings for a specific command: In Toolspace, on the Settings tab, expand the Commands collection under the Point collection. Right-click the desired command and click Edit Command Settings.

**2** If needed, scroll to Update Points and expand the collection.

**3** Edit the Allow Checked In Points To Be Modified setting.

**4** Click OK.

## Quick Reference

**Ribbon**

Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools ⚙ . Expand the Create Points dialog box. Expand Points Creation.

**Toolspace Shortcut Menu**

Settings tab: right-click Point collection ➤ Edit Feature Settings
OR
Settings tab: Point Commands collection ➤ right-click <command> ➤ Edit Command Settings

**Command Line**

ShowPointSettings

**Dialog Box**

Point Settings (page 2103)

# Editing the Point Identity Settings

Before creating or importing points, specify the settings that control how the points are numbered and how point number collisions are handled.

If you import points from an external file, and the points in your point data file do not have point numbers, use the Point Identity settings to control how the points are numbered as they are imported.

If you import points from an external file, and the points in your point data file have point numbers, specify how point number conflicts are resolved if the point file contains a point number that already exists. The following example shows how the If Point Numbers Already Exists settings resolves conflicts when your point data file contains a point number that already exists:

**Example: If you have a point in the drawing with the following properties:**

- Number: 23

- Northing: 500

- Easting: 500

- Elevation: 70.5

- Description: IP

You import a point data file containing a point with the same point number, but different properties, as follows:

- Number: 23

- Northing: 502.18

- Easting: 498.65

If you set the If Point Number Already Exists setting to Overwrite before you import the point file, the point in the drawing becomes:

Number: 23 Northing: 502.18 Easting: 498.65 Elevation: blank Description: blank

All properties are overwritten, even properties that aren't defined in the point data file, such as elevation and description.

If you set the If Point Number Already Exists setting to Merge before you import the point file, the point in the drawing becomes:

Number: 23 Northing: 502.18 Easting: 498.65 Elevation: 70.5 Description: IP

The number, northing, and elevation are overwritten, but the elevation and description in the drawing are preserved.

**To edit the Point Identity settings**

1 Open the Edit Point Settings (page 2103) dialog box using one of the following methods:

- Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools ⊕ . Expand the Create Points dialog box. Expand Points Creation.

- Edit settings for a specific command: In Toolspace, on the Settings tab, expand the Commands collection under the Point collection. Right-click the desired command and click Edit Command Settings.

2 If needed, scroll the dialog box to Point Identity and expand the collection.

3 To specify point names and point numbers and to resolve duplicate point names and point numbers, edit the following settings:

- Next Point Number

- Use Sequential Numbering

- Point Number Offset

- Sequence Point Numbers From

- If Point Numbers Are Supplied

- Force Names

- If Point Numbers Already Exist

- If Point Names Already Exist

Point Settings (page 2103)

## Editing the Default Point Creation Settings

Use the point creation settings to change the command entry prompts, point elevations and description key options.

The settings you specify when you right-click CreatePoints ➤ Edit Command Settings establish the default settings in the Create Points dialog box. When you select the Create Points command, you can expand the Create Points dialog box and edit these default settings.

**To edit the Point Creation settings**

1   Open the Edit Point Settings (page 2103) dialog box using one of the following methods:

■ Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools 🔧 . Expand the Create Points dialog box. Expand Points Creation.

■ In Toolspace, on the Settings tab, expand the Commands collection under the Point collection. Right-click the CreatePoints ➤ Edit Command Settings.

2   If needed, scroll to Points Creation and expand the collection.

3   Specify the settings.

4   Click OK.

**Quick Reference**

## Editing the Default Layer Settings

Before creating points, specify the default layer for the points you create.

**To edit the Default Layer settings**

1 Open the Edit Point Settings (page 2103) dialog box using one of the following methods:

■ Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools  . Expand the Create Points dialog box. Expand Points Creation.

■ In Toolspace, on the Settings tab, expand the Commands collection under the Point collection. Right-click the CreatePoints ➤ Edit Command Settings.

2 If needed, scroll to Default Layer.

3 To specify a new Layer, click the Value cell and specify a layer in the Layer Selection dialog box.

4 Click OK.

## User-Defined Property Classifications

You can use User-Defined Property Classifications to organize and group specific types of user-defined properties.

With user-defined properties, you can assign, label, edit, and query point data. User-defined properties are grouped together in User-Defined Property Classifications. For example, if you want to group all user-defined properties for points representing trees, start by creating a classification called Trees. This classification is displayed as a collection in User-Defined Property Classifications on the Settings tab of Toolspace. Then create and add properties that are specific to the classification. For example, in the Tree Classification some

properties you might create are name, species, and height. Each property you create is displayed in the Toolspace list view.

# Creating a User-Defined Property Classification

Create a User-Defined Property Classification that contains a common group of properties.

**To create a user-defined property classification**

1  On the Settings tab in Toolspace, expand the object Collection.

2  Right-click User-Defined Property Classifications. Click New.

3  In the User-Defined Property Classification dialog box, enter a name for the classification.

4  Click OK.

The new classification is displayed under User-Defined Property Classifications on the Settings tab of Toolspace and also in the list view window.

## Quick Reference

Toolspace Shortcut Menu

Settings tab ➤ Point collection ➤ right-click User-defined Property Classification ➤ New

# Creating a User-Defined Property

Add user-defined properties to User-Defined Property Classifications collection.

**To create a user-defined property**

1  On the Settings tab in Toolspace, expand the object folder.

2  Expand the User-Defined Property Classifications folder.

3  Right click a classification. Click New.

4  In the New User-defined Property Dialog Box (page 1811) dialog box, enter a name, description, and property field type.

5  Click OK.

The new property is displayed in Toolspace and also in the list view window.

## Quick Reference

Toolspace Shortcut Menu

Settings tab ➤ Point collection ➤ right-click a named User-defined Property Classification ➤ New

# Editing, Copying, or Deleting User-Defined Properties

Use the shortcut menu in the Toolspace list view to make edits to user- defined properties.

**To edit a user-defined property**

**1** On the Settings tab in Toolspace, click a User-defined Classification.

**2** In the list view window, right-click a property cell. Select one of the following:

- Edit Enumeration. For more information, see the Edit Enumeration (page 1810) dialog box.

- Delete

- Line Shading

- Copy to Clipboard

### Quick Reference

List View Shortcut menu

Right-click a user-defined property cell ➤ Edit Enumeration, Delete, Line Shading, or Copy to Clipboard

## Assigning User-Defined Properties to Point Groups

Assign a User-Defined Classification to a point group.

After you create a User-Defined Classification, you can assign it to a point group using the Classification column of the Point Groups item list view. The properties within the classification are displayed as columns in the Point Group item list view.

**To assign user-defined properties to a point group**

**1** In the drawing, define the properties within the User-Defined Classification. For more information, see Creating a User-Defined Property Classification (page 417).

**2** In Toolspace, on the Prospector tab, click the Point Groups collection.

**3** In the Point Groups list view window, click the Classification column. Select the User-Defined Classification you want to assign to the specific point group.

**4** In Toolspace, on the Prospector tab, select the point group to which you assigned the User-Defined Classification.

**5** In the point group list view window, right-click a column heading. Select the user-defined properties you want to display in the list view window.

> **NOTE** You can arrange the display of columns in the list view by dragging column headings. For more information, see Customizing a List View (page 84).

## Importing and Exporting User-Defined Property Values

Import and export User-defined property values using Point File Formats and the Import and Export commands.

When you compose a Point File Format, the user-defined property names are displayed in the Point File Formats - Select Column (page 2122) dialog box. You can select a property and assign it to a specific column.

**To import user-defined property values into the drawing and assign them to points**

**1** In the drawing, define the properties within the User-Defined Classification.

**2**  Define a point file format that contains columns with the user-defined properties. The point file must have a column containing the point identity, either Name or Number, that identifies which point is assigned the user-defined property.

**3**  Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools 🛠️ .

**4**  Click the Import Points button.

**5**  Specify information in the Import Points dialog box. For more information, see Importing Point Data (page 503).

**To export user-defined properties**

**1**  Click Output tab ➤ Export panel ➤ Export Points 🛠️ .

**2**  Specify settings in the Export Points dialog box. For more information, see Exporting Point Data (page 505).

## Quick Reference

Ribbon

Click Output tab ➤ Export panel ➤ Export Points 🛠️

Menu

Click Points menu ➤ Import/Export Points ➤ Export Points.

Command Line

ExportPoints

# Point Styles

Point styles control how point symbols display in a drawing.

Manage point styles the same way you manage all object styles in AutoCAD Civil, using the Toolspace Settings tree. In the Settings tree, all objects have a standard object style grouping called an object style collection, which you use to create, edit, copy, and delete the styles for that object. For more information, see The Object Style Collection (Settings Tree) (page 94).

When defining a point style, select from a set of default point symbols, or create a point symbol using an AutoCAD Block. For more information about creating an AutoCAD Block, see AutoCAD Help.

Assign a point style to a drawing point either when you create the point or import the point. Use either the Prospector Points list view or the Point Editor to change the point style. The point style referenced by a point is not necessarily the point style used to display the point in the drawing. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

# Overview of Point Styles

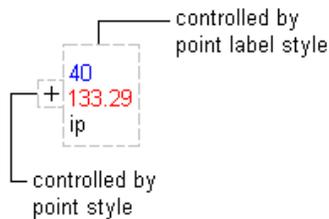
Use styles to control the appearance of a point symbols and a point labels in a drawing.

A point can directly reference two styles:

■  Point Style. Defines how a point symbol is displayed in the drawing. To change a point symbol, either edit the point style or change the point so that it references a different point style. For more information, see Point Styles (page 419).

- Point Label Style. Defines how a point is labeled in the drawing. To change the way a point is labeled, you can either edit the point label style or change the point so that it references a different point label style. For more information, see Point Labels and Tables (page 421).

The point style determines the appearance of the point symbol, and the point label style determines how the point is labeled:



Although an individual point can reference a point style and a point label style, when possible, you will want to use point groups to control the display of point symbols and point labels for points sharing similar characteristics. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

## Creating a Point Style

Use the Settings tree to create a point style.

A point style specifies the symbol that displays at the X Y location for the point in the drawing. The style can also specify scaling for the symbol and its appearance in 3D views.

**To create a point style**

1. In Toolspace, on the Settings tab, right-click the Point Styles collection ➤ New.

2. In the Point Style dialog box, click the Information (page 2114) tab. Enter a name and description for the point style.

3. To define the symbol used to display the point, click the Marker (page 2115) tab. Specify the symbol type and options for size, scaling, and rotation.

4. To define how the point displays in 3D views, click the 3D Geometry (page 2116) tab. Specify the 3D Geometry settings.

5. To define the display properties for the point style, click the Display (page 2117) tab. Specify the display properties for the symbol.

6. To view summary information about the style, click the Summary (page 2117) tab.

7. Click OK.

### Quick Reference

Toolspace Shortcut Menu

Dialog Box

Point Style (page 2114)

# Creating a Point Style Based on an Existing Point Style

Use the Settings tree to create a point style based on an existing point style.

Create a point style from an existing point style by copying an existing point style and then editing the copy.

**To create a point style from an existing point style**

1  In Toolspace, on the Settings tab, right-click the point style you want to copy. Click Copy.

    A copy is created and its properties are displayed in the Point Style dialog box.

2  In the Point Style dialog box, click the Information (page 2114) tab. Enter a name and description for the new point style.

3  Use the tabs in the Point Style (page 2114) dialog box to modify the point style's properties. For more information, see Creating a Point Style (page 420).

## Quick Reference

Toolspace Shortcut Menu

  Settings tab: right-click Point Style item  ➤  Copy

Dialog Box

# Editing a Point Style

Use the Settings tree to edit a point style.

**To edit a point style**

1  In Toolspace, on the Settings tab, right-click the desired point style. Click Edit.

2  In the Point Style (page 2114) dialog box, edit the properties of the point style.

    For more information, see Creating a Point Style (page 420).

## Quick Reference

Toolspace Shortcut Menu

  Settings tab: right-click Point Style item  ➤  Edit

Dialog Box

  Point Style (page 2114)

# Point Labels and Tables

Label and table styles control the appearance and behavior of point labels and tables in a drawing.

This section describes characteristics unique to point labels and point tables. For general information about labels and tables, see Labels and Tags (page 1463) or Tables (page 1555).

**Point Labels**

Assign a point label style to a drawing point either when you create the point or import the point. Use the Points list view on the Prospector tab or the Point Editor to change the style. The point style referenced by a point is not necessarily the point style used to display the point in the drawing. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

**Point Tables**

When you insert a point table into a drawing, specified point information is automatically displayed in the table.

## Point Label Styles

Use the Settings tree to manage and create point label styles.

You can create multiple label styles for point objects.

You can label points when you create them, or you can use point groups and description keys to specify how points are labeled in a drawing. You can also edit text on individual point labels.

For information about changing existing point label styles, see Modifying Labels in a Drawing (page 1533).

**To edit point label style defaults**

1   On the Settings tab in Toolspace, expand the Points collection.

2   Click the Label Styles collection, right click ➤ Edit Label Style Defaults.

For more information, see Adding Text Components to Labels (page 1503).

**To create a point label style**

1   On the Settings tab in Toolspace, expand the Points collection.

2   Click the Label Styles collection, right click ➤ New. For more information, see Creating and Editing Label Styles. (page 1477)

For more information, see Adding Text Components to Labels (page 1503).

**To edit point label text**

1   In the drawing, right-click a point ➤ Edit Label Text.

2   At the command line you are prompted to select a text component.

3   In the Text Component Editor dialog box, make the necessary changes.

4   Click OK.

For more information, see Adding Text Components to Labels (page 1503).

## Point Tables

Use Point tables to display information about points in a drawing.

Specify the points to include in the table by selecting them from the drawing or specifying a point group. The point information is automatically displayed in the table when you insert the point table into the drawing.

Unlike some objects, that have multiple table styles, points have only the point table style.

You create and edit tables for most objects using the same common procedures and standard dialog boxes. The procedure in this topic explains how to access the point table creation command. It provides a link to information about the Point Table Creation dialog box. For information about modifying tables, see Modifying Tables (page 1567).

**To create a point table**

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Tables Menu ➤ Add Point Table ⊞ .

2   In the Point Table Creation (page 2135) dialog box, change the generic table settings as needed.

3   Click 🔷 to select a point group that specifies the points to be included in the table.

4   Click ↖ to select points in the drawing to be included in the table.

5   Click OK.

6   Select the location for the upper-left corner of the table in the drawing.

## Quick Reference

Ribbon

Click Annotate tab ➤ Labels & Tables panel ➤ Add Tables Menu ➤ Add Point Table ⊞

Menu

Click Points menu ➤ Add Tables.

Command Line

AddPointTable

# Managing Points

You can manage points using an AutoCAD Civil project.

For example, you can add points to a project and protect them so they can be viewed and copied by others, but not modified. For general information about project management, see Project Management (page 125). For information about working with points in a project management environment, see Working with Vault Project Points (page 166).

**NOTE** Survey points that are created using the Prospector Survey tab are not included in project management operations even if they are selected. For example, any Survey points included in the selection list during the Add to Project command are not added to the project.

You can populate a project with points by creating the points in the drawing and adding them to the project. For more information, see Creating a Project Point Database.

For a recommended procedure for checking out, editing, and checking in a large number of project points, see Modifying A Large Number of Project Points (page 494).

# Locking and Unlocking Points

Lock a point to prevent its properties from being modified in a drawing.

A locked point is designated by  in the Prospector tree and the Point collection list view. The icon is displayed only if the Toolspace tree drawing state icons are displayed. For more information, see Drawing Item State Icons (page 141).

**NOTE** A locked point is locked only in the drawing. A protected point is protected at the project level. For more information, see Protecting Project Points (page 171).

A locked point cannot have any of its properties changed, including its point style and point label style. It cannot be edited, deleted, or overwritten. However, you can reposition its label in the drawing.

When you are working with a drawing point that is not related to a project point, lock the point to prevent changes as previously described. Unlock the point to change it, including changing its XYZ values.

When you work with a local copy of a project point or Survey point, the locking behavior of a point changes. When you check a drawing point into a project, the local copy of the point is automatically locked, so that no changes can be made to it as described previously.

If you unlock a point with either a project state of checked in, checked out to other, or protected, you cannot modify its XYZ values, but you can change its point styles.

If you need to change a local copy of a project point in a drawing, use the Allow Checked In Points To Be Modified setting. For more information, see Editing the Update Points Settings (page 412). It is important to remember that any changes you make to the point can never be checked in to the project.

**WARNING** If you edit points without checking them out, you cannot check the points in to the project. Your changes exist only in the drawing in which you made them.

Lock or unlock all the points in a drawing using the Points collection shortcut menu. Lock or unlock individual drawing points using the list view shortcut menu. Lock or unlock all the points in a point group point list using a single command.

**To lock or unlock points**

1  In Toolspace, on the Prospector tab, click the Points collection to display the Points list view.

2  Select the desired points. For more information, see Selecting Items in a List View (page 84).

3  Right-click then click Lock or Unlock.

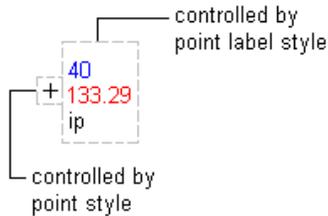
# Controlling the Appearance of Points in a Drawing

Several factors control how a point displays in a drawing.

**Point Style and Point Label Style**

The point style and the point label style control the basic appearance of a point symbol and label in a drawing.

The point style determines the appearance of the point symbol, and the point label style determines how the point is labeled:



Each individual drawing point can directly reference a point style and a point label style. These *individual point styles* are assigned when a point is created. The individual point styles assigned during point creation are determined either by description key matching or by the styles specified in the Create Points dialog box. A point is not required to reference a point style or point label style. (If a point does not reference a point style, the style referenced by the layer on which the point is created is used.

If a point does not reference a point style or point label style, the point style or point label style property for the point is empty when viewed in the Point Editor or the Points list view. You can change or remove individual point styles using the Point Editor or Points list view.

A point group can reference a default point style and a default point label style. View or change these point group default styles using the Information tab (page 2108) or the Overrides tab (page 2113) on the Point Group Properties dialog box. If you change the style on one tab, the other tab updates to reflect the change.

In addition, the default styles for a point group can be designated as point group override styles. Use the check box on the Overrides tab (page 2113) of the Point Group Properties dialog box to specify that a point group style is an override style.

The following describes, in order of precedence, which of the previously described styles are used to display a point in a drawing:

**Style**

| | |
|---|---|
| Point Group Override Styles | The Object Style Collection (Settings Tree) (page 94)<br>If the point belongs to more than one point group that specifies override styles, the override styles specified by the highest point group in the point group display order are used to draw the point. For more information, see Changing the Point Group Display Order (page 526). |
| Individual Point Styles | The Label Styles Collections (Settings Tree) (page 95) |
| Point Group Default Styles | Point File Formats Collection (Settings Tab) (page 496) |
| The _All Points group | Description Key Sets Collection (Settings Tree) (page 538) |

**NOTE** All points belong to the _All Points point group. To display all the points in a drawing that use the same style, specify an override style for the _All Points point group, and move it to the top of the point group display order.

**Point Style Display Settings**

Use the Point Style display settings to control whether the point symbol and/or the point label is drawn for any point that is displayed using the point style. On the Display tab in the Point Style dialog box, the Visible column controls the visibility of point symbols and point labels. To change the visibility of point symbols, change the visibility for the Marker component. To change the visibility of point labels, change the visibility for the Label component.

**Layers**

Use the point layer to control the appearance of a point in a drawing.

Specify a point layer for a point by setting its Layer property. Set the Layer property either during point creation (using description key matching or the options in the Create Points dialog box) or after a point is created (using the Point Editor or the Points list view).

If a point belongs to more than one point group, the highest point group controls the visibility of the point in the point group display order.

A point can be displayed using the properties of a layer, such as visibility, color, line type, and line weight. If an individual point style or point label style is used to display a point (as described earlier in this topic), the ByBlock or ByLayer specifications in the point style or point label style refer to the layer that is assigned to the point.

# Printing Points

The Copy To Clipboard command lets you copy a list of drawing or project points to another application for printing.

To print a list of points in a drawing or project, click the drawing or project Prospector tree collection to display the points in a list view. Right-click the list view and select Copy To Clipboard to copy the list view into a file you can print. For information, see Copying Items from a List View (page 86).

# Zooming and Panning to Points

Use the list view shortcut menu to automatically zoom or pan to points in the drawing.

**To zoom or pan to points**

**1**  In Toolspace, on the Prospector tab, click the drawing Points collection.

**2**  In the list view, select the points you want to zoom or pan to. For more information, see Selecting Items in a List View (page 84).

**3**  Right-click and click Zoom To or Pan To.

**Quick Reference**

Toolspace Shortcut Menu

Prospector tab: Points collection ➤ right-click points in List View ➤ Zoom To, Pan To

# Creating Points

You can use the Create Points dialog box to create points using a variety of methods.

For standardization, you can use a drawing template that contains point settings, point styles, and point label styles.

In the Create Points dialog box, choose commands from the following lists:

■ Miscellaneous

■ Intersection

■ Alignments

■ Surface

■ Interpolate

■ Slope

■ Import Points

You can expand the Create Points dialog box to access the settings that are relevant to point creation. If you change the settings in this dialog box the changes are reflected in the CreatePoints command settings. For more information, see Edit Feature Settings - Point Dialog Box (page 2103).

You can also use the Civil transparent commands in combination with the Create Points Manual command to create points using known information such as angle and distance. For more information about the Civil transparent commands, see Transparent Commands (page 1581).

You can use description key substitution while creating drawing points to automatically assign point style, point label style, layer, full description, and scale and rotation of the point symbol. For more information, see Understanding Description Keys (page 537).

## Before You Create Points

Save time and effort by considering certain issues before creating points.

The following factors can affect both the point creation process and the way you work with points after they are created:

■ When creating drawing points, work in a drawing based on a template which contains the point settings, point styles, point label styles, and description keys you want to use when creating the point. For more information, see Drawing Templates (page 109).

■ Plan how you will control the point style and point label style used to draw points in a drawing. You can set the point styles at the point group level, or at the point level, and automatically assign this method of style selection during point creation. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

■ If you plan to use description keys to assign styles, layers, and other information when creating drawing points, make sure that the description keys are present in the drawing before you create the points. For more information, see Understanding Description Keys (page 537).

■ Specify settings that control, among other things, how you are prompted during the point creation commands and how the created points are numbered. For more information, see Editing the Default Point Creation Settings (page 415).

**NOTE** If prompted for an elevation or description and you want to create a point without these, enter a period (.) at the prompt.

# Creating Points Using Miscellaneous Methods

Use the icons in the Miscellaneous list to access commands that are commonly used for creating points.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in a drawing. For more information, see Before You Create Points (page 427).

## Creating Points at Specified Coordinates

Creates a point at specified or selected location in the drawing.

Enter X, Y (and Z, if prompted) coordinates at the command line, or click a location in the drawing.

For more information, see Specifying Locations in a Drawing (page 115)

**To create points at specified coordinates**

1 Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2 Click Home tab ➤ Create Ground Data panel ➤ Points Menu ➤ Create Points - Miscellaneous ➤ Manual ⊕.

> **NOTE** You can also use transparent commands to specify point locations within a larger operation, such as the creation of an alignment or a parcel lot line. Using transparent commands, you can calculate the location for a point from information such as angle and distance, or from point object information, such as a point number. For more information, see Transparent Commands (page 1581).

3 Specify the location for the point in the drawing. For more information, see Specifying Locations in a Drawing (page 115).

4 If prompted, enter the point name, description, and elevation.

5 Optionally, repeat steps 4 and 5.

6 Press Enter to end the command.

> **NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

# Creating Points by Geodetic Direction and Distance

Creates a point by using a specified geodetic direction.

From the starting point, enter the geodetic azimuth and the geodesic distance to the location where you want to create the point. To use this command, you must assign a coordinate system to the drawing.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in a drawing. For more information, see Before You Create Points (page 427).

**To create points by geodetic direction and distance**

1 Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2 Set the zone and transformation settings for the drawing.

3 Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Miscellaneous ➤ Geodetic Direct ⊕ .

4 Specify a starting point.

5 Enter the geodetic azimuth from the point specified in Step 5 to the location where you want to create the point.

6 Enter the geodesic distance, which is the distance measured from the point specified in Step 5 to the location where you want to create the point.

7 If prompted, enter the point name, description, and elevation.

8 Optionally, repeat steps 5-8.

9 Press Enter to end the command.

---

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

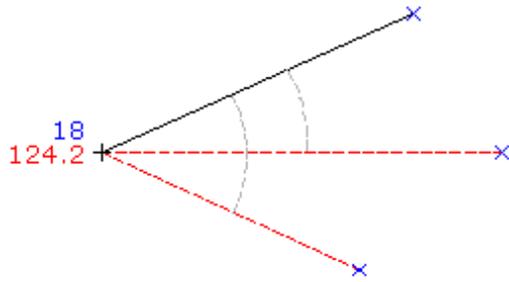
## Creating Points by Resection

Creates a point at a position calculated from the measured angles between three known points.

To create the point, enter the backsight (reference) point, then enter the two points that are sighted on, followed by the angles for each of the sighted points.



**To create points by resection**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2   Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Miscellaneous ➤ Resection .

3   Specify the first point, which is the backsight (or reference) point.

4   Specify the second point.

5   Specify the third point.

6   Enter the angle between the first point and the second point.

7   Enter the angle between the first point and the third point.

8   If prompted, enter the point name, description, and elevation.

9   Optionally, repeat steps 4-9.

10   Press Enter to end the command.

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

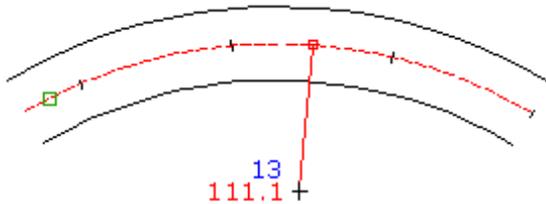
## Creating Points by Station and Offset

Creates a point at a specified station and offset distance from a line, polyline, feature line, lot line, or arc.

Use the station and the offset to specify the location of the point.



**To create points by station and offset**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2   Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Miscellaneous ➤ Station/Offset Object  .

3   Select a line, polyline, feature line, lot line, or arc.

4   Enter the starting station or press Enter to accept the default.
    The ending station is automatically calculated.

5   Enter the station at which you want to create the point or press Enter to accept the default.

6   Enter the offset distance.

7   If prompted, enter the point name, description, and elevation.

8   Optionally, repeat steps 4-8.

9   Press Enter to end the command.

---

**NOTE**  Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

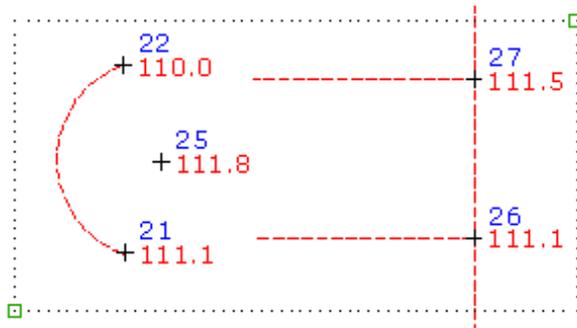
## Creating Points at Object Vertices and Critical Geometric Points

Creates points automatically at the endpoints of lines, feature lines, or lot lines, or at the endpoints and center point of arcs.

Points are created from a selection set of objects. Points are not created where lines cross unless one of the points is an end point.



To create a point where lines cross each other, use the Create Points Manual command.

**To create points at object vertices and critical geometric points**

1　Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2　Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Miscellaneous ➤ Automatic .

3　Select objects. You can select lines, feature lines, lot lines, and arcs.

4　A point is placed at each vertex of the selected object.

5　For each point, if prompted, enter the point name, description, and elevation.

6　Optionally, repeat steps 4-5.

**7** Press Enter to end the command.

---

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

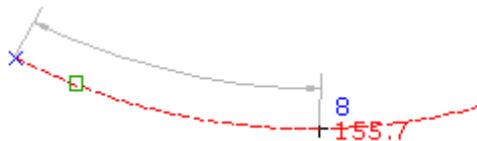
## Creating Points Along a Line or a Curve

Creates points along a line, feature line, lot line, or arc at a specified distance from an end point.

Click near the end point from which you want to measure the distance and enter a distance to specify the location for the created point along the object.



**To create points along a line or a curve**

**1** Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

**2** Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Miscellaneous ➤ Along Line/Curve ⛛ .

**3** Select a line, lot line, feature line, or arc.

The end point nearest to the point you selected is highlighted.

**4** Enter the distance from the end point.

**5** If prompted, enter the point name, description, and elevation.

**6** Optionally, do one of the following:

■ Enter another distance from the start point of the selected object and follow the prompts as previously described.

■ Press Enter, select another object, and follow the prompts as previously described.

**7** Press Enter twice to end the command.

---

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

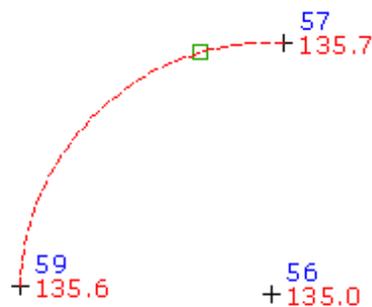
## Creating Points on a Line or Curve

Creates a point at the endpoint of a line, feature line, lot line, or arc and on points of intersection (PIs) and radius points for arcs.

Locations of the specified points are created for an arc. Select one object at a time. If you select intersecting objects, duplicate points are not created.


When you create points using this command, you work with one object at a time. After points have been added using a selected object, you can select another object and add points using that object. If the objects you select and the options you specify while using the command would result in the creation of duplicate points, for example, at the shared endpoints of two lines, only a single point is added. Duplicate points are not created.

**To create points on a line or curve**

1 Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2 Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Miscellaneous ➤ On Line/Curve .

3 Select a line, lot line, feature line, or arc.

4 Points are placed at geometric points on the selected object.

5 For each point, if prompted, enter the point name, description, and elevation.

6 Optionally, repeat steps 4-5.

7 Press Enter to end the command.

---

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

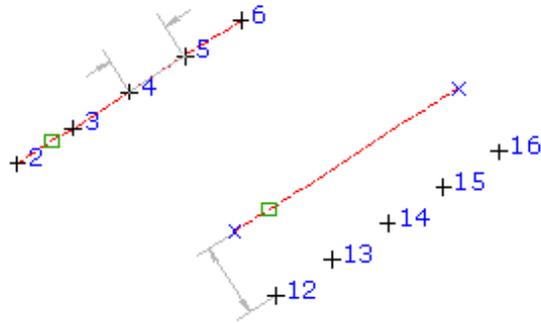
Create Points (page 2117)

## Creating a Specific Number of Points Along an Object by Dividing the Object

Creates a specific number of evenly spaced points along a line, feature line, lot line, or arc.

Specify the number of segments, and a point is placed at each vertex. Points can placed on the object or at an offset.


When you create points using this command, you work with one object at a time. After points have been added using a selected object, you can select another object and add points using that object. If the objects you select and the options you specify while using the command would result in the creation of duplicate points, for example, at the shared endpoints of two lines, only a single point is added. Duplicate points are not created.

**To create a specific number of points along an object by dividing the object**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Miscellaneous ➤ Divide Object .

3  Select a line, lot line, feature line, or arc.

4  Enter the number of segments to divide the object into.

5  Enter the offset.
   A series of equally spaced points are placed along the object at the specified offset.

6  For each point, if prompted, enter the point name, description, and elevation.

7  Optionally, repeat steps 4-7.

8  Press Enter to end the command.

---

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

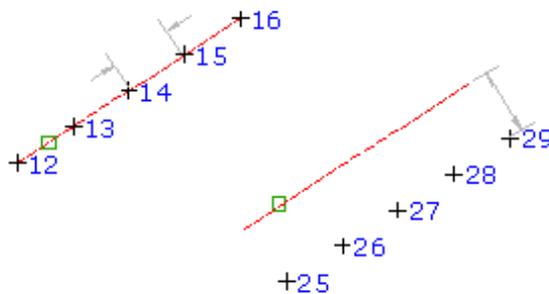
## Creating Points on an Object Using Distance Intervals

Creates points that are a specified distance apart along a line, feature line, lot line, or arc.

Specify the start and end stations on the object, distance (interval) between points, and optional offset.

Use a specified interval and offset to place points along an object.



When you create points using this command, you work with one object at a time. After points have been added using a selected object, you can select another object and add points using that object. If the objects you select and the options you specify while using the command would result in the creation of duplicate points, for example, at the shared endpoints of two lines, only a single point is added. Duplicate points are not created.

**To create points on an object using distance intervals**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2   Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Miscellaneous ➤ Measure Object ⟨icon⟩ .

3   Select a line, lot line, feature line, or arc.

4   Enter the starting station or press Enter to accept the default.

5   Enter the ending station or press Enter to accept the default.

6   Enter the offset.

7   Enter the distance interval.

    Points are placed along the object at the specified offset and interval.

8   For each point, if prompted, enter the point name, description, and elevation.

9   Optionally, repeat steps 4-9.

10  Press Enter to end the command.

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

## Creating Points on Polylines at a Specified Elevation

Creates points at the vertices of a polyline at a specified elevation.

Enter the elevation and then select the polyline. Points are placed at the vertices at the specified elevation.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in a drawing. For more information, see Before You Create Points (page 427).

**To create points on polylines at a specified elevation**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Miscellaneous ➤ Polyline Vertices - Manual .

3  Enter the elevation.

4  Select a polyline.
   Points are placed at the vertices of the polyline at the specified elevation.

5  For each point, if prompted, enter the point name and description.

6  Optionally, repeat steps 4-6.

7  Press Enter to end the command.

## Creating Points at Intersections

Use the icons in the Intersection list to access commands that you can use for creating points at intersections.

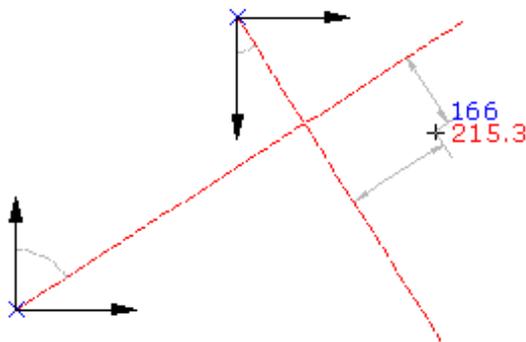
Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in a drawing. For more information, see Before You Create Points (page 427).

### Creating Points at a Direction/Direction Intersection

Creates a point at the intersection of two directions, each defined by a point and a bearing or azimuth.

Specify values by picking points in the drawing, using transparent commands, or entering values at the command line.

Create a point at the intersection by specifying the offset distance from each direction line.



**To create a point at a direction/direction intersection**

1 Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2 Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Intersections ➤ Direction/Direction ⬚ .

3 Specify the start point by doing one of the following:
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify the point.

4 Specify the direction from the start point by doing one of the following:
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify the second point.

■ Enter Z. Enter the azimuth of the direction line.

■ Enter B. Specify the quadrant and the bearing.

**5** Specify the offset distance by doing one of the following:
■ Enter a distance.

■ Pick a point in the drawing to define the offset.

■ Use Transparent commands to specify a point to define the offset.

**6** Repeat steps 4-6 to define the second direction line.

**7** Enter a description, or press Enter to skip the description.

**8** Enter an elevation for the point, or press Enter to skip the elevation.

---

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

---

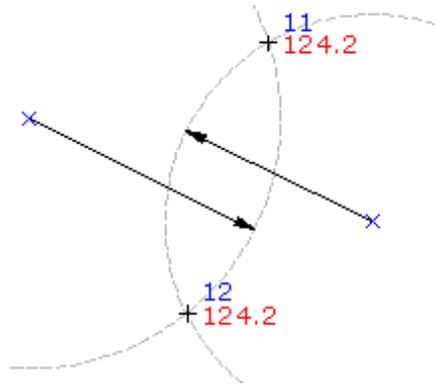
## Creating Points at a Distance/Distance Intersection

Creates a point at the intersection of two distances, each defined by a radius length.

Specify values by picking points in the drawing, using transparent commands, or entering values at the command line.


**To create points at a distance/distance intersection**

1 Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2 Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Intersections ➤ Distance/Distance 🔯 .

3 Specify the radial point by doing one of the following:
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify the radial point.

4 Specify the radius by doing one of the following:
   ■ Enter a radius value.
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify the radius.

5 Repeat steps 5-6 to specify a location for the radial point.

   In the drawing, an X marks each intersection point. If only one intersection is located then the point is automatically created.

6 Specify the intersection point by doing one of the following:
   ■ Click near the X on which you want to create the point.
   ■ Enter A to place points at both intersections.

7 Enter a description, or press Enter to skip the description.

8 Enter an elevation for the point, or press Enter to skip the elevation.

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

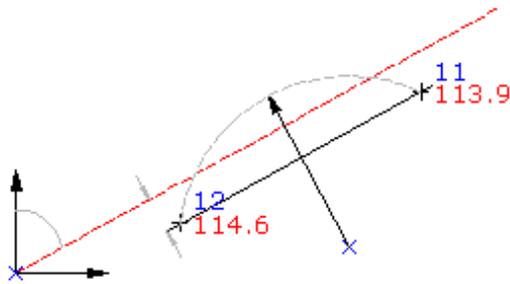
## Creating Points at a Direction/Distance Intersection

Creates a point at the intersection of a direction (line) and distance (circle).

Specify values by picking points in the drawing, using transparent commands, or entering values at the command line.



**To create points at a direction/distance intersection**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Intersections ➤ Direction/Distance ⤧.

3  Specify the radial point by doing one of the following:
   ■  Pick a point in the drawing.

   ■  Use Transparent commands to specify the point.

4  Specify the radius by doing one of the following:
   ■  Enter a radius value.

   ■  Pick a point in the drawing.

   ■  Use Transparent commands to specify the radius.

5  Specify the start point by doing one of the following:
   ■  Pick a point in the drawing.

   ■  Use Transparent commands to specify the point.

**6** Specify the direction from the start point by doing one of the following:

■ Pick a point in the drawing.

■ Use Transparent commands to define the point.

■ Enter Z, and then enter the azimuth of the direction line.

■ Enter B, and then specify the quadrant and the bearing.

**7** Specify the offset distance by doing one of the following:

■ Enter a distance.

■ Pick a point in the drawing.

■ Use Transparent commands to specify a point to define the offset.

In the drawing, an X marks each intersection point. If only one intersection is located then the point is automatically created.

**8** Specify the intersection point by doing one of the following:

■ Click near the X on which you want to create the point.

■ Enter A to place points at both intersections.

**9** Enter a description, or press Enter to skip the description.

**10** Enter an elevation for the point, or press Enter to skip the elevation.

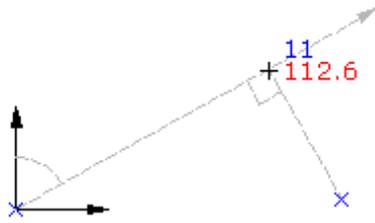
## Creating Points at a Direction/Perpendicular Intersection

Creates a point that is on a direction line and perpendicular to a selected point.

Select a point in the drawing to create a point on the direction line that is perpendicular to the selected point.


**To create points at a direction/perpendicular intersection**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Intersections ➤ Direction/Perpendicular .

3  Specify the start point by doing one of the following:
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify the point.

4  Specify the direction from the start point by doing one of the following:
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to define the point.
   ■ Enter Z, and then enter the azimuth of the direction line.
   ■ Enter B, and then specify the quadrant and the bearing.

5  Specify the offset distance by doing one of the following:
   ■ Enter a distance.
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify a point to define the offset.

6  Specify the perpendicular point by doing one of the following:
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify the perpendicular point.

7  Enter a description, or press Enter to skip the description.

8  Enter an elevation for the point, or press Enter to skip the elevation.

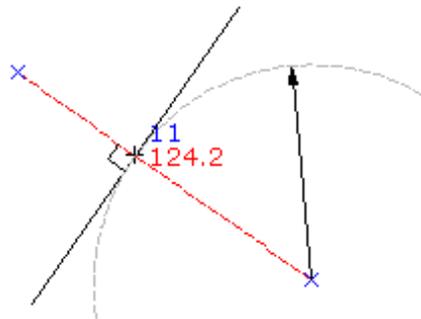
**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

### Quick Reference

## Creating Points at a Distance/Perpendicular Intersection

Creates a point that is radial to both a circle and a selected point.

Specify values by picking points in the drawing, using transparent commands, or entering values at the command line.



**To create points a distance/perpendicular intersection**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2   Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Intersections ➤ Distance/Perpendicular .

3   Specify the radial point by doing one of the following:
    ■ Pick a point in the drawing.

    ■ Use Transparent commands to specify the point.

4   Specify the radius by doing one of the following:
    ■ Enter a radius value.

    ■ Pick a point in the drawing.

■ Use Transparent commands to specify the radius.

**5** Enter a description, or press Enter to skip the description.

**6** Enter an elevation for the point, or press Enter to skip the elevation.

**9** Enter an elevation for the point, or press Enter to skip the elevation.

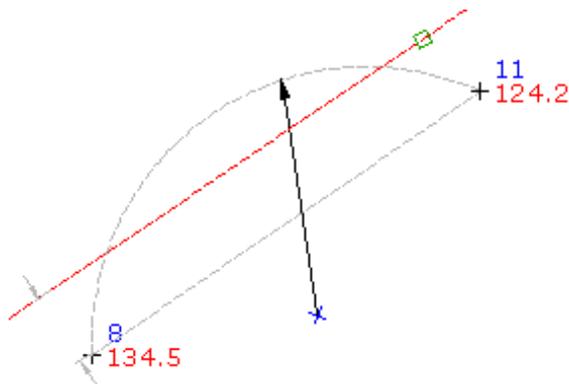
**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

**Quick Reference**

## Creating Points at a Distance/Object Intersection

Creates a point at the intersection of an object and a radial distance.

Specify values by picking points in the drawing, using transparent commands, or entering values at the command line. Points are offset from the intersection of an object and a radial distance.



**To create points at a distance/object intersection**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2   Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Intersections ➤ Distance/Object ↕⊕ .

3   Select an object.

4   Specify the offset distance by doing one of the following:

   ■  Enter a distance.

   ■  Pick a point in the drawing.

   ■  Use Transparent commands to specify a point to define the offset.

**5** Specify the radial point by doing one of the following:

- Pick a point in the drawing.

- Use Transparent commands to specify the point.

**6** Specify the radius by doing one of the following:

- Enter a radius value.

- Pick a point in the drawing.

- Use Transparent commands to specify the radius.

In the drawing, an X marks each intersection point. If only one intersection is located then the point is automatically created.

**7** Specify the intersection point by doing one of the following:

- Click near the X on which you want to create the point.

- Enter A to place points at both intersections.

**8** Enter a description, or press Enter to skip the description.

**9** Enter an elevation for the point, or press Enter to skip the elevation.

---

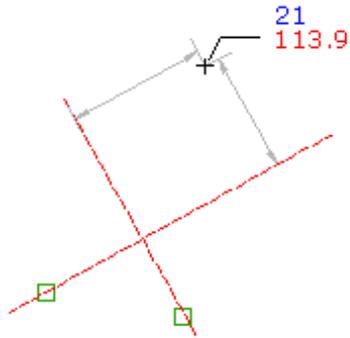
## Creating Points at an Object/Object Intersection

Creates a point at the intersection of lines, arcs, lot lines, or feature lines.

If the objects do not intersect, the command extends either object to determine the intersection point. A point is offset from the intersection of two objects.


**To create points at an object/object intersection**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Intersections ➤ Object/Object 🔶 .

3  Select an object.

4  Specify the offset distance by doing one of the following:
   ■  Enter a distance.
   ■  Pick a point in the drawing.
   ■  Use Transparent commands to specify a point to define the offset.

5  Select the second object.

6  Specify the offset distance by doing one of the following:
   ■  Enter a distance.
   ■  Pick a point in the drawing.
   ■  Use Transparent commands to specify a point to define the offset.

   In the drawing, an X marks each intersection point. If only one intersection is located then the point is automatically created.

7  Specify the intersection point by doing one of the following:
   ■  Click near the X on which you want to create the point.
   ■  Enter A to place points at both intersections.

8  Enter a description, or press Enter to skip the description.

9  Enter an elevation for the point, or press Enter to skip the elevation.

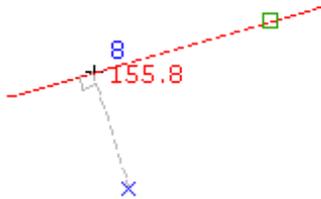
## Creating Points at a Perpendicular Intersection

Creates a point along a line or arc object, perpendicular, or radial to a specified point.

From a specified point, the created point is perpendicular on a line but radial on a curve. The point is perpendicular to a selected point and a line.



**To create points at a perpendicular intersection**

1 Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2 Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Intersections ➤ Perpendicular .

3 Select an object.

4 Specify the perpendicular point by doing one of the following:
   ■ Pick a point in the drawing.

   ■ Use Transparent commands to specify the perpendicular point.

5 Enter a description, or press Enter to skip the description.

**6** Enter an elevation for the point, or press Enter to skip the elevation.

## Creating Points at a Direction/Alignment Intersection

Creates a point either at the intersection of a direction line and an alignment or at a point offset from the intersection.

Specify values by picking points in the drawing, using transparent commands, or entering values at the command line.

Create a point that is offset from the intersection of a direction and an alignment by selecting a direction line and then specifying the offset from the direction line and the offset from the alignment.

**To create points at a direction/alignment intersection**

**1** Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

**2** Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Intersections ➤ Direction/Alignment ↓⊕ .

**3** Select an alignment object.

**4** Specify the offset distance by doing one of the following:
   ■ Enter a distance.
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify a point to define the offset.

**5** Specify the start point by doing one of the following:
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify the point.

**6** Specify the direction from the start point by doing one of the following:
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to define the point.
   ■ Enter Z, and then enter the azimuth of the direction line.
   ■ Enter B, and then specify the quadrant and the bearing.

**7** Specify the offset distance by doing one of the following:
   ■ Enter a distance.
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify a point to define the offset.

In the drawing, an X marks each intersection point. If only one intersection is located then the point is automatically created.

**8** Specify the intersection point by doing one of the following:
   ■ Click near the X on which you want to create the point.
   ■ Enter A to place points at both intersections.

**9** Enter a description, or press Enter to skip the description.

**10** Enter an elevation for the point, or press Enter to skip the elevation.

---

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

---

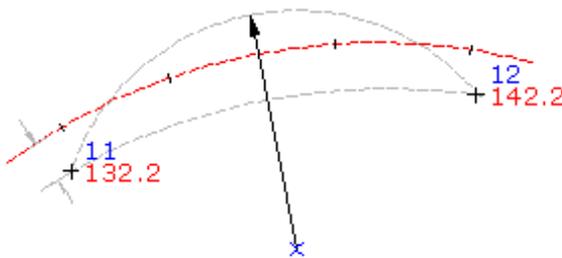
## Creating Points at a Distance/Alignment Intersection

Creates a point at the intersection of a distance line and an alignment.

The intersection is located where the radial distance from a specified point crosses the alignment.



**To create points at distance/alignment intersection**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2   Home tab ➤ Create Ground Data panel ➤ Points Menu ➤ Create Points - Intersections ➤ Distance/Alignment ↑⊕ .

3   Select an alignment object.

4   Specify the offset distance by doing one of the following:
    ■  Enter a distance.
    ■  Pick a point in the drawing.
    ■  Use Transparent commands to specify a point to define the offset.

5   Specify the radial point by doing one of the following:
    ■  Pick a point in the drawing.
    ■  Use Transparent commands to specify the point.

    In the drawing, an X marks each intersection point. If only one intersection is located then the point is automatically created.

6   Specify the radius by doing one of the following:
    ■  Enter a distance.
    ■  Pick a point in the drawing.

- ■ Use Transparent commands to specify a point to define the offset.

7  Specify the intersection point by doing one of the following:
   - ■ Click near the X on which you want to create the point.

   - ■ Enter A to place points at both intersections.

8  Enter a description, or press Enter to skip the description.

9  Enter an elevation for the point, or press Enter to skip the elevation.

---

**NOTE**  Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

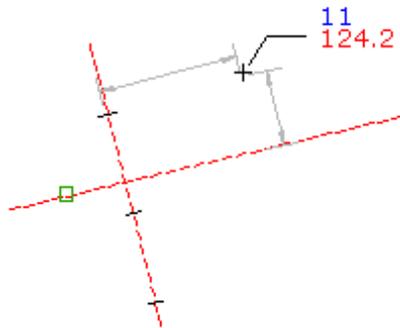
## Creating Points at an Object/Alignment Intersection

Creates a point at either the intersection of any object and an alignment or at an offset from the intersection.

If the line or arc object does not intersect the alignment, the command extends either object to determine the intersection point.


**To create points at an object/alignment intersection**

1 Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2 Home tab ➤ Create Ground Data panel ➤ Points Menu ➤ Create Points - Intersections ➤ Object/Alignment ⟨icon⟩ .

3 Select an alignment object.

4 Specify the offset distance by doing one of the following:
   ■ Enter a distance.
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify a point to define the offset.

5 Select an object.

6 Specify the offset distance by doing one of the following:
   ■ Enter a distance.
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify a point to define the offset.

   In the drawing, an X marks each intersection point. If only one intersection is located then the point is automatically created.

7 Specify the intersection point by doing one of the following:
   ■ Click near the X on which you want to create the point.
   ■ Enter A to place points at both intersections.

8 Enter a description, or press Enter to skip the description.

9 Enter an elevation for the point, or press Enter to skip the elevation.

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

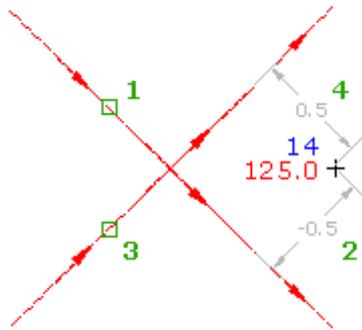
## Creating Points at an Alignment/Alignment Intersection

Creates a point either at the intersection of two alignments or an offset distance from one or both alignments.

There must be an alignment intersection in the drawing. Pick two intersecting alignments to create a point that is offset from the intersection.



**To create points at an alignment/alignment intersection**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2   Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Intersections ➤ Alignment/Alignment ⊕ .

3   Select an alignment object.

4   Specify the offset distance by doing one of the following:
     ■   Enter a distance.
     ■   Pick a point in the drawing.
     ■   Use Transparent commands to specify a point to define the offset.

5   Select a second alignment object.

6   Specify the offset distance by doing one of the following:
     ■   Enter a distance.
     ■   Pick a point in the drawing.
     ■   Use Transparent commands to specify a point to define the offset.

     In the drawing, an X marks each intersection point. If only one intersection is located then the point is automatically created.

7   Specify the intersection point by doing one of the following:
     ■   Click near the X on which you want to create the point.
     ■   Enter A to place points at both intersections.

8   Enter a description, or press Enter to skip the description.

**9** Enter an elevation for the point, or press Enter to skip the elevation.

---

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

## Creating Points Based on Horizontal Alignments

Use the icons in the Alignment list to access commands that you can use to create points relative to a horizontal alignment.

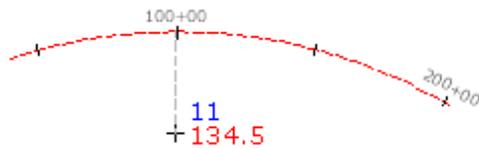
Create points either on a horizontal alignment or at an offset from the alignment.

If you want the point description to be taken from the object, specify Automatic - Object in the Prompt For Descriptions section of the Points Creation settings. The alignment name and station display in the Raw Description column in the Point Editor.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in a drawing. For more information, see Before You Create Points (page 427).

## Creating Points Offset from Alignment Stations

Creates that are offset from stations on an alignment.

Use this command to create ROWs, shoulders, and passing lanes.


**To create points offset from alignment stations**

**1**  Choose default settings, style, layers, point group, and description keys. For more information, see Before You Create Points (page 427).

**2**  Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Alignments ➤ Station/Offset  .

**3**  Select an alignment.

> **NOTE** If the selected alignment has associated profiles, the Select a Profile dialog box displays. You can select a profile from the list and the elevations for the points you create will be set from that profile. If there is no profile section for a station on the alignment, or if you select <none>, the point elevation will be set according to the Points Creation settings in the Create Points dialog box.

**4**  Enter the station number from which you want to offset a point. Do not include the station plus (+) sign.

**5**  Enter the offset. If you have selected a profile, the offset value for the profile displays as the default.

**6**  If prompted, enter the name, description, and elevation for the point.

> **NOTE**  If you want the point description to be taken from the object, specify Automatic - Object in the Prompt For Descriptions section of the Points Creation settings. The alignment name and station display in the Raw Description column in the Point Editor.

**7**  Optionally, repeat steps 4-7.

**8**  Press Enter to end the command.

> **NOTE**  Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

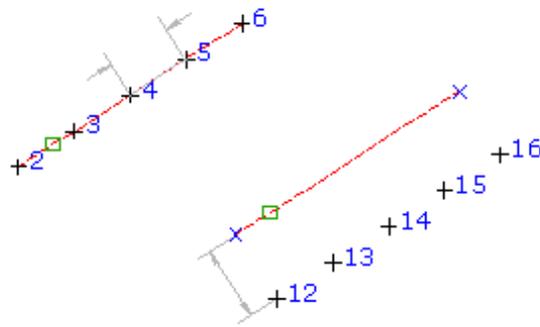
Create Points (page 2117)

## Creating a Specific Number of Points Along an Alignment

Creates points that are a specified distance apart along an alignment.

Specify the number of segments for the alignment. Points can be placed at each vertex on the alignment or at a specified offset.



Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create a specific number of points along an alignment**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2   Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Alignments ➤ Divide Alignment 🔯 .

3   Select an alignment.

> **NOTE**  If the selected alignment has associated profiles, the Select a Profile dialog box displays. You can select a profile from the list and the elevations for the points you create will be set from that profile. If there is no profile section for a station on the alignment, or if you select <none>, the point elevation will be set according to the Points Creation settings in the Create Points dialog box.

4   Enter the number of segments into which you want to divide the selected alignment.

The command calculates the distances between points by dividing the total length of the alignment by the number of segments specified.

5   Enter the offset. If you have selected a profile, the offset value for the profile displays as the default.

A series of equally spaced points are placed along the alignment at the specified offset.

6   If prompted, for each point, enter a point name, description, and elevation.

**NOTE** If you want the point description to be taken from the object, specify Automatic - Object in the Prompt For Descriptions section of the Points Creation settings. The alignment name and station display in the Raw Description column in the Point Editor.

**TIP** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

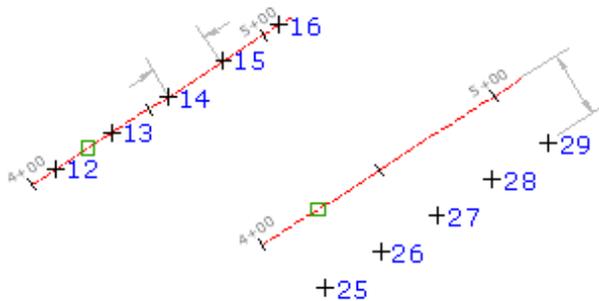
## Creating Points on an Alignment Using a Distance Interval

Creates points at equally spaced intervals along an alignment.

Specify the distance between points, and optionally an offset distance from the alignment.



Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create points on an alignment based on a distance interval**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

**2** Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Alignments ➤ Measure Alignment ⚘ .

**3** Select an alignment.

> **NOTE** If the selected alignment has associated profiles, the Select a Profile dialog box displays. You can select a profile from the list and the elevations for the points you create will be set from that profile. If there is no profile section for a station on the alignment, or if you select <none>, the point elevation will be set according to the Points Creation settings in the Create Points dialog box.

**4** Enter the starting station or press Enter to accept the default.

**5** Enter the ending station or press Enter to accept the default.

**6** Enter the offset. If you have selected a profile, the offset value for the profile displays as the default.

**7** Enter the interval.

Points are placed along the alignment at the specified offset and interval.

**8** If prompted, for each point, enter a point name, description, and elevation.

> **NOTE** If you want the point description to be taken from the object, specify Automatic - Object in the Prompt For Descriptions section of the Points Creation settings. The alignment name and station display in the Raw Description column in the Point Editor.

> **TIP** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

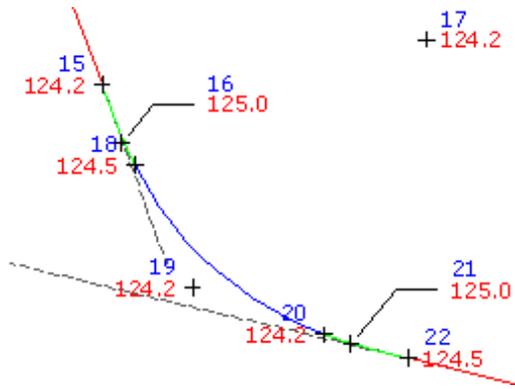
## Creating Points at the Geometry Points of Alignments

Creates a point at every geometry point on an alignment.

Geometry points are points of curvature (PC), points of tangency (PT), spiral-curves (SC), curve-spirals (CS), tangent spirals (TS), spiral-tangents (ST), and points of intersection (PI).


When creating points using this command, you are not prompted for a description if the Prompt For Descriptions Points Creation setting is set to Automatic-Object. The raw and full description for the point is automatically assigned based on the type of point created. The assigned description displays in the drawing if the current point label style contains a raw description or a full description text component.

The following table describes alignment vertex labels that are created and the description that is assigned based on the point type:

| Created Label | Definition |
| --- | --- |
| BOA | Beginning of Alignment |
| PI | Point of Intersection |
| CPI | Curve Point of Intersection |
| PT | Point of Tangency |
| PC | Point of Curvature |
| SPI | Spiral Point of Intersection |
| TS | Tangent-Spiral intersection |
| CS | Curve-Spiral intersection |
| ST | Spiral-Tangent intersection |
| CC | Curve Center or radius point |
| EOA | End of Alignment |

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create points at the geometry points of alignments**

1 Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2 Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Alignments ➤ At Alignment Geometry ⊕ .

3 Select an alignment.

**NOTE** If the selected alignment has associated profiles, the Select a Profile dialog box displays. You can select a profile from the list and the elevations for the points you create will be set from that profile. If there is no profile section for a station on the alignment, or if you select <none>, the point elevation will be set according to the Points Creation settings in the Create Points dialog box.

**4** Enter the starting station or press Enter to accept the default.

**5** Enter the ending station or press Enter to accept the default.

Points are placed along the alignment object.

**6** If prompted, for each point, enter a point name and elevation.

The created points are automatically labeled using the current label style. If the current label style contains either a raw description or a full description text component, the vertex type displays in the label.

**NOTE** If you want the point description to be taken from the object, specify Automatic - Object in the Prompt For Descriptions section of the Points Creation settings. The alignment name and station display in the Raw Description column in the Point Editor.

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

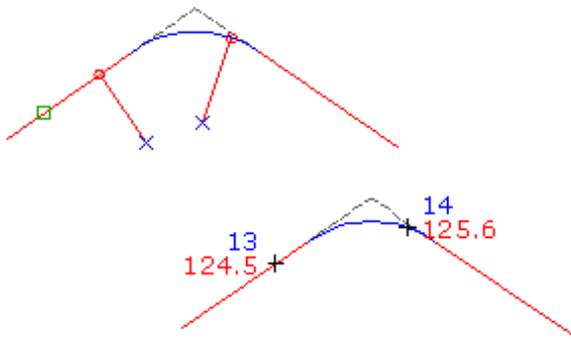
## Creating Radial or Perpendicular Points on Alignments

Creates a point on an alignment that is radial or perpendicular to a specified point.

From specified point, the created point is perpendicular on a line and radial on a curve.


Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create radial or perpendicular points on alignments**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Alignments ➤ Radial Or Perpendicular 🔬 .

3  Select an alignment.

> **NOTE** If the selected alignment has associated profiles, the Select a Profile dialog box displays. You can select a profile from the list and the elevations for the points you create will be set from that profile. If there is no profile section for a station on the alignment, or if you select <none>, the point elevation will be set according to the Points Creation settings in the Create Points dialog box.

4  Specify a point.

5  If prompted, enter the point name, description, and elevation.

> **NOTE** If you want the point description to be taken from the object, specify Automatic - Object in the Prompt For Descriptions section of the Points Creation settings. The alignment name and station display in the Raw Description column in the Point Editor.

6  Optionally, repeat steps 4-6.

7  Press Enter to end the command.

> **NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

## Creating Profile Geometry Points on Alignments

Creates points on the alignment at the geometry points of the profile view with elevations from the profile.

Profile geometry points can be points for the begin of vertical curvature (BVC), points of vertical intersection (PVI), and points of end of vertical curvature (EVC).

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create profile geometry points on alignments**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Alignments ➤ Profile Geometry Points 📍 .

3  Select an alignment in the drawing, or if there is more than one alignment, select it from the list.

4  Select a Profile from the list.

   Points are created on the alignment at the geometry points of the profile view with elevations from the profile.

5  Press Enter to end the command.

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

## Creating Points on an Alignment by Importing ASCII Files

Creates points along an alignment by importing points from an ASCII (text) file that contains station, offset, and elevation information.

The file you import can contain the station, offset, elevation, and description of each point. The elevation can be expressed as either a single value (elevation) or a rod reading with instrument height (rod, hi).

ASCII (text) files that use the following layouts (formats) can be imported:

- Station, Offset
- Station, Offset, Elevation
- Station, Offset, Rod, Hi
- Station, Offset, Description
- Station, Offset, Elevation, Description
- Station, Offset, Rod, Hi, Description

Use commas or spaces as delimiters (separators) in the file. Include one or more comment lines in the file by putting a semi-colon (;) or a pound sign (#) in the first column of a comment line.

The following is an example of data in an ASCII (text) file that is formatted using the Station, Offset, Elevation format:

```
#station, offset, elevation: subdivision 1
0 20.0 112.00
10 23.5 114.64
20 22.5 116.56
30 23.0 116.32
40 22.0 115.83
```

The first line in this example is a comment line that is ignored when the points are imported. Each of the remaining lines contains the station, offset, and elevation for a point. The file is delimited by spaces.

Before you import the file, you are prompted to describe the format of the ASCII (text) file. You can also be prompted to specify invalid indicator values for station/offsets, elevations, and rod heights.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create points on an alignment by importing ASCII files**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Alignments ➤ Import From File ⬡ .

3  In the Import Alignment Station And Offset File dialog box, browse to the folder containing the file. Click the file name, and click Open.

4  Enter a number between 1 and 6 to specify the format that describes the layout of data in your file, as follows:
    - 1: Station, Offset

- ■ 2: Station, Offset, Elevation

- ■ 3: Station, Offset, Rod, Hi

- ■ 4: Station, Offset, Description

- ■ 5: Station, Offset, Elevation, Description

- ■ 6: Station, Offset, Rod, Hi, Description

**5** Do one of the following:
- ■ Enter 1 if the file delimiter is a space.

- ■ Enter 2 if the file delimiter is a comma.

**6** If prompted, specify invalid indicators for station/offset, elevation, or rod/hi values.

**7** Select an alignment.

---

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

## Creating Points Based on Surface Elevations

Use the icons in the Surface list to access commands that you can use to create points using surface elevations.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

## Creating a Point at a Surface Elevation

Creates points at any specified location on a surface.

Point elevations are read from the specified surface.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create a point at a surface elevation**

1 Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2 Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Surface ➤ Random Points
.

3 Select a surface.

4 Specify a location within the surface boundary for the point.
The point takes its elevation from the surface at the specified location.

5 If prompted, enter the point name and description.

6 Optionally, repeat steps 4-6.

7 Press Enter to end the command.

---

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

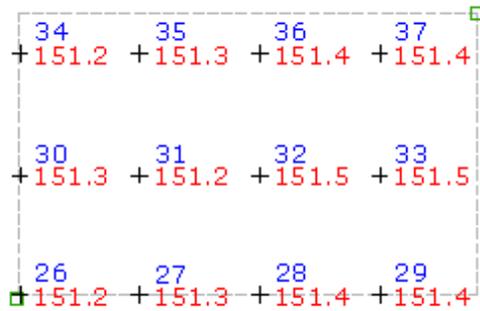
## Creating a Grid of Points at Surface Elevations

Generates a grid of points that are automatically assigned surface elevations.

Specify grid base point (lower left corner), cell size (X and Y lengths), upper right corner, and optional rotation angle.


Because this command creates points using elevations from a surface, the Prompt For Elevations setting, specified in the Points Creation settings, does not affect how you are prompted during this command.

**To create a grid of points at surface elevations**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Surface ➤ On Grid ⊞ .

3  Select a surface.

4  Specify the location of the grid base point, which is the lower left corner of the grid, by doing one of the following:

   ■ Enter X and Y coordinates on the command line.

   ■ Specify a point on the screen.

5  Enter the rotation angle or press Enter to accept the default.

6  Specify the grid X spacing by entering a value or pressing Enter to accept the default value.

7  Specify the grid Y spacing by entering a value or pressing Enter to accept the default value.

8  Specify the location of the upper-right corner of the grid by clicking on the screen.
   A single grid square and the outline of the entire grid are drawn on the screen.

9  Do one of the following:

   ■ To create the points based on the displayed grid, press Enter.

   ■ To change the grid, enter Yes and re-enter the rotation angle, grid base point, grid X spacing, grid Y spacing, and the upper right corner as previously described.

   The command calculates the coordinates of each grid point. The elevation of each calculated point is taken from the selected surface.

10 For each point, if prompted, enter the point name and description.

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

## Creating Points Along a Polyline or Surface Contour Using Distance and Surface Elevations

Creates points on a surface at specified distances along a polyline object or a surface contour.

Create points using elevations from the surface. The points are created along a polyline based on a specified distance.

The Prompt For Elevations setting, specified in the Points Creation settings, does not affect how you are prompted during this command.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create points along a polyline or surface contour using distance and surface elevations**

1 Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2 Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Surface ➤ Along Polyline/Contour  .

3 Select a surface.

4 Enter the distance between the points.

**5** Select the polyline or surface contour along which to place the points.

The points are placed along the polyline or surface contour at the specified interval.

**6** If prompted, for each point, enter the point name and description.

---

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

## Creating Points at Polyline or Surface Contour Vertices Using Surface Elevations

Creates points on a surface at the vertices of polylines or surface contours.

Points are not placed at polyline vertices that fall outside the surface boundary.

Because this command creates points using elevations from a surface, the Prompt For Elevations setting, specified in the Points Creation settings, does not affect how you are prompted during this command.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create points at polyline or surface contour vertices using surface elevations**

**1** Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

**2** Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Surface ➤ Polyline/Contour Vertices .

**3** Select a surface.

**4** Select a polyline or surface contour.

The points are placed at the polyline or surface contour vertices.

**5** If prompted, for each point, enter the point name and description.

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

# Creating Points by Interpolation

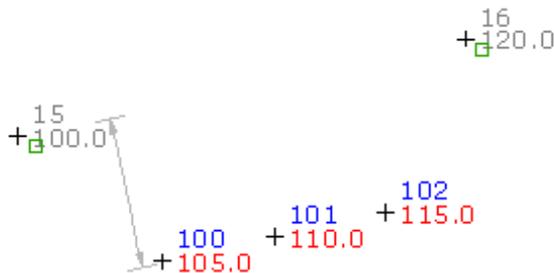
Use the icons in the Interpolate list to access commands that you can use to create interpolated points between selected points.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427)

## Creating Points by Interpolation

Interpolates a specified number of points between two existing points.

Interpolation determines point location and elevation. To use this command, you must have at least two points with elevations in the drawing.



**To create a specified number of interpolated points between two points**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

**2** Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Interpolate ➤ Interpolate ⚙.
.

**3** Specify the first point by doing one of the following:
   ■ Pick a point in the drawing.

   ■ Use Transparent commands to specify the point.

**4** Specify the second point by doing one of the following:
   ■ Pick a point in the drawing.

   ■ Use Transparent commands to specify the point.

**5** Enter the number of points to create.

**6** Enter a description, or press Enter to skip the description.

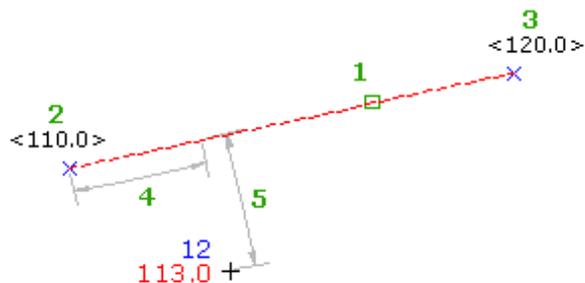
Create Points (page 2117)

## Creating Points by Relative Location

Interpolates a point between two control points based on a distance.

Select an object (1) with two control points (2) and (3) and then specify a distance (4) and offset (5) to create the point.


**To create points by relative location**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Home tab ➤ Create Ground Data panel ➤ Points Menu ➤ Create Points - Interpolate ➤ By Relative Location ⬚ .

3  Specify the interpolation region by doing one of the following:

   ■  Pick a point in the drawing and enter an elevation for the first point. Specify the second point and then either enter D to specify the difference in elevation between the two points, or enter S to specify the slope from the first point to the second point.

   ■  Use Transparent commands to specify the point.

   ■  Enter E, and select an arc, line, feature line, lot line, or polyline. Specify the distance and the offset distance by either entering the distance, picking a point, or using Transparent commands.

4  Enter a description, or press Enter to skip the description.

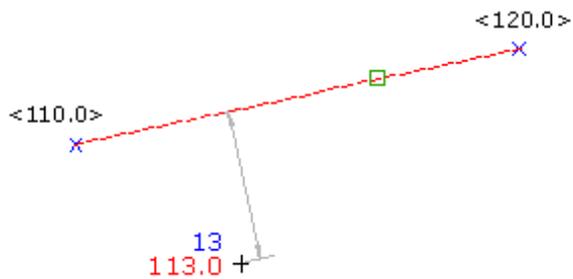
## Creating Points By Relative Elevation

Interpolates a point at a specified elevation between two control points.

Define the interpolation region by specifying the start and end control points, or click near the start point of an object.


Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create points at an elevation by interpolating between two points**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2   Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Interpolate ➤ By Relative Elevation  .

3   Specify the interpolation region by doing one of the following:

   ■   Pick a point in the drawing and enter an elevation for the first point. Specify the second point and then either enter D to specify the difference in elevation between the two points, or enter S to specify the slope from the first point to the second point.

   ■   Use Transparent commands to specify the point.

   ■   Enter E, and select an arc, line, feature line, lot line, or polyline. Enter the elevation and then specify the offset distance by either entering the distance, picking a point, or using Transparent commands.

4   Enter a description, or press Enter to skip the description.

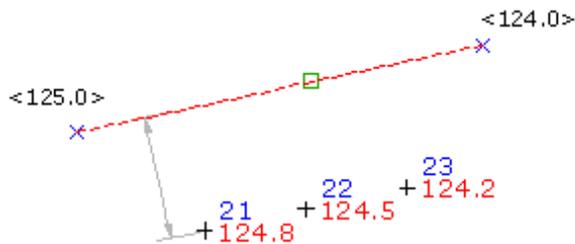
# Creating Points using Number By Distance

Interpolates a specified number of points between two control points.

Define the interpolation region by specifying the start and end control points, or click near the start point of an object.



Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To place a number of interpolated points**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

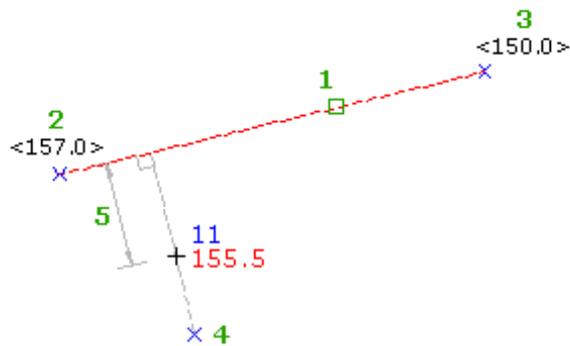
## Creating Points Perpendicular

Interpolates a point along a control line or entity that is perpendicular to a specified point.

Create an interpolated point that is perpendicular along a line by selecting an object (1) that has two control points (2) and (3).



Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create points perpendicular from selected points**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Interpolate ➤ Perpendicular
   .

3  Specify the interpolation region by doing one of the following:

   ■  Pick a point in the drawing and enter an elevation for the first point. Specify the second point and then either enter D to specify the difference in elevation between the two points, or enter S to specify the slope from the first point to the second point.

   ■  Use Transparent commands to specify the point.

   ■  Enter E, and select an arc, line, feature line, lot line, or polyline. Specify the location for the perpendicular point, and then specify the offset distance by either entering the distance, picking a point, or using Transparent commands.

4  Enter a description, or press Enter to skip the description.

## Creating Points at an Incremental Distance

Interpolates points that are a specified distance apart.

Define the interpolation region by specifying the start and end control points, or click near the start point of an object.

**To create points at an incremental distance**

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2   Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Interpolate ➤ Incremental Distance 🗗 .

3   Specify the interpolation region by doing one of the following:

   ■   Pick a point in the drawing and enter an elevation for the first point. Specify the second point and then either enter D to specify the difference in elevation between the two points, or enter S to specify the slope from the first point to the second point.

   ■   Use Transparent commands to specify the point.

   ■   Enter E, and select an arc, line, feature line, lot line, or polyline. Specify the distance between points, and then specify the offset distance by either entering the distance, picking a point, or using Transparent commands.

4   Enter a description, or press Enter to skip the description.

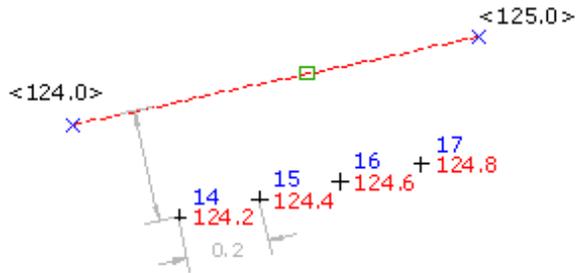
# Creating Points at an Incremental Elevation

Interpolates points at a specified elevation increment along a control line or entity.

Define the interpolation region by specifying the start and end control points, or click near the start point of an object.



Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create points at an incremental elevation**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Interpolate ➤ Incremental Elevation ⚘ .

3  Specify the interpolation region by doing one of the following:

■  Pick a point in the drawing and enter an elevation for the first point. Specify the second point and then either enter D to specify the difference in elevation between the two points, or enter S to specify the slope from the first point to the second point.

■  Use Transparent commands to specify the point.

■  Enter E, and select an arc, line, feature line, lot line, or polyline. Specify the elevation difference between points, and then specify the offset distance by either entering the distance, picking a point, or using Transparent commands.

4  Enter a description, or press Enter to skip the description.

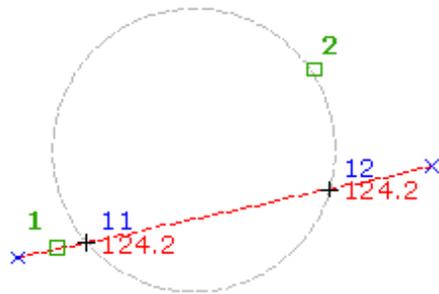
## Creating Points at Intersections

Interpolates points where two entities intersect, or would intersect if extended.

Define the interpolation region by specifying the start and end control points, or click near the start point of an object.



Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create points at object intersections**

1  Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2  Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Interpolate ➤ Intersection 🔆 .

3  Specify the interpolation region for the first intersection by doing one of the following:

   ■ Pick a point in the drawing and enter an elevation for the first point. Specify the second point and then either enter D to specify the difference in elevation between the two points, or enter S to specify the slope from the first point to the second point.

   ■ Use Transparent commands to specify the point.

   ■ Enter E, and select an arc, line, feature line, lot line, or polyline. Specify the offset distance by either entering the distance, picking a point, or using Transparent commands.

4  Repeat step 4 to specify the second interpolation region.

5  In the drawing, an X marks each intersection point. If only one intersection is located then the point is automatically created.

**6** Specify the intersection point by doing one of the following:

■ Click near the X on which you want to create the point.

■ Enter A to place points at both intersections.

**7** Enter a description, or press Enter to skip the description.

## Creating Points Based on Slope

Use the icons in the Slope list to access commands that you can use to create points based on slope and grade intersections, elevations, and distances.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

## Creating Points at Grade or Slope Intersections

Creates a point where two slopes or grades intersect.

Select a start and end point; specify the grade or slope ahead from the start point and back from the end point.

Creates a high or a low point between two existing point objects.

**To create a point where two slopes or grades intersect**

**1** Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

**2** Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Slope ➤ High/Low Point 🔼 .

**3** Specify the start point by doing one of the following:

■ Pick a point in the drawing.

■ Use Transparent commands to specify the point.

**4** Specify the second point by doing one of the following:

- Pick a point in the drawing.

- Use Transparent commands to specify the point.

**5** Specify the slope from the first point to the second point by doing one of the following:

- Enter a slope value.

- Enter G, and then enter a grade value, or enter S and then enter a slope value.

An X displays to indicate the location of the calculated slope/grade intersection.

**6** Enter Yes to accept the calculated slope/grade intersection.

**7** Enter a description, or press Enter to skip the description.

## Creating Points by Slope/Grade - Distance

Creates a specified number of points from an existing point object based on the slope or grade to a given direction and distance.

Specify start point, elevation, direction, slope or grade, distance, and number of intermediate points. Offset and end point are optional.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create points at a given slope or grade for a specified distance**

**1** Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

**2** Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Slope ➤ Slope/Grade - Distance .

**3** Specify the start point by doing one of the following:

- Pick a point in the drawing.

■ Use Transparent commands to specify the point.

**4** Specify the direction and distance by doing one of the following:

■ Pick a point in the drawing.

■ Use Transparent commands to specify the point.

**5** Specify the slope from the first point by doing one of the following:

■ Enter a slope value.

■ Enter G, and then enter a grade value, or enter S and then enter a slope value.

**6** Specify the distance along the slope/grade by doing one of the following:

■ Pick a point in the drawing.

■ Use Transparent commands to specify the point.

**7** Specify the number of intermediate points from the start along the specified direction and distance.

**8** Enter Yes to add the ending point.

**9** Enter a description, or press Enter to skip the description.

---

**NOTE** Many factors affect how the point is displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

---

Create Points (page 2117)

## Creating Points by Slope/Grade - Elevation

Creates a specified number of points from an existing point object based on the slope or grade to a given direction and elevation.

Specify start point, elevation, direction, slope or grade, target elevation, and number of intermediate points. Offset and end point are optional.

For example, you can specify a grade and an ending elevation, and then create points along the distance it takes to achieve the final elevation.

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see Before You Create Points (page 427).

**To create points at a given slope or grade based on an ending elevation**

1 Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2 Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Points - Slope ➤ Slope/Grade - Elevation .

3 Specify the start point by doing one of the following:
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify the point.

4 Specify the direction and distance by doing one of the following:
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify the point.

5 Specify the slope from the first point by doing one of the following:
   ■ Enter a slope value.
   ■ Enter G, and then enter a grade value, or enter S and then enter a slope value.

6 Specify the elevation along the slope/grade by doing one of the following:
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify the point.

7 Specify the number of intermediate points from the start along the specified direction and distance.

8 Specify the offset distance by doing one of the following:
   ■ Enter a distance.
   ■ Pick a point in the drawing.
   ■ Use Transparent commands to specify a point to define the offset.

9 Enter Yes to add the ending point.

10 Enter a description, or press Enter to skip the description.

## Creating Points by Importing Point Data

Creates points by importing point data from a file.

Import point data from most ASCII (text) files or Microsoft® Access database *(.mdb)* files. For more information, see [Importing Point Data](#) (page 503).

## Creating Points Using the Civil Transparent Commands

Use the Civil transparent commands to create points.

You use the Civil transparent commands with the Create Points Manual command, which is included in the Miscellaneous list in the Create Points dialog box.

Create the points using known information, such as angle and distance, bearing and distance, azimuth and distance, and deflection angle and distance.

For more information about Civil transparent commands, see [Transparent Commands](#) (page 1581).

Point settings, styles, layers, point groups, and description keys can all affect how a point is created or how it is displayed in the drawing. For more information, see [Before You Create Points](#) (page 427).

**To create points using the Civil transparent commands**

1 Select settings and create styles, layers, point groups, and description keys. For more information, see [Before You Create Points](#) (page 427).

2 Click Home tab ➤ Create Ground Data panel ➤ Points Menu ➤ Create Points - Miscellaneous ➤ Manual ⊕ .

3 Do one of the following:
   ■ Enter a transparent command at the command line.
   ■ Select a transparent command from the Transparent Command toolbar.

   For more information, see [Transparent Commands](#) (page 1581).

4 Follow the transparent command prompts to place the point.

5 If prompted, enter the point name, description, and elevation.

6 Do one of the following:
   ■ Continue to enter points within the transparent command.
   ■ Press Esc to end the transparent command and return to the Create Points Manual command.

**NOTE** Many factors affect how the point is displayed. For more information, see [Controlling the Appearance of Points in a Drawing](#) (page 425).

# Editing Points

You can edit individual drawing points graphically (in the drawing), or you can use the Point Editor.

Change the properties of multiple drawing points using utilities that perform batch operations, such as renumbering or changing elevation.

You cannot edit project points directly. To edit project points, you must check the points out to a drawing, modify them, and then check them back in to the project. For a procedure for changing large numbers of project points, see Modifying A Large Number of Project Points (page 494).

For more information about working with project and drawing points, see Managing Points (page 423).

## Editing Points in a Drawing

Use AutoCAD commands to move, rotate, copy, or erase a point in a drawing.

For a complete list of the AutoCAD commands that are supported for editing points and other AutoCAD Civil objects, see AutoCAD Commands and AutoCAD Civil Objects (page 1729).

When a drawing point is locked, you cannot use any command that modifies its XYZ values, including the AutoCAD Erase command.

## Rotating Point Labels Using Grips

Use grips to rotate point labels in a drawing.

In the drawing, select a point label and click 🟢 to rotate the point label.

## Editing Points Using the Point Editor

Use the Point Editor to modify the properties of drawing points.

Each row in the Point Editor Vista displays the properties for a single point. To edit, click a cell and enter new values.

For more information about working with a vista, including keeping the window active, but hidden when you are not using it, see The Panorama Window (page 102).

The Point Editor displays point information arranged in a grid. Display and hide the columns in the Point Editor the same way you display and hide the columns in a list view. For more information, see Customizing a List View (page 84).

For a complete description of each column in the Point Editor, see Point Editor (page 2130).

Edit drawing points either in the Point Editor or from the Points list view in Prospector. The Point Editor, because it is a separate window, provides more viewing area and greater flexibility in use of screen space.

To view project points in the project Points collection, use the Prospector list view. You cannot edit project points using the list view. To edit project points, you must check the points out to the drawing, modify them, and then check them back in to the project. For more information, see Managing Points (page 423).

### Listing Points in the Point Editor

Use the Prospector shortcut menus or the List Points command to open the Point Editor.

The points that are displayed when you open the Point Editor are determined by the item or items that are selected before you display the shortcut menu. You can edit either all the points in a drawing, all the points in a point group, or selected points in a list view or drawing.

Each row in the Point Editor Vista displays the properties for a single point. To edit, click a cell and enter new values.

**To open the Point Editor**

1  In Toolspace, on the Prospector tab, do one of the following:

- To include all the points in a drawing in the Point Editor, right-click the Points collection ➤ Edit Points or click Points menu ➤ List Points.

- To include all the points in a point group in the Point Editor, right-click the point group.

- To include selected points, click the Points collection. Select the points in the list view and right-click.

- To include selected points in a drawing, select the points and right-click.

2  Click Edit Points on the shortcut menu.

The Point Editor is opened. If you cannot see the Point Editor, click ▦ at the top of the Prospector tab to display the Panorama window.

3  Use the Point Editor (page 2130) to edit or view the points.

## Quick Reference

Dialog Box

Point Editor (page 2130)

## The Point Editor Shortcut Menu

Use a shortcut menu to access commands from within the Point Editor.

To display the shortcut menu, select at least one point and right-click. The commands that are available on the shortcut menu depend on whether you selected drawing or local copies of project points in the drawing, and on the state of the selected points with respect to the drawing or project.

Use the Point Editor shortcut menu to:

- Renumber selected points. (page 493)

- Change the elevation of the selected points. (page 492)

- Changing the elevations of points based on a surface. (page 493)

- Delete the selected points. (page 490)
- Zoom or pan the drawing to the selected points. (page 426)
- Lock or unlock the selected points. (page 423)

For information about the access control items on the menu, see Working with Vault Project Points (page 166).

## Deleting Points Using the Point Editor

Use the Point Editor shortcut menu to delete drawing points from within the Point Editor.

You cannot delete a locked point.

**NOTE** You can also use the AutoCAD ERASE command to delete a point.

If a deleted point is referenced by a surface, the surface will be either automatically rebuilt or marked as out-of-date, depending on the surfaceRebuild - Automatic setting.

**To delete points using the Point Editor**

1  Open the Point Editor so that it lists the point you want to delete. For more information, see Listing Points in the Point Editor (page 488).

2  Right-click the row containing the desired point. Click Delete.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Points collection ➤ right-click points in List View ➤ Delete

Object Shortcut Menu

Erase

## Editing Points Using the Object Properties Window

Use the AutoCAD properties window to change individual COGO point properties such as layer, point style, and point label style.

**To change individual point properties**

1  Select a point in the drawing, right-click ➤ Properties.

2  On the Design tab expand the AutoCAD Civil section to display the point properties for Display, Information, Coordinate, and Labeling.

3  To change a property, click in the cell and enter a new value or select a value from the list.

## AutoCAD Civil Point Properties in the Object Properties Manager

The following AutoCAD Civil point properties are displayed in the AutoCAD Properties dialog box:

**Display**

| | |
|---|---|
| Point Style | Modify the style for the point object. If the point object does not have an assigned style <default> is displayed, indicating the point group label style is being used to draw the point label. |
| XY Scale | Modify the XY scale factor for the point object. PROPERTY NOT SET indicates this property is set to a null value. |
| Z Scale | Modify the Z scale factor for the point object. PROPERTY NOT SET indicates this property is set to a null value. |
| Rotation | Modify the point object rotation.PROPERTY NOT SET indicates this property is set to a null value. |
| **Information** | |
| Point Number | Modify the point number for the point object. |
| Name | Modify the point name for the point object. |
| Raw Description | Modify the raw description for the point object. PROPERTY NOT SET indicates this property is set to a null value. |
| Full Description | Displays the full description for the point object which is derived from the Description Format Property. This is a read only value. |
| Description Format | Modify the description format for the point object. PROPERTY NOT SET indicates this property is set to a null value. |
| Survey Point | Displays the read only value of the survey flag for the point object. A True value indicates the COGO point was created using AutoCAD Civil Survey features. |
| **Coordinate** | |
| Easting | Modify the Easting value for the point object. |
| Northing | Modify the Northing value for the point object. |
| Point Elevation | Modify the Easting value for the point object. |

**Labeling**

| | |
|---|---|
| Point Label Style | Modify the style for the point object label style. If the point object does not have an assigned style <default> is displayed, indicating the point group label style is being used to draw the point label. |
| Label Is Pinned | Specify True to pin the point label. |
| Visibility | Specify True to have the point object label displayed. |

# Editing Points Using Point Editing Utilities

Use the point editing utilities to change multiple drawing points using a single command.

You cannot use the point editing utilities to edit project points directly. To edit project points, you must check the points out to a drawing, modify them, and then check them back in to the project. For information about a recommended procedure for checking out and changing a large number of project points, see Modifying A Large Number of Project Points (page 494).

## Changing the Elevations of Points

Use the Datum command to change the elevations of selected drawing points.

Updates points that were set, according to an assumed elevation, to a benchmark elevation. If a point has no elevation value, its elevation is not adjusted.

**NOTE** Use the Point Editor to edit point elevations individually.

**To change the elevation of points**

1 In Toolspace, on the Prospector tab, click the Points collection to display the Points list view.

2 In the list view, select the desired points. For more information, see Selecting Items in a List View (page 84).

3 Right-click and click Datum.

4 In response to the prompt, specify a change in elevation by doing one of the following:

- Enter a change in elevation. To specify a decrease in the elevation, use a minus sign (-) before the value.

- Enter R, for reference, then enter the old and new datum elevations. The points will be modified by the differences between the two values.

### Quick Reference

Ribbon

Click COGO Point tab ➤ Modify panel ➤ Datum

Menu

Click Points menu ➤ Edit Points ➤ Datum

Toolspace Shortcut Menu

Prospector tab: Points collection ➤ right-click points in List View ➤ Datum

## Changing the Elevations of Points Based on a Surface

Change the elevations of a point, point group, or a selection of drawing points based on the elevations in a selected surface.

The elevations of the selected points is based on their location on the surface.

**To change the elevation of points based on a surface**

1  In Toolspace, on the Prospector tab, click the Points collection to display the Points list view, or right-click a Points collection and select Edit Points to display the Point Editor.

2  Do one of the following to display the Select Surface dialog box:
   ■ Select the points to edit in the list view or the Point Editor and right-click ➤ Elevations From Surface.
   or

   ■ Click COGO Point tab ➤ Modify panel ➤ Elevations From Surface  .

3  Select a surface from the list and click OK. If you selected the command from the list view or the Point Editor, the Point Elevation column reflects the elevation from the surface. If you selected the command from the Points menu, you are prompted at the command line to select one of the following:
   ■ All: to select all points in the current drawing to move elevations to the selected surface.

   ■ Numbers: prompts the user to specify a range of numbers.

   ■ Group: displays the Point Groups dialog box where you can select a point group.

   ■ Selection: prompts the user to select points in the drawing.

### Quick Reference

## Renumbering Points

Use the Renumber command to assign new point numbers to selected drawing points.

This command adds an integer value to the point number of each selected point.

You may be prompted to resolve any numbering conflicts that arise when the renumbering occurs.

To renumber project points, check the points out of the project into a drawing, renumber them using the Renumber command, and then check them back in to the project.

**To renumber points**

1  In Toolspace, on the Prospector tab, click the Points collection to display the Points list view.

2  In the list view, select the desired points. For more information, see Selecting Items in a List View (page 84).

3  Right-click and click Renumber.

4  Enter the value to be added to the point number of the selected points.

## Quick Reference

SelectAndEditPointNumbers

# Modifying A Large Number of Project Points

Use the procedure described in this topic to make a change, such as an elevation adjustment or a change to all eastings or northings, to a large number of points in a project.

To change one or more project points, you must check the points out to a drawing, change the points, and check the points back in to the project. When you are working with a large number of project points and do not need to view the points in the drawing while you change them, you can speed up the process by not drawing the point symbols or point labels while the points are in the drawing.

Avoid drawing point labels and point symbols using point label styles and a point group override. The procedure described in this topic suggests using a throw-away drawing for this process, and instructs you to edit the Standard point style and the _All Points point group in the throw-away drawing. If you do not want to use a throw-away drawing, you can modify the procedure to create a point group and a point style you can use for working with large numbers of points.

Before beginning this procedure, you should understand how to work with project and drawing points. For more information, see Working with Vault Project Points (page 166).

**To modify a large number of project points**

1  Create a new, empty drawing.

2  In Toolspace, on the Settings tab, under the Point Styles collection, right-click the Standard ➤ Edit.

3  On the Display tab, to turn off the display of point symbols, click in the Visible column for Marker so that the light bulb icon is not available.

**4** To turn off the display of point labels, click in the Visible column for Label so that the light bulb icon is not available.

**5** Click OK.

**6** In Toolspace, on the Prospector tab, under the Point Groups collection, right-click the _All Points ➤ Properties.

**7** In the Point Group Properties dialog box, on the Overrides tab (page 2113), in the Overrides column, select the Standard point style. In the Properties column, select the check box next to Point Style.

**8** In the Overrides column, select the Standard point label style. In the Properties column, select the check box next to Point Label Style.

**9** Click OK.

**10** If the drawing has more than one point group, move the _All Points point group to the top of the point group display order. For more information, see Changing the Point Group Display Order (page 526).

**11** Check out the project points to the drawing.

> **NOTE** To quickly check out all the project points, right-click the _All Points point group in the drawing and select Check Out Points.

**12** In the drawing, edit the points using either a point utility, the Point Editor, or the Prospector Points list view.

> **NOTE** For information about changing a point property such as elevation to the same value for every point in the Point Editor or the Points list view, see Changing the Contents of a Column in a List View (page 85).

**13** Check the points in to the project. Do not keep them checked out to the drawing.

> **NOTE** To quickly select all the points in the drawing for checking in, right-click the _All Points point group and select Check In Points.

**14** Delete the throw-away drawing.

# Importing and Exporting Points

You can use commands to import point data, export point data, and transfer point data between files.

Using AutoCAD Civil, you can:

■ Import points into a drawing from either an ASCII (text) file or a Microsoft® Access database (.*mdb*) file.

■ Export points from a drawing to either an ASCII (text) file or a Microsoft® Access database file.

■ Transfer points from an ASCII (text) file or a Microsoft® Access database file to another file. You can convert the point data during the transfer, which can include changing the coordinate zone.

Importing points is a quick way to place points into a drawing. For example, if a surveyor collects point data using a data collector, the data can be downloaded from the collector as an ASCII (text) file and then imported into an AutoCAD Civil drawing.

Before you can import, export, or transfer point data, you must specify a *point file format* for each file that point data is read from or written to. The point file format describes how the point data is stored in the file. You can use the point file formats that are supplied with AutoCAD Civil or create your own formats.

# Understanding Point File Formats

Use a point file format to describe how point data is arranged in a file when you import, transfer, or export points.

A *point file format* does not contain point data; it describes the layout of a *point data file,* which is a file that contains point data.

### Using Point File Formats

When you import, export, or transfer point data, you must specify a point file format for each point data file that is read or written to. When you import points from a point data file, you specify a point file format that describes how the point data is arranged in the file that is being imported. When you export point data to a file, you specify a point file format that describes how the point data is written to the exported file. When you transfer point data from one file to another, you specify two formats, one that describes how the data is arranged in the source file and one that describes how the data is written to the destination file.

### Converting Point Data During Import or Export

A point file format can contain information that specifies the coordinate zone that was used to create the point data in the associated point data file. Use the coordinate zone information to convert point data as it is imported, exported, or transferred.

A point file format can indicate that the associated point data file contains values that can be used to adjust the elevations contained within the file. The specified values can be added to or subtracted from point elevations when you import point data.

### Point File Format Types

There are two types of point file formats:

■ User Point File Format. This point file format type describes how the point data is arranged in an ASCII (text) file.

■ User Point Database Format. This point file format type describes how point data is arranged in a Microsoft® Access database file.

Use the point file formats that are supplied with AutoCAD Civil or create your own formats. The point file formats available in a drawing are listed in the Toolspace Settings tree.

# Point File Formats Collection (Settings Tab)

Use the Point File Formats collection in the Settings tree to create and manage point file formats.

In the Settings tree, expand the Point collection and then expand the Point File Formats collection to list the point file formats available in the drawing.

Right-click the Point File Formats collection to:

■ Create a new point file format (page 500).

■ Refresh the Settings tree.

Right-click a point file format name to:

■ Change the properties of the point file format. (page 497)

■ Make a copy of the point file format. (page 502)

■ Delete the point file format. (page 503)

- Refresh the Settings tree.

You can also list available point file formats by clicking the Point File Formats collection to display a list view. For more information, see The Toolspace Item View (page 82).

## Point File Format Properties

Use a dialog box to view or change the properties of a point file format.

The properties of a point file format include:

- format file name

- default point data file extension

- comment tag

- transformation information

- column names that describe the layout of the point data in the associated point data file

- file formatting options (point file format only)

The dialog box you use to view and change the properties of a point file format depends on whether the format is a user point file format or a user point database format. For more information about the dialog box used to view and change the properties of a point file format, see Point File Format Dialog Box (page 2120). For more information about the dialog box used to view and change the properties of a user point database format, see User Point Database Format Dialog Box (page 2121).

For information about creating a new point file format, see Creating Point File Formats (page 500).

## Point File Format Coordinate Zone Transformation Property

Use the coordinate zone transformation property in a point file format to specify the coordinate zone in which the data in the associated point data file was created.

When you import or export a point data file, coordinate zone information is included in the point file format, not the point data file. Use this information to transform points from one coordinate zone to another while importing or exporting.

For example, to import an ASCII (text) file that was created in an NAD27 zone when the zone of the current drawing is NAD83, specify the NAD27 zone in the point file format. Then, when you import the points, you can select an option that converts the points to the drawing zone, NAD83.

## Point File Format Column Name Property

Use column names in a point file format to specify which point information is included in a point data file.

When creating a new point file format, you are presented with a list of unused columns:

Specify the contents of the first column in the point data file by clicking the first column heading and specifying a point property, for example, Easting, in the Point File Formats - Select Column Name dialog box. The first column heading is updated to reflect the specified column name:

Specify the contents of the second column in the point data file by clicking the second column heading in the dialog box and specifying another point property, for example, Northing:

Continue to specify column headings until the point file format column names reflect the layout of the point data file.

Some point file format columns can be used to perform calculations when they are included in the format. For more information, see Using Point File Format Properties to Perform Calculations (page 499).

## Point File Formatting Options

In a point file format, use formatting options to specify whether the associated point data file is arranged in columns or delimited by a specified character.

Choose either Columnated or Delimited By to specify how point data is stored in a point data file.

### Columnated

Use the Columnated option to separate values in the point data file by tabs. When you import the file, the data in the file is assumed to be arranged in columns and rows. Each row contains the data for a single point, and the individual values in the row are separated by tabs. When you export points or transfer data, the values in the resulting file are arranged in columns and separated by tabs, with one point per row.

For example, if your format column names are Number, Northing, Easting, and Elevation, the contents of your point data file might appear as follows:

| | | | |
|------|---------|---------|--------|
| 1002 | 5000.00 | 2010.00 | 100.00 |
| 1003 | 5001.00 | 2020.00 | 100.00 |
| 1004 | 5002.00 | 2030.00 | 100.00 |

### Delimited

The Delimited By option separates the values in the point data file by a delimiter, such as a comma or a space. When you import the file, each row in the file is assumed to contain data for a single point, with the individual values separated by the specified delimiter. When you export points or transfer data, the values in the resulting file are written to the file, one point per row, with the individual values separated by the specified delimiter.

For example, if your format column names are Number, Raw Description, Northing, Easting, and Elevation, and you specified a comma (,) for a delimiter, the contents of your point data file might appear as follows:

101,MONA,300,500,0

102,MONB,302,499,0

103,MONA,303,501,0

# Using Point File Format Properties to Perform Calculations

Use some columns in a point file format to perform calculations, such as adjusting the elevation values.

## Adjusting Elevation During Import and Transfer

During point import, use some format column names to adjust point elevation values during point import.

Use the following columns:

■ Thickness: Include this column name in the format if your data includes surface thickness values, such as the thickness of a layer of topsoil or clay. The value in the Thickness column can be subtracted from the value in the Elevation column when points are imported or transferred.

■ Z+: Include this column name in the format to define a column for point data that was taken at a height above the datum elevation. The value in the Z+ column can be added to the value in the Elevation column when the points are imported or transferred.

■ Z-: Include this column name to adjust the elevation of a point in a file. The value in the Z- column for a point can be subtracted from the value in the Elevation column when the points are imported or transferred.

The values specified for Thickness, Z+, or Z- in the point data file are not automatically used to adjust the elevation during import or export. Select the Do Elevation Adjustment If Possible option when importing points when you want elevation adjustments to occur.

## Calculating Convergence Angles During Export

Include the Convergence column in a point file format that is used for exporting points.

Use the Convergence column name to define a point file format column containing a calculated convergence angle. In state plane coordinate systems, the convergence angle is the difference between a geodetic azimuth and the projection of that azimuth onto a grid (grid azimuth) of a given point.

Use this column only when you export point data. To export points using a format containing a convergence angle, you must have set a zone in the file format and drawing, and you must turn on transformation settings for the drawing.

## Calculating Scale Factors During Export

Include the Scale Factor column in a point file format that is used for exporting points.

Use the Scale Factor column name to define a point file format column containing a calculated convergence angle. Scale factor is the value used to reduce or increase a local (geodetic) distance so that it equals the grid distance.

Use this column only when you export point data. To export points using a format containing a scale factor, you must have set a zone in the file format and drawing, and you must turn on the transformation settings for the drawing.

Export the scale factor by using the method specified in the transformation settings, such as Prismoidal or Unity.

# Managing Point File Formats

Use the Settings tree to manage point file formats. You can share a point file format and print a list of the point file formats in a drawing.

## Sharing Point File Formats

Use the Settings tree to list the point file formats for a drawing.

Point file formats are associated with a drawing. If more than one person will need to use a point file format, you can create it in a drawing template. For more information, see Drawing Templates (page 109).

## Printing Point File Formats

Use the Copy To Clipboard command to copy the list of the point file formats in a drawing to another application for printing.

To print a list of the point file formats in a drawing, click the Point File Formats collection in the Settings tree to display a list view containing the point file formats in the drawing. Right-click the list view and click Copy To Clipboard to copy the list view into a file you can print. For information, see Copying Items from a List View (page 86).

# Creating Point File Formats

Create two types of point file formats: a user point file format and a user point database format.

A point file format does not contain point data; it describes the way point data is stored in a point data file. When you create a point file format, regardless of whether it is a user point file format or a user point database format, you can specify the following properties:

■ A format name, which is displayed in the Settings tree.

■ A series of column names that describe both the point information stored in the point data file and the order in which the point information is stored.

■ The coordinate zone in which the point data was created. This information is optional, but if you include it, you can automatically perform a coordinate transformation of the point data if you import it into a drawing that uses a different coordinate zone, or if you transfer the points from one file to another.

## Creating a User Point File Format

Create a user point file format for importing or exporting ASCII files that contain point data.

When you create a user point file format, you specify the information that is included in the point data file, the layout of the information in the file, and the character that is used to separate the individual pieces of information, such as a comma or a space. For more information, see Point File Format Properties (page 497).

As you create a user point file format, you can view the file that contains your point data for reference.

**NOTE** If you are importing point data from and ASCII file that contains user defined columns, you must create a user defined classification for each column. For more information, see Importing Point Data from an ASCII File Containing User Defined Columns.

**To create a user point file format**

1   In Toolspace, on the Settings tab, right-click the Point File Formats ➤ New.

2   In the Point File Formats - Select Format Type (page 2120) dialog box, click User Point File. Click OK.

3   In the Point File Format (page 2120) dialog box, specify a name and file extension for the format.

4   Click Load to load a point data file so that you can refer to it as you create the format.

**NOTE** At any time, you can click the Parse button and the loaded file is displayed in the dialog box using the format you are building.

5 Optionally, specify a comment tag character and a coordinate zone transform.

6 Specify the format options for the file.

7 Click a column name heading that is labeled <unused>.

8 In the Point File Formats - Select Column Name (page 2122) dialog box, select a column name from the Column Name list. Specify other parameters as needed, and click OK.

9 Repeat the previous step for each column in the point file format.

10 Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click Point File Formats collection ➤ New

Command Line

CreatePointFormat

Dialog Box

Point File Format (page 2120)

## Creating a User Point Database Format

Create a user point database format for importing or exporting *.mdb* files that contain point data.

When you create a user point database format, you specify both the information included in the *.mdb* file and the order in which it is included. If the file has multiple tables, you specify the name of the table from which you want to import data or to which you want to export data.

As you create a point database format, you can view a sample point database for reference.

**To create a user point database format**

1 In Toolspace, on the Settings tab, right-click the Point File Formats ➤ New.

2 In the Point File Formats - Select Format Type (page 2120) dialog box, click User Point Database and click OK.

3 In the User Point Database Format (page 2121) dialog box, specify a name for the format.

4 Click Load to load the Microsoft® Access file that you want the new format to match, so that you can refer to it as you create the format.

5 Specify a table name if required.

6 Optionally, specify a coordinate zone transform.

7 Click a column name heading that is labeled <unused>.

8 In the Point File Formats - Select Column Name (page 2122) dialog box, select a column name from the Column Name list. Specify other parameters as needed, and click OK.

9 Repeat the previous step for each column in the user point database format.

**10** Click OK.

### Quick Reference

Toolspace Shortcut Menu

  Settings tab: right-click Point File Formats collection ➤ New

Command Line

  CreatePointFormat

Dialog Box

  User Point Database Format (page 2121)

## Creating a Point File Format Based on an Existing Format

Creates a point file format based on an existing format by copying the format.

After you make a copy of a format, the format you created is automatically opened for editing.

**To create a point file format based on an existing format**

**1** In Toolspace, on the Settings tab, expand the Point File Formats collection.

**2** Right-click the point file format you want to copy. Click Copy.

**3** Do one of the following:

- If the format you copied was a user point file format, use the Point File Format (page 2120) dialog box to change the format properties.

- If the format you copied was a user point database format, use the User Point Database Format (page 2121) dialog box to change the format properties.

### Quick Reference

Toolspace Shortcut Menu

  Settings tab: right-click Point File Formats item ➤ Copy

## Editing Point File Formats

Use the Settings tree to access formats you want to change or delete.

You can change or delete point file formats that you create or most of the point file formats AutoCAD Civil supplies. A point file format that cannot be changed or deleted has a 🔒 displayed to the left of its name in the Prospector tree.

## Changing a Point File Format

You can change any point file format that you create. You can also change most of the point file formats that are supplied with AutoCAD Civil.

A point file format cannot be changed if 🔒 is displayed to the left of its name in the Prospector tree.

**To change a point file format**

1  In Toolspace, on the Settings tab, expand the Point File Formats collection.

2  Right-click the desired point file format. Click Properties.

3  Do one of the following:

   ■  If the format is a point file format, use the Point File Format (page 2120) dialog box.

   ■  If the format is a user point database format, use the User Point Database Format (page 2121) dialog box.

4  Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click Point File Formats item  ➤  Properties

Dialog Box

Point File Format (page 2120),
User Point Database Format (page 2121)

## Deleting a Point File Format

Use the Settings tree to delete a point file format from a drawing.

If a point file format cannot be deleted, ⊕🔒 is displayed to the left of its name in the Prospector tree.

**To delete a point file format**

1  In Toolspace, on the Settings tab, expand the Point File Formats collection.

2  Right-click the desired point file format. Click Delete.

3  Click Yes to confirm.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click Point File Formats item  ➤  Delete

## Importing Point Data

Import point data from an ASCII (text) file or a Microsoft® Access *.mdb* file into a drawing.

Importing points, such as survey point data collected by a data collector, is a quick and effective way to place points into a drawing.

Before you import points, you must create a point file format that describes the layout of the point data in the point data file.

For more information, see Understanding Point File Formats (page 496) and Creating Point File Formats (page 500).

You can add the imported points to a point group, make adjustments to the data as it is imported, including elevation adjustments, coordinate transformation, or coordinate data expansion, encounter how the imported points are numbered as they are created.

**To import point data**

1 Specify the Point Identity settings, which control the point numbers of the created points. For more information, see Editing the Point Identity Settings (page 413).

2 Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools 🔧 .

3 On the Create Points (page 2117) toolbar, click the Import Points button.

4 In the Import Points (page 2124) dialog box, specify the point file format that describes the layout of the data in the point data file you are importing.

5 In the Import Points (page 2124) dialog box, click ➕ , and select the point data file you want to import.

**NOTE** To migrate points from Autodesk Land Desktop, select External Project Point Database as the format type and select the Autodesk Land Desktop point database .mdb file as the source file.

6 Optionally, specify a point group to which the imported points are added.

7 Optionally, specify advanced options for elevation adjustment, coordinate transformation, or coordinate data expansion.

8 Click OK to import the points.

## Quick Reference

Dialog Box

Create Points (page 2117)

## Importing Point Data from an ASCII File Containing User Defined Columns

Before you import point data from an ASCII (text) file that contains user-defined columns you must create a User-Defined Property Classification.

**To import point data from and ASCII file that contains user-defined columns**

1  In Toolspace, on the Settings tab expand the Point collection ➤ right-click User-Defined Property Classification ➤ New. For more information, see Creating a User-Defined Property Classification (page 417).

2  Right-click the classification that you created in the previous step and click New to create a new user-defined property. For more information, see Creating a User-Defined Property (page 417).

3  In Toolspace, on the Settings tab expand the Points collection and click Point File Formats ➤ New.

4  Select User Point File in the Point File Formats - Select Format Type dialog box and click OK.

5  Create the new point file format. For more information, see Creating Point File Formats (page 500).

6  To specify the user-defined columns, click an <unused> column heading to display the Point File Formats - Select Column Name dialog box.

7  In the Column list, select the user-defined property you created in step two.

8  On the Prospector tab click Points ➤ Create ➤ Import Points. Select the ASCII file you wish to import and select the Point File Format you defined in step five.

# Exporting Point Data

Export drawing points to an ASCII (text) file or a Microsoft® Access *.mdb* file.

Before you export points, you must create a point file format that describes the layout of the point data in the point data file. By default, all points in the drawing are exported. To export only selected points, select Limit To Points In Point Group.

A point file format describes how the point data is arranged in the file. For example, in a drawing, point properties include point number, name, description, northing, easting, and elevation. If you want to export only point number, description, and elevation, you must export points using a point file format that defines column names only for point number, description, and elevation. For more information, see Understanding Point File Formats (page 496) and Creating Point File Formats (page 500).

In addition to exporting point properties, you can also export grid northing, grid easting, latitude, and longitude if a coordinate zone and transformation settings are defined for the drawing.

You can perform a coordinate transformation on the points as you export them. To export the point data so that it is written to the point data file using a different coordinate zone from the current drawing, specify an option that performs a coordinate transformation of the point data as it is exported. To transform the point data, your point file format must have a coordinate zone defined. For more information, see Point File Format Coordinate Zone Transformation Property (page 497).

You can export either all the points in a drawing or you can export selected drawing points using a point group.

**To export point data**

1  Create a point file format that describes the layout of the exported data file. For more information, see Creating Point File Formats (page 500).

2  Do one of the following:

■  Click Output tab ➤ Export panel ➤ Export Points ⬚ to export all the points in a drawing.

■  In Toolspace, on the Prospector tab, expand the Point Groups collection. Right-click the point group name ➤ Export Points to export only the points in a point group.

**3** In the Export Points (page 2126) dialog box, in the Format list, select the point file format that describes how you want the exported point data to be arranged in the point data file.

**4** Click  to specify the file to which you want to export the data.

**5** Optionally, specify advanced options.

**6** Click OK to export the points.

## Quick Reference

Dialog Box

Export Points (page 2126)

# Transferring and Converting Point Data

Use point file formats to transfer point data from one format to another and to convert the coordinate system of a set of points.

## Transferring Point Data Between Files

Use the Transfer Points utility to transfer point data from a source file to a destination file. Either file can be an ASCII (text) file or a Microsoft® Access database file.

You must create two point file formats. The first file format describes the layout of the data in the source file, which is the file the data is read from. The second file format describes the layout of the data in the destination file, the file the data is written to.

For example, your source file point file format could indicate that the source point data file contains the following point properties in this order: point number, elevation, northing, easting, and description. Your destination file point file format could indicate that the destination file should contain the following point properties in this order: northing, easting, elevation. In this example, when you transfer the data from the source file to the destination file, the point number and description are not transferred, and the position of the elevation value is changed.

When you transfer data between two files, the points that are transferred are not deleted from the source file.

The point file format type must match the source or destination file type. For example, to transfer points from a Microsoft Access database file to an ASCII (text) file, specify a user point database format that describes the layout of the data in the Microsoft Access database (the source file) and a point file format that describes the layout of data in the ASCII file (the destination file).

**To transfer point data between files**

**1** Create point file formats for the files you want to transfer points between. For more information, see Creating Point File Formats (page 500).

**2** Click Output tab ➤ Export panel ➤ Transfer Points ⬚ .

**3** In the Transfer Points (page 2126) dialog box, under Source, specify the format and file name, including the path, for the Source file.

**4** Under Destination, specify the format and file name, including the path, for the Destination file.

**5** To create a new point file format or change an existing one, click Manage.

**6** Optionally, specify advanced options.

**7** Click OK to transfer the point data from the source file to the destination file.

Transfer Points (page 2126)

## Converting Points to a Different Coordinate Zone

Use a combination of the Point Import, Transfer, and Export commands to convert points to a different coordinate zone.

You convert the points by exporting them to a file, changing the current zone of the drawing, and importing the points back into the drawing and overwriting the original point data.

**To convert points to a different coordinate zone**

**1** Create a copy of the External Project Point Database format. For more information, see Creating a Point File Format Based on an Existing Format (page 502).

**2** Change the coordinate zone of the new format so that it matches the coordinate zone of the current drawing. For more information, see Changing a Point File Format (page 502).

**3** Export the points in the drawing using the new format. For more information, see Exporting Point Data (page 505).

**4** Change the current drawing coordinate zone to the zone you want the points to be converted to.

**5** Import the points into the drawing. For more information, see Importing Point Data (page 503).

# Using External Data References

AutoCAD Civil creates and maintains a point database file that contains all the point information in the project.

COGO points store the point number, name (optional), northing, easting, elevation, and description in each drawing.

You can also reference your own customized databases and use them to do the following:

■ Substitute point elevation data when points are accessed through a point group.

■ Substitute point raw description data.

To link these custom point databases to AutoCAD Civil, create External Data References (XDRefs). For more information, see Creating an External Data Reference (page 509). An XDRef is a pointer to an entire column of data in a custom Microsoft Access database. All of the database entries must have a point number. Then, when you use an XDRef to get a value for a point, the point number is looked up in the custom database, and the value from the specified column is used instead of the original point value that is stored in the drawing.

XDRefs do not overwrite or alter the points in the drawing. Use the External Data Reference collection on the Settings tree in Toolspace to create and manage XDRefs.

## External Data Reference Requirements

The custom databases that you can use for XDRefs must have the following features:

■ They must be Microsoft Access database files.

■ There must be a Long Integer field index column, which contains the point numbers, in each table in the database that can be used as an XDREF.

■ Currently, only Integer, Long Integer, Single, Double, and Text type fields are supported.

■ Any number of Tables can be defined in this database, but any that are referenced by XDRefs must have an index column defined.

■ Any number of additional Text or Number columns may also be defined in this database table. There are no restrictions on the names and order of the columns after the index column.

■ XDRefs are stored on the Settings tab in Toolspace under the Point collection.

## Creating an External Point Database with Microsoft Access

Use Microsoft Access to create custom point databases, and link these databases to AutoCAD Civil by using external data references (XDRefs).

You can modify the sample database located in *c:\program files\AutoCAD Civil\Sample\Civil 3D XDRef\* or create a new database.

**To create an external point database**

1 Start Microsoft Access.

2   Select Blank Database and click OK.

3   In the File New Database dialog box, use the Save In list to locate a folder for future use.

4   In the File Name box, enter a name for the database.

5   Click Create to display the Database dialog box.

6   On the Table tab, click New to open the New Table dialog box.

7   Select Design View.

8   Click OK to display the design view of the table.

9   In the first table cell in the Field Name column, enter a name for the Index Column.

10  In the first table cell in the Data Type column, select Number.

11  In the lower part of the dialog box, verify the following information:

    ■ Long Integer is the Field Size

    ■ Auto is the Decimal Places

12  In the Required field, select Yes.

13  In the Indexed field, select Yes (No Duplicates).

14  Add any additional field names below the Index Column as needed for your point information, such as DESC 1, DESC 2, ELEV 1, ELEV 2. There are no restrictions on the names and order of the columns after Index Column.

15  In the first table cell in the Field Name column, enter the name of the Index Column.

16  In the first table cell in the Sort Order column, select either Ascending or Descending.

17  In the lower part of the dialog box, change the following settings:

    ■ Primary field must be Yes.

    ■ Unique field must be Yes.

    ■ Ignore Nulls field must be No.

18  From the View menu, choose Datasheet.

19  Click Yes to display the Save As dialog box.

20  Enter a name for the table and click OK.

21  In the Table dialog box, enter point information such as point numbers, elevations, and descriptions.

22  Click File menu ➤ Save.

23  Close Microsoft Access.

## Creating an External Data Reference

External Data References (XDRefs) are associated with individual drawings. You can use XDRef's to override the raw description and elevation for a point.

**To create an external data reference**

1   On the Settings tab in Toolspace, expand the Points folder.

**2** Right-click External Data References ➤ New.

**3** Enter a name and description.

**4** Optionally, if the database is password protected, enter the password to access the database.

**5** Browse to the location of the external data file.

**6** Select the Table type, Index Column, and Value Column.

**7** Click OK. The new external data reference is listed in the External Data Reference folder under Points in Toolspace.

### Quick Reference

(page 2136)

## Changing the Properties of an External Data Reference

Edit an existing XDRef by changing its properties, such as the table and column in the Microsoft® Access database that the XDRef points to.

**To change the properties of an external data reference**

**1** On the Settings tab in Toolspace, expand the Points folder.

**2** Right-click External Data References ➤ Properties.

**3** Enter a new name and description.

**4** Select new values for the Table type, Index Column, and Value Column.

**5** Click OK.

## Converting Softdesk Point Blocks to AutoCAD Civil Points

Convert Softdesk point blocks to AutoCAD Civil points.

COGO points are created using elevations and raw description values contained within each Softdesk point block reference. When the points are converted to COGO points, the full description and raw description are the same.

### To convert Softdesk point blocks to AutoCAD Civil points

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2   Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Replace Softdesk Point Blocks .

3   Select the Softdesk point blocks to be converted. Press Enter.

### Quick Reference

Ribbon

Command Line

CreatePtConvertSdskPts

## Converting AutoCAD Points to AutoCAD Civil Points

Convert AutoCAD point objects to AutoCAD Civil points.

Each resulting COGO point acquires its elevation from the specified AutoCAD point.

### To convert AutoCAD points to AutoCAD Civil points

1   Select settings and create styles, layers, point groups, and description keys. For more information, see Before You Create Points (page 427).

2   Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Convert AutoCAD Points .

3   Select the AutoCAD points to be converted.

4   For each point, if prompted, enter the point name and description.

**NOTE** If you do not want to be prompted for a description for each point, in the Points Creation section of the Edit Point Settings dialog box set the Prompt for Descriptions Property to None. You can also use this procedure when you want to disable Prompt for Point Names and Prompt for Elevation.

**5** Optionally, repeat steps 4 and 5.

**6** Press Enter to end the command.

# Creating Blocks from COGO Points

Use this command to create an AutoCAD block for each AutoCAD Civil point in a selection set.

The blocks can be used in backward migration to other AutoCAD programs, or to create objects that represent the spatial location of specified civil points in the active drawing.

**To create blocks from COGO points**

**1** Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Blocks From COGO Points ⊞ .

**2** Specify a Spatial Filter.

**3** Under Selected Point Groups, click ⊕ and specify the point groups you want included in the block.

**NOTE** You can select the points to include in the block using both the Spatial Filter and Point Group options. For example, under Spatial Filter you could select the Current Display and under Point Groups you could also include a specified point group.

**4** In the Block Output section, under Block Creation, click either Use Existing Block or Make New Block. If you select Make New Block, enter a name.

**NOTE** The option Use Existing Block is only available if the block contains at least three attribute definitions with the exact names ELEV, POINT, and DESC. If there are no blocks in the drawing with these exact attribute definitions, this option is not available. Then you must use the Make New Block option.

**5** Under Block Layer, specify the layer on which you want to create the block.

**NOTE** The COGO points are not deleted when the blocks are created.

## Converting Land Desktop Points

Use the convert Land Desktop Points command to convert AutoCAD Land Desktop points in a drawing to AutoCAD Civil points.

When you use AutoCAD Civil to open a drawing that contains Land Desktop points, you can run this utility to perform the conversion.

Before converting the points, you can use the Convert Autodesk Land Desktop Points dialog box to set a variety of point settings. For example, you can set default layers, point creation settings, and more. For more information, see Configuring Land Desktop Point Settings.

You can automatically add the converted points to a newly created point group or to an existing point group. The existing AutoCAD Civil point number and point name conflict resolution rules are used if a point ID conflict occurs during the conversion.

**To convert Land Desktop points**

1 Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Convert Land Desktop Points to display the Convert Autodesk Land Desktop Points dialog box.

2 Configure point setting parameters by expanding the parameter, selecting a setting, then specifying a new value in the Value column.

3 To assign the Land Desktop points to a point group, select Add Points To Point Group, then choose a point group from the list or create a new point group. If you create a new point group, it is added to the Add Points To Point Group list.

4 To keep the existing layers referenced by the Land Desktop points, select Preserve Original Point Layer.

> **NOTE** When this check box is checked, the existing layer of the Land Desktop point is assigned to the AutoCAD Civil point when it is converted. If the Points Creation\Disable Description Keys setting is set to False, and the Land Desktop point matches a description key, the original point layer will still be preserved.

5 Click OK.

# Geodetic Calculator

Use the Geodetic Calculator to calculate geodetic information relative to the zone and transformation values specified in the drawing settings.

A Coordinate System zone must be specified for the drawing in order to use this command. Transformation settings must be specified in order to view/calculate local coordinates relative to the Latitude/Longitude and/or Grid coordinates.

Enter one pair of known coordinate values, either Local Northing/Local Easting, Latitude/Longitude, or Grid Northing/Grid Easting. The other two coordinate pairs are calculated.

For example, if you enter a value in the Local Northing value field, the Local Northing/Local Easting coordinate pair is assumed to contain the known data, and the values for the Latitude/Longitude and Grid Northing/Grid Easting pairs are calculated. If you enter a value into either the Latitude or Longitude value field, the Latitude/Longitude coordinate pair is assumed to contain the known data, and values for the Local Northing/Local Easting and Grid Northing/Grid Easting pairs are calculated.

If you enter a point number or select a point location in the drawing, the Local Northing/Local Easting pair is updated, and the Latitude/Longitude and Grid Northing/Grid Easting pairs are calculated.

**NOTE** You can run other commands while the Geodetic Calculator is active.

**To use the Geodetic Calculator**

1 Click Modify tab ➤ Points ➤ Geodetic Calculator.

2 In the Geodetic Calculator (page 2133) dialog box, specify starting information by doing one of the following:

■ Click ⬚ to select a point location in the drawing.

■ Enter a point number.

■ In the Value column of the Geodetic Calculator, enter a set of coordinate values, either Latitude and Longitude, Grid Northing and Grid Easting, or Local Northing and Local Easting.

3 Optionally, click ⊕ to create a point with the values for the Local coordinates you entered or calculated. You are prompted at the command line to enter a point description and elevation.

4 To perform additional calculations, enter a value for a coordinate field, such as Local Northing.

5 After you enter the value, click the Value column for another coordinate field, such as Grid Easting.

6 Update all values by clicking in another field.

# Point Command Reference

You can use these commands to quickly access point-related functionality.

The following table lists the point-related AutoCAD Civil commands and briefly describes their functionality. For more information about a command, follow the link in the Description column.

| Command | Description |
| --- | --- |
| AddPointTable | Adds a point table to a drawing. (page 422) |
| AeccCreatePtGeodeticDir | Creates Points specified by geodetic directions. (page 429) |
| ConvertPointsToSdskPoints | Creates an AutoCAD block for each AutoCAD Civil point in the selection set. Use these blocks for backward migration. (page 513) |
| CreateDescKeySet | Creates a description key set. (page 547) |
| CreatePointAlignAlign | Creates a point at the intersection of two alignments. (page 458) |
| CreatePointAtPtPcScetc | Creates a point at every intersection on the alignment. (page 463) |
| CreatePointAutomatic | Creates points at the endpoints of lines, feature lines, or lot lines, or at the endpoints and center point of arcs. (page 432) |
| CreatePointByRelElev | Interpolates point objects between two points based on desired elevations. (page 476) |
| CreatePointByRelLocation | Interpolates point objects between two points based on distance from the first location. (page 475) |
| CreatePointDirectionAlign | Creates a point at the intersection of a direction line and an alignment. (page 453) |

| Command | Description |
|---------|-------------|
| CreatePointDirectionDir | Creates a point at the intersection of two lines. (page 440) |
| CreatePointDirectionPerp | Creates a point perpendicular on a line definition. (page 444) |
| CreatePointDirectionObject | Creates a point at the intersection of a line and an object. (page 447) |
| CreatePointDistanceAlign | Creates a point at the intersection of a circle and an alignment. (page 455) |
| CreatePointDistanceDist | Creates a point at the intersection of two circles. (page 441) |
| CreatePointDivideAlign | Create a specified number of evenly spaced points relative to an alignment. (page 461) |
| CreatePointDivideObject | Creates a specified number of evenly spaced points along an object. (page 435) |
| CreatePointFormat | Creates a point file format. (page 500) |
| CreatePointGroup | Creates a point group. (page 529) |
| CreatePointHighLowPoint | Adds a high or a low point between two existing point objects. (page 483) |
| CreatePointImportFromFile | Creates points on an alignment using point data in an ASCII (text) file. (page 468) |
| CreatePointInterpolate | Interpolates two points with known elevations. (page 474) |
| CreatePointManual | Creates a point at a specified location in the drawing. (page 428) |
| CreatePointMeasureAlig | Creates points at equal intervals along an alignment. (page 462) |
| CreatePointMeasureObject | Creates points along an object using a specified distance. (page 437) |
| CreatePointNumByDist | Interpolates a specified number of point objects between two points. (page 478) |
| CreatePointObjectAlign | Creates a point at the intersection of an object and an alignment. (page 456) |
| CreatePointObjectObject | Creates a point at the intersection of two objects. (page 450) |
| CreatePointOnGrid | Creates points in a grid configuration using elevations from a surface. (page 484) |

| Command | Description |
| --- | --- |
| CreatePointRadialOrPerp | Creates points radial or perpendicular to an alignment. (page 467) |
| CreatePointRandomPoints | Creates a point at a specified location using an elevation from a surface. (page 483) |
| CreatePointResection | Creates a point at a position that is calculated from the measured angles between three known points. (page 430) |
| CreatePointSlopeGradeDist | Creates a specified number of points from an existing point object, based on slope/grade to a given direction and distance. (page 484) |
| CreatePointSlopeGradeElev | Creates a specified number of points from an existing point object, based on slope/grade to a given direction and elevation. (page 485) |
| CreatePoints | Displays the Create Points dialog box. (page 427) |
| CreatePointStationOffset | Creates points on an alignment at a specified station and offset. (page 459) |
| CreatePtAlongLnCurveSpir | Creates points along a line, feature line, lot line, or arc at a given distance from an end point. (page 433) |
| CreatePtAlongPolyContour | Creates points along a polyline or surface contour using elevations from a surface. (page 485) |
| CreatePtIncrementalDist | Interpolates point objects between two points based on an incremental distance from the first point. (page 480) |
| CreatePtIncrmntlElev | Interpolates point objects between two points based on an incremental elevation from the first point. (page 481) |
| CreatePtInterpPerpendic | Creates a point on an object that is either radial or perpendicular to the selected point. (page 452) |
| CreatePtInterpolIntersec | Interpolates point objects between two points, based on an intersection with the selected object. (page 482) |
| CreatePtOnLineCurveSpiral | Creates points at endpoints, PIs, and radius points of objects. (page 434) |

| Command | Description |
|---|---|
| CreatePtPlylineCtrVertMan | Creates points at the vertices of a polyline at a specified elevation. (page 438) |
| CreatePtPlylnCtrVertAuto | Creates points at the vertices of a polyline. (page 439) |
| CreatePtPolyContourVert | Creates points at polyline or surface contour vertices using elevations from a surface. (page 438) |
| CreatePtStationOffsetObj | Creates a point on an object at a specified station and offset. (page 431) |
| EditAllPoints | Modify point properties in the Point Editor. (page 488) |
| EditPointDatum | Changes the elevation of points. (page 492) |
| EditPointNumbers | Changespoint numbers. (page 493) |
| ExportPoints | Exports point data to a text or .mdb file. (page 505) |
| ImportPoints | Imports point data from a text or database file. (page 503) |
| SelectAndEditPointNumbers | Assign a new point number to selected points. (page 493) |
| ShowAllPGChanges | Displays and updates out-of-date point groups. (page 525) |
| ShowDescKeySetsList | Changes the description key set search order. (page 548) |
| ShowGeodeticCalculator | Calculates geodetic information relative to drawing zone and transformation. (page 516) |
| ShowPointFormats | Displays the Point File Format dialog box for creating, copying, or deleting point file formats. (page 2119) |
| ShowPointGroupProperties | Displays the Properties of a selected point group. (page 535) |
| ShowPointGroupsList | Displays all point groups. (page 525) |
| ShowPointSettings | Displays point settings. (page 410) |
| TransferPoints | Transfers points from one file (text or .mdb) to another file (text or .mdb). (page 506) |

# Point Groups

# 16

You can use named collections of points, called point groups, to organize points and to control their appearance in a drawing.

A point group has the following characteristics:

- It has persistent properties you can easily review or change.

- A points list displays the points included in a point group. The point list can be updated automatically. This might be necessary when you change the point group's properties, create new points that match the point group's properties, or erase or modify points that match the point group's properties.

- A point group can be locked to prevent changes within a drawing.

## Understanding Point Groups

Using point groups, you can organize points and control the appearance of points in a drawing.

### Reasons to Use Point Groups

Point groups provide a flexible and convenient way to identify points that share common characteristics or that are used to perform a task, such as creating a surface. You can use point groups to create groupings of points using point number, point name, point elevation, raw (field) or full description, and other characteristics.

Point groups also play a fundamental role in controlling how a point displays in a drawing. If you have a set of points that share common display characteristics, you can use a point group to identify the point style and point label style for all the points in the point group, instead of assigning a point style and a point label style to each individual point. Also, using a point group you can quickly change the style or label style for all the points in a point group at once, instead of changing each point individually.

The point group display order, the point group default styles, and the point group override styles can all affect how a point is drawn. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

### Point Group Properties

A point group is defined by properties which describe the criteria that a point must match to belong to a point group, such as its point number, its name, its raw or full description, or its elevation. Points that match the specified criteria are added to the point group's point list.

You can create a point group either before or after you create the points that belong to it. The point list is maintained dynamically, which means you are notified whenever a change occurs that could affect the point list. For more information, see Out-of-Date Point Groups (page 524).

**NOTE** A point can belong to more than one point group.

## Point Groups Collection (Prospector Tab)

Use the Point Groups collection on the Prospector tab to access point groups in a drawing. As point groups are created, they are listed by their name under the Point Groups collection.

Right-click the Point Groups collection to do the following:

■ Change the point group display order. (page 526)

■ Create a new point group. (page 529)

■ View information about out-of-date point groups before updating them. (page 524)

■ Automatically update all out-of-date point groups.

■ Refresh the display.

Expand the Point Groups collection to display a list of the point groups in the drawing. Right-click a point group to do the following:

■ Edit the point group's properties. (page 535)

■ Edit the points in the point group's point list.

■ Lock or unlock the points in the point group's point list. (page 528)

■ Export the points in the point group. (page 505)

■ Delete the points in the point group.

■ Make a copy of the point group. (page 534)

■ List the changes required to update the point group if it is out-of-date. (page 524)

■ Update the point group if it is out-of-date.

■ Delete the point group. (page 536)

■ Lock or unlock the point group in the drawing. (page 528)

■ Refresh the display.

## The _All Points Point Group

Use the _All Points point group to view a list of all the points in a drawing.

The _All Points point group is created automatically when you create a drawing. It is listed on the Prospector tab under the Point Groups collection, with the other drawing point groups.

When you create a drawing point, it is added to the _All Points point group point list. When you delete a drawing point, it is removed from the _All Points point group point list. A point can belong to other point groups in the drawing, but it is always a member of the _All Points point group.

The _All Points point group serves the following purposes:

■ It provides a default display for points that are created without a point style or point label style and do not belong to any other point group. The appearance of a point in the drawing can be controlled both by the point groups it belongs to and the order in which the point groups are displayed. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

■ It provides a complete list of all the points in a drawing.

Because the _All Points point group point list is automatically managed, you cannot change the point group properties using the Point Groups, Raw Desc Matching, Include, Exclude, and Query Builder tabs in the Point Group Properties dialog box. You can, however, change properties, such as styles and overrides using the Information tab and the Overrides tab.

## Point Group Default Styles

Use the Point Group Properties dialog box to specify a default point style and point label style for a point group.

The default point style and point label style for the point group can be viewed and changed in two locations in the point group properties dialog box: on the Information tab and on the Overrides tab.

If you change the default style on one tab, the other tab is updated to reflect the new style. The check box next to the style name on the Overrides tab indicates when the point group default style is used. If the check box is cleared, then the point group default style is used to display the point only if the point does not have an individual point style assigned. If the check box is selected, the point group default style is used to display each point in the point group, regardless of whether it has an individual point style assigned, according to the point group display order. For more information about point group display order, see Changing the Point Group Display Order (page 526).

Assign individual point styles either during point creation using the options in the Create Points dialog box or using description keys. Use the Point Editor to change individual point styles after a point is created.

For more information, see Controlling the Appearance of Points in a Drawing (page 425).

## Using Point Groups to Override Point Properties

Use the Overrides tab on the Point Group Properties dialog box to specify point property override values for the points that belong to the point group.

When a point belongs to a point group, you can override some of its individual properties using point group *overrides*. When you specify an override value, that value is used to display the point in the drawing and appears in drawing point lists. However, the stored value for the point is not changed.

You can use point groups to override the following point properties:

■ raw description

■ elevation

■ point style

■ point label style

The point group display order can affect the override values displayed in labels for raw description and elevation. It can also affect the point style and point label style that can be used to display a point in a drawing. For more information, see Changing the Point Group Display Order (page 526).

**Raw Description Override**

To specify a raw description override, click ⬚ and enter a value or click ⬚ and select or create an external data reference. For more information, see Using External Data References (page 508). To stop using the override, clear the check box.

**Elevation Override**

To specify an elevation override, click ⬚ and enter a value or click ⬚ and select or create an external data reference. For more information, see Using External Data References (page 508). To stop using the override, clear the check box.

**User-Defined Property Override**

To specify a User-Defined Property override, click ⬚ and cycle through and select ⬚ . Click in the row and select a user-defined property from the list. For more information, see Assigning User-Defined Properties to Point Groups (page 418). To stop using the override, clear the check box.

**Point Style and Point Label Style Overrides**

Use the override point style and point label style to display all the points that belong to the point group. For more information, see Point Group Default Styles (page 523) and Controlling the Appearance of Points in a Drawing (page 425).

# Managing Point Groups

You can manage and update point groups within a drawing.

To manage point groups within a drawing, you can:

- Identify and update out-of-date drawing point groups.

- Lock a point group or the points in a point group's point list.

- Change the point group display order within a drawing.

# Out-of-Date Point Groups

Use the Prospector tab or the Point Groups dialog box to identify out-of-date point groups.

Use the Prospector tree to list the point groups in a drawing. An out-of-date point group has ⬚ next to it in the Prospector tree, in the point group list view, and in the Point Group dialog box. When a point group is out-of-date, the points in the point list no longer match the criteria specified on the tabs in the Point Group Properties dialog box.

**NOTE** Out-of-date icons are displayed only if the Toolspace tree modifier icon display is active. For more information, see Drawing Item Modifier Icons (page 141).

A point group's point list may be out-of-date when one or more of the following occurs:

- You changed a point property (such as raw description or elevation) of a point belonging to the point group, so that the point no longer meets the criteria for being included in the point group.

- You created new points that match the point group's properties.

- You deleted points that belonged to the point group.

■ A point group that is included in the point group (using the Point Groups tab) became out-of-date due to one of the above causes.

For information about updating out-of-date point groups, see Updating All Out-of-Date Point Groups (page 525) and Updating a Single Out-of-Date Point Group (page 526).

## Updating All Out-of-Date Point Groups

Use the Point Groups dialog box to update all out-of-date point groups at once.

A point group is out-of-date when the points in the point list do not match the point group's properties. For more information, see Out-of-Date Point Groups (page 524).

An out-of-date point group has ![icon] next to it in the Prospector tree, the point group list view, or the Point Group dialog box.

**NOTE** Out-of-date icons are displayed only if the Toolspace tree modifier icon display is active. For more information, see Drawing Item Modifier Icons (page 141).

Before you update the point groups, you can use the Point Groups dialog box to view a list of the points that must be added to or removed from the out-of-date point groups to bring them up to date.

**To update all out-of-date point groups**

1 Click COGO Point tab ➤ Modify panel ➤ Edit Point Group List ![icon] .

   The Point Groups dialog box is displayed. Point groups marked with ![icon] are out-of-date.

2 In the Point Groups (page 2118) dialog box, click ![icon] to display information about the out-of-date point groups.

3 In the Point Group Changes (page 2119) dialog box, click ![icon] to update all out-of-date point groups.

4 Click Close in the Point Group Changes dialog box.

5 Click OK in the Point Groups dialog box.

## Updating a Single Out-of-Date Point Group

Use the Prospector tab to update an out-of-date point group.

An out-of-date point group has  ![icon]  next to it on the Prospector tab.

---

**NOTE** Out-of-date icons are displayed only if the Toolspace tree modifier icon display is active. For more information, see Drawing Item Modifier Icons (page 141).

---

A point group is out-of-date when the points in the point list do not match the point group's properties. For more information, see Out-of-Date Point Groups (page 524).

**To update a single out-of-date point group**

1   In Toolspace, on the Prospector tab, right-click a point group that is out-of-date. Click Show Changes.
    The Point Group Changes (page 2119) dialog box displays a list of the changes required to bring the point group up to date.

    ---

    **TIP** If you do not want to review the changes required to bring the point group up to date, click Update on the shortcut menu instead of Show Changes.

    ---

2   Click ![icon] to update the point group.

3   Click OK.

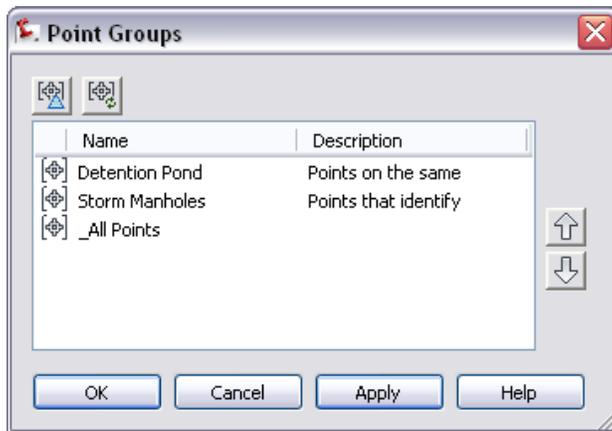
## Changing the Point Group Display Order

Use the point group display order to specify how points that belong to more than one point group are displayed in a drawing.


The point group display order for a drawing determines the order in which the point groups are drawn when a drawing is opened or graphics are regenerated. The first (highest) point group in the list is drawn last.

A point is drawn only once each time drawing graphics are regenerated. A point that belongs to more than one point group is drawn by the point group that is highest in the display order, and it is unaffected by the point groups that are lower in the display order. This can determine the point style, point label style, and the layer used to display the point. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

The point group display order is also used to display override values for elevation and description in labels. If a point belongs to more than one point group, the first point group in the display order that draws the point will determine whether override values are used. If the point group has an override for elevation or description, the label is displayed using the override value. If the point group does not have an override, the label is displayed without the override.

**To change the point group display order**

1  In Toolspace, on the Prospector tab, right-click the Point Groups collection. Click Properties.

2  In the Point Groups (page 2118) dialog box, select the point group you want to move in the display order.

3  Click ⬆ or ⬇ .

4  Click OK.

# Locking and Unlocking Point Groups

Use locking to prevent the properties of a point group from being modified in a drawing.

A locked point group cannot have its properties changed. It cannot be updated (if it is out-of-date), deleted, or overwritten.

A locked point group has  next to it in the Prospector tree and the point group list view. The icon is displayed only if the Toolspace tree drawing state icons are displayed. For more information, see Drawing Item State Icons (page 141).

Locking a point group does not lock the points in the point list. You can lock points individually in the Prospector list view, or you can lock all the points in the point group list at the same time using a single command. For more information, see Locking and Unlocking Point Lists (page 528).

**To lock or unlock a point group**

1   In Toolspace, on the Prospector tab, right-click the point group you want to lock or unlock.

2   Click Lock or Unlock.

## Quick Reference

Toolspace Shortcut Menu

# Locking and Unlocking Point Lists

Use point list locking to prevent the points in a point group from being modified in a drawing.

A locked point cannot have its properties changed in the drawing. A locked point has  next to it in point lists such as the Prospector tab Points list view. The icon is displayed only if the Toolspace tree drawing state icons are displayed. For more information, see Drawing Item State Icons (page 141).

Use a single command to lock or unlock all the points in a point group's point list.

**To lock or unlock a point list**

1   In Toolspace, on the Prospector tab, right-click the point group whose point list you want to lock or unlock.

2   Click Lock Points or Unlock Points.

# Specifying Case-Sensitive Description Matching for a Point Group

Specify whether description matching in the Point Group Properties dialog box is case-sensitive.

Case-sensitive matching is not a global setting. You set it separately for each point group.

The Use Case-Sensitive Matching check box on the Query Builder tab of the Point Group Properties dialog box specifies how description matching is performed on the Raw Desc Matching, Include, and Exclude tabs in the Point Group Properties dialog box.

**To specify case-sensitive description matching for a point group**

1 In Toolspace, on Prospector tab, right-click the point group you want to change. Click Properties.

2 In the Point Group Properties dialog box, click the Query Builder (page 2111) tab.

3 To enable or disable case-sensitive matching for raw and full descriptions, select or clear Use Case-Sensitive Matching.

4 Click Apply.

# Printing Point Groups

Use the Copy To Clipboard command to copy the points in a point group's point list to another application for printing.

To print the points in a point group, click the Prospector tab and then click the point group to display the point list in a list view. Right-click the list view. Click Copy To Clipboard to copy the list view into a file you can print. For more information, see Copying Items from a List View (page 86).

# Creating Point Groups

You create a point group by defining its properties.

Point groups organize and identify points that share common characteristics. Use point groups to assign point styles and point label styles for all the points in a point group instead of assigning styles individually.

Use the tabs on the Point Group Properties dialog box to define the properties of a point group. The tabs you use depend on which method you use to define a point group:

■ The Basic Method. Use this method to easily define the properties for many point groups. Use the Point Groups, Raw Desc Matching, Include, and the Exclude tabs of the Point Group Properties dialog box. Also, use this method when you want to identify points that belong to a point group by selecting points in a drawing.

■ The Query Builder Method. Use this advanced method to create point groups by combining expressions, which allows you to use a single tab, the Query Builder tab, to build a point group based on combinations of point properties or point groups. When you create a point group using the query builder method, the Point Groups, Raw Desc Matching, Include, and Exclude tabs are not available.

---

**NOTE** You should understand how to create a point group using the basic method before using the query builder.

---

After you create a point group, do not try to interchange the two methods to make changes to a point group. You can create a point group using the basic method and then change the point group properties using the Query Builder tab. However, you will lose the changes you made on the Query Builder tab if you then change the point group using the Point Groups tab, the Raw Desc Matching tab, the Include tab, or the Exclude tab.

You can always access the Information tab, the Overrides tab, the Point List tab, and the Summary tab regardless of the method used to define or change the point group's properties.

Because the list of points that belong to a point group (the point list) is updated dynamically, you can create point groups either before or after you create points in the drawing. If you create the points first, and then create the point group, the point list of the newly created point group is immediately updated with the existing points that match the criteria for inclusion in the point group. If you create a point group before you create points that qualify for inclusion in the point group, the point group is marked as out-of-date on the Prospector tab as points are created. You can easily update the point list to include the new points. For more information, see Out-of-Date Point Groups (page 524).

Also, you can create a point group when you import points. In the Import Points dialog box, specify the name of the point group to be created.

## Creating a Point Group Using the Basic Method

Use the basic method to easily define properties for point groups.

Include points in point groups by specifying point descriptions, point numbers, elevations, and point names. You can also include points in a point group by specifying the name of one or more other point groups or by using raw description matching.

**To create a point group using the basic method**

1 Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Point Group [⊕] .

2 In the Point Group Properties dialog box, on the Information (page 2108) tab, enter a name, description, default styles, and a layer for the point group.

3 To include points from other point groups, click the Point Groups (page 2108) tab and select the check box next to any point group you want to include.

4 To include points using raw descriptions, click the Raw Desc Matching (page 2109) tab and select the check box next to the raw descriptions you want to match.

  All points in the drawing are searched, and points with a raw description that matches a raw description specified on the tab are included in the point group.

5 To specify criteria that explicitly includes points in the point group, click the Include (page 2109) tab and define the criteria that a point must match to be included in the point group.

6 To specify criteria that explicitly excludes points from the point group, click the Exclude (page 2110) tab and define the criteria that a point must match to be excluded from the point group.

7 To specify overrides for points in the point group, click the Overrides (page 2113) tab.

8 To view the points in the point group's point list, click the Point List (page 2114) tab.

**9** To view a summary of the point group's properties, click the Summary (page 2114) tab.

**10** Click OK.

## Creating a Point Group Using the Query Builder

Use the query builder to create point groups by combining expressions.

The Query Builder tab of the Point Group Properties dialog box consolidates many of the options available on the Point Groups, Raw Desc Matching, Include, and Exclude tabs, and allows you to define a complex point group by combining expressions.

For example, to use the basic method to create a point group that includes both the points with a raw description that begins with FLOW and the points in the point group named Flow Line, you would need to use two tabs, the Include tab and the Point Groups tab. You can create the same point group using only the Query Builder tab. The following illustrates the Query Builder tab with a query that specifies that any point that either has a raw description that begins with FLOW or is a member of the Flow Line point group is included in the point group:

| Set Operator | ( | Property | Operator | Value |
|---|---|---|---|---|
| | ( | Raw Description | = | FLOW* |
| OR | | Point Group | = | * |
| | | | | |

The contents of the entire grid on the Query Builder tab is called a *query*. Each row in the query builder is an *expression*. You create a query by combining expressions using the set operators AND, OR, and NOT. For more information about building queries, see Understanding Point Group Queries (page 533).

**NOTE** Since the query builder is an advanced tool for creating point groups, it is recommended that you master point group creation using the basic method before you attempt to use the query builder.

When you first click the Query Builder tab, it displays a starting query that reflects the current contents of the Point Groups, Raw Desc Matching, Include, and Exclude tabs. After you understand how to create a point group using the basic method, you can learn how to build queries by doing the following:

■ Create a point group using the basic method.

■ In the Point Group Properties dialog box, click the Query Builder tab.

■ Examine the starting query, which is created from the information you specified on the Point Groups, Raw Desc Matching, Include, and Exclude tabs.

■ Make changes to the options on one of the above tabs, then return to the Query Builder tab and notice how the changes affected the query.

The Modify Query check box on the Query Builder tab determines which tabs in the Point Group Properties dialog box are active. When this check box is cleared, the Query Builder tab is inactive, and you can change the point group properties using the Point Groups, Raw Desc Matching, Include, and Exclude tabs. When the check box is selected, the Query Builder tab is active, you can change the query, the Point Groups, Raw Desc Matching, Include, and Exclude tabs are inactive.

In general, when you change the properties of a point group, you should set the state of the Modify Query check box once and leave it. Every time you select or clear the Modify Query check box, you can lose information on some tabs in the Point Group Properties dialog box. For example, if you change the query, and then clear the Modify Query check box to activate the other tabs in the dialog box, you lose the changes you made to the query.

**To create a point group using the query builder**

1  Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Create Point Group .

2  In the Point Group Properties dialog box, on the Information (page 2108) tab, enter a name, description, default styles, and a layer for the point group.

3  Click the Query Builder (page 2111) tab.

4  On the Query Builder tab, select Modify Query to activate the query builder.

   A starting query is created based on the contents of the Point Groups, Raw Desc Matching, Include, and Exclude tabs, and those tabs become inactive. If you are creating a new point group, the starting query is empty.

5  Each row in the query builder contains an expression. Do one of the following:

   ■ To create a new expression, activate the first row in the grid by right-clicking it and clicking Insert Row.

   ■ To modify an existing expression in the query or an existing empty row, activate the row containing the expression by clicking in it.

   ■ To delete an expression, click in the row containing the expression and press Delete.

6  Click in the Set Operator column and select a set operator from the list.

7  Click in the "(" column to turn the left parenthesis on or off for the expression.

8  Click in the Property column and select a property.

9  Click in the Operator column and select an operator.

10  Click in the Value column and enter a value that is valid for the property you specified in Step 8.

11  Click in the ")" column to turn the right parenthesis on or off for the expression.

12  Repeat Steps 5 through 11 to build the query.

13  When you finish building the query, click Apply.

14  To specify overrides for points in the point group, click the Overrides (page 2113) tab.

15  To view the points in the point group's point list, click the Point List (page 2114) tab.

16  To view a summary of the point group's properties, click the Summary (page 2114) tab.

**17** Click OK.

## Understanding Point Group Queries

You can use the query builder more effectively if you understand the components of a query.

A query consists of expressions that are combined using set operators.

### Expressions

An expression consists of the following three components:

■ property (for example: Point Number, Point Elevation)

■ comparison operators (for example: =, >, <=)

■ value (for example: 4, 20-87, 101.33)

Use properties, comparison operators, and values to create expressions such as the following:

■ Point Number = 1-100

■ Point Elevation > 1200

■ Point Group = Detention Pond

### Set Operators (AND, OR, and NOT)

Use set operators to combine or negate expressions.

For example, if you combine the first two expressions above with the OR set operator, the resulting query is:

(Point Number = 1-100) OR (Point Elevation > 1200)

The above query adds to the point group any point with either a point number between 1 and 100 or an elevation greater than 1200.

If you combine the first two expressions above with the AND set operator, the resulting query is:

(Point Number = 1-100) AND (Point Elevation > 1200)

The above query adds to the point group any point that has both a point number between 1 and 100 and an elevation greater than 1200.

The NOT operator allows you to exclude points using specified criteria. For example, if you preceded the first expression above with the NOT operator, the resulting query is:

NOT (Point Number = 1-100)

The above query excludes points from the point group if the point number falls between 1 and 100.

### Using Parentheses to Combine Expressions

You can use parentheses to combine expressions. Expressions that fall within parentheses are evaluated before they are combined with other expressions.

The following query uses parentheses to combine expressions:

(Raw Description = MON OR Raw Description = IP) AND (Point Elevation > 200)

Because the previous query is evaluated according to the parentheses, first (Raw Description = MON OR Raw Description = IP) is evaluated and then (Point Elevation > 200) is evaluated, then the two results are evaluated together using the AND set operator. The query adds to the point list only points with a raw description of MON or IP that have elevations greater than 200.

### Precedence of Operators

When parentheses are not used to combine expressions, the query is evaluated using only the following precedence of operators. The following lists the precedence of the operators from highest to lowest:

■ NOT

■ comparison operators (<> <= >= =)

■ AND

■ OR

The following query does not use parentheses to combine expressions:

Raw Description = MON OR Raw Description = IP AND Point Elevation > 200

Because the query is evaluated according to the precedence above, Raw Description = IP AND Elevation > 200 is evaluated first, then the results are evaluated with Raw Description = MON. The query adds to the point list any point that has a raw description of IP and an elevation > 200. It also adds to the point list any point with a raw description of MON, regardless of its elevation.

# Creating a New Point Group From an Existing Point Group

Create a new point group based on an existing point group by creating a copy of the existing point group and then changing the new point group's properties.

Point group names must be unique. When you create a point group by creating a copy, a new point group name is created based on the original point group name.

Change the name of a copied point group on the Information tab of the Point Group Properties dialog box.

### To create a new point group from an existing point group

1  In Toolspace, on the Prospector tab, right-click the point group you want to copy. Click Copy.

2  On the Prospector tab, right-click the new, copied point group. Click Properties.

**3** In the Point Group Properties (page 2108) dialog box, on the Information tab, change the name of the new, copied point group.

**4** Change the point group's properties using either the basic method or the query builder:

■ See Creating a Point Group Using the Basic Method (page 530).

■ See Creating a Point Group Using the Query Builder (page 531).

---

**NOTE** You must use the query builder to change the point group's properties if the Point Groups, Raw Desc Matching, Include, and Exclude tabs are inactive

---

### Quick Reference

Toolspace Shortcut Menu

# Creating a New Point Group From the Import Survey Data Wizard

A point group is created each time you import a point file using the Import Survey Data wizard.

The point group name defaults to the name of the file you import.

For more information, see Import Survey Data Wizard (page 239).

# Editing Point Groups

You can change the properties of existing point groups or delete a point group.

## Changing the Properties of a Point Group

Use the Point Group Properties dialog box to change the properties of a point group.

The Modify Query check box on the Query Builder tab controls which tabs are active in the Point Group Properties dialog box.

If the Modify Query check box is selected, the Point Groups, Raw Desc Matching, Include, and Exclude tabs are inactive. If the Modify Query check box is cleared, those tabs are active, and you can use them to change the properties of the point group.

**To change the properties of a point group**

**1** In Toolspace, on the Prospector tab, right-click the point group you want to change. Click Properties.

**2** In the Point Group Properties (page 2108) dialog box, use the Information (page 2108) tab to change the name, description, default styles, or layer for the point group.

**3** Change the point group's properties using either the basic method or the query builder:

■ See Creating a Point Group Using the Basic Method (page 530).

■ See Creating a Point Group Using the Query Builder (page 531).

### Quick Reference

## Changing Point Group Properties by Dragging Points into the Point Group

Include drawing points in a drawing point group using the Prospector tree drag-and-drop capability.

The destination point group must be visible in the Prospector tree. The drawing point you want to drag into the point group must be displayed in a list view.

**NOTE** To display all the points in the drawing in a list view, click the _All Points point group.

In the list view, select one or more points. Hold down the left mouse button, and drag the mouse to the

point group name in the Prospector tree. When the cursor display changes to        , release the mouse button
to drop the points into the point group at the tip of the cursor arrow.

The points are added to the point group's point list. The Include tab of the point group's Point Group
Properties dialog box is modified to include the point number of the points.

## Deleting a Point Group

Use the Prospector tree to delete a point group from a drawing.

Deleting a point group does not delete the points contained in the point group's point list. The points remain
in the drawing.

You cannot delete the _All Points point group from a drawing.

**To delete a point group**

1  In Toolspace, on the Prospector tab, right-click the point group you want to delete.

2  Click Delete.

### Quick Reference

# Description Keys

# 17

You can use description keys to automatically control point appearance and some point properties when creating or importing a point into a drawing.

Use description keys to automatically do the following when the drawing point is created:

■ Specify a point style, label style, and a layer for the point.

■ Specify scale and rotation of the point symbol.

■ Translate the raw description for the point into a full description.

## Understanding Description Keys

Before using description keys to create points, you should understand the contents of a description key and how the raw description for a point is used to match a description key.

### Overview

Use description keys to automatically control some drawing point properties, such as the appearance of a point in the drawing, when you create or import points. Before you create drawing points using description keys, create a series of description keys. Then, when you create or import a drawing point, the raw description for the point specifies which description key is used to create the point in the drawing. The properties defined for that description key are applied to the point as it is added to the drawing.

The following are sample description keys, showing code, point style, point label style, format, and layer properties:

| Code | Style | Point Label Style | Format | Layer |
|------|-------|-------------------|--------|-------|
| DRIV | ☑ <default> | ☑ Standard | DRIV $1 | ☑ V-NO |
| FLOV | ☑ <default> | ☑ Standard | $* | ☑ V-NO |
| GRNE | ☐ <default> | ☑ <default> | GROUNC | ☐ |
| LSCP | ☐ <default> | ☑ <default> | LANDSC/ | ☐ |
| MHF' | ☐ <default> | ☑ <default> | PMH | ☐ |

Each description key in a drawing is defined by its properties. Both the code property and the format properties are required in a description key.

Code property. Used during description key matching, for example, if the code matches the raw description for the point, then the properties specified in that description key are applied to the point when it is created.

A description key code can contain characters, called wild cards, that expand the matching capabilities of the description key. For more information, see Description Key Code (page 540).

Format property. Translates the raw description for a point into a full description. The default is $*, which indicates that the full description is the same as the raw description.

Optional description key properties include:

■ point style

■ point label style

■ layer

■ point symbol scaling information

■ point symbol rotation information

### Sample Raw Descriptions

The raw description for a point is used to determine whether a point matches a description key. The following are sample raw descriptions:

MONA U_POLE 1078 TREE OAK 5

The raw description can consist of as many as 10 alphanumeric elements separated by spaces. The leading element in the raw description (MONA, U_POLE, and TREE in the preceding sample) is compared to description key codes during description key matching. The remaining elements, called parameters, can be used to translate the raw description into a more readable full description and to rotate or scale the point symbol in the drawing.

### Description Key Matching During the Creation of Drawing Points

The description key matching process compares the leading element in the raw description of the point you are creating to each of the description key codes in the description keys contained in the drawing. The process ends either when a match is found or when all the description keys in the drawing have been searched.

If the leading element in the raw description for the point matches a description key code, the point style, the point label style, and the layer specified in the description key are used to create the drawing point. The raw description you entered is translated into a full description using the format specified in the description key. If the raw description includes scaling and rotation information, the point symbol is scaled and rotated as specified.

**NOTE** Description key matching is case-sensitive, which means that an upper case letter does not match a lower case occurrence of the same letter. For example, the raw description "TREE" would match the description key code "TREE." It would not match "Tree" or "tree."

### Accessing Description Keys

Description keys are stored in sets within a drawing. All the description key sets available in a drawing are listed in the Settings tree in the Description Key Sets collection.

# Description Key Sets Collection (Settings Tree)

You can use the Description Key Sets collection in the Settings tree to create and manage description key sets.

In the Settings tree, expand the Point collection and then expand the Description Key Sets collection to list the description keys in the drawing.

Right-click the Description Key Sets collection to:

■ [Specify the order in which the description key sets are searched during description key matching](#) (page 548).

■ [Create a new description key set](#) (page 547).

■ Refresh the Settings tree.

Right-click a description key set to:

■ [Display the name and description of the description key set](#) (page 2127).

■ [Edit the description keys in the description key set](#) (page 556).

■ [Copy the description key set](#) (page 548).

■ [Delete the description key set](#) (page 549).

■ Refresh the Settings tree.

# Description Key Settings

Control whether description keys are matched when points are created or imported, and whether the elements in a raw description are interpreted as parameters.

## Activating Description Key Matching

You can control whether description keys are matched when you create or import points.

When you create or import points, clear the Disable Description Keys check box in the Create Points dialog box if you want description key matching to occur.

**NOTE** If the Disable Description Keys setting in the Create Points dialog box is changed, then the Disable Description Keys in the Points Creation settings is changed to the same state if the Save Command Changes To Settings in the Drawing Settings is set to No. For more information about changing the Disable Description Key setting, see [Editing the Default Point Creation Settings](#) (page 415).

If description key matching is active and the raw description for the point matches a description key, the point is created with the point style, point label style, and layer specified in the description key. If a format is specified, the raw description is translated into a full description. If rotation or scaling parameters are specified in the description key, the point symbol is rotated or scaled. For a more information, see [Using Description Keys When Creating Points](#) (page 545) and [Using Description Keys When Importing Points from a File](#) (page 545).

## Controlling Whether Raw Description Values Are Interpreted as Parameters During Point Creation

You can use the Point Settings dialog box to control whether or not raw descriptions are interpreted as parameters during point creation.

Use the Match On Description Parameters ($1, $2, etc.) setting to specify whether or not parameters are used during description key matching to rotate and scale the point symbol.

■ True. Indicates that parameters are used during description key matching to scale or rotate point symbols. Because spaces are used to delimit description parameters, spaces in description key codes are not recognized. Spaces should not be used when this option is selected.

- False. Indicates that parameters are not used during description key matching to scale and rotate point symbols. Spaces in description key codes are recognized.

**To control whether raw description values are interpreted as parameters during point creation**

1   In Toolspace, on the Settings tab, expand the Commands collection under the Point collection.

2   Right-click CreatePoints. Click Edit Command Settings.

3   In the Edit Point Settings  (page 2103)dialog box, expand the Points Creation collection. For more information, see Editing the Default Point Creation Settings (page 415).

4   For Match On Description Parameters ($1, $2, etc.), select either True or False to specify whether or not raw descriptions contain parameters.

5   Click Apply.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click command name in object Commands collection  ➤  Edit Command Settings

Dialog Box

Edit Command Settings (page 1809)

# Description Key Properties

Each description key property performs a distinct function during description key matching and point creation.

Description key properties specify how a description key is matched and how the raw description for a point is translated to a full description. They can also be used to specify a point style, a point label style, and a layer for a point that matches the description key, and scaling and rotation values for the point symbol.

For a definition of all description key properties and instructions for editing them using the DescKey Editor, see Description Key Editor (page 2128).

# Description Key Code

Use the code property of a description key to specify which raw descriptions match the description key.

A description key consists of a code and a set of additional properties. When the code is matched, the other properties specified in the description key are applied to the point when it is created.

The following are sample description key codes:

DRIVS*
FLOW*
GRND*
LSCP*
MHE*
MHST*

You can either specify a simple string for a description key code or use wild card characters, such as an asterisk (**), to expand the matching capabilities of description keys.

For example, all your benchmark points might have the BM prefix in their raw descriptions, such as BM-1 and BM-2. When you add benchmark points to a drawing in AutoCAD Civil, you might want them all to

be created with the same point style, point label style, and description. To do this, you can create a description key with a code of BM*. (The asterisk means that the code will match all raw descriptions that begin with BM.) Then, all points with a raw description that begins with BM are created using the properties specified in that description key.

The following table shows wild card characters you can use in a description key code:

| Character | Function in Description Key Code |
| --- | --- |
| # (pound) | Matches any single numeric digit. |
| @ (at) | Matches any alphabetic character. |
| . (period) | Matches any non-alphanumeric character. |
| * (asterisk) | Matches any string and can be used anywhere in the search string. |
| ? (question mark) | Matches any single character, for example, ?BC matches ABC and 3BC. |
| ~ (tilde) | Matches anything but the pattern, for example, ~*AB* matches all strings that don't contain AB. |
| [...] (brackets) | Matches any one of the characters enclosed, for example, [AB]C matches AC and BC. |
| [~...] | Matches any character not enclosed, for example, [~AB]C matches XC but not AC. |
| - (hyphen) | Inside brackets, specifies a range for a single character, for example [A-G]C matches AC, BC, through GC, but not HC. |
| ' (reverse quote) | Reads the next characters exactly, for example, '*AB matches *AB. |

The following table shows examples of description key codes containing commonly used wild card characters:

| Description Key Code | Function |
| --- | --- |
| T# | Matches descriptions that consist of T followed by one digit, such as T1, T2, through T9. |
| STA# | Matches descriptions that consist of STA followed by one digit, such as STA1, STA2, through STA9. It does not match the description STA, since STA is not followed by a digit. |
| T## | Matches descriptions that consist of T followed by 2 digits, such as T01 through T99. |
| 1@ | Matches descriptions that consist of 1 followed by an alphabetic character, such as 1A, 1B, and 1C. It does not match the description 1, since 1 is not followed by an alphabetic character. |
| T. | Matches descriptions that consist of T followed by a single non-alphanumeric character, such as T- and T+. |

| Description Key Code | Function |
|---|---|
| T* | Matches descriptions that consist of T followed by any number of characters, such as T1, TOPO, T-2, and TREE. |

**NOTE** Description key matching is case-sensitive, which means that an upper case letter does not match a lower case occurrence of the same letter. For example, the raw description "TREE" would match the description key code "TREE." It would not match "Tree" or "tree."

# Description Key Format

Use the format property of a description key to create a full description for a point that matches a description key.

The following are sample description key formats:

```
DRIV $1
$*
GROUND
LANDSCAPE
PMH
DMH
```

The raw description for a point is always stored with the point and often corresponds to the point description entered by a surveyor in the field. Sometimes, for example, when you are labeling a point in a drawing, the raw description for the point does not contain information in the format you want. You can use the format property to create a full description that contains a more readable description of the point.

### Simple Methods of Specifying Full Descriptions

Define a standard full description for points that match a description key by specifying the desired description in the format property. For example, if you want all points that match a specific description key to have a full description of MONUMENT, enter MONUMENT for the format. Then, points that match the description key will be created with the full description MONUMENT.

If you want the full description to be the same as the raw description for all points that match the description key, enter $* for the format.

### Using Parameters to Translate a Raw Description into a Full Description

Create a readable full description from a raw description by either changing the order of the elements in the raw description or adding descriptive text. To do this, you must define a format that translates the raw description into a full description.

The raw description for a point consists of a list of elements separated by spaces, for example, TREE OAK 7. To re-order the elements in a raw description, you must reference the individual elements. When creating a format, you reference the leading element in a raw description using the symbol $0. You reference the remaining elements, which are referred to as parameters, using a $ followed by a number (1-9) that specifies the position for the parameter in the raw description.

For example, in the raw description TREE OAK 7, the leading element in the raw description, TREE, is referenced using the symbol $0. The first parameter, OAK, is referenced using the symbol $1. The second parameter, 7, is referenced using the symbol $2.

When a description key match occurs, the raw description is translated into a full description using the format, which references the elements in the raw description.

**NOTE** The leading element in a raw description is not referred to as a parameter. "Parameter" refers to the individual elements that follow the leading element in a raw description.

**Example**

You are creating a point, and for the raw description, you specify TREE OAK 7. One of your description key sets contains a description key with the code TREE and the format "$2 inch $1 tree."

The leading element in the raw description, TREE, matches the code in the description key, which is also TREE. The format specified in the description key, "$2 inch $1 tree," is used to translate the raw description into a full description for the point.

The $2 in the format refers to the second parameter in the raw description, which is 7. The $1 in the format refers to the first parameter in the raw description, which is OAK. The full description is created by substituting 7 for $2 and OAK for $1 in the format "$2 inch $1 tree." The text in the format ("inch" and "tree") is left unchanged. After the substitutions are made, the translated full description is "7 inch OAK tree."

The following is a chart of description key parameter substitution codes, including the code to use if you want the raw description to be used for the full description:

| Use this Code... | To do this in a format... | Example |
|---|---|---|
| $0 | Reference the leading element in the raw description. | **TREE** Oak 7 |
| $1 | Reference the first parameter in the raw description. | TREE **Oak** 7 |
| $2 | Reference the second parameter in the raw description. | TREE Oak **7** |
| $3 | Reference the third parameter in the raw description. | TREE Oak 7 **24** |
| $4, $5, through $9 | Reference the fourth parameter, the fifth parameter, through the ninth parameter. | |
| $+ | Reference all the parameters in the raw description after the leading element. | TREE **Oak 7** |
| $* | Reference all the parameters in the raw description and also the leading element. | **TREE Oak 7** |
| $$ | Insert a single $ into the description. | If you used $$200.00 as part of the format, then that part of the translated full description would be $200.00. |
| $* | Use the point's raw description for the full description. | If you used the raw descriptions UP-1, UP-2, and UP-3, and you want to use these descriptions for the full description, then use the $* as the format. |

# Specifying Point Symbol Scaling and Rotation Using Description Key Parameters

Use parameters to specify the point symbol scale or rotation value using the raw description for the point when a point matches a description key.

Parameters are elements that are included in the raw description for a point. For example, the raw description TREE OAK 7 consists of a leading element, TREE, followed by two parameters, OAK and 7, separated by spaces.

### Specifying Scale Using a Parameter

If you want the point symbol scale to be read from the raw description for the point when a description key match is found, use the scale parameter property. In the previous example, OAK is parameter 1, and 7 is parameter 2. If you wanted the description key to take the symbol scale value from the second parameter (7) you would specify Parameter 2 as the scale parameter.

For a complete description of all the options available for scaling a point symbol using a description key, see the Description Key Editor (page 2128).

### Specifying Rotation Using a Parameter

If you want the point symbol rotation to be read from the raw description for the point when a description key match is found, use the rotate parameter property. For example, a raw description Hyd 45 A consists of the leading element Hyd followed by two parameters: 45 is parameter 1, and A is parameter 2. If you wanted the description key to use 45 to rotate the point symbol, you would specify parameter 1 as the rotate parameter.

For a complete description of all the options available for rotating a point symbol using a description key, see the Description Key Editor (page 2128).

**NOTE** You can also use parameters in the raw description to create a full description by using a description key format. For more information, see Description Key Format (page 542).

# Description Key Properties That Are Stored with a Point

Some description key properties are stored with the point in the drawing.

When you create a point and description key matching is active, and a match is found, the point is created using the properties specified in the description key. The following description key properties are stored with the point, and can be changed for an individual point to alter its appearance in the drawing:

- Format
- X-Y Scale
- Z Scale
- Rotation

Use the Point Editor to change these properties.

# Managing Description Keys

You can use the Settings tree to manage description keys.

Description keys are organized into sets. The description key sets for a drawing are listed in the Settings tree under the Description Key Sets collection, which is found under the Point collection.

Each description key set contains one or more description keys. To view or edit the description keys contained within a set, use the DescKey Editor. For more information, see Editing Description Keys (page 556).

When description key matching is active and a drawing point is created, each description key code in every description key set in the drawing is searched for a match. You can control the order in which the description key sets are searched.

Include description key sets in a drawing template so they can be used in multiple drawings and shared with other people. For more information, see Drawing Templates (page 109).

## Using Description Keys When Creating Points

Use description keys when you create drawing points using the Create Points command.

When you create a drawing point and description key matching is active, the raw description you enter at the prompt initiates a search. The leading element in the raw description is compared to each description key code in every description key set in the drawing until either a match is found or all description key sets have been searched.

If a match is found, the point style, the point label style, and the layer specified in the description key are used to create the point. The raw description you entered is translated into a full description using the format specified in the description key. If the raw description includes scaling and rotation information, the point symbol is scaled and rotated as specified.

If a description key match is not found, the point is created without a point style or point label style. The point is displayed using point group styles. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

For more information about working with description keys, see Understanding Description Keys (page 537).

**To use description keys when creating points**

1  Create one or more description key sets containing the description keys you want to use to create the points. For more information, see Creating Description Keys (page 550).

2  Specify the description key sets search order. For more information, see Changing the Description Key Sets Search Order (page 548).

3  For Prompt For Descriptions Points Creation select Manual. For more information, see Editing the Default Point Creation Settings (page 415).

4  Specify the setting that indicates whether your description keys use parameters. See Controlling Whether Raw Description Values Are Interpreted as Parameters During Point Creation (page 539).

5  Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools ⬚ .

6  Expand the Create Points (page 2117) dialog box. Expand Points Creation and set the Disable Description Keysvalue to True.

7  Click a command on the toolbar. Follow the prompts to create a point.

8  When prompted for a description, enter the leading element of a raw description that matches the code specified in one of your description keys. If your description key requires parameters to complete the full description or to rotate or translate the symbol, enter the parameters, separated by spaces.

   The point is drawn using the properties specified in the description key, such as point style, point label style, and layer.

## Using Description Keys When Importing Points from a File

You can use description keys when you import points into a drawing.

Create drawing points by importing point data from a point data file, which can be either an ASCII text file or a Microsoft® Access database (*.mdb*) file. For more information about creating points by importing, see Importing Point Data (page 503).

When you import points from a point data file and description key matching is active, the raw descriptions in the point data file are used for matching. For each point that is imported, the leading element in its raw description is compared to each description key code in every description key set in the drawing until either a match is found or all description key sets have been searched.

If a match is found, the point style, the point label style, and the layer specified in the description key are used to create the point in the drawing. The raw description for the point is translated into a full description using the format specified in the description key. If the raw description includes scaling and rotation information, the point symbol is scaled and rotated as specified.

If a description key match is not found, the point is created without a point style or point label style, and the point displays using point group styles. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

For more information about working with description keys, see Understanding Description Keys (page 537).

**To use description keys when importing points from a file**

1   Create one or more description key sets containing the description keys you want to use when importing the points. For more information, see Creating Description Keys (page 550).

2   Specify the description key sets search order. For more information, see Changing the Description Key Sets Search Order (page 548).

3   Specify the setting that indicates whether or not your description keys use parameters. For more information, see Controlling Whether Raw Description Values Are Interpreted as Parameters During Point Creation (page 539).

4   Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools 🔧 .

5   Expand the Create Points (page 2117) dialog box.

6   Expand Points Creation and set the Disable Description Keysvalue to True. On the Points Creation toolbar, clickImport Points ⬆ .

7   In the Format list, specify a format name.

8   Import the points. For more information, see Importing Point Data (page 503).

    Any point with a raw description that matches a description key is created in the drawing using the properties specified in the description key, such as point style, point label style, and layer.

## Using Description Keys to Include Points in a Point Group

Use description key codes to include points in a point group.

You can include points in a point group based on description key matching. Use the Raw Desc Matching tab in the Point Group Properties dialog box to specify the description keys a point can match to be included in the point group. For more information, see Raw Desc Matching Tab (Point Group Properties Dialog Box) (page 2109).

You can also use either the raw description or the full description for a point to either include or exclude points from a point group. For more information, see Include Tab (Point Group Properties Dialog Box) (page 2109) and Exclude Tab (Point Group Properties Dialog Box) (page 2110).

# Creating a New Description Key Set

Use the Settings tree to create a description key set.

A description key set must have at least one description key in it. When you open a newly created description key set with the DescKey Editor, a starting description key is automatically added to the description key set.

**To create a new description key set**

1  In Toolspace, on the Settings tab, expand the Point collection.

2  Right-click the Description Key Sets collection. Click New.

3  In the Description Key Set (page 2127) dialog box, enter a name and description for the description key set.

4  Click OK.

   The description key set is created.

5  Right-click the new description key set. Click Edit Keys.

6  In the Description Key Editor (page 2128), edit the properties of the starting description key.

7  Add additional description keys to the description key set. For more information, see Creating a New Description Key (page 550).

## Quick Reference

Toolspace Shortcut Menu

  Settings tab: right-click Description Key Sets collection ➤ New

Command Line

  CreateDescKeySet

Dialog Box

  Description Key Set (page 2127)

# Importing a Description Key Set from AutoCAD Land Desktop

Import a description key set from AutoCAD Land Desktop.

You can import description key sets that you created in AutoCAD Land Desktop to use with COGO points.

**To import a description key**

1  Click Insert tab ➤ Import panel ➤ Land Desktop  .

2  In the Import Data From Autodesk Land Desktop Project dialog box, enter the Land Desktop Project Path and the Project name.

3  Select the Description Keys check box and click OK.

### Quick Reference

Click Insert tab ➤ Import panel ➤ Land Desktop

Menu

File menu Import ➤ Import Data From Land Desktop

# Creating a Description Key Set Based on an Existing Description Key Set

Use the Settings tree to copy a description key set.

When you create a copy of a description key set, the new description key set contains a copy of all the description keys in the original set.

**To create a description key set based on an existing description key set**

1  In Toolspace, on the Settings tab, expand the Point collection.

2  Expand the Description Key Sets collection.

3  Right-click the description key set you want to copy. Click Copy.

   A copy of the description key set is created. Its name is based on the name of the existing description key set.

4  Right-click the new description key set. Click Properties.

5  In the Description Key Set (page 2127) dialog box, enter a name and description for the new description key set.

6  Click OK.

7  Right-click the new description key set. Click Edit Keys.

8  In the Description Key Editor (page 2128), edit the description keys in the new description key set.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click Description Key Sets item ➤ Copy

# Changing the Description Key Sets Search Order

Specify the order in which description key sets are searched for matching description keys.

The Description Key Sets Search Order dialog box contains a list of description keys. The first description key set on the list is searched first, and the rest of the description key sets are searched sequentially in order, ending with the last description key set on the list.

**To change the search order of description key sets**

1  In Toolspace, on the Settings tab, expand the Point collection.

2  Right-click the Description Key Sets collection. Click Properties.

**3** In the Description Key Sets Search Order (page 2128) dialog box, click the name of a description key set to select it.

**4** Click ⬆ or ⬇ to move the point group up or down in the search order.

**5** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click Description Key Sets collection ➤ Properties

Command Line

ShowDescKeySetsList

Dialog Box

Description Key Sets Search Order (page 2128)

## Renaming a Description Key Set

Use the Settings tree to rename a description key set.

The new name does not affect the description keys contained within the set or the position of the description key set within the search order.

**To rename a description key set**

**1** In Toolspace, on the Settings tab, expand the Point collection.

**2** Expand the Description Key Sets collection.

**3** Right-click the description key set you want to rename. Click Properties.

**4** In the Description Key Set (page 2127) dialog box, enter a new name for the description key set.

**5** Optionally, enter a description.

**6** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click Description Key Sets item ➤ Properties

## Deleting a Description Key Set

Use the Settings tree to delete a description key set.

When you delete a description key set, all the description keys in the description key set are deleted.

For information about deleting an individual description key, see Deleting a Description Key (page 557).

**To delete a description key set**

**1** In Toolspace, on the Settings tab, expand the Point collection.

**2** Expand the Description Key Sets collection.

**3** Right-click the description key set you want to delete. Click Delete.

**4** Click Yes.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click Description Key Sets item ➤ Delete

## Printing Description Keys

Use the Copy to Clipboard command to either print a list of the description key sets in a drawing or to print a list of the description keys contained within an individual description key set.

To print a list of the description key sets in a drawing, click the Description Key Sets collection in the Settings tree to display a list view that contains the description key sets in the drawing. Right-click in the list view to display a shortcut menu. Use the Copy to Clipboard command to copy the contents of the list view into a file you can print.

To print a list of the description keys in a description key set, click the description key set in the Settings tree to display a list view that contains the description keys in the description key set. Right-click in the list view to display a shortcut menu. Use the Copy to Clipboard command to copy the contents of the list view into a file you can print.

For more information about the Copy to Clipboard command, see Copying Items from a List View (page 86).

## Creating Description Keys

You can use the DescKey Editor to create new description keys and to copy description keys.

You can also perform the these operations in the Prospector item view. However, the DescKey Editor, because it is a separate window, provides more viewing area and greater flexibility in your use of screen space.

## Creating a New Description Key

Use the DescKey Editor to create a new description key.

A new description key is always created with default properties. After you create the description key, you can change the properties.

**To create a new description key**

**1** In Toolspace, on the Settings tab, expand the Point collection.

**2** Expand the Description Key Sets collection.

**3** Right-click the description key set to which you want to add the description key. Click Edit Keys.

> **NOTE** You can create a new description key set to which you can add the description key. For more information, see Creating a New Description Key Set (page 547).

**4** In the Description Key Editor (page 2128), right-click in the section that contains description keys. Click New.

A new description key is created with default properties.

5   If necessary, display the columns that contain the properties you want to edit. Display and hide the columns in the DescKey Editor as you would in a list view. For more information, see Customizing a List View (page 84).

6   Edit the description key properties as needed. For more information, see Description Key Editor (page 2128).

7   Close the DescKey Editor.

## Quick Reference

Toolspace Shortcut Menu

Settings tab: Description Key Sets ➤ <description key set> ➤ right-click in List View ➤ New

# Creating a Description Key Based on an Existing Description Key

Use the DescKey Editor to copy a description key.

Create a copy of a description key within the same description key set. You cannot copy a description key from one description key set to another.

**To create a description key based on an existing description key**

1   In Toolspace, on the Settings tab, expand the Point collection.

2   Expand the Description Key Sets collection.

3   Right-click the description key set to which you want to add the description key. Click Edit Keys.

4   In the Description Key Editor (page 2128), right-click the description key you want to copy. Click Copy.

    A copy of the description key is created.

5   If necessary, display the columns that contain the properties you want to edit in the new description key. Display and hide the columns in the DescKey Editor as you would in a list view. For more information, see Customizing a List View (page 84).

6   Edit the properties of the new description key as needed. For more information, see Description Key Editor (page 2128).

7   Close the DescKey Editor.

## Quick Reference

Toolspace Shortcut Menu

Settings tab: Description Key Sets ➤ <description key set> ➤ right-click in List View ➤ Copy

# Example: Creating a Basic Description Key

This example shows how to create and use a basic description key.

In this example, you create a description key that is used to create utility pole points that have raw descriptions with a prefix of UP, for example, UP5A and UP4B. When these points are created in the drawing, they are displayed with the same symbol and layer. Each point maintains its individual description.

This example shows how to use a wild card character in the description key code so that a single description key matches any point whose raw description begins with the prefix UP.

As you work through this example, you might want more information about the contents of the columns in the DescKey Editor. For more information, see Description Key Editor (page 2128).

**Example: Creating a basic description key**

1   Before you begin, create a point style named UP_Symbol to be used to display the utility pole points created in this example. For more information, see Point Styles (page 419).

2   In Toolspace, on the Settings tab, expand the Point collection.

3   Right-click the Description Key Sets collection. Click New.

4   For Name, enter UP_Example. Click OK.

    A description key set named UP_Example is created and is listed in the Settings tree under the Description Key Sets collection.

5   Right-click UP_Example. Click Edit Keys.

    The DescKey Editor is opened. If you cannot see the DescKey Editor, click ⊞ at the top of the Settings tab to display the Panorama window.

    If you cannot see the column headings mentioned in the following steps, use the column heading shortcut menu to display or expand the column headings. You display and hide the columns in the DescKey Editor as you would in a list view. For more information, see Customizing a List View (page 84).

6   In the DescKey Editor, click in the first cell under the Code column heading. Enter UP* for the code.

    The asterisk (*) indicates that the description key will match any raw description that starts with UP, such as UP5A and UP5B.

7   Under the Point Style column heading, select the check box and click in the cell. In the Point Style dialog box, select UP_Symbol. Click OK.

    The UP_Symbol style will be used to display the symbol for points that match the description key you are creating.

8   Under the Point Label Style column heading, make sure that the check box is selected and that the Standard style is specified. The Standard style labels the point with point number, point elevation, and full description.

9   Click in the cell under the Format column heading, and enter $*.

    The dollar sign asterisk ($*) format means that the full description and raw description for the point will be the same.

    If you wanted, you could enter text, such as UTILITY POLE, which would be used as the full description for all points with a raw description beginning with UP, or you could assign a format that creates a full description from the raw description. For more information, see Description Key Format (page 542).

10  Under the Layer column heading, select the check box. Click in the cell and create a layer named PTS_UP.

11  Clear the check boxes under all other column headings.

    A point created using this description key will be placed on the PTS_UP layer.

12  Close the DescKey Editor.

13  If you have multiple description key sets defined, move the UP_Example set to the top of the search order. For more information, see Changing the Description Key Sets Search Order (page 548).

**14** Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools . In the Create Points dialog box, click  to expand the dialog box.

**15** Expand the Points Creation collection and specify the following settings:

■ For the Prompt For Descriptions, select Manual. For more information, see Editing the Default Point Creation Settings (page 415)

■ For the Disable Description Keys, set the value to False.

**16** From the Miscellaneous command list, select Manual.

**17** Pick the location for a new point.

**18** Follow the prompts. When you are prompted for the description, enter UP1A.

> **NOTE** Description key matching is case-sensitive, which means that an upper case letter does not match a lower case occurrence of the same letter. For example, the raw description "UP1A" matches the description key code "UP*", but it would does not match "up*" or "Up*".

**19** The point is drawn using the UP_Symbol point style and the Standard point label style. The point is created on the PTS_UP layer.

## Example: Using Description Key Parameters to Create a Full Description

This example shows how to use parameters in a description key format to translate a raw description into a full description.

> **NOTE** The following paragraphs are intended to help you understand this example. They do not provide a complete overview of description keys. For general information about description keys, see Understanding Description Keys (page 537). Before beginning this example, you should complete the example that shows you how to create a basic description key. For more information, see Example: Creating a Basic Description Key (page 551).

When you create a point, the description you enter at the command line is the raw description for the point. The raw description can consist of one element, such as UP5A, or of more than one element, such as UPNO 104. The leading element in a raw description is compared against description key codes during description key matching. The remaining elements in the raw description are called parameters. You can use parameters to create a full description for all points that match the description key.

In this example, you will create a description key that translate a raw description in the form UPNO <pole number> to a full description in the form U_POLE <pole number>. For example, the field (raw) description UPNO 104 will be translated to the full (drawing) description U_POLE 104.

In the raw description UPNO 104, UPNO is used to match the description key code and 104 is the first parameter. For more information, see Description Key Format (page 542).

**Example: Using description key parameters to create a full description**

**1** In Toolspace, on the Settings tab, right-click the Description Key Sets collection. Click New.

**2** For Name, enter Format_Example. Click OK.

A description key set named Format_Example is created.

**3** Right-click Format_Example. Click Edit Keys.

The DescKey Editor is opened. If you cannot see the DescKey Editor, click  at the top of the Settings tab to display the Panorama window.

If you cannot see the column headings mentioned in the following steps, use the column headings shortcut menu to display or expand the column headings. You display and hide the columns in the DescKey Editor the same way you display and hide the columns in a list view. For more information, see Customizing a List View (page 84).

4   In the DescKey Editor, click in the first cell under the Code column heading, and enter UPNO for the code.

The code will match any raw description whose leading element is UPNO.

5   Under both Point Style and Point Label Style heading columns, select the check boxes. Verify that the Standard style is specified.

**NOTE** The Standard point label style displays a full description for the point.

6   Click in the cell under the Format column heading, and enter U_POLE $1.

$1 refers to the first parameter in the raw description. This format will translate the raw description "UPNO 104" to the full description "U_POLE 104." For more information, see Description Key Format (page 542).

7   Under the Layer column heading, select the check box, click in the cell and create a layer named UP_LAYER. A point created using this description key will be placed on the UP_LAYER layer.

8   Clear the check boxes under all other column headings.

9   Close the DescKey Editor.

10  If you have multiple description key sets defined, move the Format_Example description key set to the top of the search order. For more information, see Changing the Description Key Sets Search Order (page 548).

11  Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools 🔧 .

12  In the Create Points dialog box, click ⮟ to expand the dialog box.

13  Expand the Points Creation collection and specify the following settings:
■   For the Prompt For Descriptions, select Manual. For more information, see Editing the Default Point Creation Settings (page 415)

■   For the Match on Description Parameters ($1, $2, etc.)  select True. For more information, see Controlling Whether Raw Description Values Are Interpreted as Parameters During Point Creation (page 539).

■   For the Disable Description Keys, set the value to False.

14  From the Miscellaneous command list, select Manual.

15  Pick the location for a new point.

16  Follow the prompts. When you are prompted for the description, enter UPNO 104.

The point is drawn using the full description derived from the description key, U_POLE 104.

## Example: Using Description Key Parameters to Format a Full Description and Scale a Point Symbol

This example shows how to use description key parameters to both expand the raw description for a point and to scale a point symbol.

**NOTE** The following paragraphs are intended to help you understand this example. They do not provide a complete overview of description keys. For an overview of description keys, see Understanding Description Keys (page 537). Before beginning this example, you should complete the example that shows you how to create a basic description key. For more information, see Example: Creating a Basic Description Key (page 551).

When you create a point, the description you enter at the command line is the raw description for the point. The raw description can consist of one element, such as TREE, or it can consist of more than one element, such as TREE OAK 7. The leading element in a raw description is compared against description key codes during description key matching. The remaining elements in the raw description are called parameters. You can use parameters to create a full description for a point or to rotate or scale a point.

In this example, you create a description key that translates a raw description with the format TREE <tree type> <tree size> into a full description that reads: <tree size> inch <tree type> tree, and you will scale the point symbol using the <tree size> value. For example, the raw description TREE OAK 7 will be translated to a full description 7 inch OAK tree. The point symbol will be scaled using a value of 7.

In the raw description TREE OAK 7, OAK is the first parameter and 7 is the second parameter. For more information, see Description Key Format (page 542).

**Example: Using parameters to format a full description and scale a point symbol**

1. Before you begin, create a point style named Tree_Symbol which will display the tree points created in this example. For more information, see Creating a Point Style (page 420).

2. In Toolspace, on the Settings tab, right-click the Description Key Sets collection. Click New.

3. For Name, enter Param_Example. Click OK.

   A description key set named Param_Example is created.

4. Right-click Param_Example. Click Edit Keys.

   The DescKey Editor is displayed. If you cannot see the DescKey Editor, click ⊞ at the top of the Settings tab to display the Panorama window.

   If you cannot see the column headings mentioned in the following steps, you may need to use the column headings shortcut menu to display them, or you may need to expand the column headings. You display and hide the columns in the DescKey Editor as you would in a list view. For more information, see Customizing a List View (page 84).

5. In the DescKey Editor, click in the first cell under the Code column heading, and enter TREE for the code.

   The code will match any point raw description whose leading element is TREE.

6. Under the Point Style column heading, select the check box and click in the cell. In the Point Style dialog box, select Tree_Symbol. Click OK.

7. Under the Point Label Style column heading, select the check box. Verify that the Standard point label style is specified.

8. Click in the cell under the Format column heading, and enter $2 inch $1 Tree.

   $2 refers to the second parameter in the raw description. $1 refers to the first parameter in the raw description. This format will translate the raw description "TREE OAK 7" into the full description "7 inch OAK tree."

   For more information, see Description Key Format (page 542).

9. Under the Layer column heading, select the check box. Click in the cell and create a layer named PTS_TREE. A point created using this description key will be placed on the PTS_TREE layer.

10. Under Apply To X-Y, select the check box.

11. Under Apply To Z, select the check box.

**12** Under Scale Parameter, select the check box.

**13** Under Scale Parameter, select the check box. Select Parameter 2.

Parameter 2 refers to the second parameter in the raw description, which is 7 in this example. This specifies that the second parameter in a description contains the value by which the point symbol is scaled.

**14** Clear the check boxes under all other column headings.

**15** Close the DescKey Editor.

**16** If you have multiple description key sets defined, move the Param_Example description key set to the top of the search order. For more information, see Changing the Description Key Sets Search Order (page 548).

**17** Click Home tab ➤ Create Ground Data panel ➤ Points menu ➤ Point Creation Tools 📍 .

**18** In the Create Points dialog box, click ⌄ to expand the dialog box.

**19** Expand the Points Creation collection and specify the following settings:

■ For the Prompt For Descriptions, select Manual. For more information, see Editing the Default Point Creation Settings (page 415)

■ For the Match on Description Parameters ($1, $2, etc.), select True. For more information, see Controlling Whether Raw Description Values Are Interpreted as Parameters During Point Creation (page 539).

■ For the Disable Description Keys, set the value to False.

**20** From the Miscellaneous command list, select Manual.

**21** Pick the location for a new point.

**22** Follow the prompts. When you are prompted for the description, enter TREE OAK 7.

A point is drawn and labeled with the full description 7 inch OAK tree, and the tree symbol is scaled.

**23** Create another point, and specify TREE OAK 5 for the raw description to see the impact on the full description and the scaled symbol.

# Editing Description Keys

You can use the DescKey Editor to edit and delete description keys.

To edit a description key, you must open the description key set that contains the description key.

The DescKey Editor is displayed as a vista (a tab) in the Panorama window. For more information about working with vistas, see The Panorama Window (page 102).

The DescKey Editor displays the description keys in a grid. Each row in the grid contains a description key. The columns contain the description key properties. You display and hide the columns in the DescKey Editor as you would in a list view. For more information, see Customizing a List View (page 84).

For a complete description of each column in the DescKey Editor, see Description Key Editor (page 2128).

**NOTE** You can edit description keys in the Prospector item view. However, the DescKey Editor, because it is a separate window, provides you with more viewing area and greater flexibility in your use of screen space.

# Opening the Description Key Editor

Use the Settings tree to open the DescKey Editor.

Before you can open the DescKey Editor, you must select a description key set to edit. The DescKey Editor displays all the description keys in the selected description key set.

**NOTE** You can also edit description keys in the Prospector item view. However, the DescKey Editor, because it is a separate window, provides you more viewing area and greater flexibility in your use of screen space.

**To open the Description Key Editor**

1 In Toolspace, on the Settings tab, expand the Description Key Sets collection.

2 Right-click the description key set you want to edit. Click Edit Keys.

3 Use the Description Key Editor (page 2128) to edit the individual description keys.

## Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click Description Key Sets item ➤ Edit Keys

Dialog Box

Description Key Editor (page 2128)

# Deleting a Description Key

Use the DescKey Editor to delete a description key from a description key set.

For information about deleting an entire description key set, see Deleting a Description Key Set (page 549).

**To delete a description key**

1 In Toolspace, on the Settings tab, right-click the description key set that contains the description key you want to delete. Click Edit Keys.

2 In the Description Key Editor (page 2128), right-click the description key you want to delete. Click Delete.

3 Close the DescKey Editor.

# Lines and Curves

# 18

Many commands for creating lines and curves are included in AutoCAD Civil.

## Creating Lines

You can use the AutoCAD Civil line creation commands to draft line geometry prior to defining it as alignments or parcels, for example.

Several of the AutoCAD Civil Line commands are simply the AutoCAD Line combined with an AutoCAD Civil transparent command. For example, when you run the Line By Bearing command, the AutoCAD Line command starts, but the 'BD transparent command also launches so you can immediately enter a bearing value. For more information on transparent commands, see Transparent Commands (page 1581).

## Creating Lines By Selecting a Start and End Point

The Line command on the Home tab ➤ Draw panel launches the AutoCAD LINE command. Use this command to draw a line by selecting start and end points.

**To create a line by selecting a start and end point**

1 Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line .

2 Specify the start point.

You can use the pointing device or enter coordinate values on the command line.

3 Complete the first line segment by specifying the endpoint.

To undo the previous line segment during the Line command, enter **U** or click Undo on the toolbar.

4 Specify the endpoints of any additional line segments.

5 Press Enter to end or **C** to close a series of line segments.

6 To start a new line at the endpoint of the last line drawn, start the Line command again and press Enter at the Specify Start Point prompt.

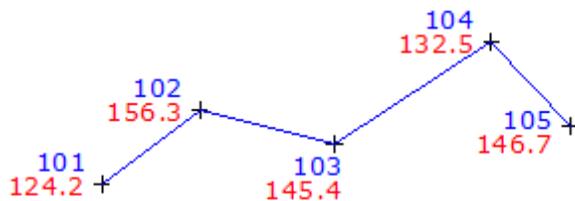
# Creating Lines by Specifying a Range of Point Numbers

The Line By Point # Range command runs the AutoCAD Line command combined with the 'PN transparent command (page 1590) so you can specify a range of point numbers through which to draw the line.

You can specify a sequence of point numbers by using a comma. For example, the sequence 1-3,7 draws a line between points 1, 2, 3, and 7.


**To create a line by specifying a range of point numbers**

1 Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line By Point # Range ⊕ .

2 Enter the number of the point at which you want to start the line.

3 Enter a hyphen (-).

4 Enter the number of the point at which you want to end the line segment and press Enter.

# Creating Lines Through Specified Point Objects

The Line By Point Object command runs the AutoCAD Line command combined with the 'PO transparent command (page 1591) so you can select point objects through which to draw the line.

To select the points, you can select any part of the point objects, such as the marker or the label.

**To create a line by specifying point objects**

1 Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line By Point Object .

2 Select the start point in the drawing.

3 Select the next point in the drawing.

4 Continue to select points to define additional line segments. Or press Enter to return to the Line command prompt where you can use additional options to define the line.

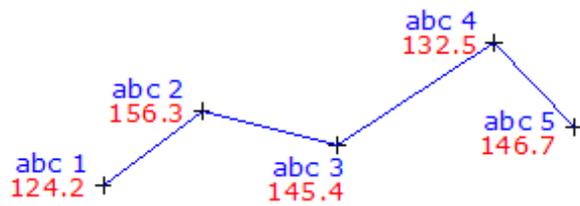
# Creating Lines by Specifying Point Names

The Line By Point Name command runs the AutoCAD Line command combined with the 'PA transparent command (page 1592) so you can specify the names of points through which to draw the line.

This command allows you to draw a line between points by specifying their names instead of their point numbers.


**To create a line by specifying point names**

1 Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line By Point Name 🔣 .

2 Enter the name of the start point.

3 Enter the name of the next point.

4 Continue to enter point names to define additional line segments. Or press Enter to return to the Line command prompt where you can use additional options to define the line.

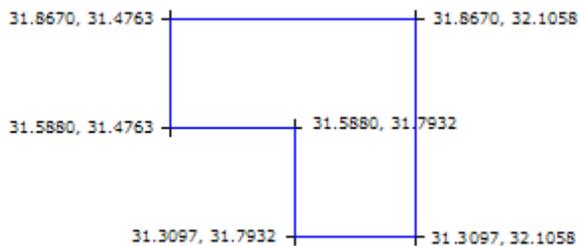
# Creating Lines by Specifying Northing/Easting Coordinates

The Line By Northing/Easting command runs the AutoCAD Line command combined with the 'NE transparent command (page 1588) so you can specify northing and easting coordinates of the line segments.

The order of the prompts is controlled by the Transparent Command Ambient drawing settings.


**To create a line by specifying northing and easting**

**1** Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line By Northing/Easting .

**2** Enter a northing value.

**3** Enter an easting value.

> **NOTE** The order in which you are prompted for northing and easting is controlled by the Transparent Command setting Prompt For Easting Then Northing, located on the Ambient Settings tab of the Drawing Settings dialog box. For more information, see Specifying Ambient Settings (page 68).

**4** Continue to enter northing and easting values to define the line segments. Or press ESC to return to the Line command prompt where you can use additional options to define the line.

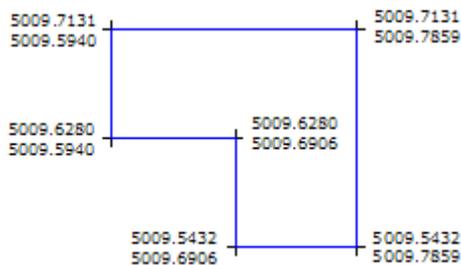
# Creating Lines by Specifying Grid Northing/Easting Coordinates

The Line By Grid Northing/Grid Easting command runs the AutoCAD Line command combined with the 'GN transparent command (page 1589) so you can specify grid northing and easting coordinates of the line segments.

A coordinate system must be specified in the drawing. The order of the prompts is controlled by the Transparent Command Ambient drawing settings.



**To create a line by specifying grid northing and easting**

**1** Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line By Grid Northing/Grid Easting .

**2** Enter a grid northing value.

**3** Enter a grid easting value.

**NOTE** The order in which you are prompted for grid northing and grid easting is controlled by the Transparent Command setting Prompt For Easting Then Northing, located on the Ambient Settings tab of the Drawing Settings dialog box. For more information, see Specifying Ambient Settings (page 68).

**4** Continue to enter grid northing and easting values to define the line segments. Or press ESC to return to the Line command prompt where you can use additional options to define the line.

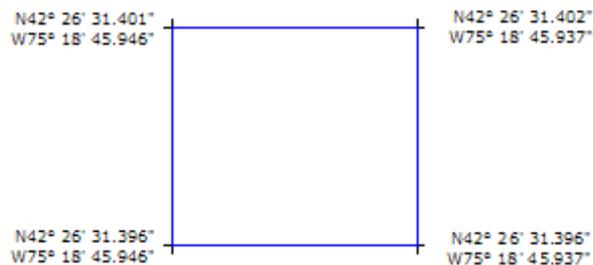
# Creating Lines by Specifying Latitudes and Longitudes

The Line By Latitude/Longitude command runs the AutoCAD Line command combined with the 'LL transparent command (page 1590) so you can specify latitude and longitude coordinates of the line segments.

A coordinate system must be specified in the drawing. The order of the prompts is controlled by the Transparent Command Ambient drawing settings.



**To create a line by specifying latitude and longitude**

**1** Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line By Latitude/Longitude ⟳ .

**2** Enter a latitude value.

**3** Enter a longitude value.

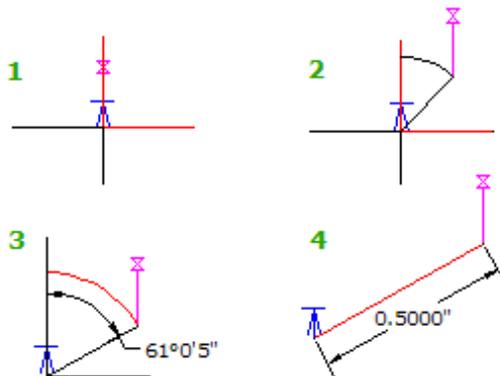
**NOTE** The order in which you are prompted for latitude and longitude is controlled by the Transparent Command setting Prompt For Longitude Then Latitude, located on the Ambient Settings tab of the Drawing Settings dialog box. For more information, see Specifying Ambient Settings (page 68).

**4** Continue to enter latitude and longitude values to define the line segments. Or press ESC to return to the Line command prompt where you can use additional options to define the line.

# Creating Lines by Specifying Bearings

The Line By Bearing command runs the AutoCAD Line command combined with the 'BD transparent command (page 1584) so you can specify a direction and distance for the line segment.

From the start point (1), specify the quadrant (2). Then specify the bearing (3) and distance (4).



**To create a line by specifying bearings**

1 Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line By Bearing  .

2 Select a temporary start point for the angle measurement by clicking in the drawing or by using the .P, .N, or .G point filters (page 1599).

3 Specify a quadrant number by either clicking in the drawing or entering a value between 1 and 4.

4 Specify the bearing within the quadrant by clicking in the drawing or entering a bearing using the angular units for the drawing.

5 Specify the distance by either clicking in the drawing or entering a distance.

6 Continue to specify bearings and distances to define line segments. Or press Enter to return to the Line command prompt where you can use additional options to define the line.

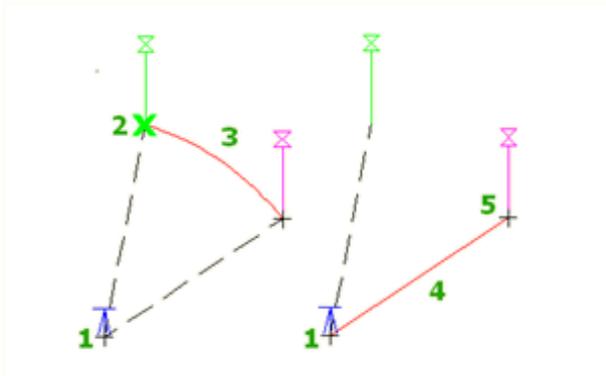
# Creating Lines by Specifying Angles

The Line By Angle command runs the AutoCAD Line command combined with the 'AD transparent command (page 1582) so you can specify an angle and a distance for the line segment.

The first sequence of prompts is for establishing a temporary reference line for measuring the angle. From the reference line (1-2), specify an angle (3), and distance (4), to specify a point (5).



**To create a line by specifying angles**

1   Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line By Angle .

2   Specify a temporary reference line for the angle by doing one of the following:
    ■ Select a line.
    ■ Enter **Points**, or **P**, and then specify a start point and endpoint for the line.

3   Specify the angle by doing one of the following:
    ■ Click in the drawing to specify the angle.
    ■ Enter a positive or negative numeric value for the angle.
    ■ Enter **C** to switch the angle between counterclockwise and clockwise, and then specify the angle.

4   Specify the distance by either clicking in the drawing or entering a distance.

5   Specify an ending point.
    This concludes the specification of the temporary reference line. Subsequent prompts for angles and distances are then used to define the line segments.

6   Enter angles and distances to define line segments. You can then press Enter to return to the Line command prompt where you can use additional options to define the line.

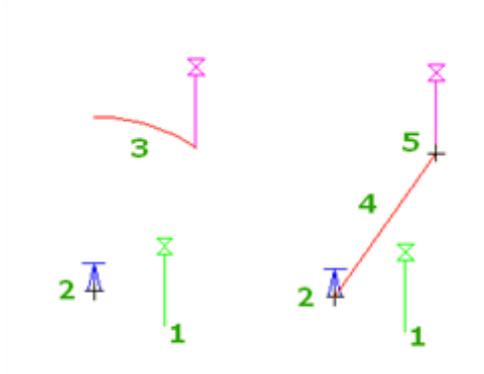
# Creating Lines by Specifying Deflection Angles

The Line By Deflection command runs the AutoCAD Line command combined with the 'DD transparent command (page 1585) so you can specify a deflection angle and a distance.

The first sequence of prompts is for establishing a temporary reference line for measuring the angle.

From the reference line (1-2) and start point (2), specify a deflection angle (3), and distance (4) to specify a point (5).



**To create a line by specifying deflection angles**

1 Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line By Deflection ⬕.

2 Specify a temporary reference line for the angle by doing one of the following:
   - Select a line.
   - Enter **Points**, or **P**, and then specify a start point and endpoint for the line.

3 Specify the angle by doing one of the following:
   - Click in the drawing to specify the angle.
   - Enter a positive or negative numeric value for the angle.
   - Enter **C** to switch the angle between counterclockwise and clockwise, and then specify the angle.

4 Specify the distance by either clicking in the drawing or entering a distance.

5 Specify an ending point.
   This concludes the specification of the temporary reference line. Subsequent prompts for angles and distances are then used to define the line segments.

6 Enter angles and distances to define line segments. You can then press Enter to return to the Line command prompt where you can use additional options to define the line.

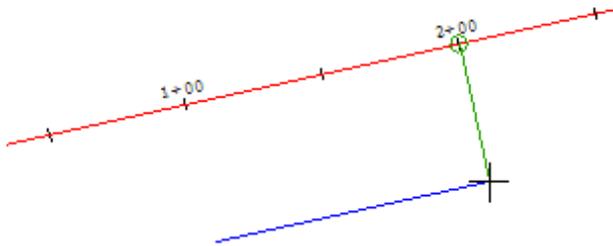
# Creating Lines by Specifying Stations and Offsets

The Line By Station/Offset command runs the AutoCAD Line command combined with the 'SO transparent command (page 1592) so you can immediately specify a station and offset from an alignment.

An alignment must exist in the drawing to use this command.



**To create a line by specifying station and offset from an alignment**

1  Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line Station/Offset ⟋⸾ .

2  Select the alignment.

3  Specify a station by either entering a station value or clicking in the drawing.

4  Specify a distance by either entering an offset or clicking in the drawing.

5  Specify a station and offset for the next point in the line. Or press Enter to return to the Line command prompt where you can use additional options to define the line.

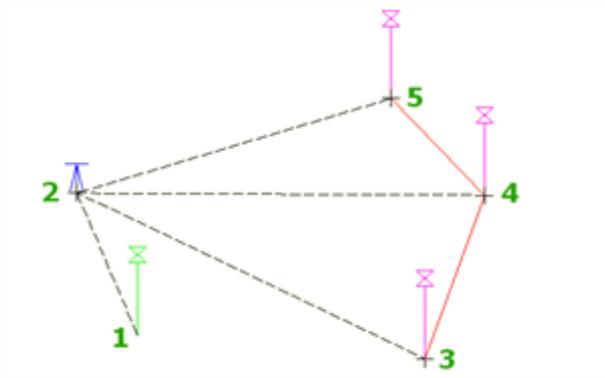
# Creating Lines by Sideshot

The Line By Side Shot command runs the AutoCAD Line command combined with the 'SS transparent command (page 1587) so you can specify one or more point locations relative to a fixed point by specifying an angle (bearing, azimuth, angle, or deflection) and distance.

After defining the reference line, specify an angle and distance to the points that will define the line segment. From the reference line (1-2) and start point (2), specify points (3, 4, 5).



**To create a line by sideshot**

1 Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line By Side Shot .

2 Specify a temporary reference line by doing one of the following:

■ Select a line.

■ Enter **Points**, or **P**, and then specify a start point and endpoint for the line.

The following prompt is displayed:

`Specify angle or [Counter-clockwise/Bearing/Deflection/aZimuth]:`

3 Enter an angle by doing one of the following:

■ Enter an angle in angular units for the drawing.

■ Enter **Bearing**, or **B**, and then specify the angle by specifying a quadrant and a bearing.

■ Enter **Deflection**, or **D**, then specify a deflection angle.

■ Enter **aZimuth**, or **Z**, and then specify an azimuth.

■ Enter **C** to switch the direction of the angle between clockwise and counterclockwise.

4 Specify a distance by either clicking in the drawing or entering a distance.

5 Continue to specify angles and distances to define line segments. Or presss Enter to return to the Line command prompt where you can use additional options to define the line.

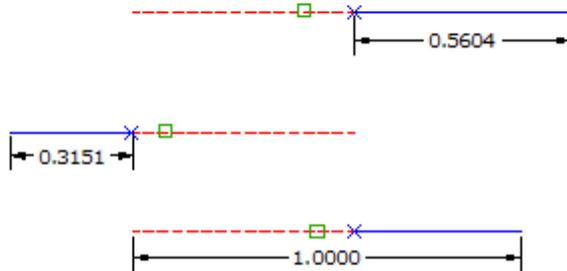
# Extending Line Lengths

The Line Extension command extends an existing line by a specified distance or alters the line to match the total length specified.

The line is extended from the end of the existing line that is closest to the selection point.



**To extend an existing line**

1 Click Home tab ➤ Draw panel ➤ Line drop-down ➤ Create Line By Extension .

2 Select the line to extend.

3 To define the length of the line, do one of the following:

■ Select two locations to specify the length that you want to add to the line.

■ Enter a positive distance to extend the line.

■ Enter a negative distance to shorten the line.

■ Enter **Total**, or **T**, and then enter the total length of the segment. You can either type the new total length, or select two locations to define the total length. This total length can be greater than (to lengthen the line), or smaller than (to shorten the line), the current length of the line.

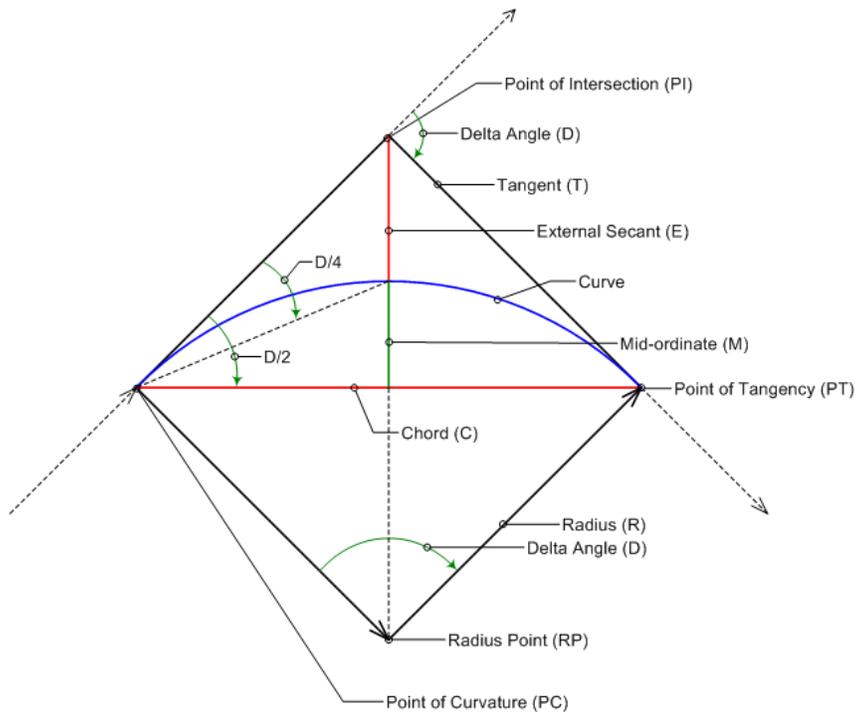
# Creating Curves

Use the curve commands to draft curve geometry prior to defining it as alignments or parcels.

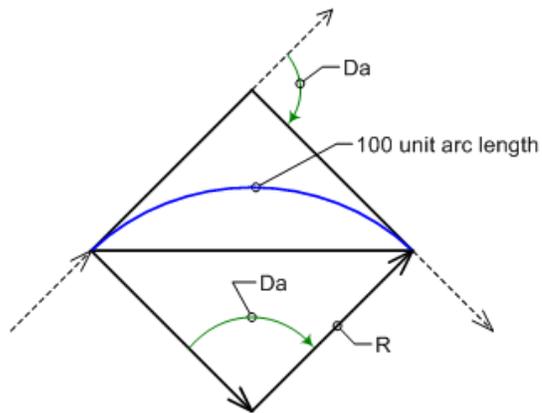
**The following illustration shows the curve parameters used by AutoCAD Civil.**


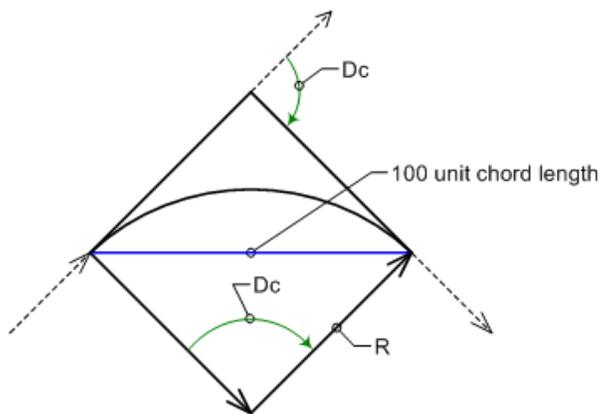
**The following illustration shows the degree of curve definition for arcs and chords.**

**Degree of Curve Arc Definition**

- Da
- 100 unit arc length
- Da
- R

**Degree of Curve Chord Definition**

- Dc
- 100 unit chord length
- Dc
- R




# Creating Curves Between Two Lines

The Curve Between Two Lines command creates a curve between two existing lines.

The selected lines are trimmed to the resulting point of curvature (PC) and point of tangency (PT).

You can use the Curve Calculator (page 593) to determine the values required for defining the curve.

**To create a curve between existing lines**

**1** Click Home tab ➤ Draw panel ➤ Curves drop-down ➤ Create Curves Between Two Lines ⌒.

**2** Select the first tangent.

**3** Select the second tangent.
The following prompt is displayed:

```
Select entry [Tangent/External/Degree/Chord/Length/Mid-ordinate/miN-dist/Radius] <Radius>:
```

**4** Enter one of the following options to define the curve:

■ Enter **Length**, or **L**, and then enter the length or pick the distance in the drawing.

■ Enter **Tangent**, or **T**, and then enter the tangent length or pick the distance in the drawing.

■ Enter **External**, or **E**, and then enter the secant length or pick the distance in the drawing.

■ Enter **Degree**, or **D**, to define the curve by degree of curve.
The following prompt is displayed:

```
Enter degree of curve (Arc), or [Chord]:
```

Enter the degree of curve in DD.MMSS format using the Arc or Chord option.

Use the Chord option if the curve is a railway curve. For a railway curve, the degree of curve is the angle at the center of a circular curve subtended by a chord of 100 units.

Use the Arc option if the curve is a roadway curve. For a roadway curve, the degree of curve is the central angle subtended by a circular arc of 100 units.

■ Enter **Chord**, or **C**, and then enter the chord length or pick the distance in the drawing.

■ Enter **Mid-ordinate**, or **M**, and then enter the distance or pick the distance in the drawing.

■ Enter **miN-dist**, or **N**, and then select the end of an existing curve. Then enter the minimum distance between the end of the new curve and the point selected on the existing curve.

---

**NOTE** The command sets the Object Snap to END for this prompt. The point you select does not have to be on an existing curve; it can be any point along the adjacent tangent.

---

■ Enter **Radius**, or **R**, and then and then enter the radius or pick the distance in the drawing.

CurveBetweenTwoLines

# Creating Curves On Two Lines

The Curve On Two Lines command creates a curve between two existing lines.

The selected lines are not trimmed to the resulting point of curvature (PC) and point of tangency (PT).

You can use the Curve Calculator (page 593) to determine the values required for defining the curve.

**To create a curve between existing lines, without trimming the lines**

1  Click Home tab ➤ Draw panel ➤ Curves drop-down ➤ Create Curve On Two Lines 𝐴 .

2  Select the first tangent.

3  Select the second tangent.
   The following prompt is displayed:

   ```
   Select entry [Tangent/External/Degree/Chord/Length/Mid-ordinate/miN-dist/Radius] <Radius>:
   ```

4  Enter one of the following options to define the curve:

   ■  Enter **Length**, or **L**, and then enter the length or pick the distance in the drawing.

   ■  Enter **Tangent**, or **T**, and then enter the tangent length or pick the distance in the drawing.

   ■  Enter **External**, or **E**, and then enter the secant length or pick the distance in the drawing.

   ■  Enter **Degree**, or **D**, to define the curve by degree of curve.
      The following prompt is displayed:

      ```
      Enter degree of curve (Arc), or [Chord]:
      ```

      Enter the degree of curve in DD.MMSS format using the Arc or Chord option.

      Use the Chord option if the curve is a railway curve. For a railway curve, the degree of curve is the angle at the center of a circular curve subtended by a chord of 100 units.

      Use the Arc option if the curve is a roadway curve. For a roadway curve, the degree of curve is the central angle subtended by a circular arc of 100 units.

   ■  Enter **Chord**, or **C**, and then enter the chord length or pick the distance in the drawing.

   ■  Enter **Mid-ordinate**, or **M**, and then enter the distance or pick the distance in the drawing.

   ■  Enter **miN-dist**, or **N**, and then select the end of an existing curve. Then enter the minimum distance between the end of the new curve and the point selected on the existing curve.

      **NOTE** The command sets the Object Snap to END for this prompt. The point you select does not have to be on an existing curve; it can be any point along the adjacent tangent.

   ■  Enter **Radius**, or **R**, and then and then enter the radius or pick the distance in the drawing.

**Quick Reference**

# Creating Curves Through a Specified Point

The Curve Through Point command creates a tangent arc that passes through a selected point between two line objects.

After selecting the two lines (1-2), select the pass-through point (3). The line objects are trimmed to the point of curvature (PC) and the point of tangency (PT).

**To create a curve between existing lines through a specified point**

1   Click Home tab ➤ Draw panel ➤ Curves drop-down ➤ Create Curve Through Point ⌒.

2   Select the first tangent.

3   Select the second tangent.

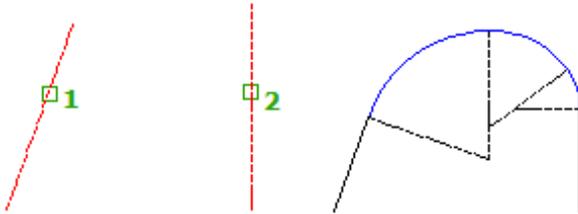
4   Select the pass-through point.

**Quick Reference**

# Creating Multiple Curves

The Multiple Curves command creates up to ten adjoined curves between two lines.

You can use this command as an alternative to designing alignment curves with spiral sections because the curves can have different lengths and radii.



**To create multiple, adjoined curves**

1  Click Home tab ➤ Draw panel ➤ Curves drop-down ➤ Create Multiple Curves.

2  Select the first tangent.

3  Select the second tangent.

4  Specify the number of curves to insert between the two tangents. You can specify a maximum of 10.

5  Specify which curve will have a floating length. One curve in the set must have a floating length that is calculated by the lengths and radii of the other curves. This is usually a middle curve.

6  Enter the length and radius for all but the floating curve, and enter the radius of the floating curve.

If the results cannot fit between the two selected line objects, the following message is displayed:

```
Curves cannot fit between the tangents chosen.
Press any key to continue.
```

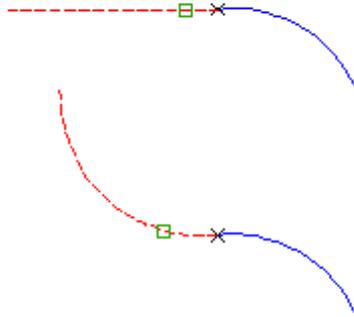
# Creating Curves From the End Of an Object

The Curve From End Of Object command creates a tangent arc from the end of a selected line or arc.

The curve is drawn from the end of the object that is closest to the object selection point.


**To create a curve from the end of an object**

1. Click Home tab ➤ Draw panel ➤ Curves drop-down ➤ Create Curve From End Of Object .

2. Select the line or arc nearest the end to which the new tangent arc is to be attached.

3. Specify one of the following types of entries to use:
   - **Point**: Enter **P** and then specify the end of the chord. The curve is then drawn.

   - **Radius**: Enter **R** and then do one of the following:
     - Enter the radius at the prompt.

     - Enter **A** and enter a degree of curve.

     - Enter **C** and enter a degree of chord.

   **NOTE** When drawing a curve, specifying a positive radius or degree of curve draws the curve clockwise or to the right of the starting angle, whereas a negative radius or degree of curve draws the type curve counterclockwise or to the left.

   After you enter the radius or degree of curve, the following prompt is displayed:

   ```
   Select entry [Tangent/Chord/Delta/Length/External/Mid-ordinate] <Length>:
   ```

4. Do one of the following:
   - Enter **Tangent**, or **T**, and then enter the tangent length, or pick the distance in the drawing.

   - Enter **Chord**, or **C** , and then enter the chord length, or pick the distance in the drawing.

   - Enter **Delta**, or **D**, and then enter the delta angle, or pick the distance in the drawing.

   - Enter **Length**, or **L**, and then enter the curve length, or pick the distance in the drawing.

   - Enter **External**, or **E**, and then enter the external distance, or pick the distance in the drawing.

   - Enter **Mid-ordinate**, or **M**, and then enter the mid-ordinate distance, or pick the distance in the drawing.

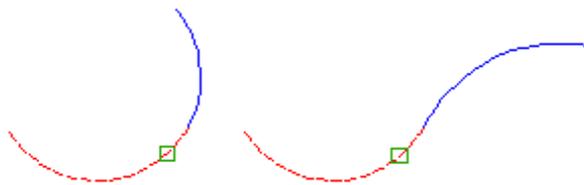
# Creating Reverse or Compound Curves

The Reverse or Compound command draws a reverse or compound curve from the endpoint of an existing curve.

A compound curve is a curve consisting of two or more arcs of different radii curving in the same direction and having a common tangent or transition curve at their point of junction. A reverse curve is an S-shaped curve.


**To create a reverse or compound curve**

1 Click Home tab ➤ Draw panel ➤ Curves drop-down ➤ Create Reverse Or Compound Curve 〰.

2 Select the arc object nearest the end to which the new compound or reverse curve is to be attached.

3 Specify whether to create a Reverse or Compound curve.

4 Do one of the following:

■ Enter the radius at the prompt.

■ Enter **A** and enter a degree of curve.

■ Enter **C** and enter a degree of chord.

After you enter the radius or degree of curve, the following prompt is displayed:

```
Select entry [Tangent/Chord/Delta/Length/External/Mid-ordinate] <Length>:
```

5 Do one of the following:

■ Enter **Tangent**, or **T**, and then enter the tangent length, or pick the distance in the drawing.

■ Enter **Chord**, or **C** , and then enter the chord length, or pick the distance in the drawing.

■ Enter **Length**, or **L**, and then enter the curve length, or pick the distance in the drawing.

■ Enter **Delta**, or **D**, and then enter the delta angle, or pick the distance in the drawing.

■ Enter **External**, or **E**, and then enter the external distance, or pick the distance in the drawing.

■ Enter **Mid-ordinate**, or **M**, and then enter the mid-ordinate distance, or pick the distance in the drawing.

# Creating Entities by Best Fit

Use the Best Fit Entities commands to use a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen as a basis to create AutoCAD lines, arcs, and parabolas.

The best fit commands are useful when you have to resurvey existing infrastructure during rehabilitation projects. In these cases, survey data may not match the original design. This requires you to edit the lines and curves in your design to best represent the actual survey data.

The best fit commands use the least square regression model to create lines, arcs, and parabolas from AutoCAD Civil points, AutoCAD points, clicks on screen, or existing entities such as lines, arcs, polylines, feature lines, etc. The line or curve that best fits through these objects represents the minimum deviation from the original design.

**NOTE** When using the best fit commands for profile design, use the Create Parabola command for vertical curves. See Vertical Curve Design (page 1068) for more information.

# Creating Lines by Best Fit

Use the create line by best fit command to use a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen as a basis to create an AutoCAD line.

The best-fitting line through the points is calculated. You can then use a dialog box to exclude any of the specified points or to select a pass-through point.

**To create an AutoCAD line by best fit from AutoCAD Civil points**

1   If you are creating a best fit line for a profile, set the profile view style vertical exaggeration to 1. See Creating and Editing Profile View Styles (page 1030) for more information.

2   Click Home tab ➤ Draw panel ➤ Best Fit drop-down ➤ Create Best Fit Line.

3   In the Line By Best Fit Dialog Box (page 1989), select From COGO Points.

4   Select two or more points. Enter G to select a point group or N to enter points by number.

    As you select points in the drawing window, a white X marks each regression point and a temporary, dashed line is displayed in real time.

5   Press Enter to complete the command.

6   In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

    As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window will be highlighted in red.

    **NOTE** When the AutoCAD line is created, it will not retain any link to the regression points.

7   Create the AutoCAD line:

    ■   Click  to create the line and keep the regression data. You may then use the data as a basis to create more lines.

    ■   Click  to create the line, clear the regression data, and close the Regression Data vista.

8   If desired, convert the AutoCAD line to an alignment or profile entity. See Converting an AutoCAD Line or Arc to an Alignment Sub-Entity (page 990) or Converting AutoCAD Entities to Profile Sub-entities (page 1096) for more information.

**To create an AutoCAD line by best fit from AutoCAD points**

1   If you are creating a best fit line for a profile, set the profile view style vertical exaggeration to 1. See Creating and Editing Profile View Styles (page 1030) for more information.

2   Click Home tab ➤ Draw panel ➤ Best Fit drop-down ➤ Create Best Fit Line.

3   In the Line By Best Fit Dialog Box (page 1989), select From AutoCAD Points.

4   Select two or more AutoCAD points.

    As you select points in the drawing window, a white X marks each regression point and a temporary, dashed line is displayed in real time.

5   Press Enter to complete the command.

6   In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

    As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window will be highlighted in red.

    **NOTE** When the AutoCAD line is created, it will not retain any link to the regression points.

**7** Create the AutoCAD line:

- ■ Click ![save icon] to create the line and keep the regression data. You may then use the data as a basis to create more lines.

- ■ Click ![checkmark icon] to create the line, clear the regression data, and close the Regression Data vista.

**8** If desired, convert the AutoCAD line to an alignment or profile entity. See Converting an AutoCAD Line or Arc to an Alignment Sub-Entity (page 990) or Converting AutoCAD Entities to Profile Sub-entities (page 1096) for more information.

**To create an AutoCAD line by best fit from existing entities**

**1** If you are creating a best fit line for a profile, set the profile view style vertical exaggeration to 1. See Creating and Editing Profile View Styles (page 1030) for more information.

**2** Click Home tab ➤ Draw panel ➤ Best Fit drop-down ➤ Create Best Fit Line ![icon].

**3** In the Line By Best Fit Dialog Box (page 1989), select From Entities. Specify the tessellation and mid-ordinate tolerance settings.

**4** Select one or more of the entities listed at the command line.

---
**NOTE** You may select several types of entities listed at the command line.

---

As you select entities in the drawing window, a white X marks each regression point and a temporary, dashed line is displayed in real time.

**5** If you selected a profile object, specify the starting and ending station on the Specify Station Range Dialog Box (page 1992).

**6** Press Enter to complete the command.

**7** In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window will be highlighted in red.

---
**NOTE** When the AutoCAD line is created, it will not retain any link to the regression points.

---

**8** Create the AutoCAD line:

- ■ Click ![save icon] to create the line and keep the regression data. You may then use the data as a basis to create more lines.

- ■ Click ![checkmark icon] to create the line, clear the regression data, and close the Regression Data vista.

**9** If desired, convert the AutoCAD line to an alignment or profile entity. See Converting an AutoCAD Line or Arc to an Alignment Sub-Entity (page 990) or Converting AutoCAD Entities to Profile Sub-entities (page 1096) for more information.

**To create an AutoCAD line by best fit by clicking on screen**

**1** If you are creating a best fit line for a profile, set the profile view style vertical exaggeration to 1. See Creating and Editing Profile View Styles (page 1030) for more information.

**2** Click Home tab ➤ Draw panel ➤ Best Fit drop-down ➤ Create Best Fit Line ![icon].

**3** In the Line By Best Fit Dialog Box (page 1989), select By Clicking On The Screen.

**4** Select a starting point and at least one other point.

> **NOTE** You may use OSNAP or transparent commands to select points.

As you select points in the drawing window, a white X marks each regression point and a temporary, dashed line is displayed in real time.

**5** Press Enter to complete the command.

**6** In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window will be highlighted in red.

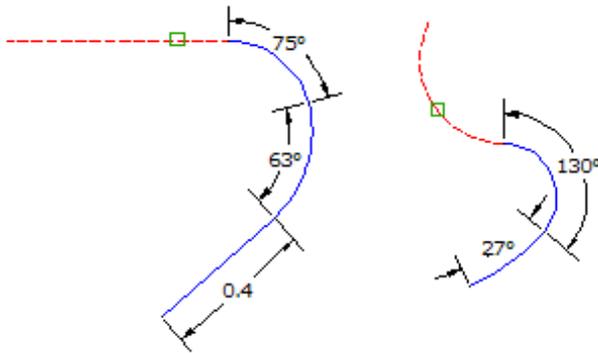
# Attaching Multiple Lines or Curves to Existing Objects

The Attach Multiple command draws multiple lines and curves from the end of an existing line or arc.

The lines or curves are drawn from the end of the object closest to the selection point.



**To attach multiple lines**

**1** Click Home tab ➤ Draw panel  Attach Multiple.

**2** Select a line or arc.

**3** Enter **Line**, or **L**, to attach a line.

**4** Enter the length of the new line section.

The new line is drawn and the following prompt is displayed:

```
Enter an attachment option [Line/Arc/Undo]:
```

**5** Continue to add line or arc segments or use the Undo option to undo the last segment.

**To attach multiple curves**

**1** Click Home tab ➤ Draw panel ▼ Attach Multiple 🔲 .

**2** Select a line or arc.

**3** Enter **Arc**, or **A**, to attach an arc.

**4** Specify one of the following types of entries to use:

- **Point**: Enter **P** and then specify the end of the chord. The curve is then drawn.

- **Radius**: Enter **R** and then do one of the following:

  - Enter the radius at the prompt.

  - Enter **A** and enter a degree of curve.

  - Enter **C** and enter a degree of chord.

---

**NOTE** When drawing a curve, specifying a positive radius or degree of curve draws the curve clockwise or to the right of the starting angle, whereas a negative radius or degree of curve draws the type curve counterclockwise or to the left.

---

After you enter the radius or degree of curve, the following prompt is displayed:

```
Select entry [Tangent/Chord/Delta/Length/External/Mid-ordinate] <Length>:
```

**5** Do one of the following:

- Enter **Tangent**, or **T**, and then enter the tangent length, or pick the distance in the drawing.

- Enter **Chord**, or **C** , and then enter the chord length, or pick the distance in the drawing.

- Enter **Delta**, or **D**, and then enter the delta angle, or pick the distance in the drawing.

- Enter **Length**, or **L**, and then enter the curve length, or pick the distance in the drawing.

- Enter **External**, or **E**, and then enter the external distance, or pick the distance in the drawing.

- Enter **Mid-ordinate**, or **M**, and then enter the mid-ordinate distance, or pick the distance in the drawing.

The new line is drawn and the following prompt is displayed:

```
Enter an attachment option [Line/Arc/Undo]:
```

**6** Continue to add line or arc segments or use the Undo option to undo the last segment.

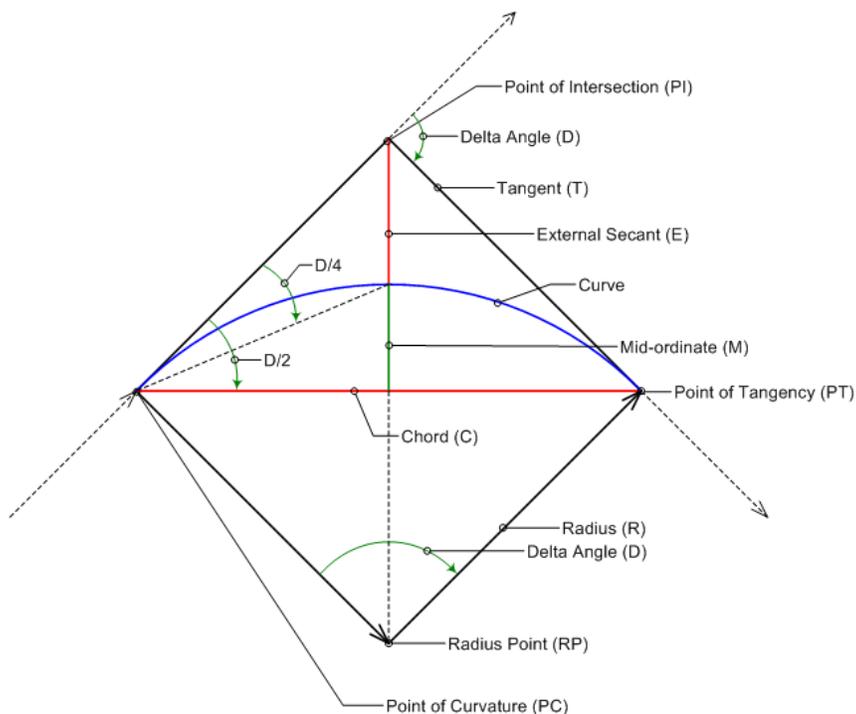
# Calculating Curve Parameters

The Curve Calculator determines curve parameters based on input.

You can keep the Curve Calculator open while you do other work and use the buttons to send the output of the curve calculations to the command line.

**NOTE** To change the units used in the Curve Calculator dialog box, use the Ambient Settings tab of the Drawing Settings dialog box. Under Angle, change the Format value to the unit you want to use. For more information, see To specify ambient settings for a drawing (page 68).

**The following illustration shows the curve parameters used by AutoCAD Civil.**



**To calculate curve parameters**

1   Click Home tab ➤ Draw panel ➤ Curves drop-down ➤ Curve Calculator ⬚ .

2   Specify whether the degree of curve is determined by arc or by chord by selecting an option from the Degree of Curve Definition drop-down list. The selected option affects how the Degree of Curve Property is calculated.

   ■ **Chord Definition**: Use this option if the curve is a railway curve. Using this option, the degree of curve is the angle at the center of a circular curve subtended by a chord of 100 units.

   ■ **Arc Definition**: Use this option if the curve is a roadway curve. Using this option, the degree of curve is the central angle subtended by a circular arc of 100 units.

**3** Specify a Fixed Property for the curve by selecting one of the following options:

- **Radius**: Specifies that the radius will be fixed.

- **Delta Angle**: Specifies that the delta angle will be fixed.

The program then holds as fixed either of the two parameters above while performing calculations.

**4** Specify one or more additional parameters for the curve.

- **Degree Of Curve**: Specifies the degree of curve.

- **Delta Angle**: Specifies the delta angle of the curve. This option is not adjustable if Delta Angle is specified as the Fixed Property.

- **Radius**: Specifies the radius of the curve. This option is not adjustable if Radius is specified as the Fixed Property.

- **Tangent Distance**: Specifies the tangent length of the curve.

- **Arc Distance**: Specifies the arc length of the curve.

- **Chord Distance**: Specifies the chord length of the curve.

- **External Distance**: Specifies the external secant length of the curve.

- **Mid-ordinate Distance**: Specifies the mid-ordinate length of the curve.

**5** Optionally you can also:

- Click  to send any of the values to the AutoCAD command line.

- Right-click and select Copy Value To Clipboard to copy the selected value to the clipboard.

- Right-click and select Copy To Clipboard to copy the entire contents of the Curve Calculator to the clipboard.

- Click  to select an arc in the drawing to display its values in the calculator. No edits you subsequently make in the calculator are updated to the arc in the drawing.

# Labeling Lines, Curves, and Polylines

You can label individual line and curve segments, one at a time, or multiple segments at once by using specified line and curve label styles.

# Labeling Individual Line and Curve Segments

You can label individual line and curve segments on lines, curves, polylines, and feature lines.

On the Toolspace Settings tab, in the General Label Style collection, set up Line and Curve label styles (page 1479) to use for the lines, curves and polylines.

On the Toolspace Settings tab, in the General Label Style collection, specify the default line label style (page 1476).

Use the Single Segment or Multiple Segment command to quickly label a line or curve using the default label style.

Use the Add Line/Curve Labels option to access the Add Labels dialog box (page 1970) if you need to create or modify a style before labeling a line or curve segment.

**To label individual line and curve segments**

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Line And Curve ➤ Add Single Segment Line/Curve Label 🏷 .

2 Select the line segment to label.

OR

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Line And Curve ➤ Add Line And Curve Labels 🏷 .

2 In the Add Labels dialog box (page 1970), under Feature, ensure that Line And Curve is selected.

3 Under Label Type, select Single Segment.

4 Specify the other options as required.

5 Click Add and then select the feature line or segment to label.

## Quick Reference

# Adding Line/Curve Tables

Use line/curve tables to consolidate information about the line and arc segments in your drawing.

Tables provide an alternative to labels for information management. Tables keep the information organized and separate from the drawing, but cross-referenced by small labels known as tags.

When segment information is displayed in table rows, table tags uniquely identify the segments in the drawing and in the initial cells of table rows. For example, if a line segment is labeled L234, its corresponding table row is also labeled L234.

The line and curve table creation commands are available from the Labels & Tables panel on the Annotate tab.

You create and edit tables for most objects using the same common procedures and standard dialog boxes. For general information about modifying tables, see Modifying Tables (page 1567).

# Renumbering Table Tags

Use the renumbering command to renumber table tags before creating tables.

In this release of AutoCAD Civil, the table tag renumbering command is available from the Tables contextual tab. It is also available from the Labels & Tables panel on contextual tabs for objects that support tags, such as Alignment and Parcel.

For more information, see Renumbering Label Tags (page 1544). The Table Tag setting process is now a drawing-wide setting. See Creating Label Tags (page 1544) for more information.

# Lines and Curves Command Reference

Quickly access Lines and Curves functionality from the command line.

| Command | Description |
|---|---|
| AttachMultiple | Attaches multiple lines or curves to existing entities (page 591) |
| CreateArcByBestFit | Creates an arc by best fit (page 585) |
| CreateLineByBestFit | Creates an AutoCAD line by best fit (page 582) |
| CreateParabolaByBestFit | Creates an AutoCAD parabola by best fit (page 589) |
| CurveBetweenTwoLines | Creates a curve between two existing lines (page 575) |
| CurveCalculator | Calculates curve parameters based on input. (page 593) |
| CurveFromEndOfObject | Creates a tangent arc from the end of a selected line or arc (page 579) |
| CurveOnTwoLines | Ceates a curve between two existing lines, but does not trim the selected lines (page 576) |
| CurveThroughPoint | Creates a tangent arc that passes through a selected point between two line objects (page 578) |
| LineExtension | Extends an existing line (page 571) |
| LineFromEndOfObject | Draws a tangent line from an existing object in the drawing (page 571) |
| LinePerpendicular | Draws a perpendicular or radial line from a selected point on an object (page 573) |
| LineTangent | Draws a tangent line from a selected point on an object (page 572) |
| MultipleCurves | Creates multiple,adjoined curves between two lines (page 579) |
| ReverseOrCompound | Draws a reverse or compound curve from the end-point of an existing curve (page 581) |

# Surfaces

# 19

Surfaces are basic building blocks in AutoCAD Civil. You can import surface information from LandXML, TIN (page 2485) (triangulated irregular network), and DEM (page 2472) (digital elevation model) files, and use points, point files, DEM data, existing AutoCAD objects, contours, breaklines, and boundaries to create surfaces.

Surfaces Workflow

## Understanding Surfaces

A surface is a three-dimensional geometric representation of an area of land, or, in the case of volume surfaces, is a difference or composite between two surface areas.

Surfaces are made up of triangles or grids, which are created when AutoCAD Civil connects the points that make up the surface data.

To use a surface in your drawing, you can create an empty surface and then add data to it. You can also import existing files containing surface information, such as LandXML, TIN (page 2485), or DEM (page 2472) files.

Points or contours are usually a primary part of the original surface information and are supplemented with breakline (page 2469) and boundaries (page 2469).

## Types of Surfaces

AutoCAD Civil supports several types of surfaces:

■   **TIN surfaces**. Formed by triangulating an arbitrary set of points.
For more information, see Creating a TIN Surface (page 601).

■   **Grid surfaces**. Formed from points that lie on a regular grid (for example, Digital Elevation Models (DEMs)).
For more information, see Creating a Grid Surface (page 603).

■   **TIN volume surfaces**. A composite surface created from a combination of points in a top (comparison) and base surface, also known as a differential surface.
For more information, see Creating a TIN Volume Surface (page 604).

- ▣ **Grid volume surfaces**. A differential surface based on user-specified top and bottom surfaces with points on a user-specified grid.
  For more information, see Creating a Grid Volume Surface (page 606).

## The Surface Object

Surfaces persist in an AutoCAD drawing as objects with the names AECC_TIN_SURFACE (TIN surface) or AECC_GRID_SURFACE (grid surface).

All AutoCAD Civil objects are aware of each other and react to changes. For example, a change in a surface results in multiple automatic updates in alignments, parcels, or other objects that reference that surface.

For overview information about AutoCAD Civil objects, see Understanding Objects and Styles (page 51).

## Surfaces Collection (Prospector Tab)

Use the Surfaces collection in the Prospector tree to access the surfaces in a drawing. As surface objects are created, they are displayed as named surfaces under the Surfaces collection.

Right-click the Surfaces collection to do the following:

- Create a new surface. (page 601)

- Import DEM data to create a surface. (page 608)

- Import TIN data to create a surface. (page 607)

- Turn on or off the surface preview (page 684). A check mark is displayed next to the Show Preview menu item when the preview option is selected.

- Export surface data to DEM. (page 714)

- Export the surface to LandXML format. (page 714)

- Refresh the view of the Surfaces collection in the Prospector tree.

If you have added a surface to the current drawing, you can expand the Surfaces collection to view the names of the surfaces or select surfaces to display a tabular list of the surfaces in the Prospector list view. For more information, see The Toolspace Item View (page 82).

Expand an individual surface name to display the surface components, including its masks (page 2477), watersheds (page 2487), and definition.

Expand the Definition collection to view and add data for the surface, such as breaklines, boundaries, and contours. The data items that are displayed depend on the surface type.

| For more information about... | See... |
| --- | --- |
| Masks | Masks (page 669) |
| Watersheds | Watersheds (page 675) |
| Definition | Understanding the Surface Definition (page 611) |

# Surface Collection (Settings Tab)

Use the Surface collection in the Settings tree to manage surface settings, surface styles, surface label styles, surface table styles, and surface command settings.

Right-click the Surface collection to do the following:

■ Edit the surface feature settings. (page 687)

■ Edit the surface label style defaults. (page 696)

■ Refresh the display of the settings tree.

Expand the Surface collection to display and edit the styles and command settings that are available for surfaces.

| For more information about... | See... |
|---|---|
| Surface styles | Surface Styles and Visualization (page 692) |
| Label styles | Surface Label Styles (page 696) |
| Table styles | Surface Table Styles (page 706) |
| Commands | Surfaces Command Reference (page 715)<br>Command Settings (page 687) |

# Creating Surfaces

You can create a surface that comprises a combination of points, breaklines, boundaries, and contours.

When you create a surface, the surface name is displayed in the ⬦ Surfaces collection in the Prospector tree so that you can perform other operations, such as adding data and editing the surface.

Initially, the surface may be empty and not be visible in the drawing. Once you add data to the surface, the surface becomes visible in the drawing in accordance to the display settings specified in the referenced surface style. See Surface Styles and Visualization (page 692).

# Creating a TIN Surface

A TIN (page 2485) surface comprises the triangles that form a triangulated irregular network.

TIN lines form the triangles that make up the surface triangulation. To create TIN lines, AutoCAD Civil connects the surface points that are closest together. The elevation of any point in the surface is defined by interpolating the elevations of the vertices of the triangles that the point lies in.

TIN surfaces are most useful for:

■ Mapping highly variable surfaces with irregularly distributed sample data representing the influence of streams, roads, and lakes.

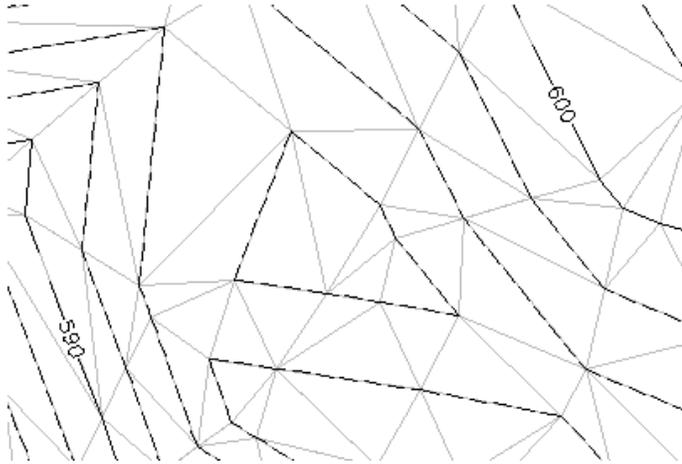
■ Examining localized areas (large-scale maps)

TIN surfaces generally take longer to build and require more disk space than grid surfaces.

When AutoCAD Civil creates a TIN surface from point data, it computes the Delaunay triangulation (page 2472) of the points. With Delaunay triangulation, no point lies inside the circle determined by the vertices of any triangle.

Breakline data (from breaklines, contours, or boundaries) influences how the surface is triangulated. A breakline edge between the points causes the program to connect these points with a triangle edge in the TIN, even if doing so violates the Delaunay property.

A TIN surface with contour lines:



**To create a TIN surface**

1  Click Home tab ➤ Create Ground Data panel ➤ Surfaces drop-down ➤ Create Surface 🖼️ .
   In the Create Surface (page 2354) dialog box, in the Type list, select TIN Surface.

2  Click 🗐 to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

   **NOTE** If you do not select a layer, the surface is placed on the current layer.

3  In the properties grid, click the Value column for the Name property and enter a name for the surface.

   **NOTE** To name the surface, click its default name and enter a new name, or use the Name Template. For more information, see Name Template Dialog Box (page 1806).

4  To change the style for the surface, click the Style property in the properties grid and click ⬜ in the Value column.

   The Select Surface Style dialog box is displayed. For more information, see Surface Styles and Visualization (page 692).

5  To change the render material for the surface, click the Render Material property in the properties grid and click ⬜ in the Value column.

   The Select Render Material dialog box is displayed. For more information, see Applying Render Materials to Objects (page 1578)

6  Click OK to create the surface.

   The surface name is displayed under the Surfaces collection in the Prospector tree. For information about adding data to the surface, see Adding and Editing Surface Data (page 611).

Create Surface (page 2354)

# Creating a Grid Surface

A grid surface (page 2475) comprises points that lie on a regular grid.

You can create a grid surface or import it from a DEM (page 2472) file.

Use grid surfaces for:

■ Mapping more uniform surfaces with evenly distributed sample data

■ Examining large study areas (small-scale maps)

Grid surfaces generally load quickly and require less disk space than TIN surfaces.

**To create a grid surface**

1  Click Home tab ➤ Create Ground Data panel ➤ Surfaces drop-down ➤ Create Surface  .
   In the Create Surface (page 2354) dialog box, in the Type list, select Grid Surface.

2  Click  to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

   **NOTE** If you do not select a layer, the surface is placed on the current layer.

3  In the properties grid, click the Value column for the Name property and enter a name for the surface.

   **NOTE** To name the surface, click its default name and enter a new name, or use the name template. See Name Template Dialog Box (page 1806).

4  To change the style for the surface, click the Style property in the properties grid and click  in Value column.
   The Select Surface Style dialog box is displayed. See Surface Styles and Visualization (page 692).

5  To change the render material for the surface, click the Render Material property in the properties grid and click  in the Value column.
   The Select Render Material dialog box is displayed. See Applying Render Materials to Objects (page 1578)

**6** Set the Grid Parameters, such as spacing and orientation. Enter their values or click  to use the drawing area to derive these values.

**7** Click OK to create the surface.

After the surface is created, the surface name is displayed in the Surfaces collection in the Prospector tree, so that you can perform other operations, such as adding data and editing the surface.

For information about adding data to the surface, see Adding and Editing Surface Data (page 611).

## Creating a TIN Volume Surface

A TIN volume surface is a composite of points in a base surface (page 2468) and comparison surface (page 2470).

A TIN volume surface provides an exact difference between the base and comparison surfaces. Therefore, the Z-value of any point in the volume surface is precisely the difference between the Z of the comparison surface at that point and the base surface at that point. This is true whether the comparison and base surfaces are both grid surface, both TIN surfaces, or one of each.

A volume surface is a persistent surface object. Therefore, you can display cut and fill contours, cut and fill points, and add labels to it. You can view volume properties (cut, fill, net) of a volume surface by selecting Surface Properties. For more information, see Editing and Viewing the Surface Definition (page 681).

If you want only to query and obtain information about a surface volume or bounded volume (page 2469), use the Volumes and Bounded Volumes utilities.

**See also:**

■ Calculating Surface Volumes (page 690)

**To create a TIN volume surface**

**1** Click Home tab ➤ Create Ground Data panel ➤ Surfaces drop-down ➤ Create Surface .
In the Create Surface (page 2354), in the Type list, select TIN Volume Surface.

**2** Click to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

**NOTE** If you do not select a layer, the surface is placed on the current layer.

**3** In the properties grid, click the Value column for the Name property and enter a name for the surface.

**NOTE** To name the surface, click its default name and enter a new name, or use the name template. For more information, see Name Template Dialog Box (page 1806).

**4** To change the style for the surface, click the Style property in the properties grid and click ⋯ in the Value column.

The Select Surface Style dialog box is displayed. For more information, see Surface Styles and Visualization (page 692).

**5** To change the render material for the surface, click the Render Material property in the properties grid and click ⋯ in the Value column.

The Select Render Material dialog box is displayed. For more information, see Applying Render Materials to Objects (page 1578)

**6** Click the Base Surface property to select the base (bottom) surface. Enter the surface name or click ⋯ to open the Select Base Surface (page 1810)dialog box where you can select the surface in the list.

**NOTE** Select a surface in the drawing by clicking 🖳 and following the instructions at the command line.

**7** Click the Comparison Surface property to select the comparison (top) surface. Enter the surface name or click ⋯ to open the Select Comparison Surface dialog box where you can select the surface in the list.

**NOTE** Select a surface in the drawing by clicking 🖳 and following the instructions at the command line.

**8** Click OK to create the surface.

The surface name is displayed under the Surfaces collection in the Prospector tree. For information about adding data to the surface, see Adding and Editing Surface Data (page 611).

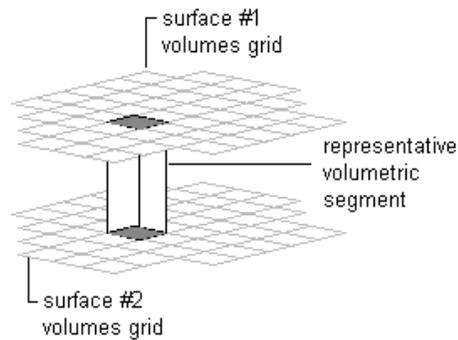
Create Surface (page 2354)

# Creating a Grid Volume Surface

A grid volume surface is a difference grid surface based on user-specified base and comparison surfaces as well as grid spacing and orientation.



A grid volume surface is an approximation of the difference between the base and comparison surfaces. It is formed by making a grid from points whose Z values are the differences between the Z values of the comparison and base surfaces. Therefore, the grid volume surface gives the exact difference only at the grid points. This is true whether the comparison and base surfaces are both grid surfaces, both TIN surfaces, or one of each.

Grid volume surfaces enable you to generate a volume quickly, which is useful for iterative site design.

**NOTE** Grid spacing has a direct correlation as to how quickly grid volumes generate.

A volume surface is a persistent surface object. Therefore, you can display cut and fill contours, cut and fill points, and add labels to it. View a volume property (cut, fill, net) of a volume surface by selecting Surface Properties. For more information, see Editing and Viewing the Surface Definition (page 681).

If you want only to query and obtain information about a surface volume or a bounded volume (page 2469), use the Volumes and Bounded Volumes utilities.

**See also:**

■ Calculating Surface Volumes (page 690)

**To create a grid volume surface**

1 Click Home tab ➤ Create Ground Data panel ➤ Surfaces drop-down ➤ Create Surface ![icon] .
   In the Create Surface (page 2354) dialog box, in the Type list, select Grid Volume Surface.

2 Click ![icon] to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

   **NOTE** If you do not select a layer, the surface is placed on the current layer.

3 In the properties grid, click the Value column for the Name property and enter a name for the surface.

   **NOTE** To name the surface, click its default name and enter a new name, or use the name template. For more information, see Name Template Dialog Box (page 1806).

4 To change the style for the surface, click the Style property in the properties grid and click ![icon] in the Value column.
   The Select Surface Style dialog box is displayed. For more information, see Surface Styles and Visualization (page 692).

**5** To change the render material for the surface, click the Render Material property in the properties grid and click ⬚ in the Value column.

The Select Render Material dialog box is displayed. For more information, see Applying Render Materials to Objects (page 1578)

**6** Click the Base Surface property to select the base (bottom) surface. You can enter the surface name or click ⬚ to open the Select Base Surface (page 1810) dialog box where you can select the surface in the list.

---

**NOTE** Select a surface in the drawing by clicking 🔲 and following the instructions at the command line.

---

**7** To set the grid parameters, such as spacing and orientation, enter their values into the Values column or click 🔲 to use the drawing area to derive these values.

---

**NOTE** The grid spacing parameters determine how precise a surface volume is. For example, small grid spacing creates a precise volume measurement (but may increase the loading time).

---

**8** Click the Comparison Surface property to select the comparison (top) surface. Enter the surface name or click ⬚ to open the Select Comparison Surface dialog box where you can select the surface in the list.

---

**NOTE** Select a surface in the drawing by clicking 🔲 and following the instructions at the command line.

---

**9** Click OK to create the surface.

The surface name is displayed under the Surfaces collection in the Prospector tree. For information about adding data to the surface, see Adding and Editing Surface Data (page 611).

# Creating a Surface From a TIN File

Use the Create Surface From TIN dialog box to create a surface by importing TIN (page 2485) format data.

Importing a TIN file creates a surface object on which you can perform all the standard data operations and editing. The import operation is displayed as the operation type Import Surface. See Understanding the Surface Definition (page 611).

You can use this command to import a TIN file from an Autodesk Land Desktop project. To import the TIN file, the accompanying PNT point file must exist in the same source directory.

**To import a surface from a TIN file**

1   Click Home tab ➤ Create Ground Data panel ➤ Surfaces drop-down ➤ Create Surface From TIN  .

2   In the Create Surface From TIN dialog box, browse to the location of the TIN file and select it.

3   Click Open to add the surface to the current drawing.

    The surface name is displayed under the Surfaces collection in the Prospector tree. For information about adding data to the surface, see Adding and Editing Surface Data (page 611).

# Creating a Grid Surface from a DEM

Use the Grid Surface From DEM dialog box to create a grid surface.

A DEM file comes in several formats. You can import either USGS DEM, ESRI Arc Grid, or GeoTIFF files.

**TIP** You can also import DEM files into an existing surface. For more information, see Adding DEM Files to a Surface (page 637).

For more information about DEM file data, see DEM Files (page 634).

**NOTE** SDTS (Spatial Data Transfer Standard (page 2482)) DEMs are not supported in AutoCAD Civil. There is a number of free utilities that you can download and use to convert SDTS data to the supported DEM format.

**To create a surface from DEM data**

1   Click Home tab ➤ Create Ground Data panel ➤ Surfaces drop-down ➤ Create Surface From DEM  .

2   In the Grid Surface From DEM dialog box, browse to the location of the file.

**3** Select the DEM (.dem), GeoTIFF (.tif), ESRI ASCII Grid (.asc or .txt), or ESRI Binary Grid (.adf) file. The filename is displayed in the File Name field.

**4** Click Open.

# Creating a Surface Reference

You can create a reference to an existing surface in a data shortcut (page 2472) or a Vault project.

The surface reference is a lightweight read-only copy of the original, but it gives you access to surface data for other objects such as alignments and profiles. Before you create the surface reference, it must exist in the current project collection on the Toolspace Prospector tab.

**NOTE** A surface reference has no data definition, but has masking and watershed analysis functionality.

**See also:**

■ Creating Data Shortcuts (page 131)

■ Vault: Checking a Drawing in to a Project (page 158)

**To create a reference to a data shortcut surface**

**1** In Toolspace, on the Prospector tab, in Master View, ensure that the correct working folder is identified on the Data Shortcuts node.

**2** Expand the Data Shortcuts ➤ Surfaces collection, right-click the desired surface, and then click Create Reference.

The Create Surface Reference dialog box is displayed, in which you can optionally change properties of the reference surface, as described in the following steps.

**3** In the Create Surface Reference dialog box, change the source of the reference by selecting a source in the Source Surface drop-down list.

**4** Click 🗇 to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

**NOTE** If you do not select a layer, the surface is placed on the current layer.

**5** In the properties grid, click the Value column for the Name property. Enter a name for the surface.

> **NOTE** To name the surface, click its default name. Enter a new name, or use the name template. For more information, see Name Template Dialog Box (page 1806).

**6** To change the style for the surface, select the Style property in the properties grid. Click ⋯ in the Value column.

The Select Surface Style dialog box is displayed. For more information, see Surface Styles and Visualization (page 692).

**7** To change the render material for the surface, select the Render Material property in the properties grid. Click ⋯ in the Value column.

The Select Render Material dialog box is displayed. For more information, see Applying Render Materials to Objects (page 1578).

**8** Click OK to create the surface reference.

The surface name is displayed in the Surfaces collection in the Prospector tree with a 🖼 next to it.

**To create a reference to a surface in a Vault project**

**1** In Toolspace, on the Prospector tab, in Master View, expand the Projects ➤ <project name> ➤ Surfaces collection, right-click the desired surface, and then click Create Reference.

The Create Surface Reference dialog box is displayed, in which you can optionally change properties of the reference surface, as described in the following steps.

**2** In the Create Surface Reference dialog box, change the source of the reference by selecting a source in the Source Surface drop-down list.

**3** Click 📑 to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

> **NOTE** If you do not select a layer, the surface is placed on the current layer.

**4** In the properties grid, click the Value column for the Name property. Enter a name for the surface.

> **NOTE** To name the surface, click its default name. Enter a new name, or use the name template. For more information, see Name Template Dialog Box (page 1806).

**5** To change the style for the surface, select the Style property in the properties grid. Click ⋯ in the Value column.

The Select Surface Style dialog box is displayed. For more information, see Surface Styles and Visualization (page 692).

**6** To change the render material for the surface, select the Render Material property in the properties grid. Click ⋯ in the Value column.

The Select Render Material dialog box is displayed. For more information, see Applying Render Materials to Objects (page 1578).

**7** Click OK to create the surface reference.

The surface name is displayed in the Surfaces collection in the Prospector tree with a 🡕 next to it.

# Adding and Editing Surface Data

You can edit and add data to a surface after you create it.

Surface data categories include:

■  **Boundaries**. Polygons that define outer, hide, and show surface boundary types.

■  **Breaklines**. Includes standard, proximity, non-destructive, and wall breaklines. You can define breaklines from objects in the drawing or import them from a file.

■  **Contours**. Includes contour data that you can define from polyline objects.

■  **DEM files**. Includes USGS Digital Elevation Model DEM files.

> **NOTE** To use SDTS files, first convert them into DEM files. For more information, see About DEM File Data (page 635).

■  **Drawing objects**. Includes Line, Point, Block, Text, 3D Faces, and Polyfaces. Used for creating surface points from AutoCAD entities.

■  **Point files**. Includes ASCII point files.

■  **Point groups**. Includes previously defined point groups.

# Understanding the Surface Definition

A surface definition is a collection of a surface build, data, and edit properties, as well as a list of the operations that you have performed on the surface. The type of definition data items that a surface can have depends on the surface type.

The Definition collection under a surface in the Prospector tree provides access to the surface possible data and edit definition items.

**See also:**

■  Editing and Viewing the Surface Definition (page 681).

### Data Definition

The data definition for a surface comprises the data components that you can add to a surface.

The following table illustrates the data categories that are supported for each surface type. If the surface type does not support a data type, the data type is not available in the surface Definition collection in the Prospector tree.

| Category | TIN Surface | TIN Volume Surface | Grid Surface | Grid Volume Surface |
|---|---|---|---|---|
| Boundaries | Yes | Yes | Yes | Yes |
| Breaklines | Yes | No | No | No |
| Contours | Yes | No | No | No |
| DEM Files | Yes | No | Yes | No |
| Drawing Objects | Yes | No | No | No |
| Point Files | Yes | No | No | No |
| Point groups | Yes | No | No ; | No |

### Edits

Data edits are operations that are not added to any of the existing data components; rather, they are added to a surface definition as edit operations.

For more information about surface edits, including the supported types of edits for the various surface types, see Surface Editing Operations (page 650).

### Operation List

The surface build process is incremental. Every time when you add data to a surface or edit the surface, the surface is updated. When data is removed, the surface is rebuilt. For information about building a surface, see Rebuilding a Surface (page 685).

To support the incremental build process, a surface has an operation list, which is a sequential list of all operations performed on the surface in its current state. For more information about the surface operations, see Surface Editing Operations (page 650) as well as the Surface Properties - Definition (page 2346) tab.

# Boundaries

A boundary is a closed polygon that affects the visibility of the triangles inside it.

When you create boundaries, you specify whether they use arc tessellation (page 615) and non-destructive breaklines (page 615).

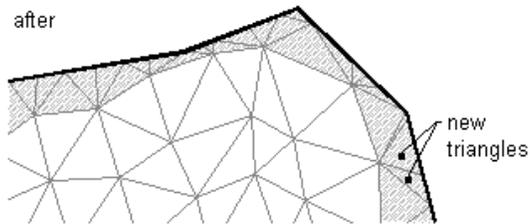
### Boundary Types

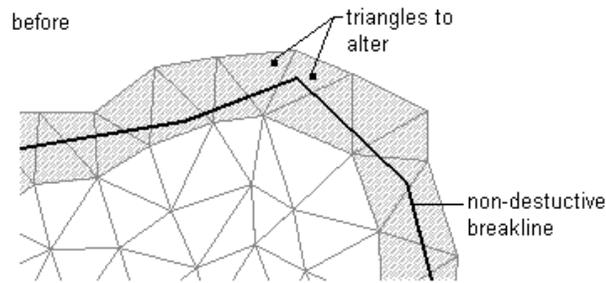
AutoCAD Civil supports the following types of boundaries:

■ **Outer**. Defines the outer boundary of the surface; all triangles inside it are visible and all triangles that are outside it, are invisible.

---
**NOTE** The outer boundary may be affected by subsequent edit operations, such as Add Breaklines. You may need to move the Add Boundary operation to the bottom of the list to achieve the expected result.

---

An outer boundary created using non-destructive breaklines (page 615):




- **Show**. Displays all triangles inside the boundary; you can use it to create visible areas within hide boundaries.

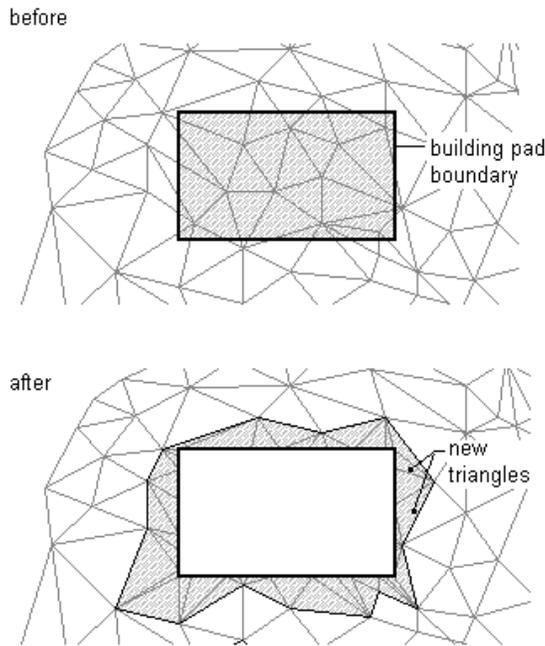
**NOTE** The effect of adding multiple boundaries to a surface is dependent on the order in which they are added. The effects of a boundary can be wholly or partially overridden by a subsequent boundary.

- **Hide**. Masks areas of the triangulation, and therefore contours are not visible in the area; used to punch holes in a surface (for example, a building footprint).
  A hide boundary created using non-destructive breaklines (page 615):

before

building pad
boundary

after

new
triangles


> **NOTE** When you use a hide boundary, the hidden surface area is not deleted. The full surface remains intact. If there are surface TIN lines that you want to remove from the surface, then use the Delete Line operation. For more information, see Deleting TIN or Grid Lines (page 651).

■ **Data Clip**. Creates a surface boundary limited by a polygon object from the drawing, such as 2D and 3D polylines, feature lines, survey figures, parcels, and circles.
You can add more than one data clip boundary to a surface. When you add data, only the most recent data clip boundary is affected. A data clip boundary does not affect the visible part of the surface, but acts as a filter on all data, such as points and breaklines added to the surface after the creation of data clip. For example, if you add a breakline to a surface following the creation of a data clip boundary, only the part of the breakline that is inside the data clip boundary is added.

Surface boundaries are defined by selecting existing polygons from the drawing. The surface definition displays the numerical ID and a list of vertices for each boundary.

## Applying a Data Clip Boundary to Imported Surfaces

You can apply a Data Clip boundary to surfaces created from imported data files, including TIN, LandXML, grading, or corridor surfaces.

**To apply a Data Clip boundary to an imported surface**

1   Create a surface from imported data (TIN, grading, or corridor). See Creating a Surface From a TIN File (page 607) , Creating a New Grading Group (page 741), Creating a Corridor Surface (page 1351).

2   Add the Data Clip boundary to the surface. See Adding Boundaries to a Surface (page 615).

3   In the Prospector tree, expand the Surfaces collection, right-click <surface name> ➤ Surface Properties.

4   In the Surface Properties dialog box, click the Definition tab.

5   Select the Add Data Clip Boundary operation and click ⇪ to move it to the top of the list.

**6** Click Apply.

**7** In the message box, click Rebuild the Surface.

## Adding Boundaries to a Surface

Use the Prospector tree to add boundaries to a surface.

When you add or remove boundaries, the surface is modified and the modification is added to the definition list for the surface.

Boundaries are defined from closed polygons which affects the visibility of the triangles inside them.

**NOTE** If the polygon is not closed, the boundary definition forces a closed polygon.

Areas hidden by boundaries are not included in calculations, such as total area and volume.

When creating a boundary, you set arc tessellation and specify whether the boundary uses non-destructive breaklines when adding boundaries to a surface.

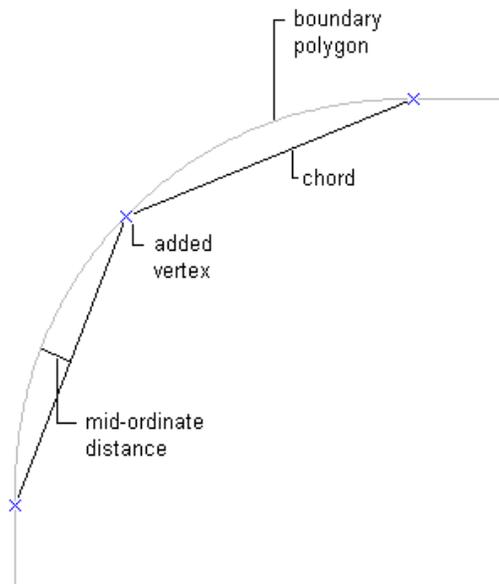
### Arc Tessellation

When you use polygons/polylines that contain curves for boundaries or breaklines, set the mid-ordinate distance of the chord segments, which is used to tessellate the arc segments of the boundary polygon/polyline:

boundary
polygon

chord

added
vertex

mid-ordinate
distance


### Non-Destructive Breaklines

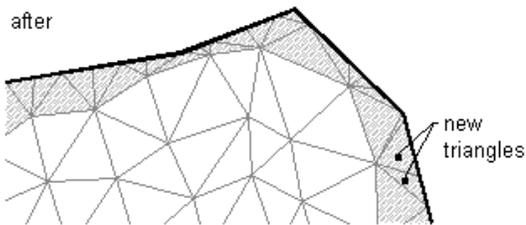
Specify whether a boundary uses non-destructive breaklines when you create it by selecting Non-destructive breaklines in the Add Boundaries (page 2359) dialog box.

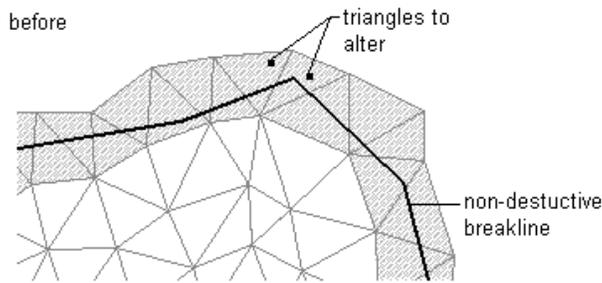
**NOTE** You cannot add non-destructive breaklines to a grid surface.

When you create a boundary with non-destructive breaklines along the edges of the boundary, the triangle edges are clipped exactly where they cross the boundary:

before
triangles to alter

non-destuctive breakline

after


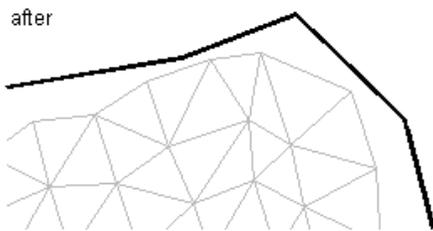


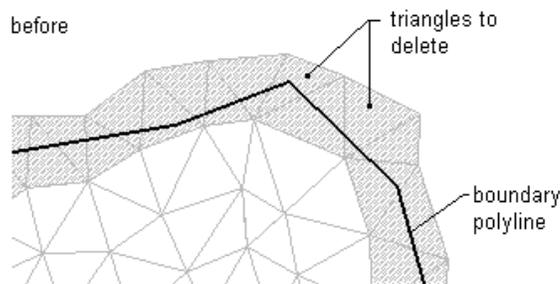
new triangles

If you create a boundary without non-destructive breaklines along the boundary edges, only triangles that are completely within or outside the boundary are affected:

before
triangles to delete

boundary polyline

after




**To add boundaries to a surface**

1   In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click ⬨ , and click Add.

2   In the Add Boundaries (page 2359) dialog box, enter the boundary name in the Name field.

3   Select the boundary type from the Type list. See Boundaries (page 612).

4   Optionally, select Non-destructive breakline specify that the boundary uses non-destructive breaklines.

NOTE  For a TIN surface, by default, the Non-destructive breakline check box is cleared and non-destructive breaklines are not used. For grid surfaces, the Non-destructive breakline field is disabled and not available.

**5** Optionally, if the polygon from which you are creating a boundary has curves, either enter a value in the Mid-Ordinate Distance field or click  to specify a distance in the drawing area.

The Add Boundaries dialog box is closed. You are prompted to select a polyline.

**6** Select one of the following to define the boundary:

- An existing polyline

- An existing polygon, such as a circle object

- An existing parcel

The boundary is created and added to the surface Boundaries collection in the Prospector tree.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Boundaries ➤ Add

Command Line

AddSurfaceBoundaries

Dialog Box

Add Boundaries (page 2359)

## Inserting Boundary Data into the Drawing

Insert boundaries into the drawing as AutoCAD polylines.

If you deleted the original AutoCAD entity and did not update the surface, you may need to insert boundaries into the drawing. In this case, you can import the boundary from the boundaries collection.

**To insert boundary data into the drawing**

**1** In the Prospector tree, click the surface Boundaries collection.

The boundaries appear in the list view in the Prospector tab.

**2** Right-click a boundary in the list view and click Insert Into Drawing.

- If the boundary does not exist in the drawing, it is added as a polyline object.

- If the boundary exists in the drawing, a message box is displayed stating that no boundaries are inserted into the drawing.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click <boundary-name> in list view ➤ Insert Into Drawing

## Editing Boundary Properties

Use the Prospector tab to view and edit boundary properties.

When you add boundaries to a surface, the icon next to the surface Boundaries collection changes to a ▣
and the boundaries are listed in the Prospector list view.

You can view additional boundary information and perform limited edits to boundary information in the
Boundary Properties (page 2360) dialog box.

**To edit boundary properties**

1 In Toolspace, on the Prospector tab, expand the surface Definition collection and click ⬈ .

   The Prospector list view displays the following:

   ■ The name of the boundary

   ■ The boundary type: Outer, Show, or Hide

   ■ Whether the boundary is trimmed with non-destructive breaklines

2 In the list view, right-click a list item.

3 Click Properties to open the Boundary Properties (page 2360) dialog box where you can edit the name of
   the boundary. All other fields are read only.

### Quick Reference

Boundary Properties (page 2360)

# Breaklines

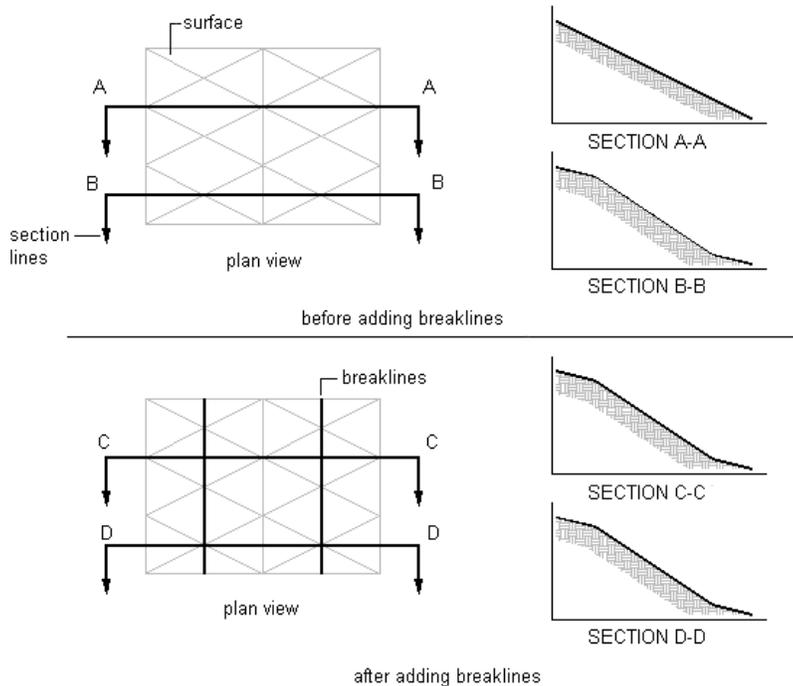
Use breaklines to define features, such as retaining walls, curbs, tops of ridges, and streams. Breaklines force
surface triangulation along the breakline preventing triangulation across the breakline.

Breaklines are critical to creating an accurate surface model because it is the interpolation of the data, not
only the data itself, that determines the shape of the model.

**NOTE** You can add breaklines only to TIN surfaces.

The effects of breaklines:

before adding breaklines

after adding breaklines


## Types of Breaklines

Define standard, proximity, wall, and non-destructive breaklines for a TIN surface.

■ **Standard**. Defined by selecting 3D lines, grading feature lines, and 3D polylines.

■ **Proximity**. Defined by drawing or selecting a grading feature line or polyline object in the drawing within the extents of the surface boundary. The XYZ coordinates of proximity breakline vertices are determined from the surface TIN points that are in closest proximity to the corresponding vertices of the defining points or entity.

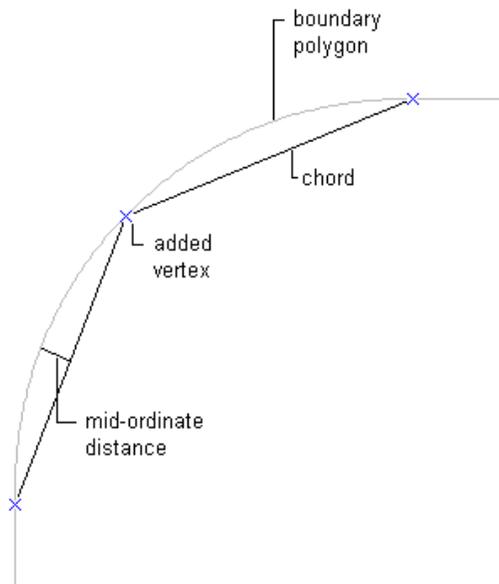
**NOTE** To specify breaklines from points, first convert the points into 3D or 3D polylines using the 'PN command. For more information, see Transparent Commands (page 1581).

■ **Wall**. Defined using grading feature lines, 3D lines, 3D polylines, or by specifying points. A wall breakline is stored as a standard breakline, but defined differently: you provide an offset side for the entire breakline, and an elevation difference for each vertex, or for the entire breakline.

■ **Non-destructive**. Defined using grading feature lines and open or closed AutoCAD objects. A non-destructive breakline maintains the integrity of the original surface.

You can also import breaklines from ASCII FLT files into the surface definition.

**Breakline Definition Options**

When you define a breakline from a polyline with curves, specify a mid-ordinate distance, which is used to tessellate the arcs in the polyline:


Access global breakline definition options in the Build options property group on the Definition tab (page 2346) of the Surface Properties dialog box.

The breakline definition options include:

■ **Convert Proximity Breaklines**. Automatically converts proximity breaklines to standard breaklines when they are created.

■ **Allow Crossing Breaklines**. Allows breaklines to cross each other.

For more information, see Editing and Viewing the Surface Definition (page 681).

## Creating Standard Breaklines

Use the Add Breaklines dialog box to create standard breaklines.

You can use 3D lines, grading feature lines, and 3D polylines as breaklines. The X, Y, and Z coordinates of each vertex on the polyline that you select are converted into TIN vertices. For 3D lines, each line that you select is defined as a two-point breakline.

**WARNING** If you select a 2D polyline with a zero elevation, then it is saved with that elevation. Use proximity breaklines if you want the elevations calculated automatically.

**To create a standard breakline**

1 In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click , and click Add.

2 In the Add Breaklines (page 2360) dialog box, enter the breakline description in the Description field.

3 Select Standard from the Type list.

4 Optionally, if the polyline from which you are creating a breakline has curves, enter a value into the Mid-Ordinate Distance field or  to select a distance in the drawing area.

The Add Breaklines dialog box closes and you are prompted to select a polyline.

**5** Select the polyline or line to define the breakline.

The breakline is created and added to the surface Breaklines collection item in the Prospector tree.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Breaklines ➤ Add

Command Line

AddSurfaceBreaklines

Dialog Box

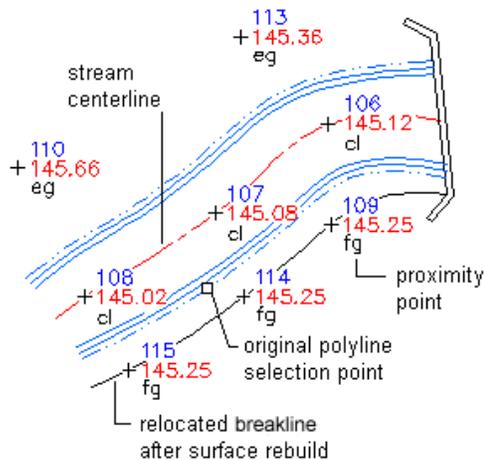
Add Breaklines (page 2360)

# Creating Proximity Breaklines

Use the Add Breaklines dialog box to define proximity breaklines that reference surface points in proximity to the vertices of the polyline that you select as the breakline.

Surface points are any surface data points used to create a TIN that are in proximity to the vertices of the polyline that you select as the breakline.

You can define proximity breaklines quickly because you do not have to precisely snap to the surface points that you want to use for the breakline. You can pick locations that are near the points that you want to use. The breakline vertices automatically snap to the nearest surface point when the breakline is added to the surface:



Define proximity breaklines by selecting a polyline. You do not have to draw the polyline precisely between surface points. The breakline definition automatically snaps to the surface point that is nearest each polyline vertex when the breakline is added to the surface.

Proximity breaklines are 2D polylines with elevations of 0. The northing, easting, and elevation are calculated for each vertex according to the closest surface point. By default, proximity breaklines are converted to standard breaklines when added to a surface. You can disable the automatic conversion of proximity breaklines to standard breaklines by setting the Convert Proximity Breaklines To Standard build option to No in the Definition tab (page 2346) of the Surface Properties dialog box.

**To define a proximity breakline**

**1** In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click ⬦ , and click Add.

**2** In the Add Breaklines (page 2360) dialog box, enter the breakline description in the Description field.

**3** Select Proximity from the Type list.

**4** Optionally, if the polyline from which you are creating a breakline has curves, enter a value into the Mid-Ordinate Distance field or click ⬦ to digitize a distance in the drawing area.
The Add Breaklines dialog box is closed. You are prompted to select a polyline.

**5** Select one or several polylines or lines to define the breakline.
This creates breaklines and adds them to the surface Breaklines collection in the Prospector tree.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Breaklines ➤ Add

Command Line

AddSurfaceBreaklines

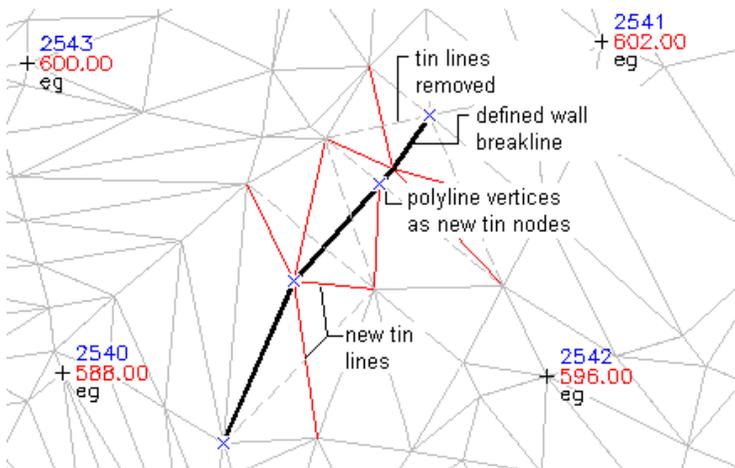
Dialog Box

Add Breaklines (page 2360)

## Creating Wall Breaklines

Use the Add Breaklines dialog box to define features, such as retaining walls or curbs as breaklines.

By creating wall breaklines, you can more accurately represent the surface. For example, for a retaining wall, you can define the differences in elevation between the material on both sides of the wall in order to represent elevations correctly.

Define wall breaklines by selecting an existing polyline or grading feature line. The polyline is extended by creating new polyline segments and vertices parallel to the original polyline, but offset at an incremented distance to represent the differences in elevation between the material on either side of the wall:


There are two methods used to define wall breaklines:

■ **Define by object vertex (Individual)**. Select a polyline, or line, and select the offset side. For each polyline vertex, you select either the vertex elevation (Existing Vertex Elevation is the default) and the corresponding offset vertex elevation (the default is Existing Polyline Vertex) or the corresponding offset vertex elevation difference. If an elevation difference option is selected, the difference value is the default for each subsequent vertex.

■ **Define by object (All)**. Select a polyline, or line object, and select the offset side. Then, enter the difference elevation to be applied for all offset vertices.

**To define walls or curbs as breaklines**

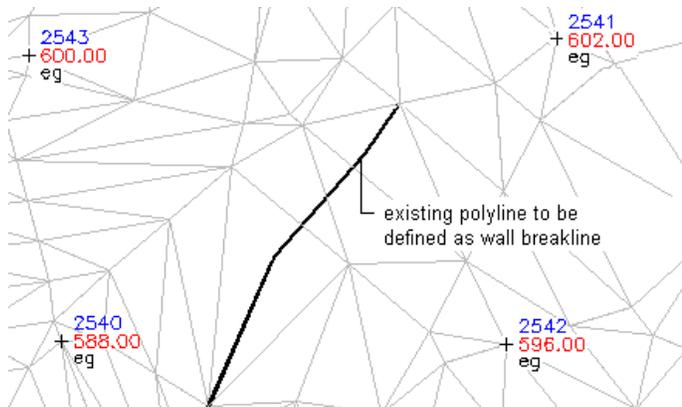
1   In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click  Breaklines, and click Add.

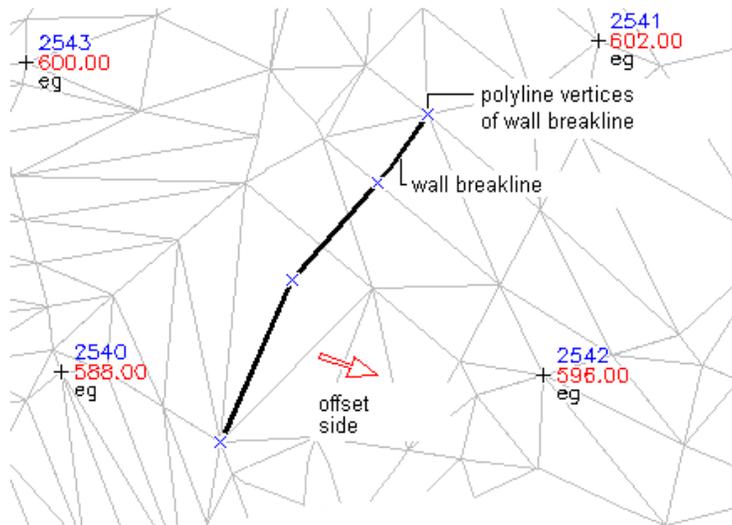
2   In the Add Breaklines (page 2360) dialog box, enter the breakline description in the Description field.

3   From the Type list, select Wall.

4   Optionally, if the polyline from which you are creating a breakline has curves, enter a value into the
    Mid-Ordinate Distance field or click  to digitize a distance in the drawing area.
    The Add Breaklines dialog box is closed. A message prompts you to select a polyline.

5   In the drawing, select the polyline to define the breakline.



6   Select the offset side for the wall breakline. This is the side for the new offset line that represents the elevation of material on the other side of the wall.


A message prompts you to specify the wall height with one value for all the points (Define By Object) or to specify values for individual points (Define By Vertex).

**7** Do one of the following:

- To define the wall breakline by object, specify **All** and enter the amount to add to elevation at each point.

- To define the wall breakline by object vertex, specify **Individual** at the prompt and enter the elevation or delta for each vertex.
  The prompts provide two ways to define elevations for each offset point: as an elevation (Elevation) or as the elevation difference (Delta) between the control point and the offset point. Deltas may be either positive or negative values.

The breakline is created and added to the surface Breaklines collection in the Prospector tree.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Breaklines ➤ Add

Command Line

AddSurfaceBreaklines

Dialog Box

Add Breaklines (page 2360)

## Creating Non-Destructive Breaklines

Use the Add Breaklines dialog box to create a non-destructive breakline from either a grading feature line or an open or closed AutoCAD object.

When defining a non-destructive breakline, surface points are created at each vertex of the object and at each intersection of a surface triangle edge and the non-destructive breakline object. The new points create additional surface triangles. Non-destructive breaklines are often needed when deleting surface areas where a clean TIN edge does not exist.

The elevation for each new point is extracted from the original surface triangle, therefore maintaining the integrity of the original surface.

**To add non-destructive breaklines**

1 In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click ⬚, and click Add.

2 In the Add Breaklines (page 2360) dialog box, enter the breakline description in the Description field.

3 From the Type list, select Non-destructive.

4 If the object from which you are creating a breakline has curves, enter a value in the Mid-ordinate distance field or click ⬚ to digitize a distance in the drawing area.

5 Click OK.

The Add Breaklines dialog box closes. A message appears prompting you to select an object.

6 In the drawing area, select the objects.

7 Optionally, select other objects or press Enter to end the command.

The breakline is created and added to the surface Breaklines collection in the Prospector tree.

**NOTE** The Description column in the Prospector list view displays the ID of the breakline that was added to the surface. To view information about the breakline vertices, open the Breakline Properties vista. For information, see Viewing Breakline Information (page 627)

## Quick Reference

Command Line

AddSurfaceBreaklines

Dialog Box

Add Breaklines (page 2360)

## Importing Breaklines from a File

Use the Add Breaklines dialog box to import breaklines from a file. The supported file format is *.flt* (ASCII file format).

**File Linking Options**

When importing breaklines, you can choose to either maintain a link to the breakline file or break the link:

- **Maintain Link To File**. Reads the breakline from the FLT file when they are added and when the surface is rebuilt. If you edit or delete the source FLT file, the Import Breakline File operation is marked as out-of-date. With this option, you cannot list individual breaklines, view them in the Breakline Properties vista, or import them into the drawing.

- **Break Link To File**. All breaklines in the FLT file are copied into the surface as Add Breakline operations. The FLT file is no longer referenced. When you rebuild the surface, the internal copy of the breakline is

used. The breaklines have the full functionality of other breakline types. You can see the breaklines listed in the Breakline Properties vista, you can pan and zoom to them, and import into the drawing.

**To import breaklines into a drawing**

1   In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click ![icon], and click Add.

2   In the Add Breaklines (page 2360) dialog box, enter the breakline description in the Description field.

3   Select From File from the Type list.

4   Select the file link option. For information, see File Linking Options (page 625).

5   Click OK.
    The Import Breakline File dialog box is displayed.

6   Select the file to import. It must have an *.flt* extension.
    The breakline is created and added to the surface Breaklines collection in the Prospector tree.

    ---
    **NOTE** The breaklines are imported and grouped by type according to their order in the *.flt* file.
    ---

## Quick Reference

Command Line

  AddSurfaceBreaklines

Dialog Box

  Add Breaklines (page 2360)

## Creating Breakline Data in a Text File

Use a text editor to create a breakline file manually.

You can then import this text file to use as breakline data for building the surface. For more information, see Importing Breaklines from a File (page 625).

**To create a breakline file manually**

1   Open an ASCII text editor, such as Notepad or Wordpad.

2   Create the file using the following structure:

    ■   Use the (#) symbol as the first character in a comment line.

    ■   Use one of the letters **P**, **S**, **W**, **L**, **R**, **N** (or **ND**) at the beginning of the line to describe the breakline type. These letters stand for Proximity, Standard, Wall, Wall Left, Wall Right, and Non-destructive. Identify a breakline type for each new breakline.

    ■   Enter the X, Y, and Z coordinates separated by a space.

    ■   A description of the breakline can follow the first coordinate of the line.

■ To create another breakline, enter the breakline type letter at the beginning of a line. In the following example, an S is placed at the beginning of line 8 of the file. All the points from this point until the next breakline letter modifier are in one breakline. This breakline is called EOP.

3 Save the file with an *.flt* file extension.

The following is an example of a breakline file:

```
# Autodesk User-Defined Breakline File

## Viewing Breakline Information

Use the Prospector list view and Breakline Properties vista to view a breakline description, type, and vertices, as well as to zoom or pan to a breakline and its vertices.

**To view breakline in a drawing**

1 Expand the surface Breaklines collection in the Prospector tree.

The breakline operations are displayed in the Prospector tree and list view.

2 Right-click a breakline operation in the Prospector tree or list view and do one of the following:

■ Click Zoom To or Pan To to see the location of the breakline operation in the drawing.

■ Click Properties to display the Breakline Properties (page 2358) vista, which displays the individual breaklines as well as a list of vertices and the coordinates and elevation for each vertex.

3 To zoom or pan to an individual breakline vertex, in the Breakline Properties vista, right-click the vertex and click Zoom To or Pan To.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ Breaklines ➤ right-click <breakline-operation-description> ➤ Properties

Dialog Box

Breakline Properties Vista (page 2358)

## Editing Breaklines

Edit any breaklines that you have defined by selecting it in the drawing. You can insert, move, and delete vertices, as well as redefine the elevation at a selected vertex.

Use any AutoCAD editing commands, including:

- Properties command (editing vertex elevations)
- Change command
- Pedit command (graphical editing of polylines)
- AutoCAD grip editing

The surface stores an ID for each of the objects that are defined as breaklines. Therefore, if you modify any of the breakline objects using any of the mentioned commands, the surface is marked as out-of-date until you rebuild it.

**NOTE** You can rebuild a surface automatically by toggling the check mark next to the Rebuild - Automatic menu entry available on the surface shortcut menu in Prospector. For more information, see Rebuilding a Surface (page 685).

**To change a breakline vertex elevation or location**

1 Select the breakline either graphically or by using an AutoCAD command, such as Properties Edit (Pedit) or Change.

2 Perform the edit to the breakline.

   If the breakline and surface definition become out-of-date, a ▽ is displayed next to its node in the Prospector tree.

3 Rebuild the surface to update the breakline definition by right-clicking the surface in the Prospector tree and clicking Rebuild.

**NOTE** You can rebuild a surface automatically by toggling the check mark next to the Rebuild - Automatic menu entry available on the surface short-cut menu in Prospector. For more information, see Rebuilding a Surface (page 685).

**To change the description of a breakline operation**

1 Click the surface Breaklines collection in the Prospector tree.

   The breakline operations with their descriptions and types are displayed in the Prospector list view.

2 Click the breakline operation description in the list view and enter a new description.

**NOTE** You cannot rename individual breakline descriptions. They are named based on the breakline operation description.

## Inserting Breakline Data into a Drawing

Insert breaklines into a drawing as AutoCAD polylines.

**NOTE** You cannot insert into the drawing breaklines that you have imported from an *.flt* file (ASCII file format), unless you used the Break Link To File option. For information, see Importing Breaklines from a File (page 625).

You may need to insert breaklines into the drawing if you deleted the original entity and did not update the surface. In this case, you can import the breakline from the breakline collection.

If any of the selected breaklines exist in the drawing, a message box is displayed stating that no breaklines are inserted into the drawing. Polyline objects are created on the current layer.

**To insert breakline data into the drawing**

1  Click the surface Breaklines collection in the Prospector tree.

The breaklines with their descriptions and types are displayed in the Prospector list view.

2  Right-click a breakline operation in the list view and click Insert to Drawing.

■  If the breakline objects in the breakline operation do not exist in the drawing, they are added to the drawing as polyline objects.

■  If the breaklines exist in the drawing, a message box is displayed stating that no breaklines are inserted into the drawing.

## Quick Reference

# Contours

Use contour data to create or modify a surface.

Surface contour data are created from polylines whose points are all at the same elevation.

You can add contour data only to TIN surfaces.

## Recommendations for Creating Surfaces from Contours

When you create a surface from contour data, especially if you want to add other data to the surface, you can generate a better surface model whose contours will match the contour data if you follow recommended guidelines.

First, create the surface and add all your contour data. For best results, add the contour data in a single operation. Do not add additional data such as spot elevations or breaklines at this time.

You can specify Minimize Flat Areas By options when adding the contour data, or you can add the contour data without the options and then use Check for Contour Problems to locate contour problems and repair

them. For information on repairing contour problems, see Checking for Contour Problems (page 709) and Minimizing Flat Areas in a Surface (page 656).

---

**NOTE** For some contour data sets, Check for Contour Problems report large numbers of errors if you add the contour data to the surface without specifying Minimize Flat Areas By options.

---

After you have added your contour data and repaired problems, verify the contours visually. Add additional contours where needed, and add spot elevation data or breaklines only where they are required to correct a specific problem. For more information on repair, see Supplementing Missing Contour Information (page 631) and Minimizing Flat Areas in a Surface (page 656). Repair all problems.

After you have identified and repaired contour problems, add additional surface data such as additional spot elevation points. Add surface boundaries last. Add boundaries starting at the outside of the surface and working toward the inside.

## Weeding and Supplementing Factors for Contours

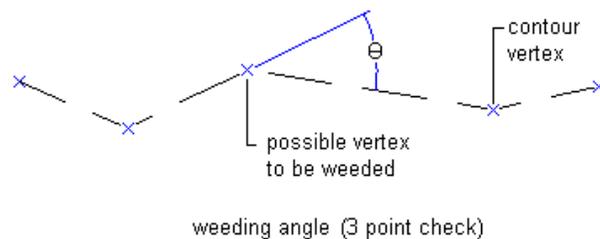
Use weeding and supplementing to add or remove vertices along a contour.

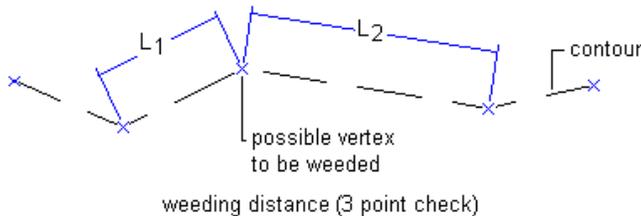
Set the weeding and supplementing parameters when you add the contour data to the surface definition in the Add Contour Data (page 2355) dialog box.

### Weeding Factors

Weeding reduces the number of points generated along the contours. The weeding factors ignore both vertices that are closer together than the distance factor and vertices that deflect less than the angle factor. A larger distance and deflection angle weeds a greater number of points. The distance factor is measured in linear units, and the angle factor is measured in angular units. The weeding factors must be less than the supplementing factors.

A point on the contour is weeded by calculating its location in relation to the vertices before and after it. If the length between these three points is less than the weeding length value, and the deflection angle is less than the weeding angle value, then the middle point is not added to the contour data file.

Examples of weeding factor parameters:


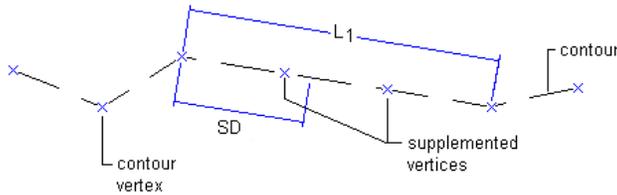


**Supplementing Factors**

Supplementing factors add vertices along contours.

The supplementing distance is the maximum distance between vertices. If the distance between vertices on a contour is greater than the supplementing factor, then points are added along the contour at equal intervals that are less than or equal to the supplementing distance. The smaller the distance, the greater the number of supplemented points.

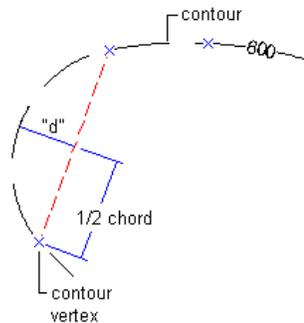
Example of the distance (SD) parameter with supplemented vertices:



if L$_1$ > supplementing distance, then vertices are added
in equal increments that are less than or equal to SD

The mid-ordinate distance is the distance from the midway point of an arc to the chord of the arc. The mid-ordinate distance is used to add vertices to a polyline curve, creating an approximation of the curve using straight line segments. The length of these segments depends on the value of the mid-ordinate distance.

Example of the mid-ordinate parameter:



if ratio of "d" to 1/2 chord > supplementing bulge factor,
then vertices will be added on the arc

## Contour Data and Surface Triangulation

Information obtained from a contour map differs greatly from data taken randomly in the field.

Since contour map data is interpolated, the information may be less accurate than direct field data. The accuracy of the final surface model depends on both the quality of the contour map and the contour interval.

If you bring contour data into the drawing as points, then the points would not be very random. In steep areas, points would be close together. In flat areas, there is a greater distance between points on different contours. In both cases, the points along the contours are generally close together. Therefore, information taken from contours does not make effective random point data, and random data points generate the best triangulation.

## Supplementing Missing Contour Information

When you create a model from contours and then generate contours from this model, in some cases, AutoCAD Civil may not generate the same set of contours.

In the most common situation, surface data is missing in either a low or high area, such as near the top of a hill, at the bottom of a valley, or on the edge of the site.

To correct this problem, place spot elevations or another contour line near the place where the surface data is missing. For example, if a contour line is missing along the top of a hill, place a new contour, breakline, or spot elevation at the estimated maximum elevation of the hill. The recommended practice is to place any interpolated data, points, or contours on a separate layer.

If you create a surface using only contour information, you may need to place breaklines or spot elevations in areas where the contour line changes direction drastically. Areas where this is likely to happen include: a crowned roadway, a swale, or a ridge. In these places, contours tend to triangulate onto themselves. In most instances, the Minimize Flat Areas operation resolves this problem. For more information, see Minimizing Flat Areas in a Surface (page 656). In severe situations, you may need to add additional point or breakline data.

For best results, always follow the suggested order of operations for adding contour data to a surface. See Recommendations for Creating Surfaces from Contours (page 629).

## Adding Contour Data to a Surface

Use the Add Contour Data dialog box to add contour data from polylines to a surface.

**To add contour data to a surface**

1  In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click Contours, and click Add.

2  In the Add Contour Data  (page 2355)dialog box, enter the contour description in the Description field.

3  Enter the distance and angle weeding factors in the corresponding fields or click to digitize a distance or angle in the drawing area. For more information, see Weeding and Supplementing Factors for Contours (page 630).

4  Enter the distance and mid-ordinate distance supplementing factors in the corresponding fields or click to select a distance or mid-ordinate distance in the drawing area.

5  Select options for minimizing flat areas in the surface. For more information, see Minimizing Flat Areas in a Surface (page 656).

6  Click OK.

7  Select the polyline to define the contour data and press Enter.

The contour data is created and added to the surface Contours collection in the Prospector tree.

**NOTE** Before displaying the Add Contour Data dialog box, it can be useful to create a selection set of contour objects using the QSELECT command at the command line or choosing Select Similar from the Edit menu.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Contours ➤ Add

Command Line

AddSurfaceContours

Dialog Box

Add Contour Data (page 2355)

## Listing and Identifying Contours

Zoom or pan to contour data and list its description and summary.

**To identify contours in a drawing**

1   Click the surface  Contours collection in the Prospector tree.

The contours with their descriptions and summaries are displayed in the Prospector list view.

2   Right-click a contour data item in the Prospector list view and click Zoom To or Pan To, to see the location of the contour data in the drawing.

## Editing Contours

Edit any contour that you have defined by selecting it in the drawing. You can insert, move, and delete vertices, as well as redefine the elevation at a selected vertex.

You can use any AutoCAD editing commands, including:

■   Properties command (editing vertex elevations)

■   Change command

■   Pedit command (graphical editing of polylines)

■   AutoCAD grip editing

The surface stores an ID for each of the objects that are defined as contours. Therefore, if you modify any of the contour objects using any of the mentioned commands, the surface is marked as out-of-date until you rebuild it.

**NOTE** You can rebuild a surface automatically by toggling the check mark next to the Rebuild - Automatic menu entry available on the surface short-cut menu in Prospector. For more information, see Rebuilding a Surface (page 685).

**To change a contour vertex elevation or location**

1   Select the contour graphically or by using an AutoCAD command, such as PEDIT or CHANGE.

2   Perform the edit to the contour.

If the contour and surface definition become out-of-date, a  is displayed next to its node in the Prospector tree.

3   Rebuild the surface to update the contour definition by right-clicking the surface in the Prospector tree and clicking Rebuild.

**TIP** You can update the surface automatically by turning on Rebuild - Automatic. For more information, see Rebuilding a Surface (page 685).

## Inserting Contour Data Into a Drawing

Insert contour data into the drawing as AutoCAD polylines using the Insert to Drawing command.

In some situations, the surface keeps breakline or contour data (a list of their point coordinates), but does not associate them with an object. This may happen, for example, when you deleted an entity that the surface depends on, but the Copy Deleted Dependent Objects option on the Definition Tab (Surface Properties Dialog Box) (page 2346) page of the Surface Properties dialog box is set to Yes. In this case, the surface simply converts its reference from a drawing entity to a list of points defining the object's geometry.

To restore the reference to the object entity, you can insert the data associated with the deleted contour.

**To insert contour data into the drawing**

1   In the Prospector tree, expand the Surfaces collection ➤ <surface name> ➤ Definition.

2   Click the Contours collection.

    The contours with their descriptions are displayed in the Prospector list view.

3   Right-click a contour operation in the list view and click Insert To Drawing.

    ■   If the contour objects in the contour operation do not exist in the drawing, they are added to the drawing as AutoCAD polyline objects.

    ■   If the contours exist in the drawing, a corresponding message is displayed.

---

**NOTE** You can insert multiple contours using the Insert To Drawing command.

---

### Quick Reference

# DEM Files

Use digital elevation model (DEM) files or SDTS files converted to a DEM format to import points into a surface.

DEM files are used to store and transfer large-scale topographic relief information for use in GIS, earth sciences, resource management, land planning, surveying, and engineering projects. DEM files typically contain land XYZ information at a regular grid-spaced interval to represent ground relief.

You can add and remove DEM files, and view DEM information. To transform DEM coordinates so they match the coordinate system of the current drawing when the surface is built, specify a coordinate system for the DEM file.

DEM files are a valuable data source for many planning and engineering tasks that might not need the type of precision gained by doing a ground or aerial survey. DEM files can also, in some places, completely eliminate the need for specific surveys. Usually, the DEM data is not precise enough to use on small-scale studies, but is ideal for large-scale planning and analysis tasks.

Some examples of projects that can benefit from DEM information include hydrologic studies, corridor planning for highways and pipelines, land use planning and analysis, slope analysis, and large-scale project visualization.

### Obtaining DEM Files

DEM files are widely available on the Internet. For example, the United States Geological Survey (USGS) provides many DEM files at their web site.

---

**NOTE** SDTS (Spatial Data Transfer Standard) format DEM data is not supported for this release of AutoCAD Civil. However, you can use free utilities to convert SDTS data to DEM format.

---

## About DEM File Data

DEM files typically contain land XYZ information at a regular grid-spaced interval to represent ground relief.

DEM files are created to strict standards, as specified by the USGS. For complete information about the DEM file format, see "Standards for Digital Elevation Models," in *National Mapping Program Technical Instructions*, published by the U.S. Department of the Interior, U.S. Geological Survey, National Mapping Division. You can find this documentation on the USGS web site.

In general, the DEM source data is contained in one section of the DEM file (Logical record type `A'), and the actual data (XYZ) information is contained in another part of the DEM file (Logical record type `B').

The following data, based on logical record type `A', is displayed for each DEM file that you add to a surface:

| Element Name | Corresponding Data Element Number in Logical Record Type 'A' | Details |
| --- | --- | --- |
| Description | 1 | The first 140 characters of a DEM file, which may include the file name and location. |
| Estimated Point Total | N/A | The estimated number of points in the DEM file, rounded up to three significant digits. |
| Coordinate System Type | 5 | The ground planimetric reference system: UTM, State Plane, or Lat/Long. |
| Zone | 6 | Code that defines the zone in ground planimetric reference system. These can be found in Appendixes 2-E and 2-F of Standards for Digital Elevation Models. The Zone is meaningful only if Coordinate System Type is UTM or State Plane. |
| Horizontal Datum | 27 | The horizontal datum of the ground planimetric reference system, such as NAD27. |
| Vertical Datum | 26 | ■ 1 = local mean sea level<br>■ 2 = National Geodetic Vertical Datum 1929 (NGVD 29)<br>■ 3 = North American Vertical Datum 1988 (NAVD 88) |

| Element Name | Corresponding Data Element Number in Logical Record Type 'A' | Details |
|---|---|---|
| | | For more information, see Appendix 2-H of the Standards for Digital Elevation Models. |
| Vertical Datum Shift | 31 | The value is the average shift value for the four quadrangle corners obtained from program VERTCON. AutoCAD Civil adds this value to the vertical datum to convert to NAVD88. If the vertical datum is NAVD88, then the vertical datum shift value should be zero. |
| DEM Level | 3 | There are three possible DEM Levels:<br><br>■ Level 1 DEMs are elevation data sets in a standardized format. This level includes 7.5-minute DEMs or an equivalent that is derived from stereo profiling or image correlation of National High Altitude Photography Program, National Aerial Photography Program, or equivalent photographs.<br><br>■ Level 2 DEMs are elevation data sets that were processed or smoothed for consistency and edited to remove identifiable systematic errors. DEM data derived from hypsographic and hydrographic data digitizing, either photogrammetrically or from existing maps, are entered into the Level 2 category after review on a DEM editing system.<br><br>■ Level 3 DEMs are derived from DLG data by using selected elements from both hypsography (contours and spot elevations) and hydrography (lakes, shorelines, and drainage). If necessary, ridge lines and hypsographic effects of major transportation features are also included in the derivation. |
| X-Y Units | 8 | The unit of measure for ground planimetric coordinates throughout the file, such as radians, feet, meters, or arc-seconds. |
| Elevation Units | 9 | The unit of measure for elevation coordinates throughout the file, such as feet or meters. |
| Minimum Elevation | 12 | The minimum elevation for the DEM. The value is the units of measure defined by Elevation Units. |
| Maximum Elevation | 12 | The maximum elevation for the DEM. The value is the units of measure defined by Elevation Units. |
| X Spacing | 15 | DEM spatial resolution for X values. The value is the units of measure defined by the XY Units. |
| Y Spacing | 15 | DEM spatial resolution for Y values. The value is the units of measure defined by the XY Units. |

## Adding DEM Files to a Surface

Use the Prospector tree to add DEM file data to a surface and to work with a DEM file data. The DEM file data is combined with any other surface data that you define.

**To add a DEM file to a surface**

1   In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click ⟨icon⟩, and click Add.

2   In the Add DEM File (page 2356) dialog box, enter the path and name of the DEM file or click ⟨icon⟩ and browse to the location of the DEM file.

3   Select the DEM file so that its name is displayed in the File Name field and click Open.

    The DEM file name and information is displayed in the corresponding Add DEM File dialog box fields.

4   Optionally, change the coordinate system of the DEM data. For more information, see Changing the Specified Coordinate System of a DEM File (page 637).

    The points of the DEM file are transformed from the specified coordinate system of the DEM file to the coordinate system of the current drawing taking into account any Transformation settings specified in the Drawing Settings dialog box.

    **NOTE** DEM files cannot be transformed for grid surfaces. If you include a DEM file as part of a grid surface definition, its coordinate system must match that of the drawing, or it cannot be added.

5   Click OK to import the DEM file into the surface.

The DEM file is added to the surface DEM Files collection in the Prospector tree.

## Quick Reference

Toolspace Shortcut Menu

   Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click DEM Files ➤ Add

Dialog Box

   Add DEM File (page 2356)

## Changing the Specified Coordinate System of a DEM File

Use the Prospector tree to specify or change a DEM file coordinate system. If the DEM file coordinate system is different from the current coordinate system of the drawing, you can specify a coordinate system for the DEM file. The coordinate system you specify for the DEM file should match the data defined in the DEM file itself.

**NOTE** Specify a coordinate system for the DEM file only if the coordinate system of the DEM file is different from the current coordinate system of the drawing and you want a coordinate transformation to occur when you build the surface.

If you used the wrong coordinate system when adding the DEM file, you can select a different coordinate system for the file by changing the DEM file properties.

**NOTE** If the coordinates are transformed, the points no longer lie on a grid. Therefore, the transformation of DEM data is not supported when adding a DEM file to a grid surface. You can change a DEM coordinate system only when adding a DEM file to a TIN surface.

The following table lists some specific examples about how coordinates are read and processed when using various coordinate system settings in your drawings and DEM files:

| When the DEM Coordinate System (source) is set to... | And the Drawing Coordinate System (destination) is set to... | The following results occur: |
| --- | --- | --- |
| NH State Plane NAD27 | NH State Plane NAD83 | The DEM file coordinate data is transformed from NAD27 to NAD83 when you build the surface. |
| NH State Plane NAD27 | None | The DEM file data is not transformed when the surface is built; the DEM file data is taken at face value. For example, point 100,100,100 in the DEM file is point 100,100,100 in the surface. |
| None | None | The DEM file data is not transformed when the surface is built; the DEM file data is taken at face value. For example, point 100,100,100 in the DEM file is point 100,100,100 in the surface. |
| None | NH State Plane NAD83 | The DEM file data is not transformed when the surface is built; the DEM file data is taken at face value. For example, point 100,100,100 in the DEM file is point 100,100,100 in the surface. |
| NH State Plane NAD83 | NH State Plane NAD83 | No transformation is applied.<br><br>**NOTE** Specifying a coordinate system for a DEM file is not necessary in this situation. However, if you are working with multiple drawings in the current project, and the drawings have different coordinate systems, it is recommended that you specify a coordinate system for the DEM file in case you need to rebuild the surface in a drawing that has a different coordinate system. |

**To change the specified coordinate system of a DEM file**

1 In Toolspace, on the Prospector tab, expand the surface Definition collection, and click 🏠 DEM Files.

2 Right-click a DEM file in the Prospector list view and click Properties.

3 In the DEM File Properties (page 2356) dialog box, select the CS Code property field and click the browse button.

4 In the Select Coordinate Zone (page 2366)dialog box, click the Category list and select a category.

**5** Select a coordinate system from the category list.

**6** Optionally, click Properties to view the properties of the selected coordinate system.

**7** Click OK to select the coordinate system and close the dialog box.

The DEM file property group displays the newly selected coordinate system.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ DEM Files ➤ right-click <DEM-file> in list view ➤ Properties

Dialog Box

DEM File Properties (page 2356)

## Importing DEM Extents

You can import the extents of a selected DEM file into the drawing as 2D polyline objects.

The polyline is drawn as a rectangle representing the four corners of the DEM extents.

**To import DEM extents**

**1** In Toolspace, on the Prospector tab, expand the surface Definition collection, and click  .

The DEM files with their names, modified dates, and sizes are displayed in the Prospector list view.

**2** In the list view, right-click the DEM file for which you want to import the extents and click Import DEM Extents.

The DEM extents are drawn as a polyline rectangle representing the four corners of the DEM extents.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ DEM Files ➤ right-click <DEM-file> in list view ➤ Import DEM Extents

## Viewing DEM Data and Properties

Zoom or pan to DEM file data, and view information about its data including its coordinate system, projection, and datum.

**To zoom or pan to DEM file data**

**1** In Toolspace, on the Prospector tab, expand the surface Definition collection and click  DEM Files.

The DEM files are displayed in the Prospector list view.

**2** In the list view, right-click a DEM file and click Zoom To or Pan To.

The drawing area displays the surface data zooming or panning to the area relative to the selected DEM data (according to the surface style settings). For information about setting and changing the surface display, see Surface Styles and Visualization (page 692).

**To view DEM file properties**

**1** In Toolspace, on the Prospector tab, expand the surface Definition collection, and click ⊞ .

The DEM files are displayed in the Prospector list view.

**2** In the list view, right-click on the DEM file and click Properties to display the DEM File (Add/Properties) Dialog Box (page 2356).

Detailed information about the DEM file is displayed in the DEM File Information field. For more information, see About DEM File Data (page 635).

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ DEM Files ➤ right-click <DEM-file> in list view ➤ Properties

## DEM Files and Memory Usage

Large TIN surfaces, such as those built from DEM files, can require a substantial amount of memory (RAM and virtual memory) and disk space to build and save the surface. TIN surfaces require about 100 bytes per point, whereas grid surfaces require about 16 bytes per point.

It is important to ensure that you have sufficient resources before you build a surface using a DEM file. Also, be aware that certain commands may take longer than expected when working with these surfaces.

### General Guidelines for DEM File Memory Usage

As a general rule, a 1 MB DEM file contains 160,000 points. For larger DEM files, the number of points grows proportionately to the DEM file size at a rate of approximately 160,000 points per 1 MB of DEM file size.

**See also:**

■ Working with Large Surfaces (page 689)

# Adding Surface Point Data from AutoCAD Drawing Objects

Use AutoCAD objects such as 3D lines to add surface point data to the surface definition.

The selected AutoCAD objects are interpreted based on their points, and specific point data is created for each object type that you add to the surface definition.

For several object types, you can specify whether to maintain the object edges when adding the object points to AutoCAD Civil.

**NOTE** Drawing objects added to the surface are added as point data. After the point data has been added to the surface there is no relationship between the surface and the original drawing objects.

You can select the following AutoCAD drawing objects to add points to a surface definition:

■ **Points**. The XYZ coordinates of the object are used to define the surface point.

■ **Lines**. The XYZ coordinates of the object endpoints are used to define surface points.

■ **Blocks**. The block insertion point XYZ coordinates are used to define the surface point.

■ **Text**. The text insertion point XYZ coordinates are used to define the surface point.

- **3D Faces**. The XYZ coordinates of the object endpoints are used to define surface points.

- **Polyfaces**. The XYZ coordinates of the object endpoints are used to define surface points.

> **NOTE** Optionally, when adding lines, 3D faces, and polyfaces, you can maintain the original AutoCAD object edges as surface triangle edges.

> **NOTE** To add COGO points to surface data, add point groups. For more information, see Point Groups (page 644).

**To add points to a surface from AutoCAD objects**

1  In the Toolspace, on the Prospector tab, expand the surface Definition collection, right-click ⌂, and click Add.

2  In the Add Points From Drawing Objects (page 2362) dialog box, select the object type from the Object Type list.

3  Click Maintain Edges From Objects if you are adding points from lines, 3D faces, or polyfaces, and you want to maintain the AutoCAD object edges. This prevents AutoCAD Civil from optimizing the edges.

4  In the Description field, enter a description for the object.

5  Click OK.

6  Select the object in the drawing or use any of the standard AutoCAD object selection methods.

The objects are added to the surface definition and are displayed in the surface Drawing Objects collection list view with their description and type.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Drawing Objects ➤ Add

Dialog Box

Add Points from Drawing Objects (page 2362)

# Moving Blocks to Attribute Elevation

Move AutoCAD block objects with attributes (such as labels or tags) at their insertion point to the elevation of one of the block's attribute objects.

Use this command when you need to use block objects in the drawing as surface point data.

For example, the block object can display an elevation value from one of its attributes, but the elevation of the block reference can be different. Using this command prepares the surface data before defining a surface from block reference objects using the Add Points From Drawing Objects (page 2362) command.

**To move block objects to their attribute elevation**

1  Select a surface. On the Surface tab, click Surface Tools panel ➤ ▼ ➤ Move Blocks To Attribute Elevation 🖼 .

2  In the Move Blocks to Attribute Elevation dialog box, select a block reference name from the list or click  to select a block reference from the drawing.

3  Under Select Elevation Attribute Tag, select the required tag.

4  Click OK.

The selected block reference objects are moved to the elevation of the specified attribute.

Command Line

MoveBlocksToAttribElev

Dialog Box

Move Blocks to Attribute Elevation (page 2370)

## Moving Text to Elevation

Move AutoCAD text objects at their insertion point to the elevation of their numeric text values.

Use this command when you need to use a TEXT object in the drawing as surface point data.

You can select AutoCAD numeric TEXT and MTEXT objects in the drawing and move each object at its insertion point to the elevation corresponding to its numeric text value.

**To move a text object to the elevation value**

1  Select a surface. On the Surface tab, click Surface Tools panel ➤ ▼ ➤ Move Text To Elevation .

2  Select the text object in the drawing or use any of the standard AutoCAD object selection methods.

3  Click Enter.

If the value of a text object is a real number, the text object is moved to the elevation corresponding to the numeric text value.

Menu

Surfaces menu ➤ Utilities ➤ Move Text To Elevation

Command Line

MoveTextToElevation

# Point Files

If you have point data files that you created either manually or by downloading a data collector, you can use the point data as surface data.

Any point file format that can be imported to create AutoCAD Civil points can be used to add points to surfaces.

The following is an example of the PENZ space-delimited format, which is just one of the point file formats recognized by the surface Add Point File command.

A PENZ space-delimited point file contains: point number, easting (X), northing (Y), elevation (Z)). Within the file, the following syntax is used for each point:

```
[Point Number] [Easting (or X)] [Northing (or Y)] [Elevation (or Z)]
```

An example of the contents of a PENZ space delimited format point text file:

```
26303 315872.971714  4838799.938284      111.250000
26304 315876.474880  4838813.524640      111.280000
26305 315873.911320  4838829.056520      111.950000
26306 315861.792509  4838799.287159      112.060000
26307 315855.883079  4838798.942969      114.160000
26308 315855.585197  4838811.389822      114.080000
26309 315861.566272  4838812.001057      111.920000
```

There are several supported point file formats. If your point files use a format that is not recognized by the surface Add Point File command, you can convert the files to a supported format.

First, you create a point file format that describes the layout of the data in the point files. Then, using the point file format, you convert the files to a supported format using the Transfer Points utility. For more information, see Transferring and Converting Point Data (page 506).

You can manually create ASCII text files that contain point data. For more information, see Creating a Point File Manually (page 644).

## Adding Surface Data from a Point File

Add points from a point file directly to an existing surface.

**To add point files to a surface**

1   In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click ⊞ , and click Add.

2   In the Add Point File (page 2361) dialog box, select the format of the point file or click ✐ to create a point file format that describes the layout of the data in the point data file.

3   Enter the point file path and name into the Source File field or click ✚ to browse and select the point file.

4   Click Open to add the point file to the surface.

    If the point file contains a line with bad data, an error (including the line number) is posted the Event Viewer and the operation continues.

    The point file is added to the Point Files item view.

**Quick Reference**

Toolspace Shortcut Menu

 Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Point Files ➤ Add

Command Line

 AddPointFile

Dialog Box

 Import Point File (page 2124)

## Creating a Point File Manually

Create a PENZ space-delimited point file containing point information and use the file to create or add data to a surface in AutoCAD Civil.

**To create a point file manually**

1  Open a text editor, such as Notepad.

2  Enter the point number, easting, northing, and elevation values. Separate each value by one or more spaces.

3  Enter the information for each point on a separate line. For best results, do not include extra spaces at the end of a line or blank lines at the end of the file. The file should consist entirely of point data. However, you can add a comment line by entering a # sign at the beginning of a line.

4  Save the file as a text file.

An example of a PENZ space-delimited point file:

```
# Autodesk Point File Format
3 379.910000    511.270000    227.620000
4 393.880000    497.100000    225.750000
5 382.640000    464.050000    223.890000
6 403.690000    429.340000    222.880000
103 190.080000   307.560000   194.250000
104 182.090000   322.940000   194.940000
105 174.100000   338.320000   195.630000
106 142.910000   340.320000   203.030000
107 117.470000   342.780000   208.460000
108 124.430000   394.400000   208.410000
109 137.700000   400.690000   205.430000
```

# Point Groups

Add point groups to a surface definition.

Use point groups to break the drawing COGO points into smaller groupings of points, to identify points that share common characteristics, such as number, name, elevation, or that are used to perform a task, such as creating a surface.

You can create point groups that contain specific points, such as all existing ground points, making it easier to manage the surface points.

See Understanding Point Groups (page 521).

## Adding Point Groups

Use the Point Groups collection of the Prospector tree to add point groups to a surface definition.

For information about creating point groups, see Creating Point Groups (page 529).

**To add a point group to a surface**

1  Create a point group if needed. For information, see Creating Point Groups (page 529).

2  In Toolspace, on the Prospector tab, right-click the surface [⊕] Point Groups collection and click Add.

3  In the Point Groups dialog box, in the list of available point groups, select the point group to add to the surface.

4  Click OK to add the point group to the surface.

The point group is added to the Point Group list view in Prospector.

---

**NOTE** For information about other point group functionality, such as viewing and changing the properties of a point group, see Understanding Point Groups (page 521).

---

### Quick Reference

# Moving Blocks to a Surface Elevation

Use the Move Blocks to Surface command to manipulate reference object block data.

You can use the reference object block data to define a surface. Moving blocks to surface can also be useful for visualization of multi-view block objects.

**To move Block Reference objects to a surface elevation**

1  Select a surface. On the Surface tab, click Surface Tools panel ➤ ▾ ➤ Move Blocks To Surface 🖱 .

2  If the drawing contains more then one surface, from the Select a Surface dialog box, select the surface or click 🖱 to pick the surface manually.

3  In the Move Blocks to Surface dialog box, select the Block Reference objects or click 🖱 to select the block reference objects directly from the drawing.

4  Click OK.

Each selected Block Reference object is moved from its current elevation to the elevation of the surface at the object insertion point.

**Quick Reference**

Ribbon

Dialog Box

Move Blocks to Surface (page 2369)

# Extracting Surface Data

You can extract AutoCAD primitive entities from an AutoCAD Civil surface.

Extracting individual components from a surface enables you to manipulate these components without exploding the surface object. The surface data available to extract is based on the display properties of the selected surface.

**NOTE** The extracted objects preserve the properties set in the current surface style.

The following table lists the extracted objects for each type of surface components.

| Surface component ... | Is extracted as ... |
|---|---|
| Points (2D and 3D) | Point objects |
| Triangles (2D and 3D) | 3D face objects |
| Border (2D) | ■ POLYLINE object<br>■ LWPOLYLINE object (if the Border Display Mode (page 2335) is set to Flatten to Elevation) |
| Border (3D) | ■ POLYLINE object<br>■ LWPOLYLINE object (if the Border Display Mode (page 2335) is set to Flatten to Elevation)<br>■ 3D face object (if Use Datum (page 2335) and Project Grid to Datum (page 2335) are set to true) |
| Major Contour (2D and 3D) | LWPOLYLINE object |
| Minor Contour (2D and 3D) | LWPOLYLINE object |
| User Contours (2D and 3D) | LWPOLYLINE object |
| Gridded (2D and 3D) | ■ POLYLINE object (if the Border Display Mode (page 2335) is set to Use Surface Elevation<br>■ LWPOLYLINE object (if the Border Display Mode (page 2335) is set to Flatten to Elevation) |

| Surface component ... | Is extracted as ... |
|---|---|
| Directions (2D and 3D) | The type of object depends on the surface style settings. See Creating a Surface Style (page 693). |
| Elevations (2D and 3D) | |
| Slopes (2D and 3D) | |
| Slope Arrows (2D and 3D) | |
| Watersheds (2D and 3D) | |

**To extract an object from a surface**

1  Select a surface. On the Surface tab, Surface Tools panel, click Extract Objects  .

2  If more than one surface is available in the drawing, in the Select a Surface dialog box, select the surface from which to extract components.

3  In the Extract Objects from Surface dialog box, under Property, deselect the components that you do not want to extract (all visible surface components are selected by default).

4  Under Value, do one of the following:

   ■ Choose Select All to select all the surface components for extraction.

   ■ Choose Select From Drawing, click  , and select the required surface components.

5  Click OK.

   Every selected surface component is extracted from the surface object.

## Quick Reference

Dialog Box

Extract Objects from Surface (page 2369)

# Surface Errors and Issues

Identify and troubleshoot errors or problems with a surface, or its data components.

# Definition Type Errors

View several error types that may be displayed in the surface's Operation Type list on the Definition tab of the Surface Properties dialog box.

The error types are:

- **Item modified** ⚠ Indicates that the definition item has been modified after being added to the surface.

- **Item not found** ⚠ Indicates that the definition item is not found when the surface properties dialog box is initialized.

- **Item not OK** 🏠⊘ Indicates that the definition item was not successfully added due to a change in the surface.

For more information about the Operation Type list, see (page 2346)

# Build Errors

Use the Event Viewer to view surface build errors that occur when data or edit operations cannot be performed due to removal of the data or its dependencies.

The following is a list of build errors that can be displayed:

| Error String | Possible Cause |
|---|---|
| Build Error - Duplicate Point | A duplicate point XY location was ignored at <XY co-ordinates>. |
| Build Error - Crossing Break-line | A crossing breakline was ignored at <starting or ending coordinate>. |
| Build Error - Breakline Cross-ing an Existing Data Point | Breakline crosses an existing point. |

# Surface Disconnection Error

Use the Surface Properties dialog box to view and correct a surface disconnection error, which can occur when a surface becomes disconnected from an external file that it references.

When this occurs, ⚠ is displayed in the Import Surface operation type on the (page 2346) of the Surface Properties dialog box indicating that the item was not found. You cannot rebuild the surface. However, additional data can be added, and certain edits (those that do not cause a rebuild) can be performed.

The problem can be fixed by editing the Operation Type parameter and entering the correct path and name for the external file.

# Unable to Rebuild Snapshot

An exclamation icon ⚠ is displayed next to the definition of the surface in the Prospector tree view and you are unable to rebuild the surface snapshot.

When you rebuild the surface snapshot, the following error message is displayed:

*Unable to rebuild Surface. Couldn't find file(s).*

If you installed AutoCAD Civil to a location other than the default, you must update the XML file's path before you can update the snapshot.

**To locate and update the XML file path**

1  To update the path, right-click the surface name in the Prospector tree, right-click, and click Properties.

2  In the Surface Properties dialog box, on the Definition tab, click the folder icon next to Import XML File.

3  In the Import XML File dialog box, browse to the location where you installed AutoCAD Civil, and locate the XML files.

4  Click Open. Click OK.

5  When prompted if you want to rebuild the surface, click Yes to update the surface properties, and rebuild the surface.

6  To update the snapshot, right-click the surface name in the Prospector tree, and click Rebuild Snapshot.

7  Right-click the surface name in the Prospector tree, and click Rebuild.

# Using the Default Surface Settings

When you import a surface TIN or XML file, the surface uses the default styles as specified in the surface settings.

To use a different style, after you import the file, change the assigned style by editing the surface properties:

1  In the Prospector tab, right-click the surface and click Properties.

2  Click the Information tab and select the desired Object Style from the drop-down list.

3  Click OK to apply the change and close the dialog box.

# Deleting AutoCAD Objects from a Surface

When trying to remove AutoCAD drawing objects using the Erase command, the surface does not reflect the change.

**To delete drawing objects from a surface definition**

1  In the Prospector tab, right-click the surface to be modified. Click Properties.

2  In the Definition tab, under Operation Type, clear the Drawing Objects check box, or you can right-click Drawing Objects and click Remove From Definition.

3  When prompted to rebuild the surface, click Yes.

The drawing objects are removed from the surface definition, and the surface is automatically updated.

# Surface Analysis Values are Not Updated

After modifying surface data, the values in the ranges of the Analysis tab of the Surface Properties dialog box are not updated. Surface legend tables are not updated either.

Using the Analysis tab of the Surface Properties dialog box, you can create ranges for slopes, elevations, directions, watersheds, and contours. These ranges require manual recalculation before the surface display or the legend table can be updated. If the surface data changes, open the Surface Properties dialog box and click the Analysis button in the Ranges area of the Analysis tab to reprocess the data. Surface legend tables that are set up to be dynamic are then automatically updated with the changes.

# Surface Editing Operations

Edit surfaces using data edit operations, which are added to a surface definition as edit operations and not to any of the existing surface data components.

You can access the data editing functionality for a surface by right-clicking ![edit icon] Edits under a surface Definition in the Prospector tree. If a surface type does not support an edit operation, the operation is not listed. The following table lists the edits that are supported for each surface type:

| Edit Operation | TIN Surface | TIN Volume Surface | Grid Surface | Grid Volume Surface |
|---|---|---|---|---|
| Add points | Yes | Editing operations are not supported | Yes | Editing operations are not supported |
| Delete points | Yes | | Yes | |
| Modify points | Yes | | Yes | |
| Move point | Yes | | No | |
| Add line | Yes | | No | |
| Delete line | Yes | | Yes | |
| Swap edge | Yes | | No | |
| Minimize flat areas | Yes | | No | |
| Smooth surface | Yes | | No | |
| Paste surface | Yes | | No | |
| Raise/Lower surface | Yes | | Yes | |
| Simplify surface | Yes | | No | |

# Adding TIN Lines

Use the Prospector tree to add new TIN lines to an existing surface. This operation modifies the way that the surface is triangulated.

The endpoints of a new line must fall at the endpoints of other surface lines. If the new line passes through one or more existing surface lines, the surface retriangulates that area.

---

**TIP** To perform this operation, ensure that the surface style has triangles visibility enabled. See Surface Styles and Visualization (page 692).

---

**NOTE** TIN volume surfaces do not support editing operations.

---

**To add TIN lines**

1   In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click ![edit icon] , and click Add Line.

**2** At the command line, you are prompted to select the endpoints for the new TIN line.

**3** Click existing vertices as the endpoints for the new TIN lines.

The triangulation of the surface is modified to reflect the new lines.

**4** Optionally, continue to select endpoints to add additional new lines.

**5** Press Enter to complete the operation.

The new TIN lines are added as Add Line operations to the Edits list view in Prospector.

---

**NOTE** The Description column in the list view displays the coordinates of the selected points that created the TIN line.

---

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Edits ➤ Add Line

Command Line

AddSurfaceLine

# Deleting TIN or Grid Lines

Use the Prospector tree to delete TIN or grid lines from a surface.

---

**NOTE** TIN or grid volume surfaces do not support editing operations.

---

Use this command to remove:

■ Long and narrow TIN triangles on the perimeter of a surface.

■ TIN or grid lines within a pond or building foundation to create a void area to prevent contours from being drawn through the void areas.

When you remove an edge, an interior border, following the adjacent lines, is created, or the exterior border is modified to follow the new lines.

---

**TIP** To perform this operation, ensure that the surface style has triangles visibility enabled and that the OSNAP Endpoint setting is disabled. See Surface Styles and Visualization (page 692).

---

**To delete TIN or Grid lines**

**1** In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click , and click Delete Line.

**2** At the command line, you are prompted to select the edges (lines) to remove.

**3** Click the edges that you want to remove and press Enter.

---

**NOTE** If you are deleting grid lines, select the grid lines, not the triangulation lines.

---

The edges are removed. An interior border, following the adjacent TIN or grid lines, is created, or the exterior border is modified to follow the new TIN or grid lines.

The edits are added as Delete Line or Delete Multiple Lines operations to the Edits list view in Prospector.

**NOTE** The Description column in the list view displays the coordinates of the vertices for the edge that was deleted.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Edits ➤ Delete Line

Command Line

DeleteSurfaceLine

# Swapping Edges

Use edge swapping to change the direction of two triangle faces in the surface model so that, for example, the triangle edges match ridges or swales.

**NOTE** TIN volume surfaces do not support editing operations.

To swap an edge, observe the following conditions:

■ You must click within 1 unit of an edge.

■ Two visible triangles are separated by the edge.

■ The edge is not a breakline edge or an edge created by an Add Line operation.

■ The quadrilateral formed by the two triangles (which are separated by the edge) is convex.

**TIP** To perform this operation, ensure that the surface style has triangles visibility enabled. See Surface Styles and Visualization (page 692).

**To swap an edge**

1  In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click 🖉 , and click Swap Edge.

2  At the command line, you are prompted to select an edge (line) to swap.

3  Click the edge to swap it.
   The edge is swapped if the criteria are met. For information, see Swapping Edges (page 652).

4  Optionally, continue to select edges to swap by clicking them.

5  Press Enter to complete the operation.
   The edits are added as Swap Edge operations to the Edits list view in Prospector.

   **NOTE** The Description column in the Prospector list view displays the coordinates of the point that you picked in the drawing area to select the edge.

### Quick Reference

# Adding Points to Surfaces

Use the Prospector tree to add points directly to a surface model.

**NOTE** TIN or grid volume surfaces do not support editing operations.

Adding points in this manner constitutes a surface edit, and can be enabled and disabled in the surface properties. This operation adds points to the surface definition rather than to the surface data components.

**NOTE** If you are adding a point to a grid surface, you can add points only outside the existing border or to a hole with no points inside the surface area. This command uses the SNAP orientation (based on the spacing and orientation of the surface being edited).

**TIP** To perform this operation, ensure that the surface style has triangles visibility enabled. See Surface Styles and Visualization (page 692).

**To add points**

1 In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click  , and click Add Point.

2 At the command line, you are prompted to select a point.

3 Click on the location for the point.
  You are prompted for the elevation of the point.

4 Specify the elevation at the command line.

5 Optionally, continue to select other points to add, by clicking their locations.

6 Press Enter to complete the operation.
  The points are added as Add Point or Add Grid Point operations to the Edits list view in Prospector.

  **NOTE** The Description column in the list view displays the coordinates and elevation for the points that were added.

### Quick Reference

# Deleting Surface Points

Use the Prospector tree to delete points from a surface and remove inaccurate or unnecessary data.

**NOTE** TIN or grid volume surfaces do not support editing operations.

The points are not deleted from any of the existing surface data components. The deleted point operations are added only to the surface definition.

**TIP** To perform this operation, ensure that the surface style has triangles or points visibility enabled. See Surface Styles and Visualization (page 692).

**To delete points**

1 In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click, and click Delete Point.

2 At the command line, you are prompted to select points.

3 Click the points you want to delete from the surface.

4 Press Enter.

5 The selected points are deleted from the surface.

**NOTE** When you delete an interior point from a grid surface, an interior border, following the adjacent grid lines, is created.

6 Optionally, continue to select other points to delete by clicking them.

7 Press Enter to complete the operation.

The deleted points are added as Delete Point, Delete Multiple Points, or Delete Grid Point operations to the Edits list view in Prospector.

**NOTE** The Description column in the list view displays the coordinates and elevation for the points that were deleted.

### Quick Reference

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Edits ➤ Delete Point

Command Line

DeleteSurfacePoint
DeleteSurfaceGridPoint

# Modifying Surface Points

Use the Prospector tree to change the elevations of individual surface points.

**NOTE** TIN or grid volume surfaces do not support editing operations.

These points are not modified in any of the existing surface data components. The modify point operations are added only to the surface definition.

To perform this operation, ensure that the surface style has points visibility enabled.

See Surface Styles and Visualization (page 692).

**To modify the elevation of single surface points**

**1** In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click ✎, and click Modify Point.

**2** At the command line, you are prompted to select the points to edit.

**3** In the drawing area, select the points.

**4** Press Enter.

**5** You are prompted to specify the new elevation for the points.

**6** Specify the elevation at the command line.

**7** Optionally, continue to select other points to modify.

**8** Press Enter to complete the operation.

**9** The modified points are added as Modify Point or Modify Multiple Points operations in the Edits list view in Prospector.

---

**NOTE** The Description column in the list view displays the coordinates and new elevation (Z) for the points that were modified.

---

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Edits ➤ Modify Point

Command Line

EditSurfacePoint

## Moving Surface Points

Use the Prospector tree to move an existing surface point to a new location. The surface triangulation is updated accordingly.

---

**NOTE** TIN or grid volume surfaces do not support editing operations.

---

The points you move are not modified in any of the existing surface data components. The move point operation is added to the surface definition. This operation does not require the surface points to be visible.

**To move surface points**

**1** In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click ✎, and click Move Point.

**2** At the command line, you are prompted to select the point you want to move.

**3** In the drawing area, click the point.

You are prompted to select the new location for the point.

**4** Click the new location in the drawing.

**5** Optionally, repeat steps 2 and 3 or press Enter to end the command.

The moved points are added as Move Point operations to the Edits list view in Prospector.

---

**NOTE** The Description column in the list view displays the coordinates of the old (from) and new (to) location of the point.

---

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Edits ➤ Move Point

Command Line

MoveSurfacePoint

## Minimizing Flat Areas in a Surface

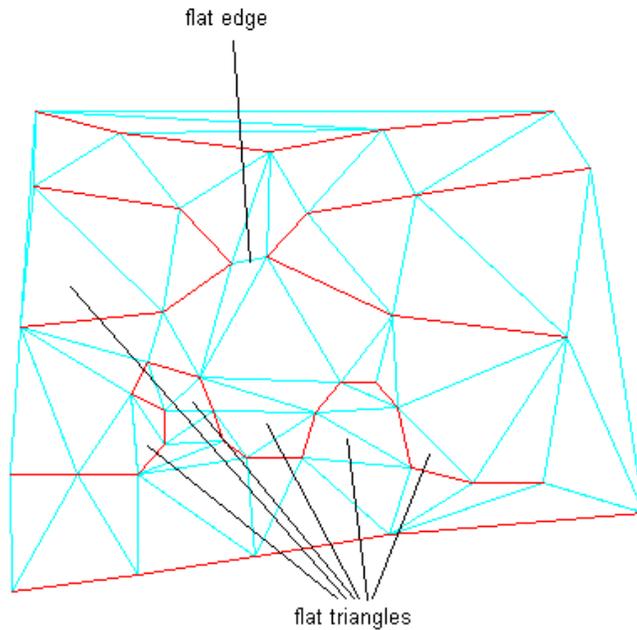
When contour data is added to a TIN surface, the resulting surface can contain flat spots (triangles whose points all come from the same contour) and flat edges (triangle edges that join points from the same contour or from different contours at the same elevation).

---

**NOTE** TIN volume surfaces do not support editing operations.

---

The following illustration shows a surface with flat areas where the triangles (in cyan) of a surface are created from red contour lines. Some of the flat triangles and flat edges are indicated:



These flat areas represent inaccuracies in the surface. When the contours of such a surface are displayed, they might not match the original contour data around the flat areas. Also, displayed contours might contain points with three contour segments emanating from them instead of the expected two segments. Use the Minimize Flat Areas operation to find and eliminate triangles that have three points at the same elevation and edges that connect points on different data contours at the same elevation.

This command reduces the number of flat areas that result from the addition of contour data to a surface. It helps create a better surface model that realistically reflects a real-world surface.

The Minimize Flat Areas operation finds flat areas defined by triangle edges that are created from either a breakline or a contour. If a surface created from point data contains a flat area defined by three points with the same elevation, the operation does not affect the surface.

You can specify the Minimize Flat Areas By options when using the Minimize Flat Areas operation or during the Add Contour Data operation.

With one exception, the following Minimize Flat Areas options work only for TIN surfaces generated from contour data. In some cases, the Swapping Edges option can change the appearance of the contours displayed on a surface that is not generated from contour data.

---

**TIP** You can view flat triangles graphically by using slope shading. If you shade the surface using one range with a slope of 0.00 percent, you will see the flat areas along the contour data.

---

### Filling Gaps

This option fills the small gaps that sometimes occur in displayed contours and creates one continuous contour. If the two ends of the gap are close enough to be connected by a single triangle edge, the gap is filled by making that edge and the two data contours it joins into a single data contour. No additional points or edges are added.

If you want to control which gaps are filled, you can add contour data without selecting this option, and then use the Check for Contour Problems operation, which reports both ends of the gap. If, after reviewing the results of the operation, you identify gaps that you do not want filled, add a surface point between the two gap endpoints with an elevation above or below the contour. Then use the Minimize Flat Areas operation with the Filling Gaps In Contour Data option selected to fill the remaining gaps.

---

**NOTE** Gaps are filled in displayed contours only. The original surface contour data is not changed.

---

### Swapping Edges

This option scans the surface looking for a flat triangle that shares a non-contour edge with a non-flat triangle. If the two triangles form a convex quadrilateral, the common edge is swapped, creating two non-flat triangles. This may result in other flat triangles sharing non-contour edges with non-flat triangles, and these edges are swapped if possible. The process continues until no more swapping is possible.

This command reverses the direction of a TIN line between four adjacent surface points. To perform this operation, ensure that the surface style has points visibility enabled.

See Editing a Surface Style (page 694).

After the command is performed, the surface size remains unchanged and the surface contains the same number of points and triangles.

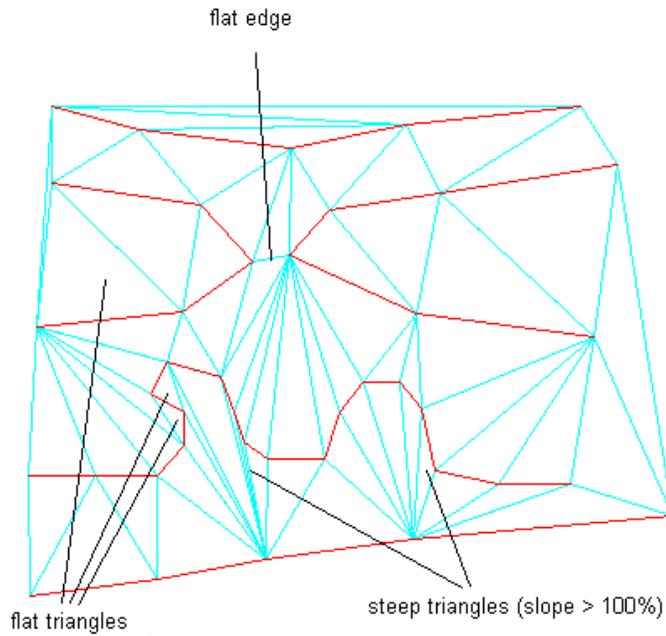
---

**IMPORTANT** The command does not remove all flat triangles and flat edges. Some of the new triangles may have extremely steep slopes.

---

flat edge

flat triangles

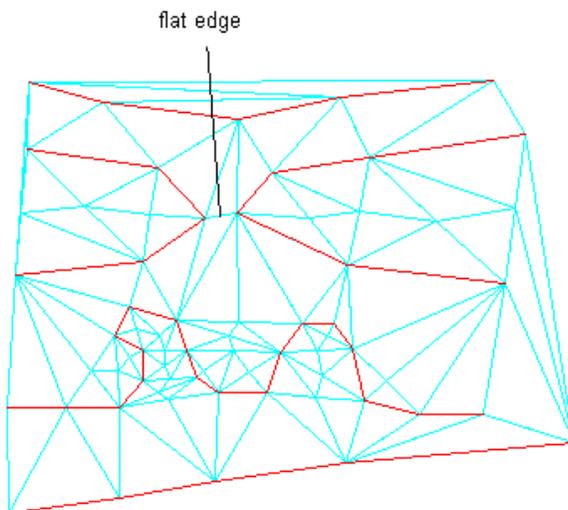
steep triangles (slope > 100%)


### Adding Points to Flat Triangle Edges

Like the previous option, this option scans the surface looking for a flat triangle that has all its points on data contours and shares a non-contour edge with a non-flat neighbor. However, instead of swapping the common edge of the triangle pair, a new point is added at the midpoint of the common edge. The elevation of the point is computed using Natural Neighbor Interpolation.

In many cases, this triangle falls at the edge of a chain of triangles that cross the flat area. Once you add the new point, the chain of flat triangles is traversed, with new points being added to flat triangle edges until the end of the chain is reached. The elevations of the points added along the chain are linearly interpolated between the elevations of the starting point and the ending point of the chain.

This option results in the removal of more flat triangles than the Swapping Edges option. Any triangle that would be removed by the Swapping Edges option is also removed by this option. This option also generally results in fewer steep triangles. However, additional points and triangles are added to the surface:



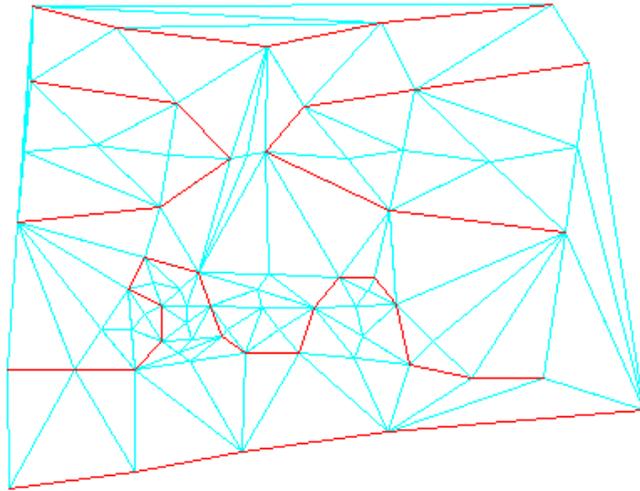
flat edge

In this illustration, 27 points are added to the surface. Most flat triangles are removed, except for some along the top and upper left borders.

**Adding Points to Flat Edges**

This option addresses flat edges, which are edges that bridge two same-elevation data contours but are not in flat triangles. The surface is scanned for any flat edges with both endpoints on data contours. If the opposing points of the two triangles containing such an edge are both at a higher elevation than the edge, or both at a lower elevation than the edge, then a new point is added at the midpoint of the flat edge. The elevation of the new point is computed using Natural Neighbor Interpolation. Because new points and edges are added, this option increases the size of the surface.

The following illustration shows the same surface after applying both the Adding Points To Flat Triangle Edges and the Adding Points To Flat Edges options. A total of 28 points are added in this example.



One benefit of the Swapping Edges option is that it does not increase the size of the surface. The Adding Points To Flat Triangle Edges and Adding Points To Flat Edges options generally produce better results, but they increase the size of the surface.

---

**TIP** You can differentiate between the display of points that are created from the contour data and the points that are added by the Minimize Flat Areas operation by changing the surface style. On the Points tab in the surface style, make the Data Point Symbol and Color different from the Derived Point Symbol and Color.

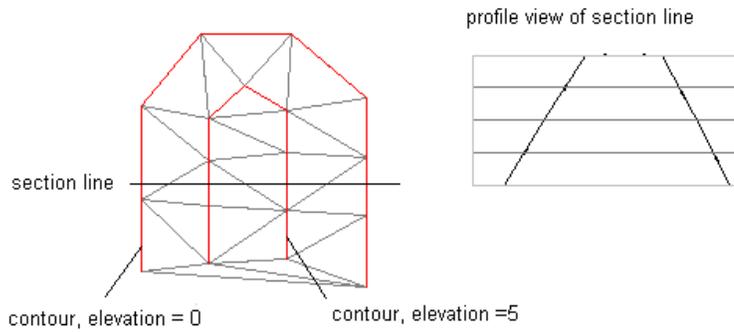
---

Before using the Minimize Flat Areas operation on a surface, you might find it helpful to evaluate flat areas so you can control the results of the operation, as shown in the following examples.

The following illustration shows a surface generated for a ridge where an open contour ends near the border of the surface but not on the border. The contours were added to the surface model with no Minimize Flat Areas. By options specified:

profile view of section line

section line

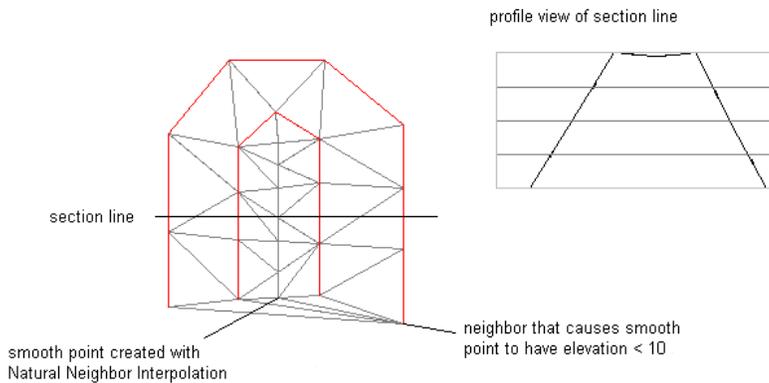
contour, elevation = 0          contour, elevation = 5


If you run the Minimize Flat Areas operation with the Adding Points to Flat Triangle Edges option, the following results are obtained:

profile view of section line

section line

smooth point created with
Natural Neighbor Interpolation

neighbor that causes smooth
point to have elevation < 10


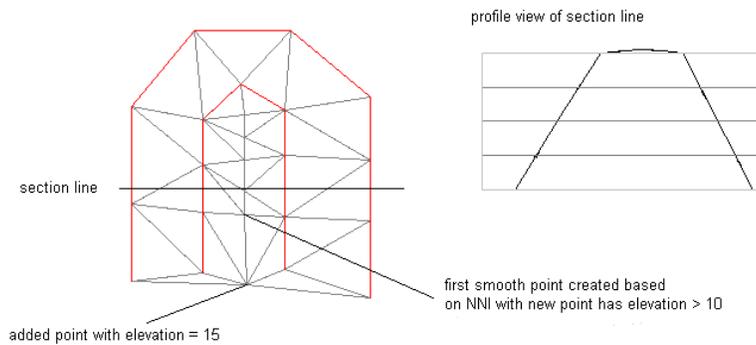
These results occur because the NNI interpolation uses surrounding points to determine an appropriate elevation for a new point. Because all surrounding elevations are lower than the flat triangle, elevations lower than the flat triangle are selected for the added points, resulting in the dip in the ridge.

In this instance, you can supplement the contour data by adding a spot elevation point near the open end of the contour, as shown in the following illustration. Then, the Minimize Flat Areas operation generates a crown as desired.

profile view of section line

section line

added point with elevation = 15

first smooth point created based
on NNI with new point has elevation > 10


**NOTE** For best results, follow the suggested guidelines for the order of operations for creating contours and adding data to a surface. For more information, see Recommendations for Creating Surfaces from Contours (page 629).

**To minimize flat areas**

1   In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click , and click Minimize Flat Areas.

2   In the Minimize Flat Areas (page 2367) dialog box, select check boxes to specify Minimize Flat Areas By options.

    The selected options are performed in the order in which they appear in the dialog box.

3   Click OK.

    The operation is added as a Minimize Flat Areas operation to the Edits list view in the Prospector tree, with the selected options listed in the Description column of the list view.

### Quick Reference

   Prospector tab: Surfaces ➤ <surface-name> ➤ Definition ➤ right-click Edits ➤ Minimize Flat Areas

Command Line

   MinimizeSurfaceFlatAreas

# Changing the Elevation of a Surface

Change the surface elevations by adding or subtracting an amount from the existing elevation of all the surface points, which raises or lowers the surface.

**NOTE** TIN or grid volume surfaces do not support editing operations.

A positive value increases the elevation; a negative value lowers the elevation.

**To raise or lower the surface**

1   In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click , and click Raise/Lower Surface.

    The following prompt is displayed:

    ```
    Amount to add to all elevations:
    ```

2   Enter a positive value to raise the surface or a negative value to lower the surface.

    The surface is adjusted to the new elevation.

    The operation is added as a Raise/Lower operation to the Edits list view in the Prospector tree.

    **NOTE** The Description column in the Prospector list view displays the value by which the surface was raised or lowered.

### Quick Reference

# Pasting Surfaces

Use the Prospector tab to paste a surface into the current surface.

**NOTE** TIN or grid volume surfaces do not support editing operations.

For example, if you have a building pad surface, you can paste it into a full-site surface. The building pad replaces that portion of the site surface that it covers.

**To paste a surface into the current surface**

1   In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click , and click Paste Surface.

2   In the Select Surface To Paste (page 1810) dialog box, in the list of surfaces, select the surface that you want to paste into the current surface, and click OK.

When the surface is pasted into the existing surface, the command adjusts the overlapping area to the elevation and contouring of the pasted surface.

The operation is added as a Paste Surface item to the Edits list view in Prospector.

**NOTE** The Description column in the Prospector list view displays the name of the surface that was pasted.

### Quick Reference

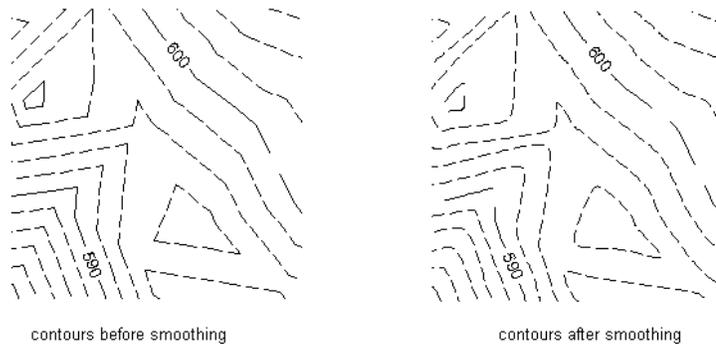
# Smoothing Surfaces

Surface smoothing adds points at system-determined elevations using Natural Neighbor Interpolation (NNI) or Kriging methods, which results in smoothed contours with no overlapping.

Only TIN surfaces support surface smoothing.

**NOTE** TIN volume surfaces do not support editing operations.

Surface smoothing resolves a problem associated with individual contour smoothing where the smoothing is applied to individual contour lines without regard to adjacent contours, which sometimes creates overlapping contours. Surface smoothing results in smoothed contours with no overlaps:

contours before smoothing          contours after smoothing


There are other benefits to surface smoothing. The Kriging method enables you to extrapolate, beyond the extents of a surface, based on the statistical trends across the existing surface. For example, if a site contains a random sample of borehole elevations (a sparse set of data points), you can statistically extrapolate a representation of a surface.

Because smoothing is an edit operation performed on a surface, you can specify smoothing properties and turn them on or off. When you turn the smoothing off, the surface reverts back to its original state, but the smoothing properties are preserved in the surface operation list. For more information about the operation list, see Understanding the Surface Definition (page 611).

**NOTE** Surface smoothing can take a considerable amount of time proportional to the number of output points. For the Kriging method, it is recommended that you use a relatively small sample point set (no more than 100 to 200 points).

## Understanding Point Interpolation/Extrapolation Output

Choose between several options when you use either of the NNI or Kriging surface smoothing methods for the interpolation and extrapolation of the point output.

**NOTE** For more information about the parameters, see the Smooth Surface (page 2357) dialog box help.

### Grid Based Location

Use the Grid Based output location to interpolate surface points (NNI), or interpolate/extrapolate surface points (Kriging) on a grid defined within specified polygon areas selected in the drawing. After the areas are defined, the grid X and Y spacing, and orientation properties can be specified.

### Centroids Location

Use the Centroids output location to interpolate surface points (NNI and Kriging) at the existing surface triangle centroids within specified polygon areas selected in the drawing.

When this option is selected, the grid X and Y spacing and the orientation properties are disabled.

### Random Points Location

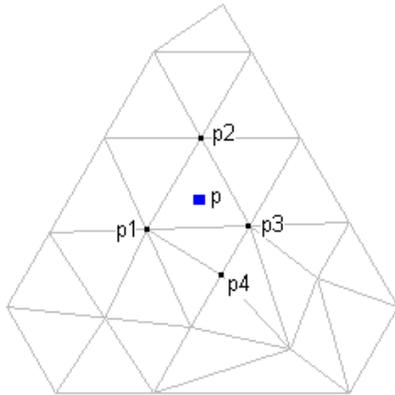
Use the Random Points output location to interpolate (NNI), or interpolate/extrapolate (Kriging) a specified number of random points within polygon areas selected in the drawing.

When this option is selected, the grid X and Y spacing and the orientation properties are disabled.

## Smoothing a Surface Using the Natural Neighbor Interpolation (NNI) Method

Use Natural Neighbor Interpolation (NNI) to estimate the elevation (Z) of an arbitrary point (p) from a set of points with known elevations.

The NNI method uses information in the triangulation from the known points to compute a weighted average of the elevations of the natural neighbors of point p. The number of neighbors (the number of points whose Z-values are averaged to get the interpolated value) depends on the triangulation: it is the number of points to which a new point (p) would be connected if inserted into the surface:



Using NNI, you select only the output locations of the interpolated points. The elevations of the interpolated points are always based on the weighted average of the elevations of the existing neighboring points. The outcome of the NNI method is more predictable than the Kriging method. NNI interpolates only within the surface, whereas Kriging can extrapolate beyond the surface border based on a selected polygon.

**To smooth a surface using Natural Neighbor Interpolation**

1   In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click  , and click Smooth Surface.

2   In the Smooth Surface (page 2357) dialog box, for the Select Method property, select Natural Neighbor Interpolation.

3   In Point Interpolation/Extrapolation Output, select the one of the Output locations: Grid Based, Centroids, or Random Points.

4   Depending on the location you selected, specify values:

  ■   **Grid Based**: Specify values for the output regions, grid spacing, and grid orientation properties.

  ■   **Centroids**: Specify the value for the output region.

  ■   **Random Points**: Specify the value for the output region.

5   Click OK to smooth the surface.

   The operation is added as a Smooth Surface item to the Edits list view in Prospector.

---

**NOTE**  The Description column in the list view displays the type of surface smoothing that was used (Kriging Smoothing or Natural Neighbor Smoothing).

---

Command Line

  SmoothSurface

Dialog Box

  Smooth Surface (page 2357)

## Smoothing a Surface Using Kriging Method

Kriging is more complex than Natural Neighbor Interpolation. It requires both a model of the spatial continuity or dependence (in the form of a covariance or semivariogram), and a sample of surface data to determine the statistical trend on which to base interpolated/extrapolated points.

Spatial prediction using Kriging involves two steps:

1   Model the covariance or semivariogram of the spatial process. This involves choosing both a mathematical form and the values of the associated parameters.

2   Use this dependence model in solving the Kriging system at a specified set of spatial points, resulting in predicted values and associated standard errors.

### Sample Data

You must select the output locations of the interpolated points. It is important to ensure that the sample data is appropriate for the interpolated point locations (the output). For example, do not select points on the opposite side of the surface to determine a trend for the interpolated/extrapolated points locations, as that trend may not be appropriate for the interpolated/extrapolated point locations.

### Semivariogram Model

Semivariance is a measure of the degree of spatial dependence between samples. The magnitude of the semivariance between points depends on the distance between the points. A smaller distance yields a smaller semivariance and a larger distance results in a larger semivariance. The plot of the semivariances as a function of distance from a point is referred to as a semivariogram.

Kriging provides five semivariogram models:

■   **Exponential**

■   **Gaussian**

■   **Monomial**

■   **Linear** (default)

■   **Spherical**

The semivariance increases as the distance increases until at a certain distance away from a point the semivariance will equal the variance around the average value, and will therefore no longer increase, causing a flat region to occur on the semivariogram called a sill. The distance from the point of interest to where the flat region begins is termed the range or span of the regionalized variable. Within this range, locations are related to each other, and all known samples contained in this region, also referred to as the neighborhood, must be considered when estimating the unknown point of interest.

The center of the neighborhood is usually the unknown value. To determine this value, all known values within the neighborhood are assigned weights using the semivariogram. These weights and known values are then used to calculate the unknown value.

**TIP** It is recommended that you understand Kriging methodology before using it to perform surface smoothing.

**To smooth a surface using Kriging**

1 In Toolspace, on the Prospector tab, expand the surface Definition collection, right-click ✏ , and click Smooth Surface.

2 In the Smooth Surface (page 2357) dialog box, for Select Method property, select Kriging.

The Kriging Method properties are available and the Kriging semivariogram model is displayed at the bottom of the dialog box.

3 In Semivariogram Model, select the model.

4 Select a point selection method from the Point Selection Method list and following the prompts as required.

5 Depending on the semivariogram model that you select, you can specify values for Parameter A, Parameter C, and the Nugget Effect.

6 In Point Interpolation/Extrapolation Output, select the output locations: Grid Based, Centroids, or Random Points.

7 Depending on the location you selected, specify values:

■ **Grid Based**: Specify values for the output regions, grid spacing, and grid orientation properties.

■ **Centroids**: Specify the value for the output region.

■ **Random Points**: Specify the value for the output region.

8 Click OK to smooth the surface.

The operation is added as a Smooth Surface item to the Edits list view in Prospector.

**NOTE** The Description column in the list view displays the type of surface smoothing that was used.

Smooth Surface (page 2357)

# Simplifying Surfaces

When you simplify a surface, you reduce the number of points or triangles in a TIN surface, while preserving the surface accuracy.

You can remove the specified amount of points in the specified surface region. The command does not remove points on breaklines and on the surface border.

**To simplify a surface**

1  Select a surface. On the Surface tab, Modify panel, click Edit Surface drop-down ➤ Simplify Surface ⬡ .

2  If more than one surface is available in the drawing, click the surface that you want to simplify or press Enter to select a surface in the Select A Surface dialog box.

3  Follow the Simplify Surface wizard sequence and the command line prompts to specify:

   ■  A simplification method (page 2371).

   ■  The surface region (page 2371) that you want to simplify.

   ■  Point reduction options (page 2371).

4  Click Apply.

   The total number of points to be removed is displayed.

5  Click Finish to remove the points.

The Simplify Surface operation appears in the surface definition in the Prospector tree.

## Quick Reference

Ribbon

  Select a surface. On the Surface tab, Modify panel, click Edit Surface drop-down ➤ Simplify Surface ⬡ .

# Removing Surface Data

You can use several methods for removing data from a drawing, surface definition, or from both.

**NOTE** When deleting AutoCAD objects, the surface definition is deleted along with the AutoCAD object if the Copy Deleted Dependent Objects option in the surface definition is set to No. For more information, see Definition Tab (Surface Properties Dialog Box) (page 2346).

# Excluding Data from the Surface Build

Hide or disable operations in the current surface build while preserving them in the surface definition list.

Excluding data is useful for comparing scenarios. For example, you can add additional points to a surface from a point file, and later disable the Add Point File operation. The surface will revert back to the original (pre-point file) triangulation.

**To exclude data from the surface build**

**1** In Toolspace, on the Prospector tab, under the Surfaces collection, right-click the surface and click Properties.

**2** In the Surface Properties dialog box, click the Definition tab (page 2346).

**3** In the Operations List, clear the operations that you want to exclude from the build and click OK.

You are prompted with a warning to confirm the changes that you made to the surface definition.

**4** Click Yes to confirm the changes.

The surface is rebuilt with the unchecked operations excluded.

# Deleting Data from the Surface

Remove a data operation permanently while retaining the AutoCAD drawing objects (for example, polylines or points) on which the data operation may be based.

There are two methods to remove a data operation from a surface:

■ Delete it from the Prospector list view.

■ Remove it from the surface operations list in the Surface Properties dialog box.

**To delete data from the surface definition using the Prospector list view**

**1** In Toolspace, on the Prospector tab, expand the surface Definition collection and click the collection from which you want to delete data.

**2** In the Prospector list view, right-click the list item and click Delete.

**3** Click Yes to confirm the deletion of the selected breaklines.

The surface is rebuilt without the deleted operation.

**To delete data from the surface operations list**

**1** In Toolspace, on the Prospector tab, right-click the surface and click Properties.

**2** In the Surface Properties dialog box, click the Definition tab (page 2346).

**3** In the Operations List, right-click the operations that you want to delete from the surface and click Remove From Definition.

You are prompted with a warning to confirm the changes that you made to the surface definition.

**4** Click Yes to confirm the changes

The surface is rebuilt with the deleted operations excluded.

# Deleting Data from the Surface and the Drawing

You can permanently remove both a surface definition item and the AutoCAD object from which it is derived.

**NOTE** If you delete an AutoCAD object, the surface definition item is deleted only if the Copy Deleted Dependent Objects option in the surface definition is set to No. For more information, see Definition Tab (Surface Properties Dialog Box) (page 2346).

**To graphically delete data from the surface and drawing**

■ In the drawing area, select the object and press Delete.
   Both the object and surface definition item are deleted.

# Deleting AutoCAD Objects

You can permanently remove the AutoCAD objects that surface definition items are derived from without deleting the surface definition item.

For all surface definition items that are derived from AutoCAD objects, ensure that the surface build parameter Copy Deleted Dependent Objects is set to Yes. Then you can graphically select and delete the AutoCAD object while preserving the surface definition.

Also, you can use the Prospector list view to delete the AutoCAD objects from which the boundaries and breaklines are derived.

**To delete AutoCAD objects from the drawing graphically**

■ In the drawing area, select the object and press Delete.
   The object is deleted.

> **NOTE** If you want to delete an AutoCAD object, and not delete the surface definition item ensure that the Copy Deleted Dependent Objects option in the surface definition is set to Yes. For more information, see Editing and Viewing the Surface Definition (page 681).

# Masks

Use masks to block out areas of a surface and prevent them from being displayed or to render a section of the surface using a specified render material.

Masks can be defined from AutoCAD Civil parcels and from the following types of polygon-type objects:

■ Polylines                    ■ Faces

■ 3D Polylines                 ■ Survey Figures

■ Circles                      ■ Feature Lines

■ Ellipses                     ■ Parcel Segments

■ Rectangles                   ■ Surfaces

When you define a mask from a selected object, the mask geometry automatically updates when you make changes to the original object. If the original object is deleted from the drawing, the mask is also deleted.

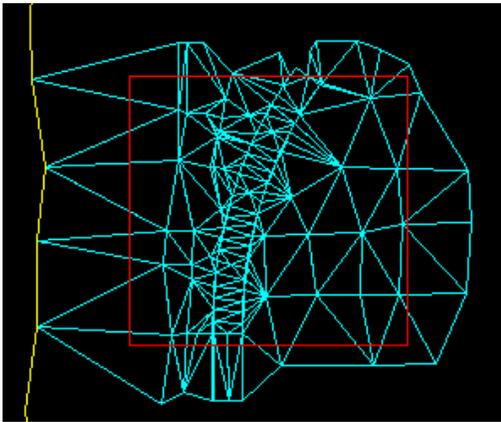
The display of the mask is based on the display settings of the referenced surface style. The display type is either trimmed to the segments of the mask or crosses the segments:

| Display Type | Trim/Cross |
| --- | --- |
| Points | Trim |
| Triangles | Cross |
| Border | N/A* |
| Contours | Trim |

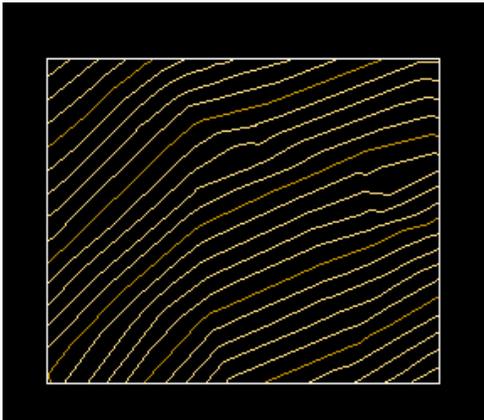
| Display Type | Trim/Cross |
|---|---|
| Grid | Trim |
| Directions | Cross |
| Elevations | Cross |
| Slopes | Cross |
| Slope arrows | Cross |
| Watersheds | Cross |

**\*** Border display is not affected by masks.

The following illustration is an example of crossing display (triangles):



The following illustration is an example of trimmed display (contours):



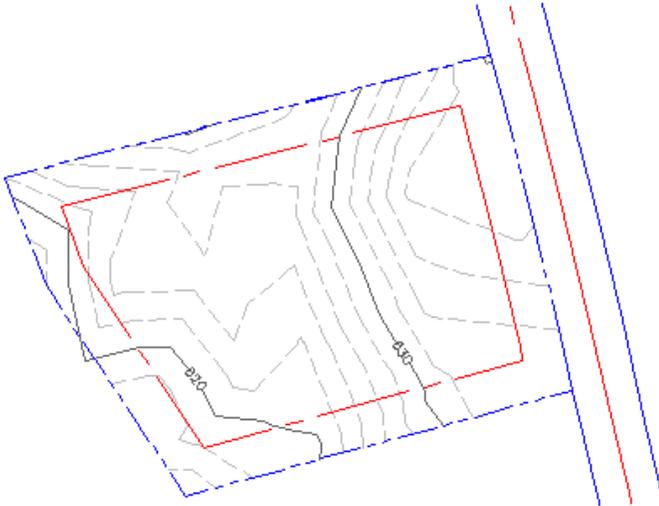
# Types of Masks

Define one of the two types of surface masks: outside or inside.

**NOTE** If you define an inside mask, you cannot use an outside mask on the same surface.

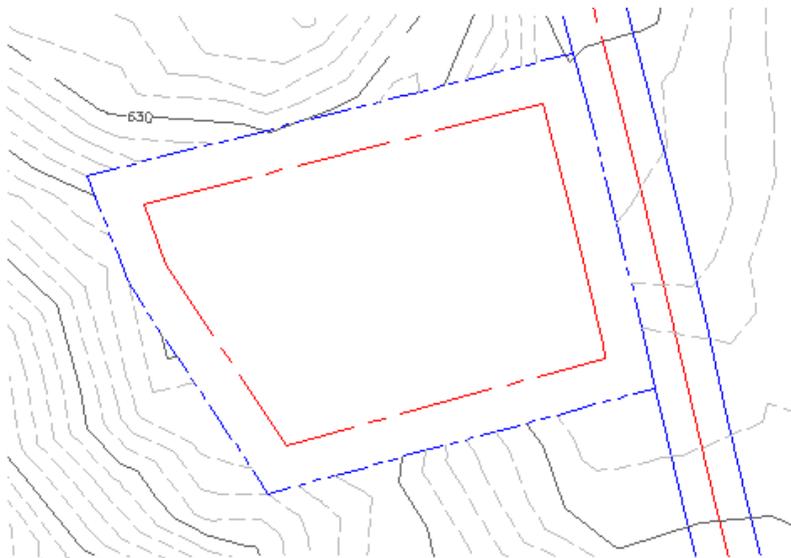
**Outside Masks**

When you define a mask as an outside type, the portion of the surface outside the defined polygon is hidden (the outside display is clipped to the mask segments):



**Inside Masks**

When you define a mask as an inside type, the portion of the surface residing inside the defined polygon is hidden:



**NOTE** Only one inside mask can be defined on a surface.

**Mask Render Only Property**

When you define an inside or outside mask as render only, the specified render material is applied to the inside or the outside of the mask polygon. The display of the surface is not masked, but when the surface is rendered, the render material pattern is displayed. The following illustration shows the render material applied to an inside mask:

# Creating a Mask

Create masks by selecting existing parcels or AutoCAD polygon-type objects.

**To create a mask**

1   In Toolspace, on the Prospector tab, expand the surface collection, right-click 🏠 Masks, and click Create Mask.

2   From the drawing, select an object or multiple objects to define the mask. Press *Enter.*

3   In the Create Mask (page 2363) dialog box, in the properties grid, click the Value column for the Name property and enter a name for the mask.

4   Click the Value column for the Description property and enter a description for the mask.

5   For Mask Type property, select Inside or Outside.

> **NOTE** If you define an inside mask on a surface, you cannot create another inside or outside mask on the same surface.

6   Depending on whether or not you want to set a selected object as a render-only mask, select Yes or No for Render Only option.

> **NOTE** If multiple objects are selected for the mask, the Render Only option is set to true and is unavailable.

7   Optionally, if the polygon object from which you are creating a mask has curves, enter a value in the Mid-Ordinate Distance field or click 📐 to digitize a distance in the drawing area.

8   Specify the render material by clicking in the Render Material row and clicking ⋯ .
The Render Material dialog box is displayed. For more information, see Applying Render Materials to Objects (page 1578).

9   Click OK.
The mask is created and added to the surface Masks collection in the Prospector tree.

**NOTE** A render-only mask must be rendered before it is displayed. See Rendering Objects (page 1579)

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ right-click Masks ➤ Create Mask

Command Line

CreateSurfaceMask

Dialog Box

Create Mask (page 2363)

# Viewing Masks

Select and view masks in the Prospector tab item view.

In the Prospector item view, you can manipulate the view of the mask, including zooming, panning, rotating, and orbiting. You can also save the view to an image file.

A render-only mask must be rendered before you can view it. For information, see Rendering Objects (page 1579).

### To view a mask in the Prospector item view

1 In Toolspace, on the Prospector tab, expand the surface ⌂ Masks collection and click the mask's name. The mask is displayed in the Prospector item view.

2 Right-click anywhere in the item view and select the option you want, such as Zoom To or Pan To.

# Changing the Display Order of Render Only Masks

Use the Mask Display Order dialog box to change the display order of a selected render-only mask.

A mask with a higher display priority is drawn last and on top of any overlapping masks.

### To change the display order of a render-only mask

1 In Toolspace, on the Prospector tab, right-click the surface ⌂ Masks collection and click Display Order. The Mask Display Order (page 2363) dialog box is displayed.

2 From the list, click a mask and click ⬆ to move the mask up in the list or click ⬇ to move the mask down.
The mask at the top of the list has the highest display priority and is drawn on top of any overlapping masks.

3 Click OK to apply the changes and close the Mask Display Order dialog box.

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ <surface-name> ➤ right-click Masks ➤ Display Order

Dialog Box

Mask Display Order (page 2363)

# Modifying a Mask

Use the Mask Properties dialog box to edit a mask's properties. You can also modify the extents, location, and positioning of a mask using the appropriate AutoCAD command (depending on the type of the originating object).

**To view and modify a mask's properties**

**1** In Toolspace, on the Prospector tab, click the surface ⌂ Masks collection.
The names and descriptions for the masks are displayed in the Prospector list view.

**2** Right-click the mask in the Prospector tree or list view and click Mask Properties.
The Mask Properties (page 2363) dialog box is displayed. Edit the name, description, boundary type, render material, and mid-ordinate distance.

**3** Click OK to apply the changes and close the Mask Properties dialog box.

**NOTE** You can move masks based on AutoCAD objects. You cannot move parcel-based masks.

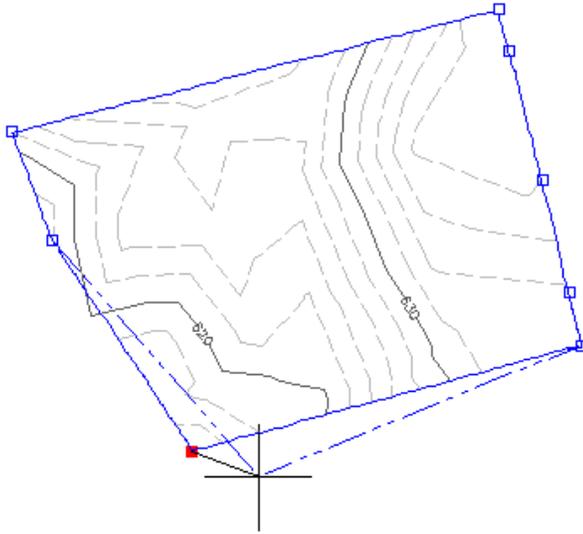
**To move a mask using the Move command**

**1** At the command line, enter **move**.

**2** Select the mask you want to move.

**3** Follow the command line prompts.

**To modify (rotate, scale, or stretch) a mask**

■ Use the AutoCAD grip editing capabilities of the original objects (for example, polylines, and circles, and parcels) to modify masks.


The mask reacts to changes made to the original object.

# Deleting a Mask

Use the Prospector tab to remove a mask from a surface by deleting the mask or by deleting the AutoCAD object that it was created from.

**To delete a mask**

1   In Toolspace, on the Prospector tab, click the surface Masks collection.

2   In the list of masks, right-click the mask and click Delete.

The mask is deleted from the surface, but the AutoCAD object (for example, a rectangle) is left in the drawing.

3   To delete the AutoCAD object, select it in the drawing area and press Delete.

### Quick Reference

Toolspace Shortcut Menu

# Watersheds

Use watersheds to analyze how water flows along and off of a surface.

Surface TIN lines are used to calculate the areas that water would flow along the surface. From these areas, the drain targets and watersheds are determined.

Different drain targets are calculated for watersheds. For example, some watersheds include a boundary point as a drain target, which is the point where the channel of water would drain off the surface. Other watersheds have depression areas that the water flows into, while some watersheds are defined as boundary segments where the drain target includes the boundary of a surface. For more information, see Types of Watersheds (page 676).

If AutoCAD Civil determines that water from one surface triangle could flow into more than one watershed, then it splits the TIN triangle to make two triangles. This ensures that each watershed consists of complete triangles, and that the boundary of each watershed consists solely of TIN edges.

# Types of Watersheds

Watershed types are based on the type of drain target the watershed has.

A drain target is the location where the water flow either stops or leaves the surface. Water that flows along an area or across a surface triangle eventually flows off the surface, or it reaches a point from which there is no downhill direction.

For each drain target in a surface, AutoCAD Civil determines the region of the surface that drains to that target. This region is called the watershed for that drain target.

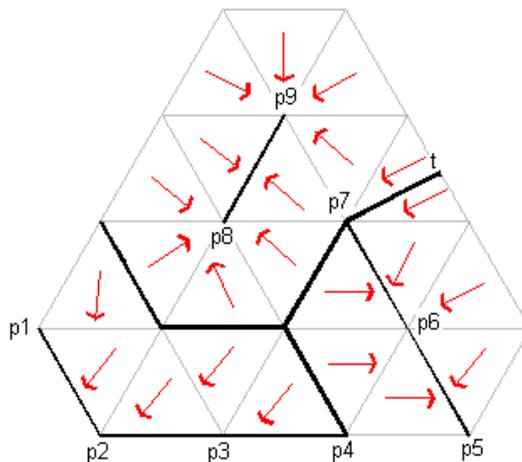
Each watershed that you delineate is categorized as one of the following types, based on drain target.

## Boundary Point

If the downhill end of a channel edge is on the surface boundary, then water flowing through that channel continues off the surface. The boundary point is the lowest end of the channel.

If a watershed has this type of drain target, it is called a boundary point watershed.

In the following illustration, point p5 is a boundary point, the drain target of the channel p7-p6-p5:

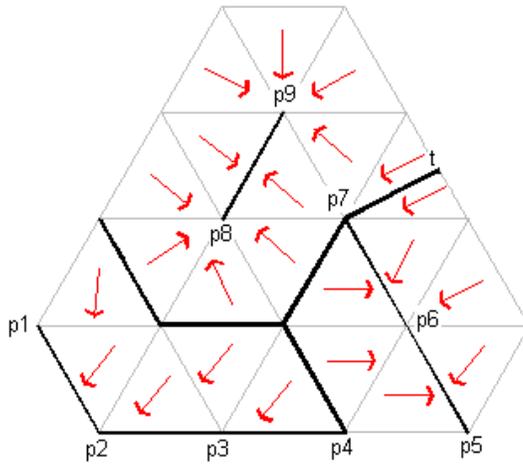


**NOTE** The "t" in the illustration indicates that the triangle was split between two watersheds because the water flowing across that triangle could go to either of two watersheds.

## Boundary Segment

If an edge on the surface boundary belongs to a triangle that slopes down toward that edge, then water flows off the surface all along that edge. A boundary segment is a connected sequence of such edges.

If a watershed has this type of drain target, it is called a boundary segment watershed.

In the following illustration, the edges p1-p2, p2-p3, and p3-p4 form a boundary segment.


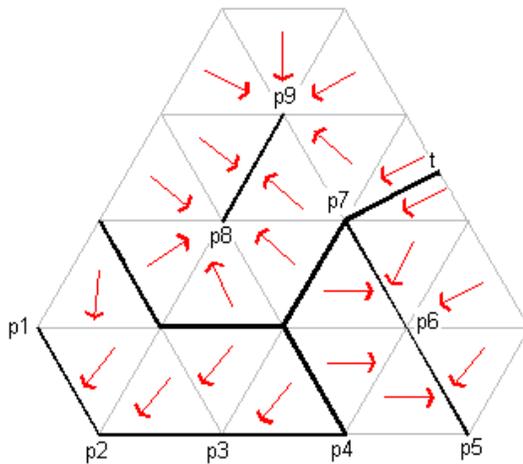
**NOTE** The "t" in the illustration indicates that the triangle was split between two watersheds because the water flowing across that triangle could go to either of two watersheds.

## Depression

If a point is at a lower elevation than all its neighboring TIN points, then when water flows to it, it has no downhill place to go. Similarly, a connected set of points that are at the same elevation and all of whose neighbors are at a higher elevation, is a single drain target. A depression is any such set of points.

If a watershed has this type of drain target, it is called a depression watershed.

In the following illustration, points p8 and p9 form a depression:



**NOTE** The "t" in the illustration indicates that the triangle was split between two watersheds because the water flowing across that triangle could go to either of two watersheds.

### Ambiguous Depression

A depression watershed can be ambiguous. A watershed is ambiguous if it does not include any drain targets, but water flowing on it can reach more than one drain target.

An ambiguous depression occurs when the depression watershed depth is less than the threshold depth, but there are multiple neighboring watersheds at points of minimum elevation on the boundary.

When such a watershed fills to overflowing, water flows to all those neighboring watersheds, so it cannot be merged into any single watershed. Instead, AutoCAD Civil keeps it as a separate watershed and lists the neighboring watersheds into which it will drain.

**Shallow Depression**

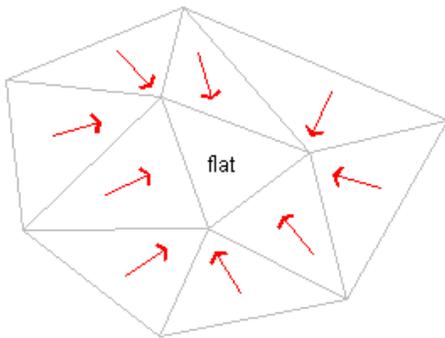
If a point is at a lower elevation than all its neighboring TIN points, then water that flows to it has no downhill place to go. Similarly, a connected set of points that are at the same elevation, and all of whose neighbors are at higher elevation, is a single drain target. A depression is any such set of points.

A shallow depression is determined by the average depth of a depression, which is the average depth of the depression when it is filled to overflowing. This is determined by dividing the value of water in the depression by the area of the top surface of the water. A depression is considered part of the watershed it drains into (provided there is only one watershed it drains into) if its average depth is less than the user-set threshold.

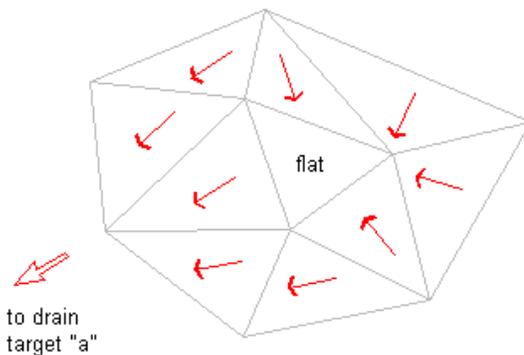
# Flat Area

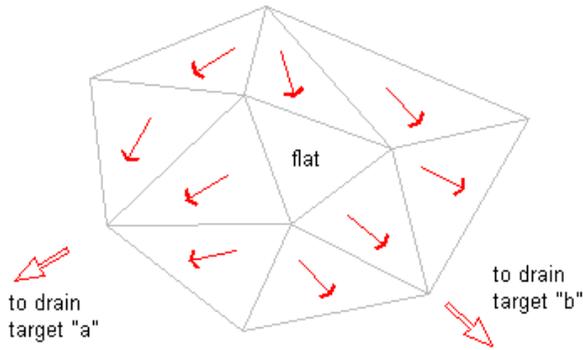
A flat area watershed is a flat area, from which water could flow down to more than one drain target. It also includes the parts of the surface that drain to that flat area. A flat area is a connected set of triangles all of whose vertices have the same elevation. Flat areas abut parts of the surface that slopes downhill.

If for every edge on the boundary of a flat area, the opposing, non-flat triangle slopes up from the edge, then the flat area is the bottom of a depression watershed:



If some of the opposing, non-flat triangles slope down from the flat area boundary, but all flow to the same drain target, then the flat area is part of the watershed for that drain target "a", as shown in the following illustration:



In the following illustration, the flat area, plus whatever part of the surface flows down to it, becomes a flat area watershed. This watershed is ambiguous because water flowing through it can flow to more than one drain target, "a" and "b":


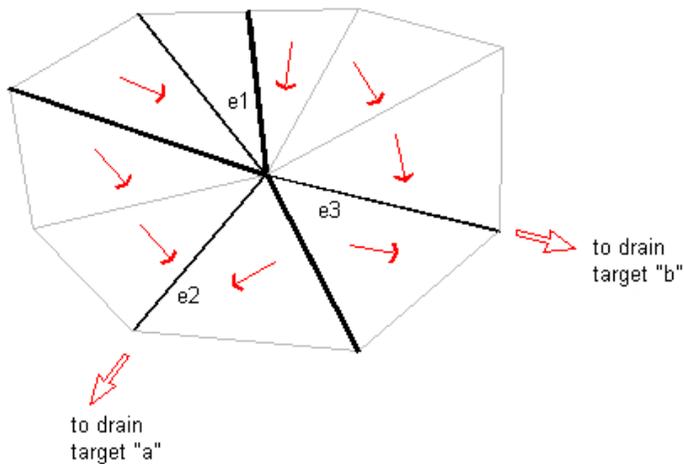
## Multi-Drain

One type of ambiguous watershed is called a multi-drain or split channel watershed.

In the following illustration, the channel edges e2 and e3 flow to different drain targets:

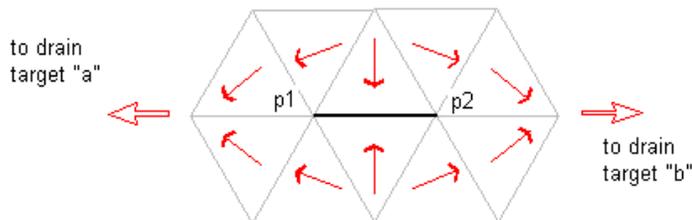
Water flowing down edge e1 could eventually reach either of these drain targets. In a case like this, AutoCAD Civil determines the region that flows to edge e1 and defines this region to be a multi-drain watershed.

Also, in this situation, AutoCAD Civil keeps track of the watersheds into which water from the multi-drain watershed might drain, in this case "a" and "b", as shown in the following illustration:



## Multi-Drain Notch

This type of watershed is called a multi-drain notch because water flowing into the notch formed from p1 and p2 and could drain to drain target "a" or drain target "b" as is shown in the following illustration:

A multi-drain notch watershed occurs where there is a a flat edge between two points on a surface:


# Generating and Displaying Watersheds

Generating and displaying watersheds on a surface is a flexible process.

**To generate and display watersheds**

1 Configure the watershed display or style settings. For information, see Creating a Surface Style (page 693).

2 Configure the watershed analysis and legend. For information, see Analyzing Surfaces (page 708).

3 Display the watershed. Watershed display is set on the Surface Style Display (page 2345)and Surface Properties Analysis (page 2343)tabs.

4 Insert the watershed legend table. For information, see Adding Surface Legend Tables (page 707).

# Viewing Watershed Properties

After you have created a watershed analysis on a surface, the watersheds are added to the surface Watersheds collection in the Prospector tree.

For information about creating a watershed analysis, see Analyzing Surfaces (page 708).

**To view watershed properties**

1 In Toolspace, on the Prospector tab, click the surface Watersheds collection.

The Prospector list view displays a tabular list of the surface watersheds with their IDs, description, type, and the ID of the watershed that they drain into.

2 Optionally, to pan or zoom to an individual watershed, right-click the watershed item in the list view and click Pan To or Zoom To.

> **NOTE** The watershed display needs to be enabled before you can view it. For information on displaying watersheds, see Surface Styles and Visualization (page 692).

# Managing Surfaces

You can manage instances of surfaces in the Surfaces collection in the Prospector tab and surface settings in the Surface collection in the Settings tab.

You can copy, export to LandXML, delete, rebuild, rename, synchronize, take a snapshot of, and change the style usage for a surface.

Every surface object has properties, which are defined and displayed in the Surface Properties dialog box (page 2346).

Surface properties include:

■ General information, including the name, description, and style for the surface. For information, see Information Tab (Surface Properties Dialog Box) (page 2346).

■ Definition attributes, including the build, data, and operation options, as well as a definition of items that are in use in the surface. For information, see Understanding the Surface Definition (page 611).

■ Analysis information, which includes properties for all types of surface analysis, including contour, direction, elevations, slopes, slope arrows, and watersheds. For information, see Analyzing Surfaces (page 708).

■ Statistics for the current state of the surface. For information, see Viewing Surface Statistics (page 689).

# Editing and Viewing the Surface Definition

Edit and view a surface definition information, including build, data, and operation options. Additionally, you can select or clear items that are included in the surface definition list.

For more information, see Understanding the Surface Definition (page 611).

**To edit the surface build and definition information**

1   In Toolspace, on the Prospector tab, expand the Surfaces collection, right-click the surface, and click Properties.

2   In the Surface Properties dialog box, click the Definition tab (page 2346).

3   To edit the general build information, expand the Build group and edit the values.

4   To specify whether certain data categories (for example, breaklines) are to be excluded from or included in the surface build, expand the Data Operations definition group and set the corresponding values to Yes or No.

5   To specify whether certain edit operation categories (for example, deleting points) are to be excluded from or included in the surface build, expand the Edit Operations group and set the corresponding values to Yes or No.

6   To reorder any of the surface operations, click the arrow buttons to the left of the Operation Type field.

7   Click Apply to make the changes or click OK to make the changes and close the Surface Properties dialog box.

    A warning message, which enables you to confirm or cancel your changes, is displayed.

## Quick Reference

Command Line

EditSurfaceProperties

Dialog Box

Surface Properties - Definition Tab (page 2346)

# Using Surface Snapshots

A snapshot is a surface operation that captures the current state of surface.

When a surface snapshot exists and the surface is rebuilt, the build process starts at the snapshot and proceeds sequentially through subsequent surface operations. Therefore, if a surface operation, such as an import of an external data file, exists prior to the snapshot operation, the surface build process does not attempt to find and open the external data file since all of the external file point data is contained in the surface snapshot operation.

## Creating a Snapshot

Use the Prospector tab to create a surface snapshot.

The current surface points and triangles resultant from previous surface operations are contained in the surface snapshot operation. When a surface is built, previous surface operations are ignored and the surface build begins at the snapshot operation.

Snapshots can be created automatically. A LandXML setting enables you to specify that a surface snapshot be created in the surface definition subsequent to the importing of a surface when using Import LandXML. For more information, see Viewing and Editing the LandXML Import Settings (page 1678).

**To create a snapshot**

■ In Toolspace, on the Prospector tab, expand the Surfaces collection, right-click the surface, and click Create Snapshot.

---

**NOTE** If there is an existing snapshot operation, a warning dialog box is displayed from which you can confirm or cancel the operation.

---

Surface operations that are included in the snapshot are marked with  in the Prospector tree.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: right-click <surface-name> ➤ Create Snapshot

## Rebuilding a Snapshot

You can rebuild a snapshot if any of the operations that precede it in the surface operation list change or are removed.

If the snapshot operation is out-of-date,  is displayed next to its node in the Prospector tree.

**To rebuild a snapshot**

■ In Toolspace, on the Prospector tab, expand the Surfaces collection, right-click the surface, and click Rebuild Snapshot.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: right-click <surface-name> ➤ Rebuild Snapshot

## Deleting a Snapshot

You can remove an existing snapshot.

**To delete a snapshot**

■ In Toolspace, on the Prospector tab, expand the Surfaces collection, right-click the surface, and click Remove Snapshot.

■ A warning dialog box is displayed in which you can confirm or cancel the operation.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: right-click <surface-name> ➤ Remove Snapshot

## Snapshots and the Surface State

The out-of-date icon can be displayed at several places in the Prospector tree or surface definition depending on the status of the snapshot and the surface.

■ Out-of-date snapshot. When an active snapshot is out of date, 🔰 is displayed next to the snapshot operation in the Definition tab of the Surface Properties dialog box.

■ Out-of-date surface. If the surface is out of date when you attempt to create a snapshot, a warning dialog box is displayed, indicating that the snapshot will be created based on the current (out-of-date) state of the surface.

■ Out-of-date data. If the surface data is out of date (Rebuild - Automatic is disabled) and is contained in an active snapshot, the data item is shown as out of date 🔰 in the Prospector tree, but the surface is not shown as out of date.

# Changing a Surface Name, Description, or Style

Change an existing surface name, description, and style usage.

**To rename a surface**

1 In Toolspace, on the Prospector tab, expand the Surfaces collection, right-click the surface, and click Properties.

2 In the Surface Properties dialog box, click the Information tab (page 2346).

3 To edit the name of the surface, enter a new name in the Name field.

4 To edit the description of the surface, enter a new description in the Description field.

5 To change the style for the surface, select a style from the Object Style list or use the standard style selection controls.

6 Click Apply to make the changes, or click OK to make the changes and close the Surface Properties dialog box.

## Quick Reference

Object Shortcut Menu

Surface Properties

Command Line

EditSurfaceProperties

Dialog Box

Surface Properties - Information Tab (page 2346)

# Copying a Surface

Create a copy of an existing surface.

When a surface is copied, the copy is named using a naming convention. For example if the original surface that is copied is named 'Surface 1', the new surface is named 'Surface 1 (1)'. If Surface 1 is copied again, the new surface is named 'Surface1 (2)'. If 'Surface 1(1)' is copied, the new surface is named 'Surface 1 (1) (2)'.

**To copy a surface**

1   In the drawing area, select the surface, right-click, click Basic Modify Tools ➤ Copy.

2   At the command line, you are prompted to specify a base point for the surface.

3   Pick an insertion point in the drawing area.
    The surface is copied in the drawing and added as a new surface to the Prospector tree.

4   To edit the name of the surface, right-click the surface in the Prospector tree and click Properties.
    The Surface Properties dialog box is displayed with the Information tab (page 2346) active. The Name field contains the name of the copied surface, which is, by default " <surface-name> (1)."

5   Enter a new name in the Name field.

6   To edit the description of the surface, enter a new description in the Description field.

7   To change the style that the surface is using, select a style from the Object Style list or use the standard style selection controls.

8   Click Apply to make the changes, or click OK to make the changes and close the Surface Properties dialog box.

## Quick Reference

Object Shortcut Menu

Dialog Box

Surface Properties - Information Tab (page 2346)

# Previewing a Surface

You can preview a surface in the Prospector item list view.

**To preview a surface**

1   In Toolspace, on the Prospector tab, right-click the Surfaces collection and click Show Preview.

    **NOTE** A check mark is displayed next to the Show Preview menu item when the preview is enabled.

**2** In the Prospector tree, click the surface that you want to preview.

The surface is displayed in the Prospector item view.

> **NOTE** The preview of the surface uses the same display styles as the surface in the drawing area.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: right-click Surfaces ➤ Show Preview

## Rebuilding a Surface

When you make changes to a surface, such as editing data or the build parameters, the surface may become out of date and you can rebuild it.

If the surface definition is out of date, ▽ is displayed next to its node in the Prospector tree.

AutoCAD Civil enables you to either automatically or manually rebuild a surface.

### To automatically rebuild a surface

■ In Toolspace, on the Prospector tab, expand the Surfaces collection, right-click the surface and click Rebuild - Automatic.

> **NOTE** A check mark is displayed next to the Rebuild - Automatic menu item when it is enabled.

When changes are made to the surface, it is automatically rebuilt and updated.

### To manually rebuild a surface

■ In Toolspace, on the Prospector tab, expand the Surfaces collection, right-click the surface, and click Rebuild.

> **NOTE** If the surface definition is out-of-date, ▽ is displayed next to its node in the Prospector tree.

The surface is rebuilt and updated in the drawing.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ right-click <surface-name> ➤ Rebuild

## Deleting a Surface

Delete a surface, which erases it from the drawing and removes it from the Surfaces collection in the Prospector tree.

### To delete a surface

■ In Toolspace, on the Prospector tab, expand the Surfaces collection, right-click the surface, and click Delete.

The surface is erased from the drawing and removed from the Surfaces collection in the Prospector tree.

**NOTE** You cannot delete a surface from the Prospector tree if it has associated dependencies (such as other objects). You can determine if the surface has dependencies by the orange triangle attached to the surface icon. The Delete command for such surface is missing from the shortcut menu.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ right-click <surface-name> ➤ Delete

## Locking a Surface

Lock a surface so that its properties and geometry cannot be changed. Certain tabs in the Surface Properties dialog box and some menu items cannot be selected.

For more information about controlling access to a project surface using AutoCAD Civil project management functionality, see Using Vault (page 138).

**To lock a surface**

■ In Toolspace, on the Prospector tab, expand the Surfaces collection, right-click the surface, and click Lock.

In the Prospector tree, '✍ is displayed next to the surface.

The surface is locked and its geometry cannot be edited.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Surfaces ➤ right-click <surface-name> ➤ Lock

## Moving, Scaling, or Rotating a Surface

Use standard AutoCAD commands to move, scale, and rotate a surface.

For more information about each AutoCAD command, refer to the Help.

**NOTE** The AutoCAD Mirror command is not supported on surfaces.

**To move, scale, or rotate a surface**

1 At the command line, enter the command, for example **Move**.

2 Follow the command-line prompts.

**NOTE** When moving, scaling, or rotating a surface, you should be aware that if you want to affect only the surface and not the data, you should select only the surface. After moving, scaling, or rotating as surface, a 'Transform By' operation is added to the surface definition and is reapplied during subsequent rebuilding of the surface. If the surface data in the drawing needs to be moved, scaled, or rotated, then the surface should not be selected since the surface is rebuilt according to location of its dependent data.

# Editing Surface Settings

Use surface settings to specify the default behavior for surface-related commands.

Settings are handled in a standard way throughout AutoCAD Civil. You access settings using the Settings tree. You can control settings at three levels: the drawing level, the object collection (feature) level, and the command level. It is important that you understand how the different levels of settings work together. For more information, see Specifying Drawing Settings (page 63).

You can use the Settings tree Surface collection shortcut menu to establish defaults for all surface-related commands. You can change surface-specific settings at this level, or you can override the drawing ambient settings.

Use the Commands collection under the Surface collection to change surface settings for a specific command. You can change surface-specific settings at this level, or you can override the drawing ambient settings.

**NOTE** Overrides to the drawing ambient settings at the Surface collection level and the surface Commands collection level affect only the specified level. The drawing level settings are not changed.

The topics in this section describe only those settings that affect surface-related commands, and do not cover the drawing ambient settings that you can change at the surface collection level and the surface command level, even though those settings are displayed in the Edit Feature Settings dialog box. For more information, see Specifying Ambient Settings (page 68).

## Changing Surface Creation Settings

Use the Surface Creation settings in the Edit Feature Settings - Surface (page 2329) dialog box to specify surface-related settings before you create surfaces.

For example, before creating or importing surfaces, you may want to specify the default surface style and default surface label styles.

If a closed lock appears in the Lock column for a property, the property is locked at a higher level of the Settings tree and cannot be changed at this level.

If you change a property value, a check mark appears in the Override column. This override is also reflected in the property table for related objects higher up the Settings tree, where an arrow appears in the Child Override column.

**To the change surface creation settings**

1  Do one of the following:

   ■ **To edit settings for all surface-related commands**: In Toolspace, on the Settings tab, right-click the Surface collection and click Edit Feature Settings.

   ■ **To edit settings for a specific command**: In Toolspace, on the Settings tab, expand the Commands collection under the Surface collection. Right-click the name of the command for which you want to change settings and click Edit Command Settings.

   The Edit Feature Settings - Surface (page 2329)dialog box is displayed.

2  Expand the Surface Creation property group.

3  To specify the default surface type, edit the Surface Default Type settings.

4  To specify the default grid surface spacing and orientation, edit the following settings:

   ■ Grid Surface X-Spacing

   ■ Grid Surface Y-Spacing

   ■ Grid Surface Orientation

**5** To specify the default name format for a surface, expand the Default Name Format property group and edit the Surface Name Template setting.

**6** Click Apply.

Settings tab: right-click Surface collection ➤ Edit Feature Settings
Or
Settings tab: Surface ➤ Commands ➤ right-click <command-name> ➤ Edit Command Settings

Dialog Box

Edit Feature Settings - Surface (page 2329)

# Changing Surface Style Settings

Use the Surface Style settings to specify default surface styles and surface label styles before you create surfaces.

You can use the default styles specified in these settings to establish the default setting for the style in the Create Surface dialog box.

**To change the surface style settings**

**1** Do one of the following:

- **To edit settings for all surface-related commands**: In Toolspace, on the Settings Tree, right-click the Surface collection and click Edit Feature Settings.

- **To edit settings for a specific command**: In Toolspace, on the Settings tree, expand the Commands collection under the Surface collection. Right-click the name of the command you want to change settings for and click Edit Command Settings.

**2** Expand the Default Styles property group.

**3** To specify a default surface style, change the Surface Default Style setting.

**4** To specify a default spot elevation label style, change the Surface Spot Elevation Label Style setting.

**5** To specify a default slope label style, change the Surface Slope Label Style setting.

**6** To specify a default point style, change the Point Style setting.

**7** Click Apply.

# Viewing Surface Statistics

AutoCAD Civil provides extensive statistics based on the current state of the surface.

Surface statistics categories include:

- **General**. Common to all surface types. Includes information such as bounding extents and elevations.
- **Extended**. Available for (non-volume) TIN and grid surfaces. Includes information such as 2D and 3D area as well as grade and slope values.
- **Grid**. Specific to grid surfaces. Includes information such as grid spacing and orientation.
- **TIN**. Specific to TIN surfaces. Includes information the number, area, and length of surface triangles.
- **Volume**. Specific to volume surfaces. Includes volume statistics.

**To view the statistics for a surface**

1  In Toolspace, on the Prospector tab, expand the Surfaces collection, right-click the surface, and click Properties.

2  In the Surface Properties dialog box, click the Statistics tab (page 2352).

3  To view the statistics for the surface, expand the corresponding category.

Dialog Box

   Surface Properties - Statistics Tab (page 2352)

# Troubleshooting Surface Errors

Identify and troubleshoot errors or problems with a surface, or its data components, in several ways.

For surface troubleshooting information, see Surface Errors and Issues (page 647).

# Working with Large Surfaces

In AutoCAD Civil you can build, edit, and save large surfaces. The term "large surface" applies to a surface with a number of points exceeding one million (generally, 1 million points for a grid surface or a snapshot of a TIN surface, and 2 million points for a TIN surface).

AutoCAD Civil has a mechanism for handling operations with large surfaces. When you save a drawing containing a large surface, the data pertaining to the large surface is written to a separate file that is saved in the same location where the surface drawing resides. The TIN surface companion files have the *.mms* file extension, and the grid surface files have the *.grs* file extension. The file name of a surface companion file has the *<drawing_name>_<surface object handle>.mms* format.

**NOTE** Every time you move the drawing file to a different location, you must move the companion file to the same location.

For more details on working with large surfaces, see:

# Calculating Surface Volumes

Use surface utilities to query composite and bounded volume differences between surface.

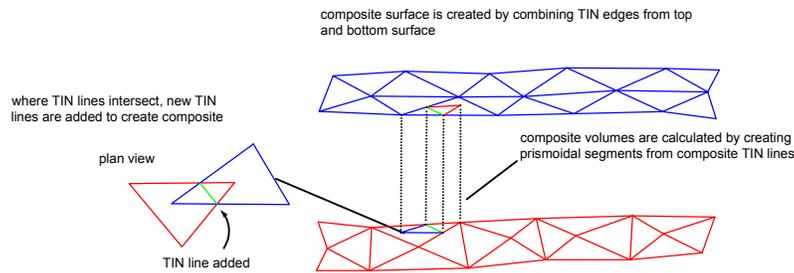
Composite volumes use top and bottom surfaces (a surface pair) to establish cut, fill, and net volume values. Bounded volumes use an existing AutoCAD object (for example, a polyline or polygon) to calculate the cut, fill, and net volume for the area bounded by the object.

# Calculating Composite Volumes

Calculate volumes using the composite method, which triangulates a new surface, based on points from both surfaces.

This method uses the points from both surfaces, as well as any location where the edges of the triangles between the two surfaces intersect to create prismoidal segments from composite TIN lines.

The new composite surface elevations are calculated based on the difference between the elevations of the two surfaces, as follows:



This method gives accurate volume measurements between the two surface definitions.

**See also:**

■ Creating a TIN Volume Surface (page 604)

■ Creating a Grid Volume Surface (page 606)

**To calculate composite surface volumes**

**1** Open, create, or import the TIN or grid surfaces for which you want to measure the composite volume. See Creating Surfaces (page 601).

**NOTE** The Composite Volumes utility compares two surfaces (surface pairs), so you must have two surfaces available in your drawing.

**2** Click Analyze tab ➤ Volumes And Materials panel ➤ Volumes drop-down ➤ Volumes 🗔 .

**3** Do one of the following:

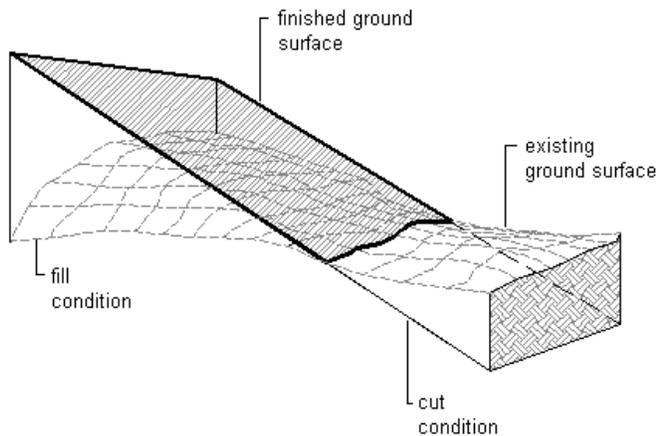
■ In the Composite Volumes (page 2364) vista, click  and select the surfaces to compare by clicking the <select surface> entry from the Base Surface and Comparison Surface columns (for the base and comparison surfaces respectively).

■ In the Composite Volumes vista, click  and select both the base and comparison surfaces from the drawing area.

After you select the surfaces, the volumes are calculated and the following information is displayed:

■ **Cut**. The amount of material that has to be removed.

■ **Fill**. The amount of material that has to be added.



■ **Net**. The difference between the cut and the fill. For example, if a volume is 200 m3 of cut and 100 m3 of fill, the net is 100 m3 <cut>.

■ **Net Graph**. A graphical percentage representation of the whole volume. A fill net is displayed as a green bar indicating that material needs to be added to the project site. A cut net is displayed as a red bar, indicating that material must be removed.

## Quick Reference

Ribbon

Click Analyze tab ➤ Volumes And Materials panel ➤ Volumes drop-down ➤ Volumes 

Menu

Surfaces menu ➤ Utilities ➤ Volumes

Command Line

ReportSurfaceVolume

Dialog Box

Composite Volumes (page 2364)

# Calculating Bounded Volumes

Use the Bounded Volume utility to calculate the volume of an area as defined by a polyline, or polygon, or parcel.

You can quickly calculate and display the net volume, cut, and fill for a bounded area on a volume surface.

For volume surfaces, the volume of the bounded area is calculated based on the difference of elevations that were originally used for volume calculation. For terrain surfaces, the volume is calculated from the zero elevation to the elevations in the bounded area.

**See also:**

■ Creating a TIN Volume Surface (page 604)

■ Creating a Grid Volume Surface (page 606)

**To calculate bound volumes**

1  Open, create, or import the surface for which you want to measure the bounded volume. See Creating Surfaces (page 601).

2  Click Analyze tab ➤ Volumes And Materials panel ➤ Volumes drop-down ➤ Bounded Volumes 🔳 .

3  You are prompted to select the polyline, or polygon, or parcel that defines the bounded areas on the surface.

   The net volume, cut, and fill values are displayed at the command line.

   **TIP** Press F2 to open the AutoCAD Text Window where the results are also displayed.

# Surface Styles and Visualization

Surface styles control the surface appearance in both 2D and 3D views.

Access and manage the surface styles in the Settings tab in Toolspace, where you can create, edit, copy, and delete them. For more information, see The Object Style Collection (Settings Tree) (page 94).

You can assign a surface style to a surface when you create or import a surface. You can also change the surface style using the surface list view.

The surface styles contain parameters and display settings for the creation of surface data objects, including:

■ **Borders**. Includes interior and exterior border and datum display.

■ **Contours**. Includes minor, major, depression, and user-defined contour lines display.

- **Grid**. Includes primary and secondary grid display.

- **Points**. All surface points for the TIN or grid surfaces.

- **Triangles**. TIN face information.

- **Analysis**. Includes directions, elevations, slopes, and slope arrows.

- **Watersheds**. Watersheds analysis display.

For general information about AutoCAD Civil styles, see Object Styles (page 53).

# Creating a Surface Style

Use the Settings tree to create a surface style.

A surface style defines how a surface is displayed in the drawing. You can apply the surface style to either a TIN surface, a grid surface, or a volume surface.

You can create and manage surface styles on the Settings tab in Toolspace.

**To create a surface style**

1 In Toolspace, on the Settings tab, right-click the Surface Styles collection and click New.

2 In the Surface Style dialog box, click the Information (page 2334) tab and enter a name and description for the surface style.

3 To define the display of surface borders, click the Borders (page 2335) tab and specify the settings.

4 To define the display of surface contours, click the Contours (page 2336) tab and specify the settings.

5 To define the display of surface grid, click the Grid (page 2338) tab and specify the settings.

6 To define the display of surface points, click the Points (page 2339) tab and specify the settings.

7 To define the display of surface triangles, click the Triangles (page 2341) tab and specify the settings.

8 To define the display of watersheds, click the Watersheds (page 2341) tab and specify the settings.

9 To define the display the analysis, click the Analysis (page 2343) tab and specify the settings.

10 To define the display of the various surface components, click the Display (page 2345) tab.

11 To view summary information about the style, click the Summary (page 2345) tab.

12 Click Apply.

# Creating a Surface Style Based on an Existing Surface Style

Use the Settings tree to create a surface style based on an existing surface style.

You create a surface style based on an existing surface style by making a copy of the existing surface style and then editing it.

**To create a surface style based on an existing surface style**

1  In Toolspace, on the Settings tab, right-click the name of the surface style you want to copy and click Copy.

   A copy is created, and its properties are displayed in the Surface Style dialog box.

2  In the Surface Style dialog box, click the Information (page 2334) tab and enter a name and description for the new surface style

3  Use the Surface Style (page 2334) dialog box to change any of the surface style properties. For more information, see Creating a Surface Style (page 693).

## Quick Reference

Toolspace Shortcut Menu

   Surface Style (page 2334)

# Draping Images On Surfaces

Use the Drape Image command to overlay an image, such as an aerial photo, over a surface.

Before draping an image on a surface, insert the image into the drawing. The Drape Image command orients, aligns, and renders the inserted image so that the original flat image reshapes to replicate the relief of the surface terrain.

**To drape an image over a surface**

---

**TIP** To perform this operation, ensure that the surface display style has triangles visibility enabled. See Editing a Surface Style (page 694). Also, ensure that Realistic is a default type of materials set in the Material Editor in the Materials window (to view the settings, at the command line, enter MATERIALS).

---

1 Click Insert tab ➤ Reference panel ➤ Attach 📄 .

2 Navigate to the location where the image is saved, select the image, and click Open.

3 In the Attach Image dialog box, specify Insertion Point, Scale, and Rotation or select Specify on Screen to do the adjustments in the drawing.

4 Click OK.

5 Select a surface. On the Surface tab, Surface Tools panel, click Drape Image 🖾 .

6 In the Drape Image dialog box, select the image from the Image list or click 🖳 to select the image from the drawing.

7 From the Surface list, select the surface on which you want to drape the image or click 🖳 to select the surface from the drawing.

8 Under Render Material Name, enter the name for the new render material. This name will be associated with the new render material which is created from the image that you have imported.

---

**NOTE** By default, the name of the new render material is comprised of the surface name and the image file name.

---

9 Click OK.

The image is draped over the surface. This image becomes associated with the new render material, which is added to the materials palette.

If the image is smaller than the surface, the draping only occurs on the area covered by the image. If the area of the image exceeds the area of the surface, the image is cropped along the surface boundary.

---

**NOTE** If you view your drawing in 2D plan view, the image displays in its 2D planar view.

---

# Surface Labels and Tables

Use surface label and table styles to control the appearance and behavior of surface-related labels and tables in a drawing.

The topics in this section describe what is unique to surface labels and tables. For a general overview of labels, see Labels and Tags (page 1463). For an overview of tables, see Tables (page 1555).

**Surface Labels**

Surfaces can be labeled automatically when created, using the specified label styles. After creating a surface, you can also add labels for the various components of the surface.

**Surface Tables**

You can use commands to insert surface legend tables into a drawing. Surface legend tables are used to display surface analysis information. When you insert a table into the drawing, the detailed surface information is inserted into the table.

# Surface Label Styles

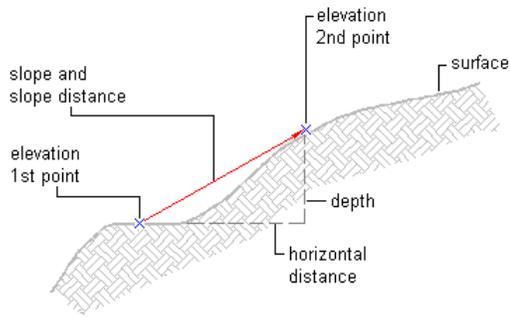
Use the Settings tab of Toolspace to manage surface label styles. You specify which label styles to use when you create surfaces, when using the Add Labels dialog box to add slope and spot elevation labels.

For information about creating and using label styles, see Understanding Labels (page 1466).

You can create and use:

| This type of surface label style... | Labels... |
|---|---|
| Slope | A slope on a surface. The slope can be from a single point as it resides on a TIN face or surface grid cell, or between two points. |
| Spot elevation | A random point location with an elevation anywhere within a surface. |
| Watershed | The centroid of a watershed when the watershed component is displayed. |
| Contour | Contours at major, minor, and user-defined increments. |

## Slope Label Styles

A slope label style is used for labeling a slope on a surface.


The slope can be labeled as a grade or slope, and is formatted using the slope label style. The direction of the slope is represented by a direction arrow component defined in the slope label style.

A slope label style requires these elements:

- Font (set in the Label Style Composer)

- Text height (set in the Label Style Composer)

- Orientation (set in the Label Style Composer)

- Directional arrow (set in the Label Style Composer)

- Position above/below directional arrow (set in the Label Style Composer)

- Attributes (set on the Properties tab of the Text Component Editor - Contents dialog box)

- Slope/Grade value

- Formatting/Precision (set in the Label Style Composer)

- Percent

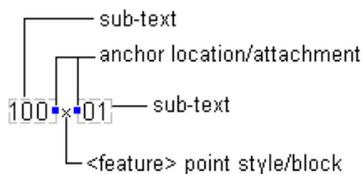
- Decimal

- Run/Rise

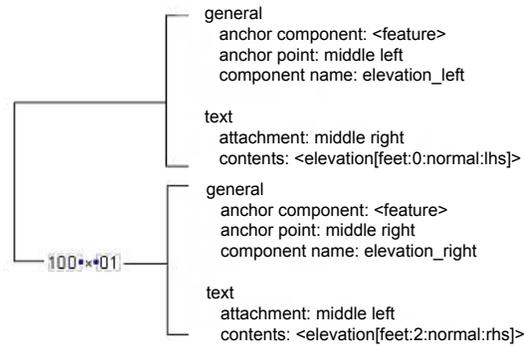
## Spot Elevation Label Styles

Spot elevation labels are required for labeling a random point location with an elevation anywhere within a surface.

The spot elevation label style is configured in the Label Style Composer. When a spot elevation is created, the command can specify an existing point style and label style at create-time, or a block can be specified in the composition of the spot elevation label style.



The following examples illustrate a label style that can label a spot elevation at the elevation decimal point. The decimal point of the spot elevation value is represented by a block, or a point style specified at creation time. The labeled elevation consists of two subtext components in the label style, each with different properties:

```
          ┌──  general
          │        anchor component: <feature>
          │        anchor point: middle left
          │        component name: elevation_left
          │    text
          │        attachment: middle right
          │        contents: <elevation[feet:0:normal:lhs]>
          │──  general
          │        anchor component: <feature>
          │        anchor point: middle right
          │        component name: elevation_right
─ 100·×·01 ─│    text
          │        attachment: middle left
          └──      contents: <elevation[feet:2:normal:rhs]>
```


## Watershed Label Styles

Watershed label styles are used to draw a label at the centroid of a watershed when the watershed component is displayed, using the surface style.

Manage watershed label styles under the Surface collection in the Settings tree.

## Contour Label Styles

Use the Add Labels (page 1970) dialog box to add contour label lines to a surface.

Use the Add Labels dialog box to specify:

■ Labeling placement and spacing options

■ Major contour label style and increment properties

■ Minor contour label style and increment properties

■ User-defined contour label style

# Adding Surface Labels

You can label single slopes, spot elevations, and contours by using specified surface label types.

Watershed labels are created automatically. Their display is controlled by the surface style and cannot be added using this command.

## Adding Slope Labels

You can label individual slope points or label a slope between two points on the surface in the current drawing.

The slope can either be from a single point as it resides on a TIN face or surface grid cell, or between two points. The slope can be labeled as a grade or slope with a negative value representing a decreasing slope or grade. The direction of the slope is represented by a direction arrow component defined in the slope label style.

### Two-Point Slope Labels

You can create a slope label by selecting two points. The first point (XYZ) is the origin of the vector and the second point (XYZ) determines direction and slope.

**One-Point Slope Labels**

Create a slope label by selecting a single point. The normal of the surface triangle is determined and the selected point (XYZ) and the direction of the triangle normal are passed to the slope label style.

For more information about setting the slope label styles, see Slope Label Styles (page 696).

**To add slope labels**

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Surface ➤ Slope 🖋 .

2   At the command line, enter either **One-point** or **Two-point** depending on the type of the slope label that you want to add and then press *Enter*.

3   Digitize the location of the first point and the second point (if applicable).

4   Optionally, repeat Step 3 to add more slope labels.

OR

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Surface ➤ Add Surface Labels 🖋 .

2   In the Add Labels dialog box, select Surface in the Feature list.

3   Select Slope from the Label Type list.

NOTE If you want to view or edit the settings for slope labels, click 🖾 to open the Edit Command Settings - AddSurfaceSlopeLabel dialog box.

4   Select the label style for the slope from the Slope Label Style list or use the standard style selection controls.

NOTE Ensure that the slope label style is appropriate for one-point or two-point slope labels. A slope label style that was composed for a start point and end point may not be appropriate for a one-point slope label.

5   Click Add.

6   At the command line, enter either **One-point** or **Two-point** depending on the type of the slope label that you want to add and then press *Enter*.

7   Digitize the location of the first point and the second point (if applicable).

8   Optionally, repeat Step 7 to add more slope labels.

## Adding Spot Elevation Labels

Spot elevation labels are required for labeling a random point location with an elevation anywhere within a surface.

For more information about setting the spot elevation label styles, see Spot Elevation Label Styles (page 697).

**To add surface spot elevation labels**

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Surface ➤ Spot Elevation 🏷️ .

2 Select the point to label.

OR

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Surface ➤ Add Surface Labels 🏷️ .

2 In the Add Labels dialog box, select Surface in the Feature list.

3 From the Label Type list, select Spot Elevation.

---

**NOTE** If you want to view or edit the settings for spot elevation labels, click 🗹 to display the Edit Command Settings - AddSurfaceSpotElevLabel dialog box.

---

4 Select the label style for the spot elevation from the Spot Elevation Label Style list or use the standard style selection controls.

5 Select the marker style for the spot elevation from the Marker Style list or use the standard style selection controls.

6 Click Add. You are prompted at the command line to select a point in the drawing area.

7 In the drawing, click the location of the point.

8 Optionally, repeat Step 7 to add more spot elevation labels.

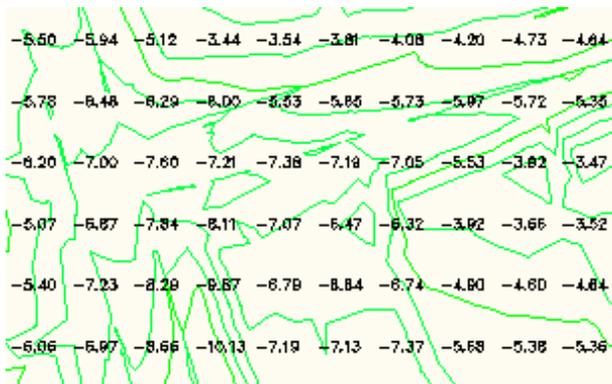
## Adding Spot Elevation Labels On Grid

You can create a grid of surface spot elevation labels in the current drawing.

The following illustration shows a grid of surface spot elevation labels.


For more information about setting the spot elevation label styles, see Spot Elevation Label Styles (page 697).

**To add surface spot elevations on grid labels**

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Surface ➤ Spot Elevations On Grid 
    .

2  Follow command line instructions to add a grid spot elevation label.

OR

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Surface ➤ Add Surface Labels  .

2  In the Add Labels dialog box, select Surface in the Feature list.

3  From the Label Type list, select Spot Elevations on Grid.

---

**NOTE** If you want to view or edit the settings for spot elevation labels, click  to display the Edit Command Settings - AddSpotElevLabelsOnGrid dialog box.

---

4  Select the label style for the spot elevation from the Spot Elevation Label Style list or use the standard style selection controls.

5  Select the marker style for the spot elevation from the Marker Style list or use the standard style selection controls.

6  Click Add. You are prompted at the command line to select a point in the drawing area.

7  Follow command line instructions to add a grid spot elevation label.

8  In the drawing, click the location of the point.

9  Optionally, repeat Step 7 to add more spot elevation labels.

## Quick Reference

Menu

Surfaces menu ➤ Add Surface Labels ➤ Add Surface Labels

Command Line

AddSpotElevLabelsOnGrid
AddSurfaceLabels

## Adding Watershed Labels

Watershed labels can be considered an attribute of a watershed and not a separate component since they require no placement. Watershed labels are drawn at the watershed centroid.

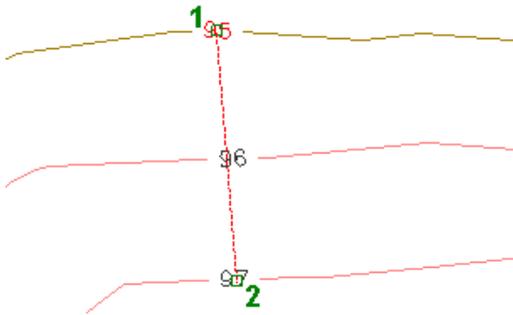
For more information about setting the watershed label styles, see Watershed Label Styles (page 698).

## Adding Single Contour Labels

Use specified contour label styles to add single contour labels to a surface.

You can create contour labels by specifying line segments that cross contour lines of a surface. Add Single, Multiple, or Multiple at Interval contour labels. Modify the properties of contour label lines to change the label style for major, minor, and user-defined contour labels.

Use a line or polyline of an existing object as a label line or draw label lines on the fly for single or multiple contours.



**NOTE** The line that is used to place the contour labels is a custom object called the Surface Contour Label Group object. The default layer for this object is set on the Object Layers tab of the Drawing Settings dialog box.

**TIP** Freezing the default layer of the contour label line freezes the contour labels. To control the visibility of the contour label line, change its display settings in the contour label line properties.

To make a contour label mask out the contour use the Background Mask property in the contour label style. Edit the contour label style using the Label Style Composer, and on the Layout tab under Border, set the value for Background Mask to True.

You can also use the Masking property in the AutoCAD Properties palette to mask contour lines. For more information, see Background Mask (page 1496).

**To add single surface contour labels**

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Surface ➤ Contour - Single 🏷 .

2   Select the contour to label.

OR

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Surface ➤ Add Surface Labels 🏷 .

**2** In the Add Labels dialog box, from the Label Type list, select Contour - Single to add single contour labels by picking a single point on a surface contour line.

---

**NOTE** If you want to view or edit the settings for surface contour labels, click ⊞✓ to display the Edit Command Settings - AddContourLabelingSingle dialog box. Set the Display Contour Label Line to false to display contour label lines only when its label is selected.

---

**3** Depending on the type of surface contour lines (major, minor, or user-defined) that the contour label line crosses, specify the label styles for the corresponding contour lines:

- From the Major Contour Label Style list, select the style for major contour lines.

- From the Minor Contour Label Style list, select the style for minor contour lines.

- From the User Contour Label Style list, select the style for user-defined contour lines.

**4** Click Add.

**5** Click on the contour line where you want to place a label. You can add as many labels as you want. Press *Enter* when finished.

---

**6** **NOTE** You can set the default interval value. In the Add Labels dialog box, ⊞✓ to display the Edit Command Settings - AddContourLabelingSingle dialog box and set the Interval Along Contour property.

---

All the surface contours that were intersected by the contour label line are labeled at the specified intervals along their entire length.

## Quick Reference

Menu

Surfaces menu ➤ Add Surface Labels ➤ Add Surface Labels

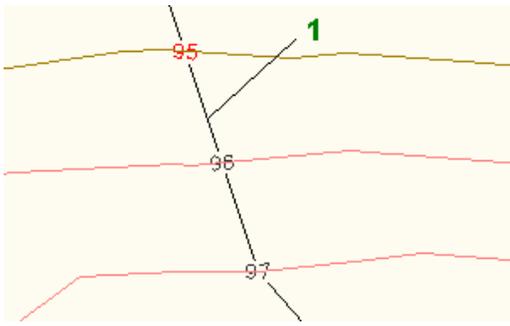
Command Line

AddSurfaceContourLabelingGroup
AddSurfaceLabels

## Adding Multiple Contour Labels

You can use specified contour label styles to add multiple contour labels to a surface.

You can create contour labels by specifying line segments that cross contour lines of a specified surface. You can add multiple contour label types. Modify the properties of contour label lines to change the label style for major, minor, and user-defined contour labels.

Use a line or polyline of an existing object as a label line or draw a label line (1) that crosses multiple contours.


To make a contour label mask out the contour use the Background Mask property in the contour label style. Edit the contour label style using the Label Style Composer, and on the Layout tab under Border, set the value for Background Mask to True.

You can also use the Masking property in the AutoCAD Properties palette to mask contour lines. For more information, see Background Mask (page 1496).

**To add multiple surface contour labels**

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Surface ➤ Contour - Multiple ⬁.

2  Select the contours to label.

OR

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Surface ➤ Add Surface Labels ⬁.

2  From the Label Type list, select Contour - Multiple to add multiple contour labels either along the contour label line or polyline by picking segments to create Surface Contour Label Group objects from the line or polyline objects.

---

NOTE If you want to view or edit the settings for surface contour labels, click ⬚ to display the Edit Command Settings - AddContourLabeling dialog box. Set the Display Contour Label Line to false to display contour label lines only when its label is selected.

---

3  Depending on the type of surface contour lines (major, minor, or user-defined) that the contour label line crosses, specify the label styles for the corresponding contour lines:

   ■ From the Major Contour Label Style list, select the style for major contour lines.

   ■ From the Minor Contour Label Style list, select the style for minor contour lines.

   ■ From the User Contour Label Style list, select the style for user-defined contour lines.

4  Click Add.

5  Click on the contour line to specify the start point. Drag the contour label line across multiple contour lines until you reach the desired end point. Alternatively, after you specify the start point, you can click at individual points on the contour lines to create a contour label polyline. Press *Enter*.

---

6  NOTE You can set the default interval value. In the Add Labels dialog box, ⬚ to display the Edit Command Settings - AddContourLabeling dialog box and set the Interval Along Contour property.

---

All the surface contours that were intersected by the contour label line are labeled at the specified intervals along their entire length.

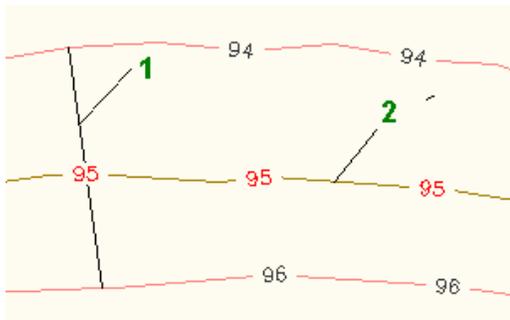
AddLabels

## Adding Multiple Contour Labels at an Interval

You can use specified contour label styles to add multiple contour labels to a surface at a specified interval.

Create contour labels by drawing a contour label line (1) that crosses surfaces contours and specify the interval (2) between the labels along those contours.



Modify the properties of contour label lines to change the label style for major, minor, and user-defined contour labels.

**To add multiple surface contour labels at an interval**

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Surface ➤ Contour - Multiple At Interval .

2 Click on the contour line to specify the start point. Follow the prompt in the command line to specify the next point on a contour label line and the interval along the contour line. Press *Enter*

OR

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Surface ➤ Add Surface Labels .

2 From the Label Type list, select Contour - Multiple at Interval to add multiple contour labels at a set interval along the entire length of the contour crossed by the label line segment.

NOTE If you want to view or edit the settings for surface contour labels, click to display the Edit Command Settings - AddContourLabelingGroup dialog box. Set the Display Contour Label Line to false to display contour label lines only when its label is selected.

**3** Depending on the type of surface contour lines (major, minor, or user-defined) that the contour label line crosses, specify the label styles for the corresponding contour lines:

   ■ From the Major Contour Label Style list, select the style for major contour lines.

   ■ From the Minor Contour Label Style list, select the style for minor contour lines.

   ■ From the User Contour Label Style list, select the style for user-defined contour lines.

**4** Click Add.

**5** Click on the contour line to specify the start point. Follow the prompt in the command line to specify the next point on a contour label line and the interval along the contour line. Press *Enter*.

---

**NOTE** You can set the default interval value. In the Add Labels dialog box, click ⊞ to display the Edit Command Settings - AddContourLabelingGroup dialog box and set the Interval Along Contour property.

---

All the surface contours that were intersected by the contour label line are labeled at the specified intervals along their entire length.

# Modifying Surface Labels

Modify the display and location of surface and contour labels.

For information about modifying labels, see Inserting and Managing Labels in Drawings (page 1522). For more information about which properties of different label types can be modified, see Managing Layout Properties for Label Styles (page 1492).

# Surface Table Styles

Use the Toolspace Settings tab to manage surface table styles.

You can create and use the following types of surface table styles:

| This surface table style... | Places the following surface information in the table... |
|---|---|
| Direction | Aspect or direction ranges, colors, and area |
| Elevation | Elevation ranges, colors, area, and volume |
| Slope | Slope ranges, colors, and face areas |

| This surface table style... | Places the following surface information in the table... |
| --- | --- |
| Slope Arrow | Slope arrow ranges, colors, and face areas |
| Contour | Contour ranges, colors, areas, and volumes |
| Watershed | Number, type, description, color, hatching, and drainage area for the watersheds |
| User-Defined Contour | User-defined contour ranges, colors, areas, and volumes |

# Adding Surface Legend Tables

Use surface legend tables to organize and consolidate information about the surfaces in your drawing.

You can create surface legend tables for all types of surface analysis, including directions, elevations, slopes, slope arrows, contours, and watersheds. For more information about surface analysis, see Analyzing Surfaces (page 708).

You create and edit tables for most objects using the same common procedures and standard dialog boxes. For information about modifying tables, see Modifying Tables (page 1567).

You can control the display of the analysis in the drawing by adjusting the surface style Display settings.

Before creating a surface legend table, generate the surface analysis from the Analysis tab on the Surface Properties dialog box.

**To create a surface legend table**

1  Generate the surface analysis that you are going to display in the legend table. See Analyzing Surfaces (page 708).

2  To edit the styles for the tables, on the Settings tab, expand the Surface collection, expand the Table Styles collection, and select the collection for the type of legend that you want to add. In the Settings list view, right-click the style and click Edit.

3  To add the legend table, click Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Add Surface Legend Table ⊞ .

4  You are prompted to select the surface from the drawing area.

5  You are prompted to enter the table type. Enter one of **Directions**, **Elevations**, **Slopes**, **SlopeArrows**, **Contours**, **UserContours**, or **Watersheds**.

6  You are prompted to specify if you want the table to update automatically if the analysis information changes. Enter **Dynamic** to enable automatic updating.

7  You are prompted to select the upper left-hand corner for the table in the drawing area.
   The legend table is displayed.

## Quick Reference

Menu

Surfaces menu ➤ Add Legend Table

Command Line

AddSurfaceLegendTable

# Analyzing Surfaces

You can perform many types of surface-related analysis, including contour, directions, elevations, slopes, slope-arrows, watersheds, and water drop path.

Surface analysis types include:

- **Directions**. Used for aspect analysis. Renders surface triangles differently according to the direction they face.

- **Elevations**. Used for elevation banding analysis. Renders surface triangles differently according to their elevation range.

- **Slopes**. Renders surface triangles differently according to the slope range they fall within.

- **Slope Arrows**. Used for slope direction analysis. Places a slope directional arrow at each triangle centroid. The arrow color is based on the color assigned to a slope range, similar to slope analysis.

- **Contours**. Renders contour lines differently in according to their elevation range.

- **User-Defined Contours**. Renders user-defined contour lines differently according to their elevation range.

- **Watersheds**. Renders watersheds differently according to their type.

- **Contour Problems**. Used to locate problems with contours that are drawn according to the surface style contour settings.

- **Water Drop**. Used to trace the path that water would take across a surface.

Use the Analysis tab (page 2343) in the Surface Style dialog box to control the display and styles for direction, elevation, slope, and slope arrow analysis. Contours and watersheds have corresponding tabs (Contours tab (page 2336) and Watersheds tab (page 2341)), where their style and display are controlled. Use the Analysis tab (page 2349) in the Surface Properties dialog box to create the actual analysis.

To check for contour problems using a separate utility, click Analyze ➤ Ground Data panel ➤ Contour Check .

To perform water drop analysis in a separate utility, click Analyze ➤ Ground Data ➤ Water Drop .

# Creating Surface Analysis

Use the Analysis tab in the Surface Style dialog box to set up the analysis display and the Analysis tab in the Surface Properties dialog box to create the analysis.

**To perform surface analysis**

1   In Toolspace, on the Settings tab, right-click the Surface Styles collection and click New.

2   In the Surface Style dialog box, click the Information (page 2334) tab and assign a name and description to the style.

3   Click the Analysis (page 2343) tab and modify the properties as required.

**4** For contour analysis, to modify the default analysis values, click the Contours (page 2336) tab and modify the Contour Ranges property group as well as the Major and Minor display settings.

**5** For watershed analysis, click the Watersheds (page 2341) tab and modify the properties as required.

**6** Click the Display (page 2345) tab and modify the display settings so that the analysis is displayed correctly.

**7** Click OK to save the style and close the Surface Style dialog box.

**8** In Toolspace, on the Prospector tab, expand the Surfaces collection, right-click the surface for which you want to create an analysis, and click Properties.

**9** In the Surface Properties dialog box, click the Analysis (page 2349) tab and select the analysis that you want from the Analysis Type list.

> **NOTE** The Analysis tab displays varying fields and options depending on the type of analysis that you select.

**10** Optionally, select a legend style. For information about creating a legend, see Adding Surface Legend Tables (page 707).

**11** Modify the range or watershed parameters as required and click ⬇ to generate the analysis.

**12** Optionally, modify the details of the analysis by editing the fields in the Details table. For more information, see the Analysis (page 2349) tab.

### Quick Reference

Dialog Box

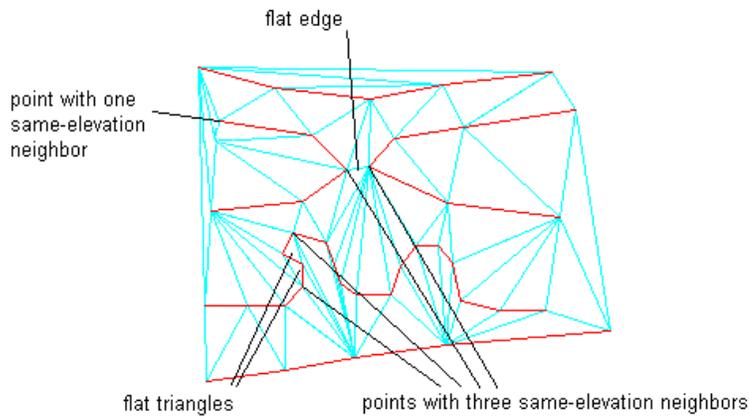
Surface Properties: Analysis Tab (page 2349)

# Checking for Contour Problems

Use the Check for Contour Problems utility to identify problems with contours that are drawn according to the surface style contour settings.

> **NOTE** The Check for Contour Problems utility operates on TIN surfaces only.

The utility takes into account the base elevation and interval specified in the surface style. When the utility encounters an invalid condition, a warning is displayed in the Event Viewer.

The utility looks at every surface point that falls on a contour. For each point, the utility counts the number of neighboring points (that is, points to which it is connected by an edge or a point that lies on the opposite side of a triangle that it belongs to) that fall at the same elevation. If the number of same-elevation neighbors is one, the warning "Contour ends at [x,y,z]" is displayed in the Event Viewer. If the number of same-elevation neighbors is more than two, the warning "Multiple contours at [x,y,z]" is displayed in the Event Viewer. In the second case, if the point is on the border of the surface, the warning "Multiple contours at border point [x,y,z]" is displayed.


The "contour ends" condition can mean that a gap in the data contour was too wide for the triangulation process to connect the ends with an edge. You can fill this gap by creating and adding a breakline that connects the two ends.

The multiple contours condition, which occurs when a point has more than two neighboring points with the same elevation, generally happens in a flat area of the surface. When this condition is detected, you can use the Minimize Flat Areas operation to correct the problem. For more information, see Minimizing Flat Areas in a Surface (page 656). If the point is on the surface border, the flat area can simply be an unintended artifact of the triangulation process. You can remove these unintended triangles by using the Delete Line operation or by adding a hide boundary.

If no contour problems are found, a message is displayed in the Event Viewer stating that no problem were found for the surface style setting for contour base elevation and interval.

---

**NOTE** All contour problems occur when the elevation of a data contour point is the same as the elevation at which a contour is drawn. If no points in the surface are at contour elevations, there will be no problems with drawn contours. It is often possible and acceptable to adjust the contour base elevation value to create a condition where no points fall on surface contours, thus avoiding contour problems entirely.

---

**To check for contour problems**

1 Click Analyze tab ➤ Ground Data panel ➤ Contour Check  .

2 If more than one surface is available in the drawing, click the surface on which to perform the check or press Enter to select a surface in the Select A Surface dialog box.

3 Click OK.

Any detected contour problems are displayed in the Event Viewer.

## Quick Reference

Command Line

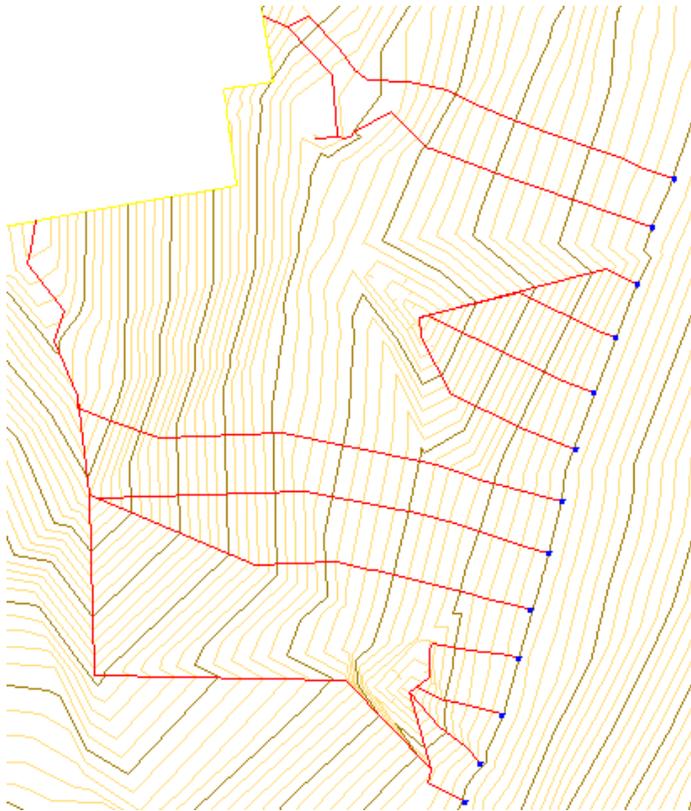
CheckForContourProblems

# Drawing Water Drop Paths

Use the water drop utility to trace the path that water takes across a surface.

The utility draws a 2D or 3D polyline that represents a flow of water and also marks the start point of the path. If a channel splits, then new polylines are drawn to follow each water drop path.

For example, multiple water drop paths can be drawn from a contour line to illustrate the water flow at different points along the contour:



You can use either a 2D or 3D polyline to draw the flow line. The line type that you use depends on your analysis requirements. Following are usage examples for each line type:

- **2D polyline**. Delineate an area that represents a drainage area for water runoff analysis. You create a closed 2D polyline using AutoCAD editing commands. You can use the resulting closed 2D polyline to query the area and perform other analysis.

- **3D polyline**: You want to perform visualization and drape the lines over the surface. You can also create grading feature lines from the water drop lines for grading purposes.

**To perform water drop analysis**

1 Click Analyze tab ➤ Ground Data panel ➤ Water Drop 💧.

2 If more than one surface is available in the drawing, click the surface on which to perform the water drop analysis or press Enter to select a surface in the Select A Surface dialog box.

3 In the Water Drop (page 2367) dialog box, in the properties grid, click the Value column for the Path Layer property. Enter a name for the layer on which to draw the water drop polyline or click ⬚ to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

**4** To specify the type of polyline to use for the water drop path, click the Path Object Type field. Select the type.

**5** To specify whether to draw a marker at the start of the water drop path, click the Place Marker At Start Point field. Select either Yes or No.

**6** To set the style for the start point maker, click the Start Point Marker Style property. Click [···] in the Value column.

The Point Style dialog box is displayed.

**7** Click OK.

---

**NOTE** To be certain that any changes that you make to the water drop settings persist, ensure that the drawing setting Save Command Changes To Settings is set to Yes. For information, see Specifying Ambient Settings (page 68)

---

**8** Click a point on the surface for the start of the water drop path.

**9** Click another point to draw another water drop path or press Enter if finished.

## Displaying and Calculating Catchment Areas

Use the Catchment Area command to analyze water runoff and display the surface drainage area. The data obtained from running this command helps you perform H&H (hydrology and hydraulics) tasks, such as designing detention ponds, storm sewers, and other tasks aimed at the prevention of soil erosion.

The command defines the surface region with a depression low point (catchment point), delineates the region with a boundary, and calculates the area of the catchment region.

You can use a water drop path utility (page 711), to determine an accurate placement of catchment regions and catchment points.

---

**NOTE** The Catchment Area command performs the analysis only on the selected surface region and does not account for overflow situations occurring in the neighboring surface regions.

---

**To display a catchment region and calculate its area**

**1** Locate an area of interest in the drawing.

**2** Optionally, perform the following steps:

    **a** Click Analyze tab ➤ Ground Data panel ➤ Water Drop 💧✳ ..

    This command creates a polyline that represents the water drop path from a point on the selected region to the depression point in this region.

    **b** Select the water drop path polyline, right-click, and choose Properties.

    **c** In the Properties manager, under Geometry, navigate to the last vertex and copy and paste the X- and Y-coordinate values (comma-separated with no space) into a text file.

**3** Click Analyze tab ➤ Ground Data panel ➤ Water Drop 💧✳ ..

**4** In the Catchment Area dialog box, click the Value column for the Catchment Layer property and click ⊡ to select an existing layer, or create a layer in the Create Layer dialog box (page 1986).

> **BEST PRACTICE** It is useful to place the catchment region on a separate layer. Then you can control visual style elements, such as color and line types.

**5** Click the Value column for the Catchment Object Type, and select a line type.

> **TIP** If you select 2D Polyline, you can use the AutoCAD Area command on the catchment region. If you select 3D Polyline, you can use the elevation values of the polyline vertices for analysis.

**6** Click the Value column for the Catchment Marker property, and specify whether you want to mark the catchment point.

**7** Click ⊡ in the Value column of the Catchment Marker Style property, and then select a style in the Catchment Marker Style dialog box. Click OK.

**8** If more than one surface is available in the drawing, click the surface on which to perform the catchment region analysis, or press Enter to select a surface in the Select A Surface dialog box.

**9** Specify a catchment location. You can either paste the coordinates that you copied in Step 2 or click in the desired location.

    The catchment region boundary appears on the drawing, and the value of the region area displays at the command line.

**10** Repeat Step 11 for other coordinates or locations.

# Exporting Surface Data

You can export an AutoCAD Civil surface from a drawing to a DEM file compatible with either USGS or GeoTIFF formats, enabling you to use the surface in applications that support these formats.

## Exporting to DEM

You can export surface data to a DEM file and use the surface in other applications that support DEM data files.

Applications such as AutoCAD MAP 3D and AutoCAD Raster Design support both USGS and GeoTIFF standards. You can export all types of AutoCAD Civil surfaces, including terrain and volume surfaces.

**To export surface data to a DEM file**

1   Open a drawing with surfaces that you want to export to DEM.

2   Select a surface. Click Surface tab ➤ Surface Tools panel ➤ Export To DEM ⬆ ..

3   If more than one surface is available in the drawing, and you have not selected the surface in the previous step, in the drawing, click the surface which you want to export.

4   In the Export Surface to DEM (page 2368) dialog box, under Export, add information on the exported file, such as DEM file name, coordinate system, grid spacing, and elevation.

5   Specify if you'd like to use the default null elevation or specify a custom value and enter the value.

6   Click OK.

The surface data is imported to a DEM file in the location that you specified.

The exported DEM file inherits the coordinate zone assigned to the drawing. If the drawing does not have a coordinate zone assigned, you must specify one.

## Exporting to LandXML

Export a TIN surface to a LandXML format file.

For more information about AutoCAD Civil LandXML import and export functionality, see Viewing and Editing LandXML Drawing Settings (page 1678).

**To export a surface to a LandXML format file**

1 In Toolspace, on the Prospector tab, expand the Surfaces collection, right-click the surface, and click Export LandXML.

The Export LandXML (page 1983) dialog box is displayed with the current surface selected for export.

2 To change the export selection set (for example, to add another surface), select or clear the check boxes in the data tree.

3 Click OK to export the surface to a LandXML format file.

4 In the Export LandXML dialog box, enter the name for the LandXML file.

The file is saved with the *.xml* extension.

# Surfaces Command Reference

You can use commands to access surface functionality quickly.

The following table lists the surface-related AutoCAD Civil commands and briefly describes their functionality.

| Command | Description |
| --- | --- |
| AddContourLabeling | Adds multiple surface contour labels at points of intersection with contour label line (page 702) |
| AddContourLabelingGroup | Adds multiple surface contour labels at a set interval (page 702) |
| AddContourLabelingSingle | Adds a single surface contour label (page 702) |
| AddSpotElevLabelsOnGrid | Adds a spot elevation label on grid (page 700) |
| AddSurfaceBoundaries | Adds a boundary to an existing surface (page 615) |
| AddSurfaceBreaklines | Adds a breakline to an existing surface (page 618) |
| AddSurfaceContours | Adds contours to an existing surface (page 632) |
| AddSurfaceDEMFile | Adds a DEM file to an existing surface (page 637) |
| AddSurfaceDrawingObjects | Adds points from AutoCAD objects (page 640) |
| AddSurfaceGridPoint | Adds a grid point to an existing surface (page 653) |

| Command | Description |
|---|---|
| AddSurfaceLabels | Invokes a labeling tool used to add slope elevations or slope labels (page 698) |
| AddSurfaceLine | Adds a new TIN line to an existing surface (page 650) |
| AddSurfacePoint | Adds a point directly to the surface (page 653) |
| AddPointFile | Imports a point file into an existing surface (page 643) |
| AddSurfacePointGroup | Adds a point group to the surface definition (page 644) |
| AddSurfaceSlopeLabel | Adds a slope label to a surface (page 698) |
| AddSurfaceSpotElevLabel | Adds a spot elevation label to a surface (page 700) |
| CatchmentArea | Displays catchment regions and calculates the area of catchment regions (page 712) |
| CheckForContourProblems | Identifies Problems with Contours (page 709) |
| CreateSurface | Creates a TIN or Grid terrain and volume surface (page 601) |
| CreateSurfaceComposite | Calculates a composite volume between two surfaces (page 690) |
| CreateSurfaceGridFromDEM | Creates a grid surface from a DEM (Digital Elevation Model) file. (page 608) |
| CreateSurfaceFromTIN | Creates a TIN surface from a TIN data file (page 607) |
| CreateSurfaceReference | Creates a surface reference (page 609) |
| CreateSurfaceMask | Creates a mask on a surface (page 672) |
| CreateSurfaceStyle | Creates a new surface style (page 693) |
| CreateSurfaceWaterdrop | Creates a water drop path on the surface (page 711) |
| CreateSurfCntrLabelLine | Adds a contour label to a surface (page 702) |
| DeleteSurfaceGridPoint | Deletes a point from a grid surface (page 654) |
| DeleteSurfaceLine | Deletes a TIN line from a surface (page 651) |
| DeleteSurfacePoint | Deletes points from a TIN surface to remove inaccurate or unnecessary data (page 654) |
| DeleteSurfaceSlopeLabel | Deletes a slope label (page 706) |
| DrapeImage | Drapes an image onto a surface (page 695) |

| Command | Description |
| --- | --- |
| EditSurfacePaste | Pastes a surface into the current surface (page 662) |
| EditSurfacePoint | Modifies a surface point (page 654) |
| EditSurfaceProperties | Edits the properties of a surface (page 681) |
| EditSurfaceMask | Edits a surface mask (page 674) |
| EditSurfaceSettings | Displays the Edit Feature Settings - Surface dialog box (page 687) |
| EditSurfaceStyle | Edits the style of an existing surface (page 694) |
| EditSurfaceSwapEdge | Swaps the direction of two triangle faces (page 652) |
| MinimizeSurfaceFlatAreas | Minimizes the flat areas on a surface created from contours (page 656) |
| ModifySurfaceContourLabels | Modifies a contour label style (page 706) |
| ModifySurfaceSlopeLabel | Modifies a slope label style (page 706) |
| ModifySurfSpotElevLabel | Modifies a spot elevation label style (page 706) |
| MoveBlocksToAttribElev | Moves a block to an elevation value specified in one of its nested attribute values (page 641) |
| MoveBlocksToSurface | Moves a block object to a surface elevation (page 645) |
| MoveTextToElevation | Moves text to the elevation corresponding to its numeric value (page 642) |
| MoveSurfacePoint | Moves a surface point (page 655) |
| RaiseLowerSurface | Raises or lowers the entire surface (page 661) |
| RebuildSurface | Rebuilds a surface (page 685) |
| ReportSurfaceVolume | Displays composite volume information for two surfaces (page 690) |
| ReportSurfBoundedVolume | Calculates the volume of a bounded area (page 692) |
| SimplifySurface | Simplifies a surface by removing points (page 666) |
| SmoothSurface | Smooths the surface (page 662) |
| SurfaceModifyGridPoint | Modifies grid surface points (page 654) |
| SurfaceExportToDem | Exports surface data to a DEM file (page 714) |
| SurfaceExtractObjects | Extracts selected components from a surface (page 646) |

718

# Sites

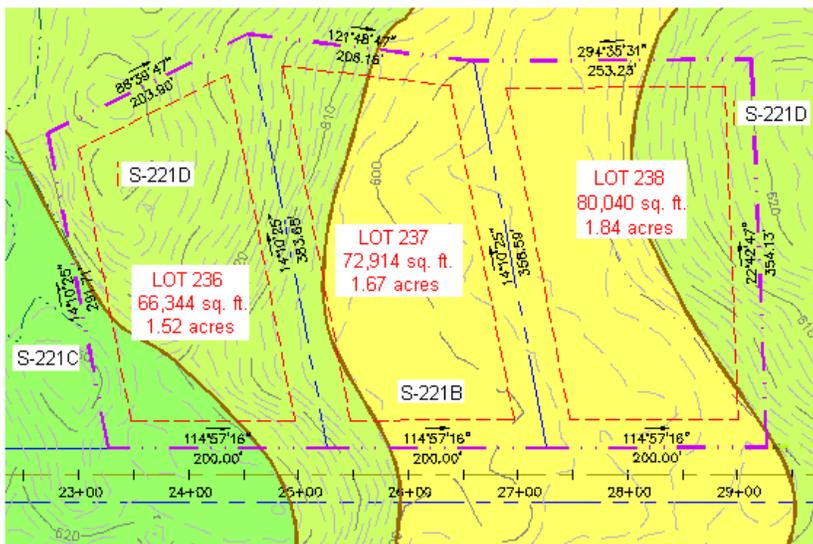
# 20

In AutoCAD Civil, you can manage objects with a common topology in a collection called a site. The objects that share in the topology are parcels, alignments, gradings, and feature lines.

## Understanding Sites

Use sites to collect or group collections (parcels, alignments, gradings, and feature lines) by a topology that they have in common.

Examples of sites include soil maps, watersheds, or subdivisions. Sites can geographically overlay each other as is shown in the following illustration, while remaining independent. For example, a soils map and a subdivision with roads and lots can overlay each other, but remain independent of each other. Therefore, a parcel in a soils site would never be affected by an alignment in a subdivision site, even if their extents overlap.



All objects in a site topology collection share a common topology and have relationships to each other.

**NOTE** Editing an object, or moving an object from one site to another, can cause changes to other objects that share the same topology.

When you create parcels and gradings, you specify a site for them. If you create these objects before explicitly creating a site, a default site named Site 1 is created for them.

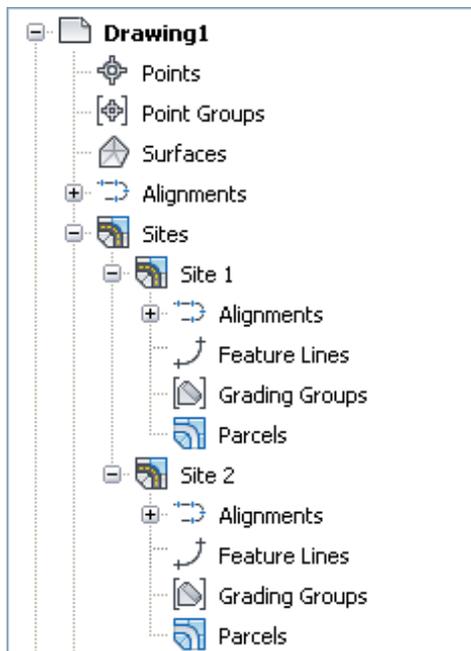
When you create an alignment, you may either accept the default <none> site selection, place the alignment on an existing site, or create a new site. When an alignment is placed on a site, it will create parcels if it forms closed regions and subdivide existing parcels on the site if it crosses through them. Accepting the <none> site selection places the alignment in the top-level Alignments collection, which prevents it from forming or interacting with parcels or any other objects. See Alignment and Site Interaction (page 721) for more information.

**NOTE** An object, such as an alignment, parcel, or grading, can only exist in one site. All dependent objects, such as profiles and sections, exist in the same site as the parent object.

## Sites Collection

Use the Prospector tree to access the Sites collection, which can contain one or more site topology collections.

Each site topology collection contains collections for alignments, gradings and parcels:



**NOTE** You can assign names to the site topology collections, but the Sites collection cannot be renamed.

Alignments may be assigned to either the Alignments collection within a topology collection or the top-level Alignments collection. When placed in the topology collection's Alignment collection, an alignment subdivides parcels it crosses over and creates new parcels if it forms closed regions. Alignments that are placed in the top-level Alignments collection do not interact with parcels or any other objects on any site. See Alignment and Site Interaction (page 721) for more information.

Expand the Sites collection node to view the sites in the collection. The site names with their respective area and perimeter values are displayed in the Prospector tab list view.

Access all site-related functionality by right-clicking the Sites collection and the named site topology collection (for example, Site 1 or Site 2) in the Prospector tree.

# Site Topology Collection

Use the named site topology collection (for example, Site 1) under Sites in the Prospector tree to edit or list the properties of a particular site, including its name, description, and 3D geometry.

Each named site topology collection contains collections of alignments, gradings, and parcels.

Right-click the named site topology collection to:

■ Edit and display the properties of the site, including 3D geometry and numbering conventions.

---

**NOTE** Parcel-related properties of a site are accessible from the site's Parcels collection. For more information, see Site Parcels (page 809).

---

■ Zoom or pan to the site.

■ Report on the site

■ Export the site to a LandXML format file.

■ Refresh the Prospector tree.

# Alignment and Site Interaction

When alignments are placed on a site, they will interact with other objects on the site.

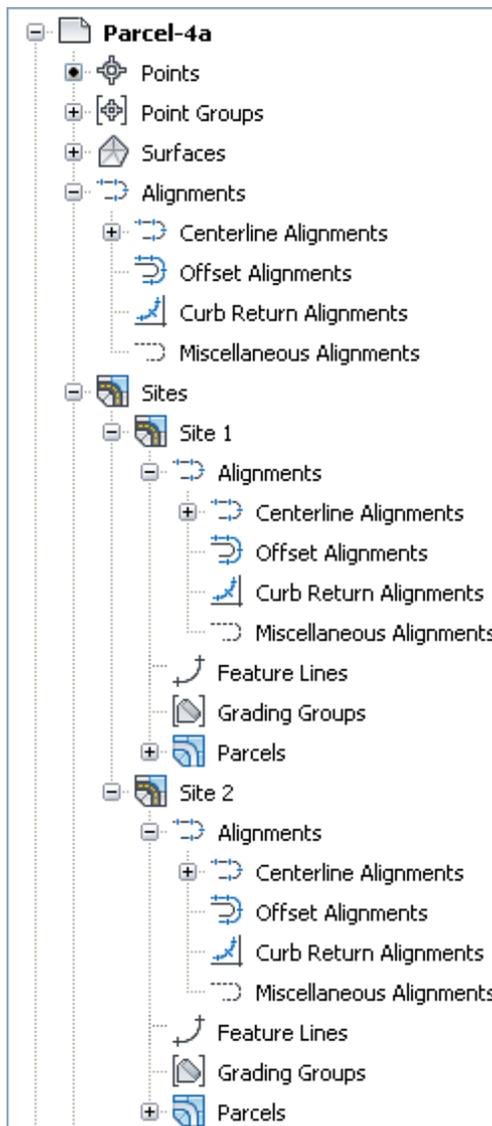
Alignments interact with sites in two ways:

■ If an alignment exists on a site with parcels, the alignment will subdivide any parcels it crosses over.

■ If one or more alignments on a site form a closed region, a parcel will be created from the region.

Alignments may be assigned to either of two collections:

■ The top-level Alignments collection. When placed in this collection, an alignment will not interact with any other objects, including itself.

■ The Alignments collection within a topology collection, or site. When placed here, alignments will interact with other alignments and parcels on the site. If you want alignments to form parcels by closed regions but not subdivide existing parcels, assign alignments and parcels to separate sites.


If you do not want an alignment to interact with other objects, accept the default <None> site selection when you create the alignment. Alignments can be moved or copied onto sites at a later time if interaction with other objects is desired.

## Importing from and Exporting to LandXML

You can import from and export to LandXML files.

When objects that are grouped under the Sites collection are exported to a LandXML file, the site name is exported with them.

When objects are imported from a LandXML file into the drawing, two site pickers are displayed:

■ **Alignments Site** allows you to specify the site on which the alignments will reside. The default selection is <None>, which places the alignments in the top-level Alignments collection and prevents them from interacting with parcels.

- Parcels Site allows you to specify the site on which the parcels will reside. If no sites exist in the drawing, the parcels are placed on the default site (Site 1). If the LandXML file has a site name for its features, then that site name is created in the drawing and the parcels are assigned to it.

For more information about importing to and exporting from a LandXML file, see LandXML Import and Export (page 1673).

# Managing Sites

After you create a site, you can edit its properties and add objects to it.

Before working with sites, you should review the following aspects of site functionality:

- Sites can be copied or moved. If there is a naming conflict at the destination site, the site name is automatically appended with the next sequential number.

- Objects can be copied or moved between sites. If there is a naming conflict at the destination site, the object name is automatically appended. For example, if the identical "Parcel A" object is copied three times into the same site, the name conflict is resolved as Parcel A (1), Parcel A (2), and Parcel A (3).

- Parcel linework, grading objects, and alignments can only belong to one unique site and do not interact with objects in a different site.

- Sites can only be deleted after all objects have been deleted from the site.

# Creating a Site

Use the Prospector tree to create a new site. You can create a site before creating the site topology (alignments, parcels, and grading).

**NOTE** When creating parcels and gradings, you must specify a site for them. You can create a new site when creating these objects. If you do not specify a site, a default site (Site 1) is created for them. You can rename the site using the Site Properties (page 724) dialog box.

**To create a site**

1 In Toolspace, on the Prospector tab, right-click the Sites  collection and click New.
   The Site Properties (page 2325) dialog box is displayed with the Information tab active.

2 Enter a name and description for the site in the corresponding fields.

3 Click the 3D Geometry (page 2325) tab and specify the 3D display settings for the site.

4 Click the Numbering  (page 2326)tab and specify the numbering properties for alignments and parcels.

5 Click OK.
   The site is added to the Sites collection in the Prospector tree.

Dialog Box

  Site Properties (page 2325)

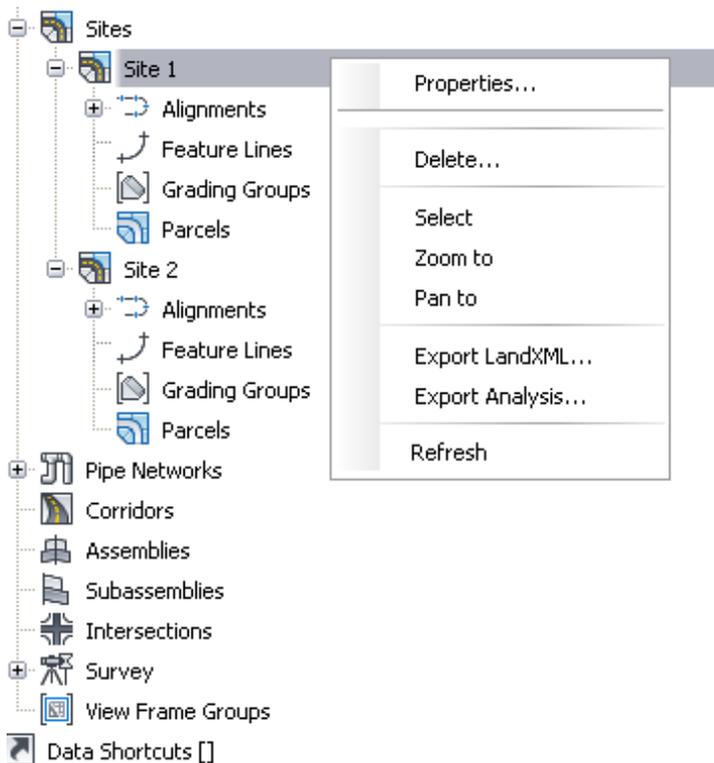
# Editing Site Properties

A site has two types of properties: those that deal with the general site and those that are associated with the site but are primarily related to the parcel objects.

### General Site Properties

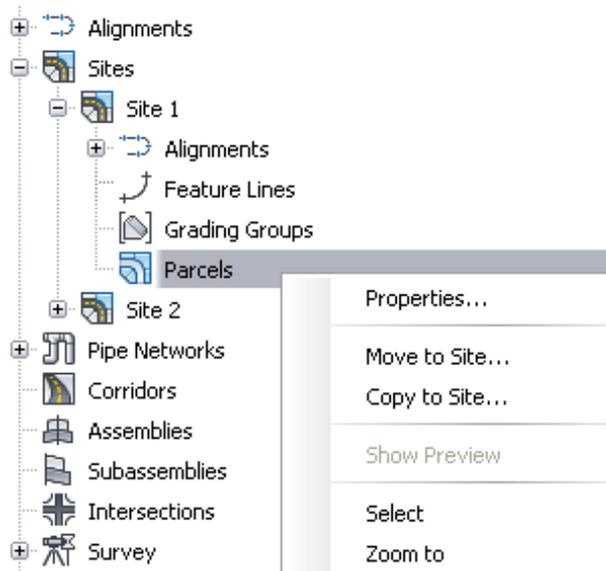
General site properties are applicable to all objects in a site. These properties include the site name, site description, 3D geometry display settings, and parcel and alignment numbering.

Access these properties by right-clicking the named site collection node (for example, Site 1) in the Prospector tree.



### Site Parcel Properties

Certain site properties are specific to the Parcels collection within a site. These properties include site parcel style, site area label style, parcel style display order, area, perimeter, and frontage.

Access these properties by right-clicking the Parcels collection under the named site collection.


**NOTE** For information about editing Site Parcel properties, see Site Parcels (page 809).

**To edit site properties**

1   In Toolspace, on the Prospector tab, expand the Sites collection, right-click a site, and click Properties.

2   Optionally, on the Information (page 2325) tab, edit the name and description for the site.

3   Optionally, click the 3D Geometry (page 2325) tab and edit the 3D display settings for the site.

4   Optionally, click the Numbering (page 2326) tab and edit the numbering properties for the parcel components.

5   Click OK.

Command Line

   EditSite

Dialog Box

   Site Properties (page 2325)

# Specifying a Site for Topology Objects

When you create a parcel, alignment, or grading object, you are prompted to specify a site name.

Use the same site for all objects that share a common topology and have specific relationships to each other.

**NOTE** Editing an object could cause changes to other objects that share the same topology.

**To specify a site for topology objects**

1 Follow the specific procedure to create the object requiring a site (for example, parcel, alignment or grading object).

2 When the Create dialog box for the object is displayed, do one of the following:

- Click the Site list and select the site to which you want to add the object.
  When creating an alignment, select <None> to assign the alignment to the top-level Alignments collection. See Alignment and Site Interaction (page 721) for more information.

- Click the Down arrow next to the Site list and click Pick From Drawing.
  The following prompt is displayed:

  `Select object in site:`

  Select an object (parcel, alignment, or grading object) contained in the site to which you want to add the new object.

- Click the Down arrow next to the Site list and click Create New, then use the Site Properties (page 2325) dialog box to define the new site and click OK.

3 Perform the remaining object creation steps.

# Deleting a Site

Use the Prospector tree to delete a site. You must first delete all the objects that are contained in the site.

**To delete a site**

1 Delete any objects that are included in the site.

2 In Toolspace, on the Prospector tab, expand the Sites collection, right-click a site, and click Delete.
  The site is removed from the Prospector tree.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Sites ➤ right-click <site-name> ➤ Delete

# Moving and Copying

You can move or copy site objects from one site to another. The contents of an entire site, including alignments, grading groups, or parcels, can be moved or copied together or individually.

---

**NOTE** If there is a naming conflict, duplicate objects should be deleted from the destination site prior to moving or copying sites or objects within a site. If duplicates objects occur, the names are automatically resolved. For example, if the destination site contains an Alignment - (1), it is renamed to Alignment - (1) (1).

---

# Move Objects to a Site

Move site objects (alignments, gradings, and parcels) to a destination site, removing them from the source site.

Objects in the same site can interact with each other. To prevent this interaction, move one or more objects to another site.

Multiple sites can exist in the same geographic location.

Objects to move can be accessed from the Prospector tab for entire site collections or individual objects within the collection. A shortcut menu is also available from the drawing for valid objects within a site.

**To move objects to a site**

1 In Toolspace, on the Prospector tab, expand Sites.

2 Right-click a site, or collections or individual objects within the site, and click Move To Site.

3 In the Move To Site dialog box, under Destination Site, select an existing site from the list, or click to either pick a site in the drawing or create a new site.

When moving only alignments, select <None> to move the alignments to the top-level Alignments collection. See Alignment and Site Interaction (page 721) for more information.

4 Navigate in the data tree to view the selected objects and expand the collections. Select or clear the check boxes to filter the objects that you want to move.

5 Click OK. The selected objects are moved to the destination site. The original source site objects are removed.

## Quick Reference

Dialog Box

Move To Site (page 2327)

# Copy Objects to a Site

Copy site objects (alignments, gradings, and parcels) to a destination site, while keeping the original objects at the source site.

Objects in the same site can interact with each other. Edits made to one object can affect other objects in the site.

Objects to copy can be accessed from the Prospector tab for entire site collections or individual objects within the collection. A shortcut menu is also available from the drawing for valid objects within a site.

**To copy objects to a site**

1 In Toolspace, on the Prospector tab, expand Sites.

2 Right-click a site, or collections or individual objects within the site, and click Copy To Site.

**3** In the Copy To Site dialog box, under Destination Site, select an existing site from the list, or click ![icon]
to either pick a site in the drawing or create a new site, which is then returned and displayed in the list.

When copying only alignments, select <None> to copy the alignments to the top-level Alignments collection. See Alignment and Site Interaction (page 721) for more information.

**4** Navigate the data tree to view the selected subcomponents and expand the collections. Select or clear the check boxes to filter the objects that you want to copy.

**5** Click OK. The selected objects are copied to the destination site. The original site objects remain in the source.

# Sites Command Reference

The following table lists the site-related AutoCAD Civil commands and briefly describes their functionality. For more information about a command, follow the link in the Description column.

| Command | Description |
| --- | --- |
| CreateSite | Creates a site (page 723) |
| EditSite | Edits the properties of a site (page 724) |
| MoveToSite | Moves objects to another site (page 726) |
| CopyToSite | Copies objects to another site (page 727) |

# Grading

# 21

Use the grading tools and commands in AutoCAD Civil to design finished ground surfaces.

You create grading projections by applying grading criteria (page 2475) to a footprint. The grading objects are grouped into named collections to create your final surface designs and compute volumes.

You can also use the feature lines commands to create and edit 3D feature lines. Feature lines can be included directly into surfaces as breakline data, or you can use them as grading object footprints.

⊚ Grading Workflow

## Understanding Grading Objects

A grading object has its own properties and behavior, like other object types in AutoCAD Civil.

Before you start grading, you must configure settings and establish criteria such as the following:

- **Grading site**: Gradings are created in a site topology. If you do not want a grading to interact with other objects in a site, create a new site for your grading objects.

- **Grading group**: Grading objects in a grading group (page 2475) are consolidated to create one grading group surface so you can compute volumes. Before you create gradings, decide how you want to manage them with regard to surface creation and volume computations.

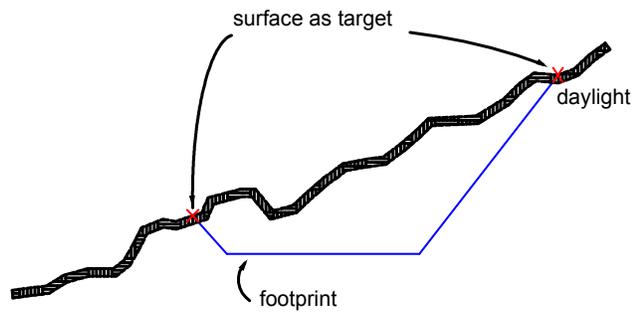
- **Grading footprints**: Grading objects are projected toward their target from a selected footprint. Footprints can be feature lines that you create specifically for this purpose, or you can export corridor feature lines or use parcel lot lines.

- **Grading targets**: Grading objects require a target. This can be a surface, a distance, or an elevation.

**Section view of surface as target**

surface as target

daylight

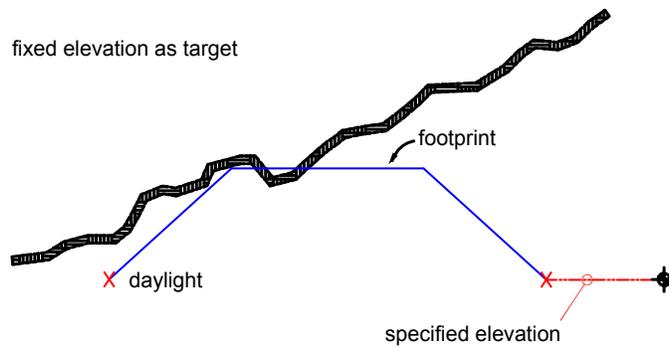
footprint


**Section view of elevation as target**

fixed elevation as target

footprint

X daylight

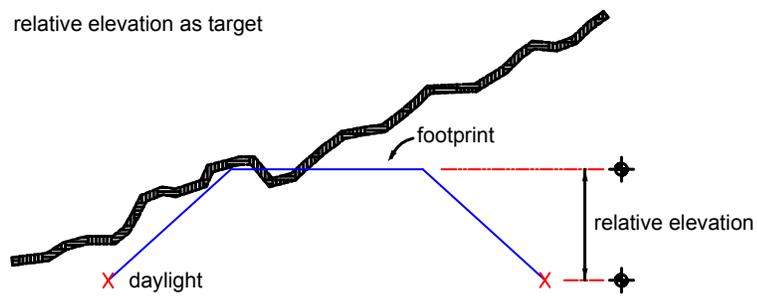
specified elevation


**Section view of relative elevation as target**

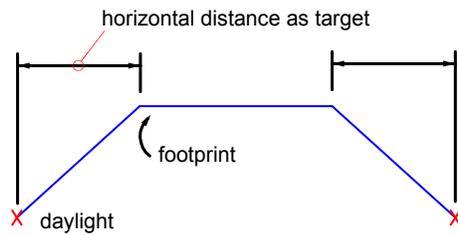
relative elevation as target

footprint

relative elevation

X daylight


**Section view of distance as target**



- **Grading criteria**: When you start grading, you specify grading criteria (page 2475). This is how many of the grading settings, such as grading target, are specified.

The list of grading objects defined in the drawing appears in Toolspace, within the Sites collection on the Prospector tab.

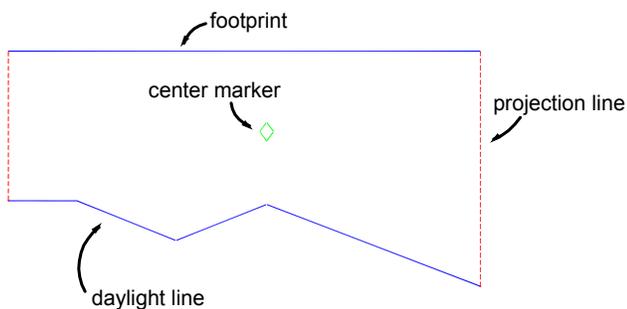
Grading styles (page 737) and Grading Criteria Sets appear in Toolspace on the **Settings** tab.

## Parts of a Grading Object

A grading object normally consists of the footprint, the daylight line, the projection lines, and the face.

The face is the area bounded by the lines that define the grading. It is marked with a center marker (page 2470).

**Plan view of grading object**

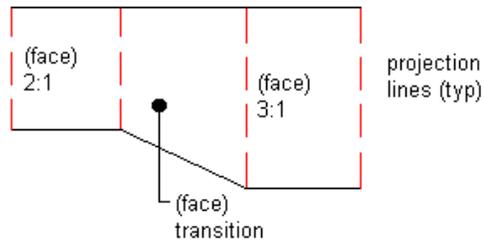


The footprint can be an open or closed figure. The footprint must be either a feature line (page 2473), a lot line, or the resulting daylight line (page 2472) of another grading.

A feature line is a line that represents some important feature in the drawing, such as a ridge line or the bottom of a swale. A feature line can be drawn with the Draw Feature Line command, or created from 2D and 3D polylines, lines, and arcs. You can also export feature lines from corridor models.

The target for the grading can be a surface, a distance, an elevation, or a relative elevation.

## Grading Regions

You define grading regions where a grading object requires different criteria along different parts of the footprint.


Where you need regions, you apply the criteria to only part of the footprint rather than the entire footprint.

For example, you might have a grading region with a slope of 3:1, and another region with a slope of 2:1, separated by a transition region, in which the grading merges from 3:1 to 2:1. Regions to which criteria have been applied are called control regions.

You are prompted to create a transition region if you specify the start point of a grading region to begin within an existing grading on the same footprint. You can also insert transition regions by using the Grading Creation Tools.

# Grading and Surfaces

Grading groups can be automatically turned into surfaces that dynamically update when you edit the grading. You can also create a detached surface from a grading group, which is no longer associated with the gradings and does not update when you edit the grading.

You can specify the Automatic Surface Creation setting when you create the grading group (page 741), or you can create the surface later by changing the Grading Group Properties (page 799). When you create an automatic (or dynamic) surface, the surface is displayed in the Surfaces collection in the Prospector tree. For dynamic surfaces, the surface properties show that it was created from a grading group.

### Editing Dynamic and Detached Surfaces

Dynamic surfaces created from grading groups are updated when you edit the grading object. If you turn on Rebuild Automatic in the Surface menu the surface updates as soon as you make the edit. You can also use the surface edit tools to refine the surface, such as adding spot elevations.

Detached surfaces created from grading groups are not updated when the grading object is edited.

You can edit both dynamic and detached surfaces like any other surface.

### Pasting Grading Surfaces

Both dynamic and detached surfaces can be pasted into other surfaces, except for the grading's target surface. By pasting a dynamic surface, any changes you make to the grading group will be reflected in the final surface.

---

**TIP** To paste a dynamic grading surface into another surface (the "destination surface"), you must select the Paste command from the destination surface node in the Prospector tree.

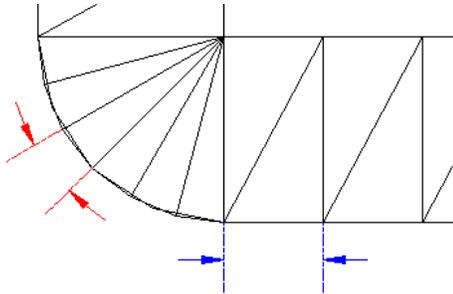
---

You cannot paste the grading surface into the surface that you are using as the target surface. This is disallowed because of the dynamic relationship between the gradings and the target surface. To accomplish this task you should create a copy of the target surface and paste the grading surface into the copy.

### Surface Breaklines and Tessellation Settings

When you create a surface from a grading group, the grading group faces are included as breaklines. The perimeter is included as a boundary.

The surface is built by adding extra breaklines between the footprint and daylight line for better surface definition. These extra breaklines are controlled by the tessellation settings, which you specify for each grading group. Tessellation parameters control the triangulation of surface (for both dynamic and detached surfaces) generated from the grading group.

Tessellation spacing represents the distance between the breaklines along the footprint segments. Tessellation angle represents the angular spacing of breaklines around corners.


Finer values of spacing lead to a more accurate representation of the grading model, but increase the computation time. These values should be set according to the size of grading object in consideration.

### Calculating Volumes

To use the Grading Volume Tools, a dynamic surface must exist for the grading group and a Volume Base Surface must be specified in the Grading Group Properties. You can also use the surface volume commands to compute volumes between dynamic or detached surfaces and any other surface.

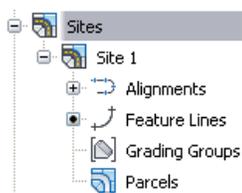
### Using Feature Lines as Surface Data

You can include feature lines as breakline data in a surface. Many of the feature line editing commands (page 751) also work on 3D polylines, parcel lines, and survey figures, giving you a wide variety of options for configuring the 3D data to include in finished ground surfaces.

If the Rebuild - Automatic setting for the surface is enabled, and you edit the feature line, parcel line, or polyline that is used as breakline data, the surface is rebuilt as soon as you make an edit.

# Feature Lines Collection (Prospector Tab)

Use the Feature Lines collection in the Prospector tree to manage feature line styles and layers. You can also view feature line information, such as length, elevation, and grade.

In Toolspace, on the Prospector tab, select the Feature Lines collection to display a list box of all the feature lines in the site. You can edit only the feature line style or layer values. Information such as length, elevation, and grade is read-only.


A black dot glyph indicates a feature line in the site. To edit the feature line style, expand the Site collection, right-click Feature Lines and select Properties. In the dialog box, set the feature line style priority on the Options tab (page 1915). If no feature lines have been created in the site, you can set the feature line style priority to determine the precedence for assigning elevations when feature line segments intersect. Then, when feature lines are created and points intersect, the elevations will be determined accordingly. You can

also set the default feature line style priority, using the command settings for Create Site. If feature lines exist in the site, you can also use the Properties command to view statistics about the feature lines.

Icons indicate the state of the feature line. ⬚ indicates a feature line with no dynamic links. ⬚ indicates a feature line with a dynamic alignment link. ⬚ indicates a feature line with a dynamic corridor link. For more information, see Creating Feature Lines (page 743).

These feature line icons display a small green square in the lower corner if the feature line is in use as a surface breakline ⬚ . You can find the name of the surfaces by listing or viewing the properties of individual feature lines. For more information, see Adding a Feature Line to a Surface as a Breakline (page 786).

You can edit a feature line Style or Layer value by clicking the cell to open a style or layer dialog box. To edit multiple values, use Ctrl+left-click to select multiple rows. Then right-click the column heading and click Edit to open a Select Style or Layer Selection dialog box. For more information about the AutoCAD Civil list view, see The Toolspace Item View (page 82).

Right-click the Feature Lines collection to do the following:

■ View properties for the site feature lines (page 801).

■ Apply feature line names (page 746).

■ Apply feature line styles (page 746). If the feature line does not have a style set, the context menu Edit Feature Line Style option is disabled. The style can be set in the Feature Line Properties dialog box.

■ Remove dynamic links to alignments (page 747). If there is no feature line dynamic link, the Remove Dynamic Links command is unavailable.

■ Raise or lower feature line elevations (page 764).

■ Add a feature line to a surface as a breakline (page 786).

■ Move all of the feature lines from this site to another.

■ Copy all of the feature lines in a site to another site.

■ Select all site feature lines (page 747).

■ Select all site grading groups (page 748).

■ Zoom to the site feature lines.

■ Pan to the site feature lines.

■ Refresh the view of the feature lines in the Prospector tree.

For more information, see The Toolspace Item View (page 82).

| For more information about ... | Follow this link ... |

| Feature Line Creation Methods | Creating Feature Lines (page 743) |
| Editing Feature Line Methods | Editing Feature Lines (page 751) |

## Grading Groups Collection (Prospector Tab)

As you create each grading group (page 2475) , they are displayed in the Grading Groups collection on the Prospector tab in Toolspace.

Right-click an individual grading group in the Grading Groups collection to do the following:

■ View properties for the grading group (page 799).

■ Delete the selected grading group.

■ Zoom to the extents of the grading group.

■ Pan to the site grading groups.

■ Select all gradings in the grading group (page 748).

■ Refresh the view of the grading group in the Prospector tree.

Expand the Grading Groups collection to view the names of the grading groups and to display a tabular list of the grading groups at the bottom of the Prospector tab. For more information, see The Toolspace Item View (page 82).

| For more information about ... | Follow this link ... |
| --- | --- |
| Grading Groups | Using Grading Groups (page 741) |
| Grading Creation Methods | Creating Grading (page 790) |
| Grading Editing Methods | Editing Grading (page 793) |

## Grading Collection (Settings Tab)

Use the Grading collection in the Settings tree to manage grading settings, grading styles, grading criteria sets, and grading command settings.

Right-click the Grading collection to do the following:

■ Edit the grading feature settings. (page 736)

■ Refresh the display of the Settings tree.

Expand the Grading collection to display and edit grading styles (including center markers and slope patterns), criteria sets, and command settings that are available for grading.

| For more information about ... | See ... |
| --- | --- |
| Grading Styles | Using Grading Styles (page 737) |
| Grading Criteria Sets | Using Grading Criteria (page 739) |
| Commands | Grading Command Reference (page 804) |

## Changing Grading Settings

Specify settings for all Grading commands with the Grading Feature Settings. Specify settings for specific Grading commands and override feature settings with the Grading Command Settings.

# Changing Grading Feature Settings

You can use the Grading Settings dialog box to change settings related to grading.

The settings you define in this dialog box override any ambient settings (page 1856) that have been established for the drawing as a whole. The General setting Save Command Changes To Settings is typically set to No. If you change it to Yes, then each time you run an affected command, the values you specify are saved as defaults for the next time you run the command.

**To change the grading feature settings**

1  In Toolspace, on the Settings tab, right-click Grading ➤ Edit Feature Settings.

2  In the Edit Settings (page 1875) dialog box, change the existing settings.

3  Click OK to save the changed settings in the drawing.

## Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click Grading collection ➤ Edit Feature Settings

Dialog Box

Grading Settings (page 1875)

# Changing Grading Command Settings

You can change the prompted values for a specific command, such as CreateGrading.

**TIP** The General feature setting Save Command Changes To Settings is typically set to No. If you change it to Yes, then each time you run an affected command, the values you specify are saved as defaults for the next time you run the command. This setting affects the grading criteria and styles in the Grading Creation Tools (page 1892) dialog box as well as the grading commands.

**To change default values for grading commands**

1  In Toolspace, on the Settings tab, expand Grading.

2  Expand the Commands collection and right-click a command name such as CreateGrading. Click Edit Command Settings.

3  In the Edit Settings (page 1875) dialog box, expand the command-specific property, such as Grading Creation, and edit the values.

4  Click OK.

## Quick Reference

# Using Grading Styles

You can use grading styles to control the display of each grading component.

Create styles to use for different types of gradings and for the various phases of your project. Create a style to use specifically in the design phase which shows lines, patterns and other grading subcomponents.

A style you use for plotting may show only the final grading geometry.

Grading styles are located on the Toolspace Settings tab. Slope pattern styles are located in the Multipurpose Styles collection because they are used for corridor objects as well as for gradings.

# Creating Grading Styles

Use the Grading Style dialog box to control the grading appearance.

Use the Slope Pattern Style (page 1901) dialog box to create different styles of slope patterns, which are referenced by grading styles.

You can create and save an unlimited number of grading styles. After you save the styles, they are located in the Grading Styles collection on the Toolspace Settings tab.

**To create a new grading style**

1  In Toolspace, on the Settings tab, right-click Grading Styles ➤ New.

2  In the Grading Style dialog box, click the Information tab (page 1894) and enter a name and optional description for the grading style.

3  To define the size of the center marker for a grading, click the Center Marker tab (page 1895).

4  To define the slope pattern for a grading, click the Slope Pattern tab (page 1895).

5  To define the display properties for the grading style, click the Display tab (page 1801) and select the display properties.

6  To view summary information about the style, click the Summary tab (page 1803).

7  Click OK to save the new style.

**To create a new slope pattern style**

1  In Toolspace, on the Settings tab, expand Multipurpose Styles ➤ Slope Pattern Styles.

2  Select Standard or another existing style that is similar to what you want. Right-click and click Copy. The Slope Pattern Style dialog box is displayed.

3  On the Information tab (page 1901), enter a name and optional description for the new style.

4  On the Layout tab (page 1902), edit parameter values for each component of the slope pattern and add or delete components as required.

5  Click OK to save the new style.

## Quick Reference

# Setting the Current Grading Style

Specify a grading style to apply to each grading you create.

If you want the Grading Creation Tools dialog box (page 1892) to continually retain the style you last entered, in Toolspace, on the Settings tab, right-click Grading, select Edit Feature Settings, and specify Yes for the General setting Save Command Changes To Settings.

**See also:**

■ Changing Grading Command Settings (page 736)

**To specify a grading style**

1  Click Home tab ➤ Create Design panel ➤ Grading drop-down ➤ Grading Creation Tools .

2  In the Grading Creation Tools (page 1892), click  to view the current criteria and the style.

3  Select the grading style that you want to apply from the list of all the styles defined in the drawing. When grading to a surface or elevation, there can be two style types, one for cut slopes and one for fill slopes.

4  Create the grading.

The grading style is applied to the grading and to any grading you create until you change the style by making another selection from the Grading Creation Tools.

# Editing Grading Styles

Use the Settings tree to edit existing styles, copy existing styles to create new ones, or delete styles.

**To edit, copy, or delete a grading style**

1  In Toolspace, on the Settings tab, expand the Grading collection. Expand the Grading Styles collection.

2  Right-click a grading style. Click Edit, Copy, or Delete.

If you are copying a style, use the Information tab in the Grading Style (page 1894) dialog box to change the name of the style before saving the style. The style appears in the Grading Styles collection with the new name.

You cannot delete a style that is currently applied to an object. First assign another style to the object and then delete the style.

## Quick Reference

Settings tab: Right-click Grading Style item ➤ Delete

Dialog Box

Grading Styles (page 1894)

# Using Grading Criteria

You can create grading criteria, or parameters, to define how grading is created from the footprint, and apply the criteria to other gradings.

There are many standard grading situations. For example, you may frequently need to create grading with a slope of 3:1 and a target of a relative elevation. By defining a set of grading criteria with these values and saving it, you can easily apply these same values to any grading that you create.

# Creating Grading Criteria

Grading criteria are settings that specify the grading method. The settings are consolidated in named criteria to eliminate repetitive prompting when you are creating gradings.

The grading method settings include the following:

■ **Target**. Choices include surface, elevation, relative elevation, or distance.

■ **Projection type**. Choices include cut/fill slope, cut slope, fill slope, and distance.

■ **Interior corner overlap resolution**. Choices include averaging the slopes and increasing or decreasing one of the slopes. For more information and illustrations of the options, see Criteria Tab (Grading Criteria Dialog Box) (page 1883).

■ **Associated values**. Depending on the target and projection type, you can specify default elevations, distances, and cut/fill slopes to use.

Organize and access the criteria in the Settings tree, using the Grading Criteria Sets folders.

When setting up new criteria, it is recommended you use a descriptive naming convention. For example, the standard AutoCAD Civil drawing templates include several different criteria with names like "Surface @ 2-1 Slope." By using a clear naming convention, you do not need to review the criteria properties to know how it was defined.

**About Criteria Locking**

Click the icon to lock or unlock a criteria value. This criteria locking affects the prompts you receive and the values you can enter when creating or editing grading.

Lock criteria values to prevent them from being changed when you create or edit gradings.

For example, consider the different lock conditions for a criteria that is defined to grade at a slope of 3:1 to a relative elevation of 1.50:

**Both values are unlocked**

■ When creating a grading, you are prompted for both values. The prompts default to 3:1 and 1.50, but can be changed.

■ Either value can be edited.

■ If the criteria definition is edited to change either value, it affects only the default prompt value for grading creation; existing grading objects do not change.

■ If the criteria definition is edited and one of the values is changed from unlocked to locked, that locked value is applied to all gradings that use the criteria.

**Slope value is locked, relative elevation is unlocked**

■ When creating grading, you are prompted only for the relative elevation value. Grading objects that use this criteria always have a 3:1 slope.

■ If the criteria definition is edited to change the locked slope value to 2:1, the change applies to all grading objects that use that criteria. If the criteria definition is edited to unlock the slope value, it does not change existing gradings, but allows you to edit the slope value for existing grading objects.

■ If the criteria definition is edited to change the unlocked relative elevation value, it affects only the default prompt value for new grading objects created with the criteria. If the criteria definition is edited to lock the relative elevation, all grading objects using that criteria are set to the locked relative elevation value.

**Both values are locked**

■ When creating grading, you do not receive prompts for the criteria values.

■ If the criteria definition is edited to change either value, the change applies to all grading objects that use the criteria.

■ If the criteria definition is changed to unlock either value, it does not change the grading objects but allows you to edit the value for existing grading objects that use the criteria.

**To create a new grading criteria set**

**1** In Toolspace, on the Settings tab, expand Grading.

**2** Right-click the Grading Criteria Sets collection and click New.

**3** In the Grading Criteria Set Properties (page 1888) dialog box, enter a name and optional description for the set and click OK.

**To create a new grading criteria**

**1** In Toolspace, on the Settings tab, expand Grading.

**2** Expand the Grading Criteria Sets collection. The defined sets are listed.

**3** Right-click a named grading criteria set. Click New.

**4** In the Grading Criteria dialog box, click the Information tab (page 1882) and enter a name and an optional description.

**5** Click the Criteria tab (page 1883), and edit the values to define the criteria you want.

**6** Lock the items that you do not want to change when you are creating grading objects. For example, if you are setting up a criteria to always create a 3:1 slope, lock the Slope value by clicking the lock icon.

**7** Click OK.

**Quick Reference**

Toolspace Shortcut Menu

Settings tab: Right-click a grading criteria set ➤ New

Dialog Box

Grading Criteria (page 1882)

# Setting Default Grading Criteria

Apply a set of grading criteria to each grading that you create.

**To set default grading criteria**

1  Click Home tab ➤ Create Design panel ➤ Grading drop-down ➤ Grading Creation Tools ⬚ .

2  In the Grading Creation Tools (page 1892) dialog box, click ⬚ (Select A Criteria Set).

3  Select the grading criteria that you want to apply.

   Click ⬇ if you want to view the settings for the current criteria.

4  Create the grading.

   The grading criteria is applied to each grading you create until you change criteria by making another selection from the Grading Creation Tools.

# Using Grading Groups

You can specify which collection a grading object is part of.

Once you create a surface from a grading group, you can use the Grading Volume Tools (page 1899) to adjust the elevation of the grading group to balance cut and fill volumes.

# Creating a New Grading Group

Use the Prospector tab of Toolspace to create a new grading group.

Grading groups are used to organize gradings into named collections for surface creation and volume computations.

You can choose whether to automatically create a surface from the grading group, and you can identify a base surface for volume calculations.

You can also create new grading groups while using the Grading Creation Tools command.

**To create a new grading group**

1  In Toolspace, on the Prospector tab, expand Sites, then expand the site to which you want to add the new grading group.

2  Right-click Grading Groups ➤ Create Grading Group.

3  In the Create Grading Group (page 1881) dialog box, enter a name and an optional description for the grading group.

**4** Optionally, to create a surface for the grading group, select Automatic Surface Creation to activate additional options for the output surface and the base surface. It also creates a surface in the Surfaces collection in the Prospector tree.

> **NOTE** When you create a surface using the Automatic Surface Creation option, the Grading Group is listed on the Definition tab of that surface's Properties dialog box.

**5** Optionally, if you plan to do any calculations of cut and fill volumes for the grading group surface, select Volume Base Surface and select the base surface from the list.

**6** Click OK.

## Changing the Grading Group of a Grading Object

A grading object can be moved from one grading group to another.

If you do not want certain grading objects to be included in the same grading group, you can move them to a different group. There must be at least two grading groups in the same site.

**To change the grading group of a grading object**

**1** Select a grading. Click Grading tab ➤ Modify panel ➤ Change Group  .

**2** Select one or more grading objects in the drawing.

**3** In the Select Grading Group (page 1900) dialog box, select or create a grading group for the grading object to be in.

**4** Click OK.

### Quick Reference

Ribbon

Command Line

ChangeGradingGroup

Dialog Box

Select Grading Group (page 1900)

# Creating Feature Lines

You can select a parcel lot line or feature line (page 2473) as the grading footprint.

A feature line is a special type of line that grading commands recognize and use as a footprint.

A feature line represents an object in the drawing from which you want to grade, such as a swale or a ridge line. You can draw feature lines, create them by converting existing objects, or export feature lines from corridors. Surfaces can use a feature line as a breakline.

### Curved Feature Lines

Unlike 3D polylines, feature lines support arcs without tessellation (page 2484). Tessellation is undesirable in a grading footprint because it results in many small grading faces joined by radial corners. To avoid tessellation, you can create a feature line from a 2D polyline with arcs, and then apply elevations using theGrading Elevation Editor. If you want to create a grading from a footprint that has tessellated curves, you can use the Fit Curve (page 777) command to convert the tessellation to true arcs.

### See also:

- Exporting Corridor Feature Lines (page 1369)

# Creating Feature Lines from Objects

You can create a feature line by converting existing 2D or 3D polylines, lines, or arcs. You can select objects in the current drawing or from an Xref.

Names can be assigned to feature lines. Any command that prompts to select a feature line includes an option to select by name from a list. The name is optional so that you can just name the significant feature lines in your drawing.

You can specify the CreateFeatureLines (page 736) command settings prior to creating feature lines.

Settings control which layer the lines are placed on and whether the original objects are deleted.

**To create a feature line from existing objects**

1 Click Home tab ➤ Create Design panel ➤ Feature Line drop-down ➤ Create Feature Lines From Objects ⬚ .

2 In the drawing, select one or more polylines, lines, or arcs. Then press Enter.

NOTE You can enter Xref to select an object from an Xref.

You can select the objects one at a time, or you can make a multiple selection by drawing a window.

3 In the Create Feature Lines (page 1907) dialog box, specify the feature line options.

The feature line retains the elevations of the objects from which it was made. To edit these elevations, see Editing the Elevations of a Feature Line (page 753).

# Assigning Elevations to a Feature Line During Creation

When creating a feature line you can manually enter an elevation or assign an elevation from a surface or from grading objects when creating a feature line from objects.

**To manually assign feature line elevations**

1   Click Home tab ➤ Create Design panel ➤ Feature Line drop-down ➤ Create Feature Lines From Objects .

2   In the Create Feature Lines  (page 1907) dialog box, select the Assign Elevations check box and press OK.

3   In the Assign Elevations (page 1908) dialog box, enter an elevation in the edit box select the Elevation option and press OK. If the object is a 3D polyline with varying elevations, the first point is set to the specified elevation and the rest of the points are raised/lowered by the same relative amount so that the elevation differences between the points remain.

**To assign feature line elevations from a surface**

1   Click Home tab ➤ Create Design panel ➤ Feature Line drop-down ➤ Create Feature Lines From Objects .

2   In the Create Feature Lines dialog box (page 1907), select the Assign Elevations check box and press OK.

3   In the Assign Elevations (page 1908) dialog box, select the From Surface option.

    **NOTE** If there are no surfaces in the drawing, the From Surface option is unavailable.

4   Select a surface from the list or click the arrow icon to select it in the drawing.

5   Select the Insert Intermediate Grade Break Points check box to insert intermediate grade breaks where the entity crosses surface TIN lines. Additional elevation points are created at these locations.

**To assign feature line elevations from a grading in the current site**

1   Click Home tab ➤ Create Design panel ➤ Feature Line drop-down ➤ Create Feature Lines From Objects .

2   In the Create Feature Lines dialog box (page 1907), select the Assign Elevations check box.

3   Select the From Gradings option. This option is similar to the From Surfaces option but acquires the elevations directly from any gradings that it overlaps in the site that the feature line is to be created in.

    **NOTE** If there are no gradings in the drawing, the From Gradings option is unavailable.

**4** Select the Insert Intermediate Grade Break Points check box to insert intermediate grade breaks where the entity crosses surface TIN lines. Elevation points are created at these locations.

# Creating Feature Lines from Alignments

You can create a feature line from an alignment, and use this feature line to grade from the alignment geometry.

You can also create a link from the feature line to the alignment so that it updates dynamically if the alignment is edited. If the feature line is linked to the alignment, you cannot edit it directly.

However, it updates automatically when you make edits to the alignment or its profile. These edits also update any gradings attached to the feature line. If the feature line is not dynamically linked, it does not maintain its relationship with the alignment and you can edit it.

You can specify the CreateFeatureLineFromAlign (page 736) command settings prior to creating feature lines.

**To create a feature line from an alignment**

**1** Click Home tab ➤ Create Design panel ➤ Feature Line drop-down ➤ Create Feature Lines From Objects .

**2** In the drawing, select an alignment. Then press Enter.
If there are no sites in the drawing, a site will automatically be created.

**3** In the Create Feature Line From Alignment (page 1909) dialog box, specify the feature line options.

# Applying Feature Line Names

Apply optional names to feature lines to distinguish significant feature lines.

After creation, you can edit the names of individual feature lines using the Properties command, or using the grid control in Prospector.

This command is used to apply a name template to a selection set of feature lines.

You can specify the CreateFeatureLines (page 736) command settings prior to creating feature lines.

**To apply a feature line name**

1  In the drawing, select a feature line, right-click, and click Apply Feature Line Names.

2  In the Apply Feature Line Names (page 1915) dialog box, in the Name field, enter a name for the feature line.

   To name the feature line, either select its default name and enter a new name, or use the name template. For more information, see Name Template Dialog Box (page 1806).

## Quick Reference

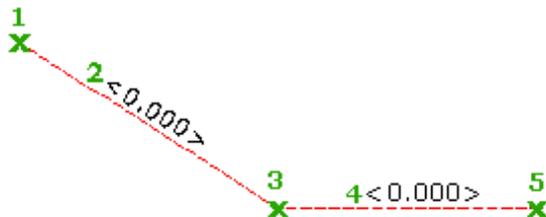
## Drawing Feature Lines

Draws feature line segments.

Use this command to draw straight and curved feature line segments. This command has options to specify the elevations of the feature line, including an option to retrieve the elevations from a surface.



Arcs are created tangential to the previous segment except when the Second Point option is selected to create a three-point arc.

**To draw straight segments of feature lines**

1 Click Home tab ➤ Create Design panel ➤ Feature Line drop-down ➤ Create Feature Line 🛠 .

2 In the Create Feature Lines  (page 1907) dialog box, specify a site, an optional name, and an optional style for the feature line. Select a layer and note that the option to use a selected entity layer is disabled. Click OK.

3 Select the start point for the line. You can use Osnaps or transparent commands to snap to existing geometry.

4 Specify the elevation for the start point by doing one of the following:

■ Enter an elevation at the command line.

■ Enter Surface (S) and select a surface from which to obtain the elevation.

> **NOTE** If there are no surfaces in the drawing, the Surface option is not available. If there is only one surface in the drawing, that surface is selected automatically.

The following prompt is displayed:

```
Specify the next point or [Arc]:
```

5 Select the next point.

The following prompt is displayed:

```
Specify grade or [SLope/Elevation/Difference/SUrface/Transition] <0.000>:
```

> **NOTE** See To draw curve segments of feature lines (page 750) for information about the Arc option.

6 If you wish to specify each elevation point as you create points, skip down to Step nine. To continue drawing points without establishing the elevation until the end:

■ Enter the Transition command.

■ Create a new point. When Transition is selected, as each subsequent point is created the elevation prompt will default to Transition.
```
Transition or [SLope/Elevation/Difference/SUrface] <Transition>
```

7 Press **Enter** to continue drawing another point(s) without specifying the elevation.

8 After creating points, select and enter the desired keyword to specify the elevation, grade, slope, or elevation difference. If you end the command while still in the Transition prompt, you will be prompted to specify an ending elevation.

9 Do one of the following to establish the elevation of the second point:

■ Enter a grade. The grade is applied to the segment between the first and second points.

■ Enter Slope (SL) and enter a slope. The slope is applied to the segment between the first and second points.

■ Enter Elevation (E) and enter an elevation. The elevation is applied to the second point and the grade of the segment between the points is calculated.

■ Enter Difference (D) and enter an elevational difference between the first and second points.

■ Enter Surface (SU) and specify a surface from which to obtain the elevation of the second point.

10 Specify the next point on the feature line by doing one of the following:

■ Select the next point in the drawing.

■ Enter Length (L) and enter a length. When you use this option, the direction of the segment is assumed to be the same as the end of the previous segment.

11 Specify the elevation of the point using the options described in Step 6.

**To draw curve segments of feature lines**

1 Complete Steps 1-4 in Drawing Feature Lines (page 748) to draw straight segments.

2 When you are prompted to select the next feature line point, enter Arc (A). The following prompt is displayed:

```
Specify arc end point or [Radius/SecondPnt/Line/Undo]:
```

**NOTE** If you have not drawn any feature line segments, you are first prompted to establish the arc direction. For more information, see To establish arc direction (page 750).

3 Do one of the following:
■ Select the end point for the arc.

■ Enter Radius (R) and specify a radius.
After entering the radius, the following prompt is displayed:

```
Specify arc end point or [Length]:
```

Select the end point or enter Length. If you use the Length option, specify a length and then a direction for the arc.

**NOTE** Because this option specifies a radius and the arc is tangent to the previous segment, the actual end point of the arc may not be at the selected end point.

■ Enter SecondPnt (S) and specify the second point for the arc.
After selecting the second point, the following prompt is displayed:

```
Specify arc end point or [Length]:
```

Select the end point or enter Length. If you use the Length option, specify a length and then a direction for the arc.

**NOTE** The Length option creates an arc that is tangent to the previous segment and passes though the second point. The arc may stop short of the second point if the length is shorter than the arc length to the point.

4 Specify the elevation of the end point.

5 Continue to select arc points or enter Line to draw straight segments or Close to close the feature line.

**To establish arc direction**

1 If you use the Arc option of the Draw Feature Line command prior to drawing any segments, it defaults to drawing a three-point arc. The following prompt is displayed:

```
Specify arc second point or [Direction]:
```

2 Do one of the following:
■ Click a location in the drawing to establish the direction of the arc.

■ Enter an angle at the command line. Use the DD.MMSS (degrees, minutes, seconds (page 2472)) format.

■ Enter Bearing (B). Temporary graphics are displayed on screen and the following prompt is displayed:

```
Specify quadrant (1-4) or [aZimuth/Angle]:
```

Use your mouse to click one of the four bearing quadrants as indicated by the temporary graphics, or enter the quadrant number at the command line.

After defining the quadrant, the following prompt is displayed:

```
Specify bearing or [aZimuth/Angle]:
```

Use your mouse to specify the bearing or enter it at the command line. Use the DD.MMSS format.

■ Enter Azimuth (Z). Temporary graphics are displayed on screen and the following prompt is displayed:

```
Specify azimuth or [Bearing/Angle]:
```

Use your mouse to specify the azimuth or enter it at the command line. Use the DD.MMSS format.

**3** After you have established the arc direction, the following prompt is displayed:

```
Specify arc end point or [Radius/SecondPnt/Line]:
```

See To draw curve segments of feature lines (page 750) for more information.

# Editing Feature Lines

You can use feature line editing commands with several different object types in addition to feature lines.

**NOTE** You can use the feature line commands to edit survey figures, including control points. You should update the survey database after editing a feature line. If you do not, the next time you recalculate the figure from the database, your edits to the feature lines will be overwritten.

**NOTE** You can also use the feature line commands to edit parcel lines.

The following table lists which objects are supported for each command.

| | Feature Lines | Parcel Lines | Survey Figures | 3D Polylines | 2D Polylines |
|---|---|---|---|---|---|
| Elevation Editor (page 755) | X | X | X | | |
| Quick Elevation Edit (page 754) | X | X | | | |
| Edit Elevations (page 757) | X | X | X | X | |

| | Feature Lines | Parcel Lines | Survey Figures | 3D Polylines | 2D Polylines |
|---|---|---|---|---|---|
| Set Grade/Slope Between Points (page 758) | X | X | X | X | |
| Set Elevation By Reference (page 759) | X | X | X | X | |
| Insert Elevation Point (page 765) | X | X | X | X<br><br>**NOTE** Inserts PI rather than elevation point. | |

# Editing the Elevations of a Feature Line

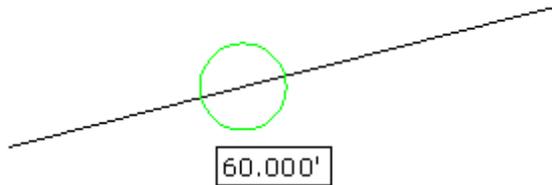
You can edit the elevation of a feature line using the Grading Elevation Editor, the command line, or several different tools on the Edit Elevations panel.

You can use many of these commands on objects other than feature lines. See the Quick Reference tab of each topic for a list of supported objects for each command.

## Quickly Editing Feature Line Elevations

Use the Quick Elevation Edit command to interactively edit the elevation or grade of any feature line or parcel line in a specified site.

The elevation is displayed at vertices and elevation points, and the grade is displayed along segments. Click to edit the value on the command line.



**To quickly edit feature line elevations**

1  Click Modify tab ➤ Design panel ➤ Elevations Drop-down ➤ Quick Elevation Edit .

   **NOTE** The current site is listed at the command line. If you want to select a different site or an object in the desired site, enter Site. Then, select either an object in the drawing or select Enter to access a list of available sites in the Select Object(s) dialog box.

2  Move your mouse over the geometry you want to edit.

   ■ Triangles  are displayed when you hover over a vertex or intersection point. The elevation is displayed in a tooltip.

   ■ Circles  are displayed when you hover over an elevation point (page 2473). The elevation is displayed in a tooltip.

   ■ Arrows  are displayed when you hover over a segment. The arrow points to the end of the segment that is closest to the cursor. This is the point that will have its elevation changed with the grade edit.The grade is displayed in a tooltip.

   ■ Gray glyphs  are displayed when you hover over an elevation or grade that cannot be edited. Uneditable lines include objects such as daylight and dynamically linked feature lines.

   When you locate the elevation or grade you want to edit, click your mouse.

3  Do one of the following:
   ■ Enter the new elevation or grade at the command line.

   ■ If you clicked an elevation point, you can also enter Surface to open the Select Surface dialog box and select a surface to obtain the elevation from.

   **NOTE** The Surface option only appears if there are surfaces in the drawing.

■ If you clicked a grade point, you can also enter Slope and specify a slope. It edits the elevation at the end of the segment in the direction that the arrow is pointing.

**NOTE** If the feature lines are being used as surface breaklines and the surface Rebuild-Automatic setting is turned on, you can see the surface updating automatically as you make each edit.

**To quickly edit feature line elevation points by selecting a reference**

1 Click Modify tab ➤ Design panel ➤ Elevations Drop-down ➤  Quick Elevation Edit.

2 Enter Reference.

3 Select the reference point to use. When picking the reference point, it defaults to a point in the site, but you can also select the Pick option to use OSNAP to pick any location in the drawing.

4 Move the cursor around the reference point and a yellow line is drawn on screen from the reference point to the closest point.

5 Do one of the following:
■ Enter a grade. The grade is applied between the reference point and the point on the feature line.

■ Enter Slope and then enter a slope. The slope is applied between the reference point and the point on the feature line.

■ Enter Difference and then enter the elevational difference. The elevational difference is applied between the reference point and the point on the feature line.

The assigned elevation for the point is displayed at the command line.

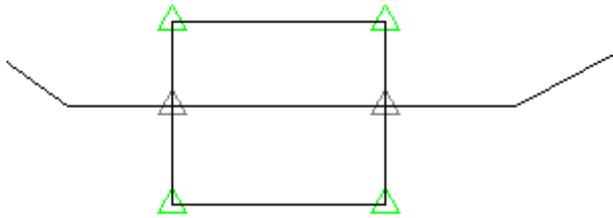
## Editing Feature Lines with the Grading Elevation Editor

Edit the vertex elevations of feature lines, survey figures, and parcel lines with the Grading Elevation Editor.

Use the Grading Elevation Editor to edit feature line elevations in a tabular dialog box. You can also assign an elevation from an existing surface.

Changes you make in the editor dynamically change the elevation in the drawing.

Within the editor, each vertex is displayed on its own row, and is marked with a triangle or circle.


- Green triangles ▲ mark the points that represent the major horizontal geometry points. For example, when you create a feature line, all vertices are shown as triangles. If you insert points of intersection (PI), they are also shown as triangles.

- White triangles ▲ indicate split points, where two feature lines cross although neither has a geometry point at that location. You cannot directly edit the elevation of these points.

- Circles ● mark the elevation change points. Insert a new elevation point (page 2473) by using the Insert Elevation Point icon in the Grading Elevation Editor.

- Grade arrows display at segment midpoints (pointing downhill) to indicate feature line flow directions and to display the segment that is being edited when a single row is selected.

---

NOTE When a vertex is a shared point with another intersecting feature line, a small + symbol ▲ is displayed with the icon for that row.

---

When two features, such as feature lines, lot lines or survey figures cross and neither feature has a geometry point at that location, a split point is created. You cannot edit this point directly, as it is controlled by the grades of the two crossing segments which must have the same elevation at the crossing point. If the two elevations are different, a grade break is inserted into one to match the elevation of the other.

You can assign a priority to feature line styles so that when two feature lines with different styles cross, the one with the higher priority will set the elevation. Feature lines without a style have the lowest priority. Use the Options tab in the Feature Line Site Properties (page 1915) dialog box to set the feature line style priority.

If two feature lines have the same style or no style, then the feature line that is modified last becomes dominant, causing the other feature line to break at that point. To control the elevation at that point, use the Insert PI command to create a vertex at the split point.

When you click a row, a marker is displayed in the drawing, displaying the vertex that you are on.

**To edit a feature line, using the Grading Elevation Editor**

1 Click Modify tab ➤ Edit Elevations panel ➤ Elevation Editor ▦ .

2 Select the feature line or an other object.

3 Change the elevation in the Grading Elevation Editor (page 1889) dialog box.

The Elevations From Surface option is unavailable if there are no surfaces in the drawing. If there is only one surface, that surface is automatically used to assign the elevation. If there is more then one surface, you are prompted to select the desired surface.

If no feature line rows are selected, the elevation of all points are updated. If the feature line is off of the surface, a warning message displays. If some elevations are updated, but one or more points are off of the surface, a message displays, indicating the number of points that could not be assigned elevations.

The feature line is updated in the drawing, and the grading is adjusted.

## Editing Feature Line Elevations at the Command Line

Edits the vertex elevations of a survey figure, parcel line, or 3D polyline at the Command prompt.

Use this command to step through each vertex and elevation point on a feature line or figure. You can change elevations and grades, also insert, move, and delete elevation points.

**To edit a feature line from the command line**

1 Click Modify tab ➤ Edit Elevations panel ➤ Edit Elevations  .

2 Select the feature line or other object.

3 To select the vertex or elevation point to edit, press Enter without entering a value. You can also enter Next or Previous to change the direction the command uses to step through the points.

■ A triangle  is displayed on the feature line when you select a vertex or intersection point.

■ A circle  is displayed on the feature line when you select an elevation point (page 2473).

4 Do one of the following:
■ Enter an elevation and press Enter to modify the elevation and stay at the current point. The updated values are displayed.

■ Enter Grade and specify a grade.

■ Enter Surface and select a surface to obtain the elevation from.

- Enter Insert and select a location for a new elevation point along the feature line.
  The following options are available only for elevation points:

- Enter Move and select a new location for the elevation point.

- Enter Delete to delete the current elevation point.

5 As you make each change, the feature line is updated in the drawing and the grading is adjusted.

6 Enter Exit to end the command.

## Setting a Grade or Slope Between Points

Use to edit the grade/slope between two vertices on a feature line, survey figure, parcel line, or 3D polyline

Specify grade, slope, point elevations, or elevation difference between points. For the selected segment (1), you specify the start point (2), the elevation (3), and the end point (4). Then specify the grade, slope, elevation or elevation difference.

**To set a grade or slope between points**

1 Click Modify tab ➤ Edit Elevations panel ➤ Set Grade/Slope Between Points ⬚ .

2 Select the feature line or other object.

3 Select the start point of the segment you want to edit.

4 Optionally, specify the elevation of the start point by entering an elevation or by entering Surface and selecting a surface to obtain the elevation from.

5 Select the end point of the segment.

6 Do one of the following to establish the grade or slope between the points:
   - Enter a grade.
   - Enter Slope and specify a slope.
   - Enter Elevation and specify an elevation for the end point.
   - Enter Difference and specify an elevational difference between the two points.

## Quick Reference

## Setting Feature Line Elevation by Reference

Sets a vertex elevation on a feature line, survey figure, parcel line, or 3D polyline at a given grade/slope from a specified location

Example: Specify the elevation of a ditch footprint in relation to a building pad elevation. Temporary graphics show the reference point and the vertices on the feature line.

**To set feature line elevation by reference**

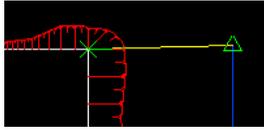
1 Click Modify tab ➤ Edit Elevations panel ➤ Set Elevation By Reference ⬚ .

2 Select the reference point to use.

The elevation of the selected point is displayed at the command line.

**3** Select the feature line or other object to which you want to apply the elevation.

Temporary graphics are drawn on-screen to show the reference point and the vertices and elevation points on the feature line.



**4** Do one of the following:

- ■ Click to select the first point selected on the feature line. Or move your mouse to snap to a different point on the feature line, and then click to select it.

- ■ Enter Insert and then select a point on the feature line at which to insert a new elevation point. On 3D polylines, a new PI is inserted.

The distance between the selected point and the reference point, and the elevation and grade of the selected point, are displayed at the command line.

**5** Do one of the following:

- ■ Enter a grade. The grade is applied between the reference point and the point on the feature line.

- ■ Enter Slope and then enter a slope. The slope is applied between the reference point and the point on the feature line.

- ■ Enter Difference and enter the elevational difference. The elevational difference is applied between the reference point and the point on the feature line.

The assigned elevation for the point is displayed at the command line.

**6** The original reference point remains active. Select another feature line to continue setting elevations in reference to this point. Or, press Enter to end the command.

# Raising or Lowering Feature Line Elevation by Reference

Use the Raise/Lower By Reference command to raise or lower a feature line, based on a grade, slope or relative elevation from a reference point.

Select the Pick option to pick any location in the drawing or use the transparent commands to select a COGO point or surface elevation.

**To raise or lower feature line elevation by reference**

1   Click Modify tab ➤ Edit Elevations panel ➤ Raise/Lower By Reference ↗‡ .

2   Select the reference point to use. Select the Pick option to use OSNAP to pick any location, in the drawing or use the transparent commands to select a COGO point or surface elevation.

    The elevation of the selected point is displayed at the command line.

3   Select the feature line or other object that you want to raise or lower.

4   Select a point on the object you selected.

    The distance between the selected point and the reference point, and the elevation and grade of the selected point, are displayed at the command line.

5   Do one of the following:

    ■ Enter a grade. The grade is applied between the reference point and the point on the feature line.

    ■ Enter Slope and enter a slope. The slope is applied between the reference point and the point on the feature line.

    ■ Enter Difference, and enter the elevational difference. The elevational difference is applied between the reference point and the point on the feature line.

    The assigned elevation for the point is displayed at the command line.

6   The original reference point remains active. Select another feature line to continue setting elevations in reference to this point. Or, press Enter to end the command.

## Setting Adjacent Feature Line Elevations by Reference

Use the Adjacent Elevations By Reference command to set the elevations along a feature line, survey figure, lot line or 3D polyline, based on a grade, slope or elevation difference from points along another feature line.

This command is similar to setting elevations in stepped offset, without first creating the offset.

Using this command, you can edit the elevations of one feature line and then update the elevations of another related feature line that exists alongside the first.

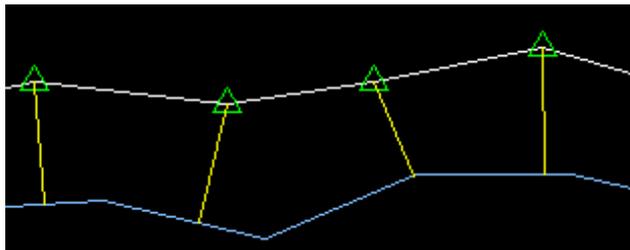
**To set adjacent feature line elevations by reference**

1 Click Modify tab ➤ Edit Elevations panel ➤ Adjacent Elevations By Reference  .

2 Select the reference object.

3 Select the feature line or another object you want to edit.

Glyphs are displayed at each point that will be edited along the feature line, as well as yellow lines projected to the reference feature line, which display the location of the reference elevations for each point.



Only points that fall within the range of the reference object can be modified.

4 Do one of the following:

■ Enter the elevational difference. The elevational difference is applied between the reference point and the point on the feature line.

■ Enter Grade and enter a grade. The grade is applied between the reference point and the point on the feature line.

■ Enter Slope and enter a slope. The slope is applied between the reference point and the point on the feature line.

■ Enter Variable. The Variable option steps along each point prompting for the elevation difference, grade, or slope. It does not insert any new points along the feature

The assigned elevation for the point is displayed at the command line.

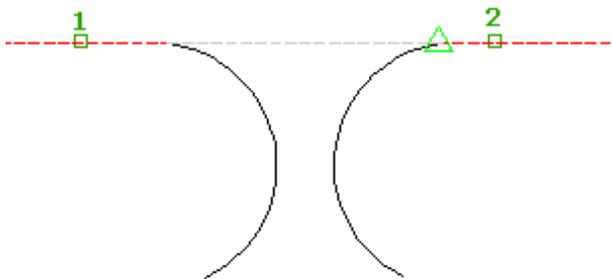
## Extending a Grading By Reference

Use the Grade Extension By Reference command to edit an elevation by extending the grade of a segment on another feature.

This command is used to apply the same grade from a segment across a gap to a point on another feature line. For example, you can extend a grade across an intersection.



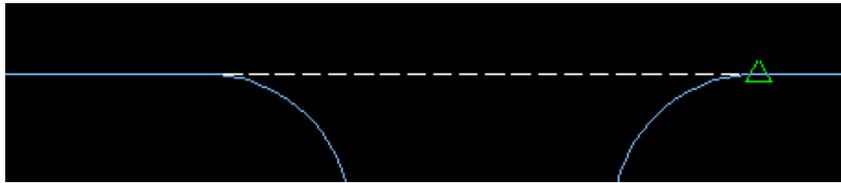
**To extend a grading by reference**

1   Click Modify tab ➤ Edit Elevations panel ➤ Grade Extension By Reference .

2   Select the reference segment.

    The segment is highlighted and the grade and slope are displayed in the command line.

3   Select the feature line or an other object that you want to edit.

    As the cursor is moved along the feature line, it snaps to the nearest point that you can edit, displaying a yellow line from the reference point to the edit point.


**4** Specify the point.

The grade, slope, elevation and distance to the point are displayed in the command line.

**5** Press Enter to use the default reference grade. Do one of the following:

- Enter a grade. The grade is applied between the reference point and the point on the feature line.

- Enter Slope and then enter a slope. The slope is applied between the reference point and the point on the feature line.

- Enter Difference and enter the elevational difference. The elevational difference is applied between the reference point and the point on the feature line.

The assigned elevation for the point is displayed at the command line.

**6** Enter the grade to that point. The reference grade is the default.

**7** Select another reference segment. Press Enter to end the command.

## Raising or Lowering Feature Lines

Use the Raise/Lower command to raise or lower the elevation for a selection of feature lines, figures, lot lines, polylines or 3d polylines.

If the selected feature lines all have the same constant elevation, an Elevation option is available to set the elevation value.

**To raise or lower features lines**

**1** Click Modify tab ➤ Edit Elevations panel ➤ Raise/Lower $+\mathcal{I}^{\dagger}$ .

**2** Select the feature line or other objects to edit.

**3** Enter the elevation difference by which to raise or lower the feature lines.
The default elevation difference is 1.0.

**4** If the selected feature lines are all at the same elevation, an Elevation keyword appears. Select the Elevation option to specify an elevation for the feature lines. The default is the elevation of the feature lines.

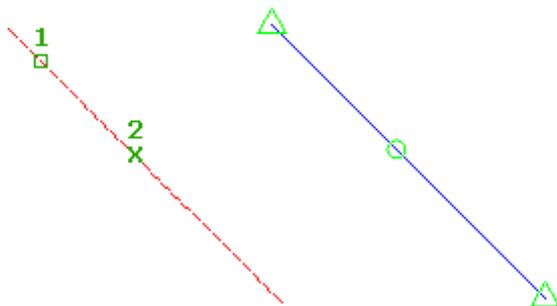
## Inserting a Feature Line Elevation Point

Use the Insert Elevation Point command to insert an elevation point (page 2473) on a feature line.

Specify a location, distance, or increments at which to insert multiple points. When a single point is inserted, you can specify the elevation.


**To insert a feature line elevation point by selecting a location**

**1** Click Modify tab ➤ Edit Elevations panel ➤ Insert Elevation Point ╪⬦ .

**2** Select the feature line or other object.

**3** Click to select the location along the feature line to insert the elevation point.

**4** Specify the elevation by entering a value. Or enter Surface to obtain the elevation from a surface. If only one surface is in the drawing it is selected automatically.

**5** Select another point or specify a distance to insert another point.

**To insert a feature line elevation point by specifying a distance**

**1** Click Modify tab ➤ Edit Elevations panel ➤ Insert Elevation Point ╪⬦ .

**2** Select the feature line or other object.

**3** Enter Distance.

**4** Select an existing point on the feature line to specify the start of the distance. If you select a point other than the start or end point, you must then select the direction.

**5** Enter a distance to define the location of the elevation point.

**6** Do one of the following to define the elevation of the point:

- Enter a grade.

- Enter Slope and enter a slope.

- Enter Elevation and enter an elevation. Or enter Surface to obtain the elevation from a surface.

- Enter Difference and enter an elevational difference.

**To insert multiple elevation points at an increment**

**1** Click Modify tab ➤ Edit Elevations panel ➤ Insert Elevation Point ╪⬦ .

**2** Select the feature line or other object.

**3** Enter Increment.

**4** Enter a value to define the length of the increment. Points are placed equidistant along the feature line using the specified increment.

**NOTE** Using this option, you are not prompted for elevations. The points are automatically assigned the elevation that exists at their location on the feature line.

## Inserting a High or Low Elevation Point

Inserts a high or low elevation point onto a feature line, survey figure, parcel line, or 3D polyline.

This command inserts the break point where two grades intersect. Specify the grade or slope ahead from the start point and back from the end point.

**To insert a high or low feature line elevation point**

**1** Click Modify tab ➤ Edit Elevations panel ➤ Insert High/Low Elevation Point  .

**2** Select the feature line or other object.

**3** Select the start point and the end point of the span that you want to add the point to. These points can span multiple feature line segments.

After you select the start and end points, an arrow is displayed at the start of the span. The command line displays the start and end elevations and the distance between the start and end points.

**4** Enter the grade (or enter Slope and specify a slope) from the start point.

Enter a positive value to grade up or a negative value to grade down.

**5** Enter the grade back from the end point.

**NOTE** If an intersection cannot be found with the entered values a "No solution found" message is displayed.

## Setting Feature Line Elevations from a Surface

Use the Elevations From Surface command to assign the elevations of a surface to the geometry points of one or more feature lines, parcel lines, survey figures, or 3D polylines.

Elevations are assigned to each vertex. You can include intermediate elevation points at any break points along the surface. Elevations obtained from the surface are not dynamic.

**To set feature line elevations from a surface**

**1** Click Modify tab ➤ Edit Elevations panel ➤ Elevations From Surface  .

**2** In the Set Elevations From Surface (page 1914) dialog box, select a surface.

**3** Select the Insert Intermediate Grade Break Points check box to insert intermediate grade breaks where the entity crosses surface TIN lines. Elevation points are created at these locations.

**4** Click OK.

**5** Do one of the following:

- Select the feature line or other object.

- Enter Multiple, and then select multiple objects.

- Enter Partial, and then define a portion of the feature line to assign elevations to.

**6** The feature line is assigned the elevations of the underlying surface. To edit these elevations, see Editing the Elevations of a Feature Line (page 753).

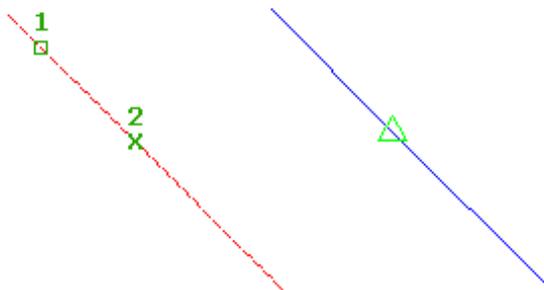
# Inserting Feature Line PIs

Use the Insert PI command to insert points of intersection on a feature line.

Points of intersection break the existing horizontal geometry of the feature line. You can use this command to convert a split point into a geometry point for editing.



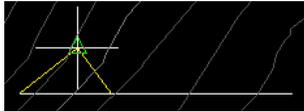
Split points are created when two feature lines cross and neither has a geometry point. A split point cannot be edited as it is controlled by the grades of the two crossing segments which must have the same elevation at the crossing point. If their elevations are different, a grade break will be inserted into one to match the

elevation of the other. If the feature lines have the same style or no styles are assigned, the segment that is modified last will become dominant, causing the other segment to break at that point. Use the Insert PI command to create a vertex at the split point so that you can have direct control over the elevation at that point.

**To insert points of intersection into feature lines**

1   Click Modify tab ➤ Edit Geometry panel ➤ Insert PI ⊹.

2   Select the feature line or other object.
    Temporary graphics are drawn on screen.
    



3   Click to insert the PI.

4   Enter Distance. Then specify a distance from the start point at which a PI point along the feature line is inserted.

5   Enter Increment. Specify distance between points, then click the feature line to to automatically insert PI points separated by the specified distance. As this command inserts multiple points, the elevation for each point will be determined by the existing elevation of the feature line at each point.

6   Do one of the following:
    ■   Enter the elevation for the point.

    ■   Enter Surface to obtain the elevation from a surface in the drawing.

    **NOTE** You are not prompted for the elevation if the object you selected is a 3D polyline.

**To insert points of intersection into a crossing point**

1   Click Modify tab ➤ Edit Geometry panel ➤ Insert PI ⊹.

2   Use OSNAP to select the intersection point.
    Temporary graphics are drawn on screen.

3   Click to insert the PI.

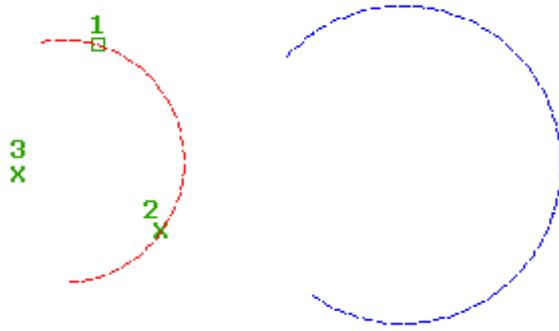
# Editing Feature Line Curves

Use the Edit Curve command to edit the radius of feature line (or survey figure) arcs.

When the radius is changed, the new arc is displayed and the existing arc is indicated with dashed highlighting.


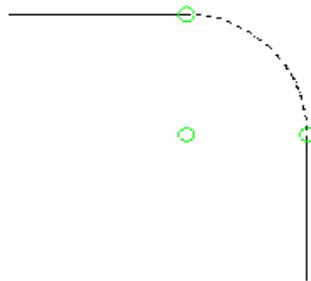
**To edit feature line curves**

1 Click Modify tab ➤ Edit Geometry panel ➤ Edit Curve  .

2 Select the curve to edit. The curve is highlighted, and the points are displayed.

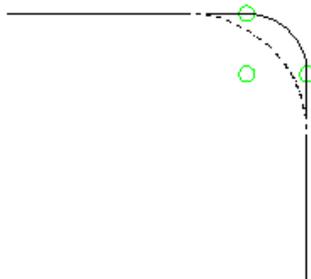
3 In the Edit Feature Line Curve (page 1916) dialog box, edit the curve. Use the Radius edit box to specify the radius.

4 Use the Maintain Tangency option to control the curve tangency state.

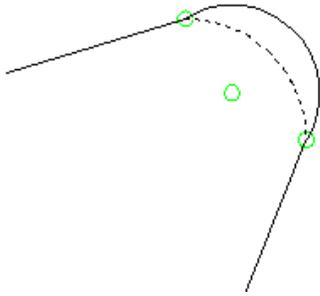


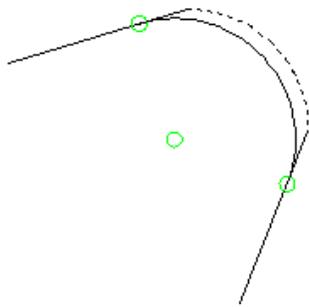
**The curve is highlighted and the arc start, center and points are displayed with glyphs.**

When the radius is changed, if the arc is tangent to the segments on either side, the tangency is maintained. Before selecting OK in the Edit Feature Line Curve dialog box, the new arc is displayed. At the same time, the existing arc remains visible with the dashed highlighting.



**The start and end points remain constant if the arc is not tangent.**

If the arc is not tangent, the start and end points of the arc are held when the radius is changed.


If the curve is not tangent, the Maintain Tangency button is activated. If you toggle this button the curve will be adjusted to make it tangent to the adjacent segments. If the curve is tangent, the button is disabled.


**NOTE** When the Delete option is selected, the segments on either side of the curve are extended to an intersection point.

**Segments extend to intersection point.**

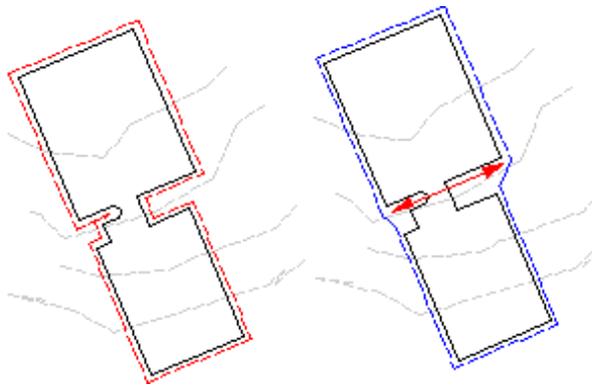
# Filleting Feature Lines

Fillets a feature line, survey figure, or 3D polyline.

This command can be used to round the corners of feature lines. The fillet can span multiple segments and can be used to join two connecting feature lines.



**To fillet feature lines**

1   Click Modify tab ➤ Edit Geometry panel ➤ Fillet ✛ .

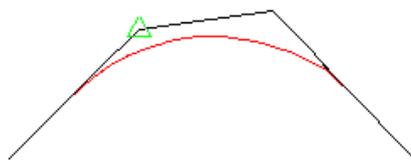
2   Select the feature line or other object.

The currently specified radius is displayed at the command line.

3   Do one of the following:

- Select the corner to fillet. When you move your mouse over the feature line, a triangle highlights the corners that can be filleted and the current radius value is displayed.

   **Single corner fillet**

   **Multiple corner fillet**


- Enter Radius to specify a different radius.

- Enter All to fillet all corners.

- Enter Join to join a connecting feature line and then select the feature line.

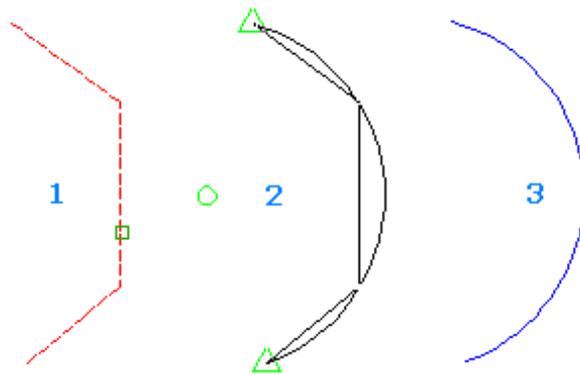
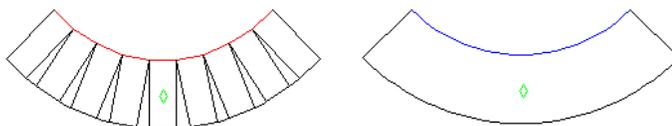
# Converting Tessellated Lines to Arcs

Fits a curve from a selection of vertices with a feature line, survey figure, parcel, or 3D polyline

Use this command to convert tessellated lines to true arcs, or to add fillets to straight segments. You can specify start and end points or set options for automatic arc generation.



Tessellation occurs when you convert a 2D polyline with arcs to a 3D polyline. It also occurs when you export feature lines with arcs from corridor models.

**Grading created from tessellated footprint (left) compared with grading created from arc (right)**


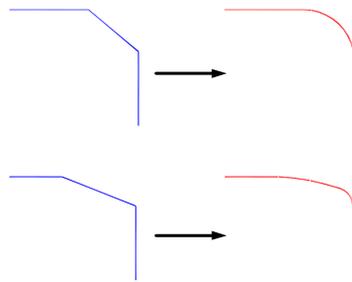
Feature line points that define a grade break are inserted as elevation points on the arc when using this command.

There are three ways to select the segments to turn into arcs.

- **Automatic selection**: As you move your mouse over the feature line, arcs appear where they can be inserted. Click your mouse to insert the arc.

- **Specifying start and end points over multiple segments**: Use this method to define an arc using specified start and end points.

- **Specifying start and end points for a single segment**: Use this method to replace a single segment (such as a chamfered corner) with an arc. If the corner is asymmetrical, two arcs are inserted that are tangent to the line segments and to each other.



You can specify the command options by editing the FitCurveFeature command settings, or by using the Options keyword when running the Fit Curve command.

**To fit a curve**

1  Click Modify tab ➤ Edit Geometry panel ➤ Fit Curve  .

2  Select the feature line or other object.

3  Do one of the following:

- Move your mouse over the feature line. Arcs appear where they can be inserted. Click your mouse to insert an arc.

- Enter Points (P). Then select the start and end point on the feature line for the arc location. This option ignores the minimum number of segments setting.
  If the start and end points span more than one segment but the points do not define an arc, an error message is displayed indicating that an arc cannot be created between the specified points. This error occurs if the segments do not all curve in the same direction or if there is a straight segment that is composed of multiple small segments (which therefore have no deflection angle).

  **NOTE**  If the segments can define an arc but are not within the tolerance, you are prompted with an option to override the tolerance setting and insert the arc.

- Enter Options (O) to display the Fit Curve (page 1913) dialog box where you can change the tolerance and minimum number of segments settings.

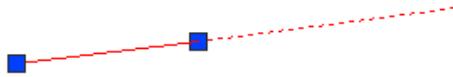
# Smoothing Feature Lines

Use to replace feature line segments with arcs.

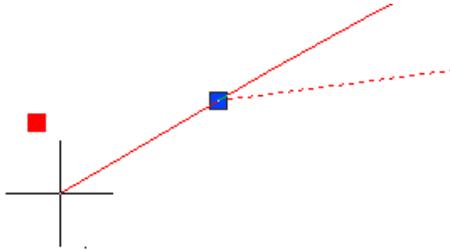
Use this command to smooth feature lines that were created from tessellated polylines. Select the Straighten option command to restore straight lines.

**Before and after smoothing**

When you select the object after smoothing, red tangent lines extend from the grips at the ends of the feature. You may need to zoom into the end to see them.

**Zoom in to end of feature line to see grip**


You can use these grips to adjust the arc directions at the start and end of the feature line.

**Select and move grip to adjust arc direction**


**Zoomed out view showing arc adjustment**

**To smooth feature lines**

1　Click Modify tab ➤ Edit Geometry panel ➤ Smooth ⌇ .

2　Select the feature line(s) to smooth or straighten.

3　Do one of the following:

■　Press Enter to smooth the lines.

■　Enter Straighten to straighten lines that were previously smoothed.

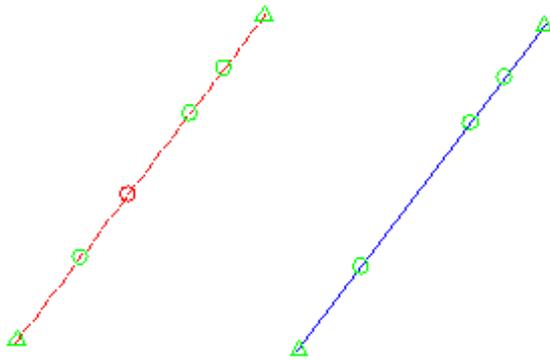
# Weeding Vertices

Use the Weed Vertices command to reduce the number of vertices on a feature line.

Vertices are weeded if found to be unnecessary for line location, based on weeding factors of angle, grade, length, and 3D distance. Points selected for weeding are highlighted in red.

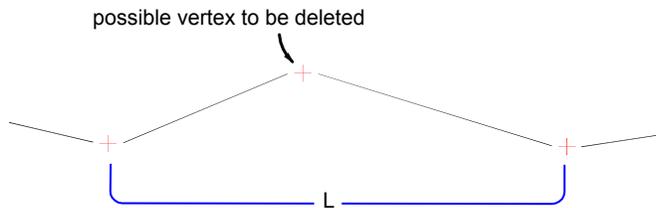


The weeding factors delete vertices that:

■ Are closer together in 2D space to their two neighboring vertices than the Length factor.

weeding length factor (plan view)

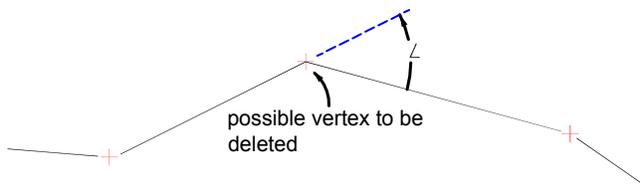
possible vertex to be deleted

L


if L < length factor, then the vertex will be deleted

■ Have a 2D deflection angle that is less than the Angle factor.

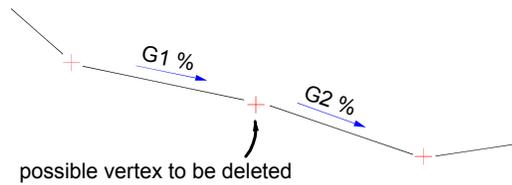
weeding angle factor (plan view)

possible vertex to be deleted


if angle < angle factor, then the vertex will be deleted

■ Have a difference in grade that is less than the Grade factor.

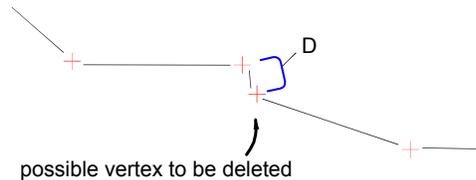
weeding grade factor (profile view)

possible vertex to be deleted


if the difference between G1 and G2 < grade factor,
then the vertex will be deleted

■ Are closer together in 3D space to their two neighboring vertices than the 3D Distance factor.

weeding 3D distance factor (profile view)

possible vertex to be deleted


if D is < 3D distance factor, then the vertex will be deleted

Larger factors weed more vertices.

You can choose which factors you want to be used to calculate the weeding. For example, if you only want to apply a length factor, select the Length check box and specify a length, and clear all other check boxes.

You can set the defaults to be used for this command by editing the WeedFeatures command settings.

**To weed vertices**

1 Click Modify tab ➤ Edit Geometry panel ➤ Weed  .

2 Do one of the following:
   ■ Select the feature line or other object.

   ■ Enter Multiple and then select multiple objects to weed.

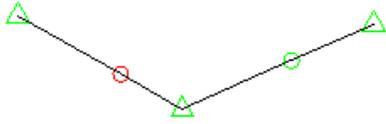
   ■ Enter Partial and then select the object and the portion of the object to weed.

   The vertices of the object(s) you selected are highlighted with green triangles and the Weed Vertices (page 1911) dialog box is displayed.

3 Select the check boxes for the weeding factors that you want to apply and specify the values to use.

When you specify a value that will delete a vertex, that vertex is highlighted in red in the drawing, and a message is displayed in the dialog box indicating how many vertices will be deleted. After you change a value, press Tab to update the message and the drawing display.

**Points selected for weeding are highlighted in red**



4 Click OK to delete the vertices.

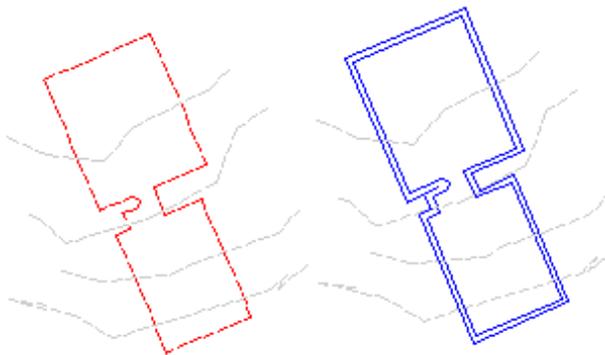
# Creating a Stepped Offset

Creates a new feature line from an offset and difference in elevation from a selected feature line, survey figure, polyline, or 3D polyline.

Specify the offset distance, the side, and elevational difference or absolute elevation.


**To create a stepped offset by specifying a distance**

1 Click Home tab ➤ Create Design panel ➤ Feature Line drop-down ➤ Create Feature Line From Stepped Offset ⟳ .

2 Do one of the following to specify the location for the offset:

■ Specify the offset distance, then select the object to offset.

■ Enter Through, then select the object to offset and select a through point. The offset will be drawn through this point.

3 Do one of the following:

■ Specify a point on the side where you want to place the offset. Then specify the elevational difference or the absolute elevation for the offset.

■ Enter Multiple and specify the side and elevational difference for each offset.

If you enter Variable, it will display a marker at the first point on the offset feature line. You can specify the elevation difference from the original point or the absolute elevation. After you enter a value, it will move to the next point and prompt for its elevation. It will continue to do this for each point on the feature line until you end the command.

4 Select another object to offset, or press Enter to end the command.

## Adding a Feature Line to a Surface as a Breakline

Adds feature lines to a surface as breakline data.

Use this command to select one or more feature lines from a drawing and add them to a surface. You can use breaklines to define features, such as retaining walls, curbs, tops of ridges, and streams.

When this command is selected, it will prompt for the surface, then prompt with the Add Breaklines dialog box.

**To add a feature line to a surface as breakline**

**1** Right-click a feature line ➤ Add To Surface As Breakline.

> **NOTE** If there are no surfaces in the drawing, you are prompted to create one.

**2** In the Select Surface dialog box, select a surface, and press OK. Or, select the Add button to create a new surface.

**3** In the Add Breaklines (page 2360) dialog box, specify the breakline options. Press OK.

> **NOTE** If you list a feature line or view its properties, you will see the names of the surfaces and breakline collections that the feature line is part of.

### Quick Reference

## Creating Grading

You can use the Grading Creation Tools to create grading from a footprint or to copy the criteria and style from another grading.

Use the tools to specify the grading group and criteria and then use the Create Grading options.

# Creating Grading from a Footprint

Before you create grading, you need to select a grading group to associate the grading objects with. After you create a grading object, you can move it to a different grading group within the same site.

Feature lines and grading are created by default on the layers specified by the drawing settings (page 1854).

Use the Grading Creation Tools (page 1892)to specify the grading criteria and style for the grading. Then create the grading by selecting the footprint from which the grading is projected. Command prompts vary, depending on the values that have been set in the grading criteria. For example, if the criteria has a target of Distance, which is not locked (page 739), you are prompted to enter a number for the distance.

**See also:**

■ Changing Grading Command Settings (page 736)

**To create grading from a footprint**

1   Click Home tab ➤ Create Design panel ➤ Grading drop-down ➤ Grading Creation Tools .

2   Click and specify the grading group. Or create a new group.

3   Click to override the layer setting and then specify the layer for the grading.

4   Select a grading criteria for the grading from the list.

    If you have more than one set of named grading criteria, click to select the grading criteria set you want.

5   If the criteria you selected uses Surface as its target, specify which surface to target. The selected surface is displayed in the status bar of the layout toolbar. To select a different surface, click .

6   Select a grading style for the grading to use from the drop-down list.

    If you don't see the style selector, click to display the list of styles.

7   Click the arrow and then click Create Grading.

8   Click the footprint in the drawing. If you select a line, arc, or polyline, you are prompted to convert it to a feature line.

9   Click in the drawing to indicate the side of the footprint that you want to apply the grading. If you are grading from another grading's daylight line, you are not prompted for the grading side because only one side is available.

10  Specify whether the grading should be applied to the entire length of the line. To apply the grading to a subset of the line, enter n, then follow the command line prompts and on-screen arrows to specify the start and end points on the footprint.

    Depending on the criteria definition, you may be prompted to specify a distance and a slope value. For more information about the various options, see Criteria Tab (Grading Criteria Dialog Box) (page 1883).

11  Respond to any remaining prompts to complete the grading.

# Creating Grading by Copying an Existing Grading

Copy the criteria and style from an existing grading and apply it to a grading you create.

After selecting the grading from which to copy the criteria and style, create the new grading by selecting the footprint from which the grading is projected and selecting the side of the footprint from which to grade.

**To create grading by copying an existing grading**

1   Click Home tab ➤ Create Design panel ➤ Grading drop-down ➤ Grading Creation Tools  .

2   In the Grading Creation Tools (page 1892) dialog box, click the arrow next to  . Click  Copy Create Grading.

3   In the drawing, select the grading from which you want to copy the criteria and style.

4   Select the footprint in the drawing and select the side of the footprint from which to grade.

   If you are grading from another grading's daylight line, you are not prompted for the grading side because only one side is available.

5   Click in the drawing to indicate the side of the footprint to which you want to apply the grading.

   Depending on the criteria definition, you may have to specify a distance and a slope value. For more information about the various options, see Criteria Tab (Grading Criteria Dialog Box) (page 1883).

6   Specify whether you want to apply the grading to the entire length of the line. To apply the grading only to a region, enter n and then specify the start and end points on the footprint that define the region.

7   Respond to any remaining prompts to complete the grading.

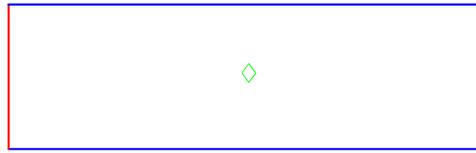
# Inserting a Transition

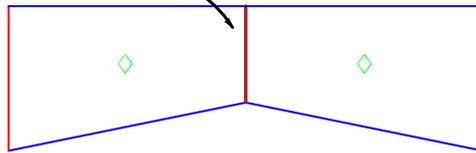
Add a transition to fill an area between two existing grading objects or to create a grading that has transitioning values.

A transition is an area that merges the grading of the regions on either side, for example, from 3:1 to 2:1.

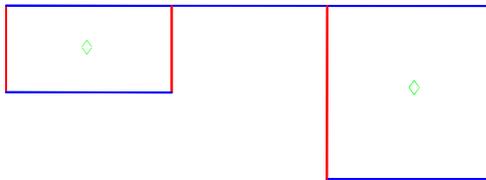
There are several ways to create transitions:

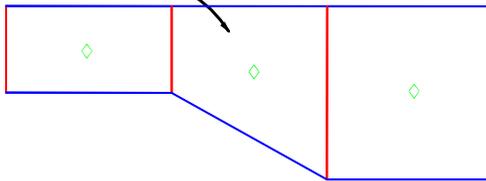
■  You can select a location within an existing grading.

existing grading


transition inserted


■ You can select a location between two existing gradings. The transition start and end points are defined by the existing projection lines.

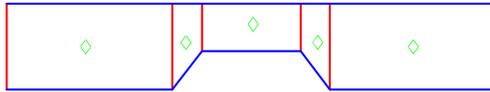
existing grading


transition inserted


■ You can select start and end points for the transition and then define the parameters to use at each end. You can use the same criteria for both ends or you can switch criteria.

In addition, you are sometimes prompted to create transitions when you use the Create Grading command. This occurs when the start point of a new grading is inside or touching an existing grading.

new grading insertion point

grading inserted and transitions created


**To insert a transition between existing gradings**

1  Click Home tab ➤ Create Design panel ➤ Grading drop-down ➤ Grading Creation Tools.

2  Click the arrow next to. Click Create Transition.

3  Select the feature line.

4  Click the location where you want to add the transition (between two existing regions).
   The transition is added and the grading is updated.

**To insert a transition within an existing grading**

1  Click Home tab ➤ Create Design panel ➤ Grading drop-down ➤ Grading Creation Tools.

2  Click the arrow next to. Click Create Transition.

3  Select the feature line.

4  Enter Points.

5  Select the grading side.

6  Select the location where you want to add the transition (within an existing grading). The station of the point you selected is displayed at the command line. You can change it or press Enter to accept the location.
   The transition is added and the grading is updated.

**To insert a transition by defining different criteria and values**

1  Click Home tab ➤ Create Design panel ➤ Grading drop-down ➤ Grading Creation Tools.

2  Click the arrow next to. Click Create Transition.

3  Select the feature line.

4  Enter Points.

5  Select the grading side.

6  Select the location where you want to add the transition. The station of the point you selected is displayed at the command line. You can change it or press Enter to accept the location.

7  Follow the prompts to define the criteria values for the start of the transition.

After you define the values, the following prompt is displayed:

```
Select the end point or [Criteria/Next/Previous/Both/Length]:
```

**8** Do one of the following:

■ Select the end point by clicking a location in the drawing. Then follow the prompts to define the criteria values for the end point.

■ Enter Length to specify a length for the transition. Then follow the prompts to define the criteria values for the end point.

■ Enter Criteria and select a different criteria to apply to the end point of the transition. If you select a criteria that is different from the criteria applied to the start point, the two are blended to create the transition.

---

**NOTE** The following three options are available only if other gradings exist on the footprint.

---

■ Enter Next to define the transition end point as the edge of the next grading on the footprint (up station).

■ Enter Previous to define the transition end as the edge of the previous grading on the footprint (down station).

■ Enter Both to straddle the grading transition between the next and previous grading edges on the footprint. This option overrides the selected start point.

Command Line

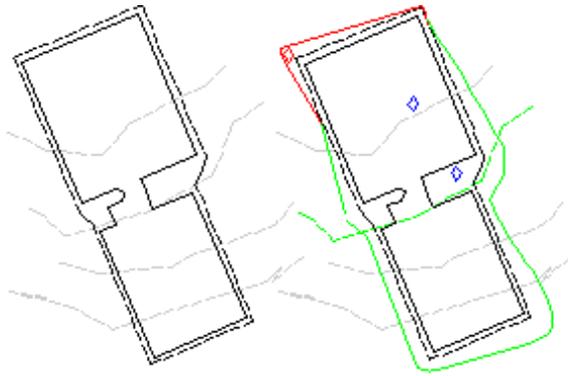
CreateGradingTransition

Dialog Box

Grading Creation Tools (page 1892)

# Filling a Void Area

Fill a hole in the site grading by creating a grading with no criteria applied to it.

Any area bounded by feature lines or lot lines that is not already a grading should be converted to an infill grading to ensure correct contour display and volume calculations.


**To fill a void area**

1 Click Home tab ➤ Create Design panel ➤ Grading drop-down ➤ Grading Creation Tools ⬛.

2 Click the arrow next to ⬛. Click ⬛ Create Infill.

3 Click the area that you want to fill. Valid areas that can be converted to infill are highlighted as you move the cursor over them.

The grading face is added and the grading is updated.

# Editing with Grips

Use grips to adjust the component lines in a grading by changing the footprint geometry or the grading components.

Click a projection line in a region. Then change the start or end station point for that region by using a grip to drag the line to another location.

| Component | Description |
| --- | --- |
| Feature lines | Grip appears at each vertex. Move the grip as you would when you edit a polyline. |
| Projection lines | Grip appears on projection lines. Slide the projection line along the footprint to change the start or end point of the region. |
| Elevation points | Grip appears at any location on a feature line or lot line to mark an intermediate elevation point. Move the point to its correct location. |

**To edit using grips**

**1** In the drawing, select the grading or feature line you want to edit.

**2** Click the grip. The grip turns red to show it is active

**3** Drag the grip to move the line.

Grips do not appear on grading component lines that are constrained or locked by the grading criteria.

# Deleting Gradings

Use the Delete Gradings  command to delete a grading.

Surfaces based on deleted grading objects remain in the drawing.

**To delete a grading**

**1** Select the grading. Click Grading tab ➤ Modify panel ➤ Delete Grading ◺ .

**2** Select a point in the grading or site to delete the grading object.

# Grading Properties

You can view and change grading group and grading properties.

# Grading Group Properties

Edits grading group properties.

These properties can be used to create the grading group and to control the surface properties of the grading group.

If you chose not to create a dynamic surface for the grading group when you created it, use the Grading Group Properties to create this surface. You can also specify the surface to use for volume calculations.

**To view and edit properties for a grading group**

1  In Toolspace, on the Prospector tab, expand the Site collection.

2  Expand the Grading Groups collection. Right-click the grading group you want to edit.

3  Click Properties to open the Grading Group Properties (page 1891) dialog box.

4  Change the properties on the Information tab, or click the Properties tab to review the settings, styles, criteria, and volumes for the grading group.

5  Click OK.

# Using Grading Utilities

You can use grading utilities to balance cut and fill volumes in a grading design, and to create a detached surface from a grading group.

# Displaying and Adjusting Surface Volumes

Use volume tools to display and adjust the elevation of a grading design.

You can change the elevation of either an entire grading group or a selection of grading objects. Use this command to optimize cut and fill requirements.

A dynamic surface must exist for the grading group and a Volume Base Surface must be specified in the Grading Group Properties to use most of the Grading Volume Tools.

---

**TIP** If you are designing a detention pond and want to size it by volume, it may help to create a temporary surface to use as the Volume Base Surface for comparison. To do this, draw a polyline around the pond rim, assign it the rim elevation, and add it as breakline data to a surface. When you use such a surface as the Volume Base Surface for the grading group, you can more easily see how much volume the pond can contain.

---

**To adjust cut and fill volumes**

1  Click Analyze tab ➤ Volumes And Materials panel ➤ Grading Volume Tools 🔷 .

2  In the Grading Volume Tools (page 1899), click 🔲 .

3  In the Select Grading Group (page 1900) dialog box, select a grading group or create a new one.

4  Optionally, click 🔲 to review and change properties for the grading group.

---

**NOTE** If you do not see the information displayed in the Cut, Fill, and Net volumes boxes, check the Grading Group Properties to ensure Automatic Surface Creation is selected and a Volume Base Surface is specified.

---

5  Select either Entire Group or Selection to identify the grading objects for which you want to raise or lower to make the volume adjustments. For Selection, click 🔲 and select objects in the drawing.

6  In the numeric field in the upper right of the Grading Volume Tools, enter the distance (typically feet or meters) by which the grading objects will be raised or lowered for each elevation adjustment.

**7** Do one of the following:

- To manually adjust the grading elevation, click  or  and note the changed values for cut, fill, and net volume.

- To automatically adjust the elevation to meet a net volume target, click . Enter the target volume in the Auto-Balance Volumes dialog box, then click OK. The elevation is adjusted several times, getting as close to the target as possible.

---

**NOTE** Automatic volume balancing is an iterative process, adjusting the gradings up or down in progressively smaller steps to achieve the target volume. Typically the resulting volume is not exactly what was entered as the target value. To prevent it from excessively adjusting and recomputing the volumes, it stops when the result is within a tolerance of 0.1% of the starting net volume. If the result is not close enough to your target volume, you can run the command again.

---

# Creating a Detached Surface from a Grading Group

You can create a detached or static surface from a grading group.

A detached surface does not update to reflect changes to the grading group.

If the Automatic Surface Creation setting is selected for the grading group, it maintains a dynamic surface that reflects changes.

If the grading group has a detached surface and a dynamic surface, it can be difficult to view and select one of the surfaces unless they are on different layers and using different styles.

**To create a detached surface**

**1** Click Home tab ➤ Create Ground Data panel ➤ Surfaces drop-down ➤ Create Surface From Grading .

**2** In the Select Grading Group (page 1900) dialog box, specify the site and the grading group.

**3** Click OK. The detached surface is created.

# Grading Command Reference

The following table lists the grading-related commands and briefly describes their functionality.

Run these commands by entering them directly at the command line.

| Command | Description |
|---|---|
| AddFeatureLineLabels | Adds line and curve labels to feature lines (page 787) |
| AdjacentFeatureElevsByRef | Sets adjacent feature line elevations by reference (page 762) |
| ApplyFeatureLineNames | Applies names to feature lines (page 746) |
| ApplyFeatureLineStyles | Applies feature line styles (page 746) |
| BreakFeatures | Breaks a feature line into two feature lines (page 784) |
| ChangeGradingGroup | Changes the grading group of the selected grading object (page 742) |
| Convert3dPolys | Converts 3D polylines to 2D polylines (page 789) |
| ConvertPlines | Converts 2D polylines to 3D polylines (page 789) |
| CopyCreateGrading | Creates grading by copying the criteria and style from an existing grading (page 792) |
| CreateDetachedGradingSurf | Creates a static surface from a grading group. (page 803) |
| CreateFeatureLines | Creates a feature line by converting existing objects (page 743) |
| CreateFeatureLineFromAlign | Creates a feature line by converting alignments (page 745) |
| CreateGrading | Creates grading from a footprint (page 791) |
| CreateGradingGroup | Creates a new grading group (page 741) |
| CreateGradingInfill | Fills a hole in the site grading with a grading face (page 797) |
| CreateGradingTransition | Inserts a transition between two existing regions (page 794) |
| DeleteElevPoint | Deletes elevation points (page 767) |

| Command | Description |
|---|---|
| DeleteFeaturePI | Deletes points of intersection (page 771) |
| DeleteElevPoint | Deletes feature line elevation points (page 767) |
| DeleteGradings | Deletes a point in a grading or site (page 799) |
| DrawFeatureLine | Draws a feature line (page 748) |
| EditFeatureCurve | Edits feature line curves (page 773) |
| EditFeatureElevs | Edits feature line or lot line elevations, using the command line (page 753) |
| EditGrading | Edits grading criteria, using the command line (page 794) |
| EditPlineElevs | Edits elevations of 2D polylines (page 790) |
| FeatureElevsFromSurf | Creates feature line elevations from a surface (page 768) |
| FeatureGradeExtensionByRef | Extends a grading by reference (page 763) |
| FeatureLineProperties | Specifies feature line style (page 801) |
| FeatureLineRemLinks | Removes feature line dynamic links (page 747) |
| FilletFeature | Rounds the corners of feature lines (page 776) |
| FitCurveFeature | Converts tessellated curves to true arcs for better grading results (page 777) |
| GradingEditor | Edits grading criteria, using the Editor (page 793) |
| GradingElevEditor | Edits feature line elevations, using the Grading Elevation Editor (page 753) |
| GradingTools | Opens the Grading Creation Tools (page 791) |
| GradingVolumeTools | Opens the Grading Volume Toolbar (page 802) |
| InsertFeatureElevPoint | Inserts an elevation point (page 765) |
| InsertFeatureHighLowPoint | Inserts high or low elevation points into feature lines (page 767) |
| InsertFeaturePI | Inserts points of intersection (page 769) |
| JoinFeatures | Joins multiple feature lines to create a single object (page 771) |
| OffsetFeature | Offsets feature lines at an elevational difference (page 783) |

| Command | Description |
| --- | --- |
| QuickEditFeatureElevs | Edits the elevations of a feature line by snapping to editable points in the drawing (page 754) |
| RaiseLowerFeatures | Raises or lowers feature line elevations (page 764) |
| RaiseLowerFeaturesByRef | Raises or lowers feature line elevations by reference (page 761) |
| ReverseFeature | Reverses the direction of feature lines for stationing purposes (page 772) |
| SetFeatureGrade | Specifies the grade or slope between selected points on a feature line (page 758) |
| SetFeatureRefElev | Sets the feature line elevation in relation to an existing elevation in the drawing (page 759) |
| SmoothFeature | Smooths out jagged feature lines (page 779) |
| TrimFeatures | Trims a feature line (page 785) |
| WeedFeatures | Deletes vertices and elevation points from feature lines (page 781) |

# Parcels

# 22

AutoCAD Civil makes it easy to design subdivisions by providing a site topology that includes intelligent parcel objects, which maintains relationships between objects so your design changes are dynamically updated.

Parcels Workflow

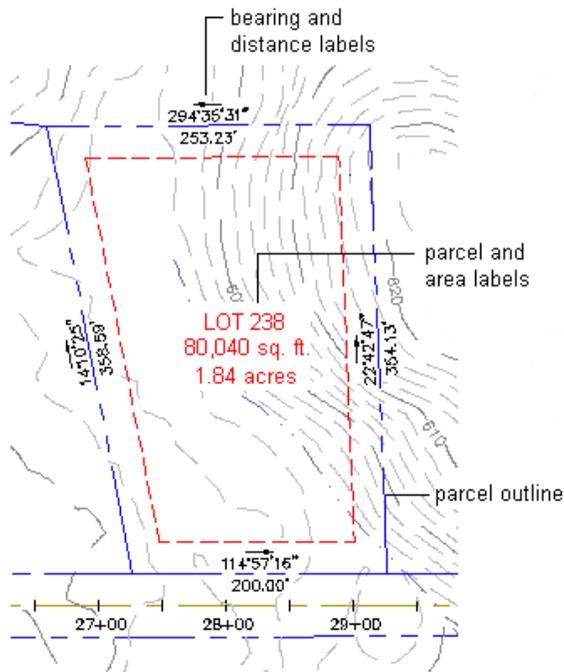
Parcels Best Practices

## Understanding Parcels

Parcel objects in AutoCAD Civil are typically used to represent real estate parcels, such as lots in a subdivision.

Parcel objects can also represent other features with closed boundaries, such as bodies of water and soil regions.

## Parcel Components

A parcel boundary is a closed polygon. The points where line segments join are called nodes. There are two segment types: line and curve.


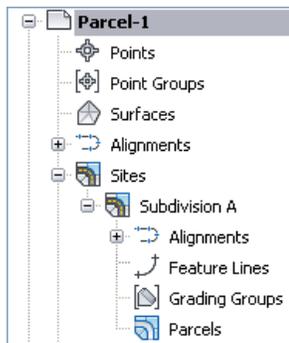
Each parcel has an area label, which refers to the parcel as a whole. You can click the area label to select the parcel. A parcel can also have segment labels, and associated tables, which display information about the parcel. Labels can contain user-defined property fields.

Each parcel maintains information about its segments and nodes, and the area they enclose. If you change one component, related components are updated.

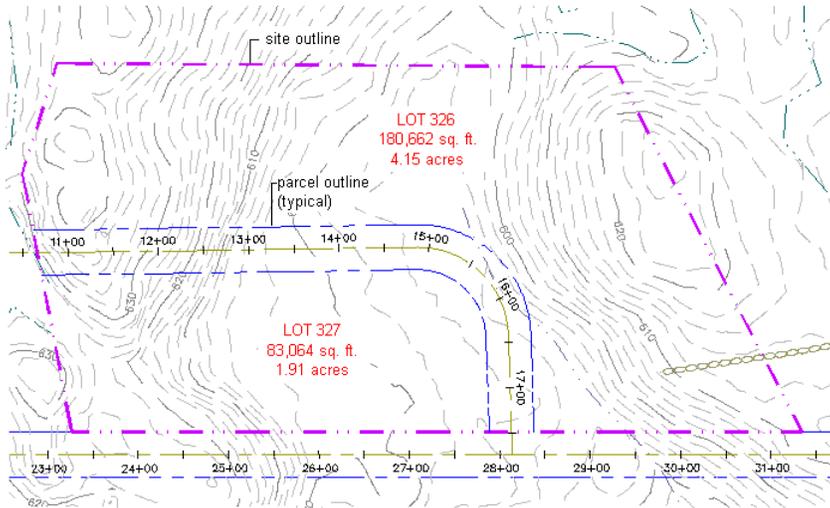
# Parcel Collections

Parcels are contained in a parcels collection, which in turn is contained in a site.

A drawing can include any number of sites, but each site has only one parcels collection. No unique parcel can belong to more than one site. You can see these relationships in the Sites collection in Toolspace, on the Prospector tab:



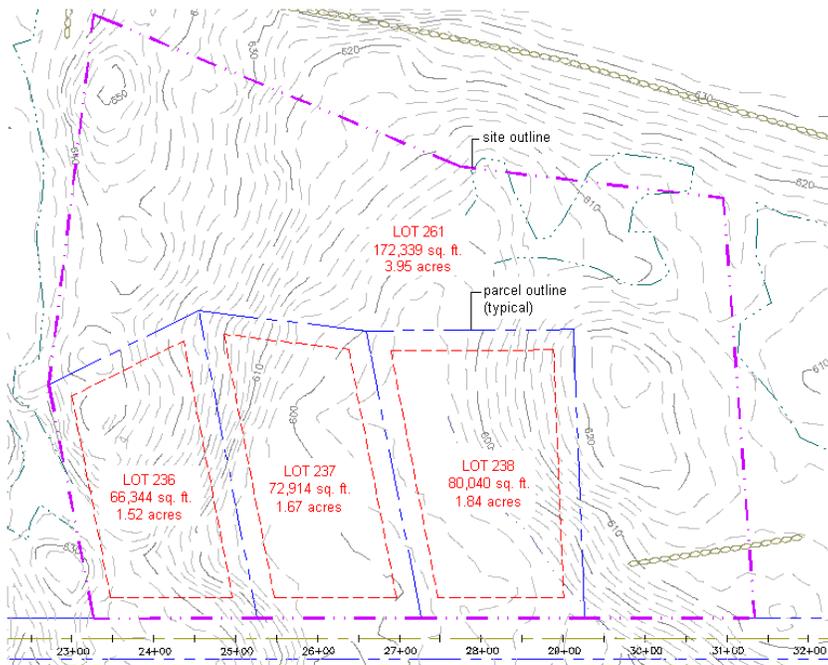
For more information about Parcels collections, see Parcels Collections (Prospector Tab) (page 811).

Parcels in a collection can be either unattached or touching, but they cannot overlap. If you attempt to overlap two parcels, the region of overlap defines a third parcel. Similarly, if an alignment crosses a parcel, it divides the parcel into two parcels. In the following illustration, before adding the alignment, the site was all one parcel:


In situations that require overlapping parcels, such as overlaying a subdivision with soil regions, you can put the subdivision parcels in one site and the soil region parcels in another site. Multiple sites can overlay one another because their topologies are independent. Although everything within a site is topologically related, sites are not topologically related to each other.

**NOTE** To prevent an alignment from changing a parcel, the two objects should be in different sites. To prevent an alignment from interacting with any parcel objects, select <none> when prompted to select a site. See Understanding Alignment Objects (page 855).

# Site Parcels

Associated with every site is a site parcel. The site parcel boundary is the outermost extent of a site, containing all alignments, gradings, and parcels. Objects within a site parcel do not have to touch.


The site parcel has an area label, which you can hide or show. You can control the color and line type of the site parcel boundary, and you can control its draw order relative to the boundaries of the parcels that it encloses.

For the purposes of calculating the area and perimeter of a site, an alignments area is zero and its perimeter is twice the sum of its length. Adding an alignment does not affect a site parcels area, but can add to its perimeter. If you add an alignment to an existing site

- With *none* of the alignment overlaying the original site parcel, the site parcels perimeter increases by twice the length of the alignment.

- With *all* of the alignment overlaying the original site parcel, the site parcels perimeter does not increase.

- With *some* of the alignment overlaying and some of it projecting, the site parcels perimeter increases by twice the length of the part that projects.

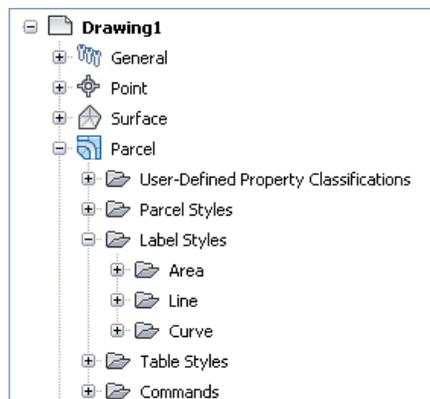
In some circumstances, an unclosed sequence of parcel segments can define a valid parcel. With such a parcel, as with an alignment, its area is zero, and its perimeter is twice the sum of its segment lengths.

# Parcel Styles

Use styles to control the appearance of parcels, their labels, and their tables.

The Standard style is provided by default. Define additional styles as needed.

View the available parcel styles in the Parcels collection in Toolspace, on the Settings tab:



For more information about the Parcel collection, see Parcel Collection (Settings Tab) (page 812).

You can create, modify, copy, rename, or delete any style, including the Standard style, by right-clicking a style in the Parcel tree and then clicking an item on the shortcut menu. Note, however, that you cannot delete a style that is in use.

| For more information about ... | Follow this link ... |
|---|---|
| Setting up styles for a project | Setting up Parcels |
| Parcel styles | Parcel Styles (page 828) |
| Parcel label styles | Parcel Label Styles (page 833) |

# Parcel Settings

Use Parcel settings to specify default styles and other default properties for new parcels.

To set or change parcel settings, go to the Toolspace Settings tree and right-click Parcels ➤ Edit Feature Settings.

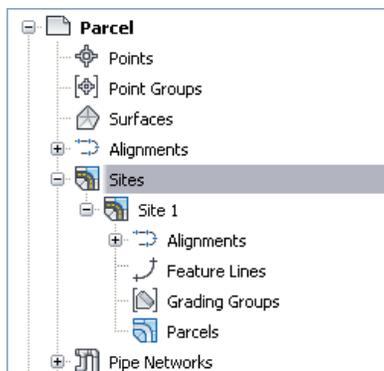
For more information about the Parcel collection, see Parcel Collection (Settings Tab) (page 812).

For more information about parcel settings, see Parcel Settings (page 824).

# Parcel Properties

Use Parcel properties to view or edit details of existing parcels.

To view or edit parcel properties, go to the Toolspace Prospector tab, right-click a parcel and click Properties. The following illustration shows two parcels: OPEN SPACE 100, and OPEN SPACE 101:



For more information parcel collections, see Parcels Collections (Prospector Tab) (page 811).

You can also right-click a selected parcel in a drawing, then click Parcel Properties. To select a parcel, click the text of its area label. If you have selected it correctly, the label text and its anchor point are highlighted. If the area label is not visible, see Hiding or Showing Parcel Labels (page 842).

For more information about parcel properties, see Parcel Properties (page 825).

# Parcels Collections (Prospector Tab)

Use the Parcels collections in the Prospector tree to access the parcels in a drawing.

Each parcel in a site is displayed as a named object under the Parcels collection of the site. Right-click a Parcels collection to do the following:

■  Edit properties of the collections site parcel (page 825).

■  Move or copy parcels to another site (page 726).

■  Zoom or pan to the collections site parcel in the drawing (page 819).

■  Generate a parcels report.

- Export parcels to LandXML format.

- Refresh the view of the Prospector tree.

Expand the Parcels collection to view the names of the parcels and to display a tabular list of the parcels in the Toolspace item view. For more information, see The Toolspace Item View (page 82).

## Parcel Collection (Settings Tab)

Use the Parcel collection in the Settings tree to manage parcel settings, styles, and command settings.

Right-click the Parcel collection to do the following:

- Edit parcel settings (page 824).

- Edit parcel label style defaults (page 832).

- Refresh the display of the Settings tree.

Expand the Parcel collection to display and edit the styles and command settings that are available for parcels.

| For more information about ... | Follow this link ... |
| --- | --- |

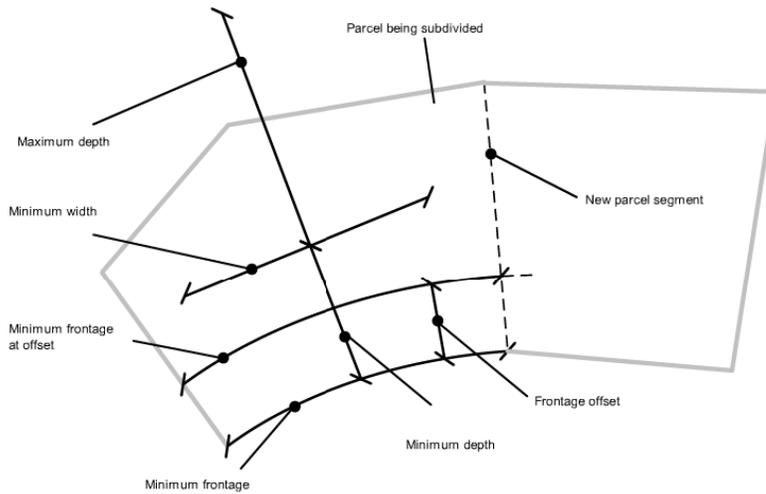
| Parcel Label Styles | Parcel Label Styles (page 833) |
| Parcel Table Styles | Parcel Table Styles (page 843) |
| Parcel Commands | Parcels Command Reference (page 853)<br>Editing Parcel Command Settings (page 825) |

## Creating Parcels

Create parcels from drawing objects, by layout, or by subdividing an existing parcel.

When you create parcels from drawing objects, ensure that they have no drawing errors that would make them invalid topology sources. Use the drawing cleanup tools in Autodesk Map. When you create parcels by layout, you draw parcel segments directly.


**You can define parcel sizing criteria when creating or editing parcels by subdividing existing parcels.**

# Parcel Design Considerations

Before creating parcels, identify the different types of parcels you need and decide how to display them so that different types are visually distinct.

You can design styles for parcels, labels, and tables. These styles control the appearance of the parcels and the information displayed in labels and tables. For more information, see Parcel Labels and Tables (page 831).

You may want to design more than one style for a given parcel type. For example, if your project drawings are consulted by several different users who want to see different information emphasized, use styles to provide customized views of the same drawing. Information that is visible in one set of styles can be hidden, de-emphasized, or emphasized in another.

After you design the required styles, you can save them in a drawing template. When you create a new drawing, you can base it on the template, which makes every style in the template available in the new drawing. The necessary styles for a project typically include parcel styles, area label styles, segment label styles, and table styles.

Extend the styles concept by using drawing layers to manage how features display. For example, a parcel style has a segment layer property, which assigns segments to a particular layer, and a segment color property. Specify the segment color property of a parcel style explicitly, or specify it By Layer, which lets you change the color of many segments at once by changing the color of their layer. As you can with styles, save layer definitions in a drawing template.

# Default Settings for New Parcels

The default properties for new parcels determine how new parcels are displayed. For more information, see Parcel Settings (page 824).

When you initiate a parcel creation session, you open the Create Parcels (page 2005) dialog box. This dialog box displays the default settings for new parcels. You can revise these settings before you create any parcels.

**To set how new parcels display**

1   Click Home tab ➤ Create Design panel ➤ Parcel drop-down ➤ Create Parcel From Objects ⬚ .

**2** If you clicked Create Parcel From Objects, click objects in the drawing to select them. When you finish, press Enter.

This step occurs only if you are creating from objects.

**3** In the Create Parcels (page 2005) dialog box, you can edit default settings before creating any parcels.

## Creating Parcels From Objects

Create parcels from AutoCAD objects by defining a selection set of objects in the drawing.

AutoCAD objects that you can convert to parcels include polygons, closed polylines, and other closed sequences of lines or arcs.

Select objects in the current drawing or from an xref. The objects you select must be free of drawing errors, such as gaps at intersection points.

---

**TIP** To remove drawing errors from source geometry, use the drawing cleanup tools in Autodesk Map before you import the objects.

---

**To create parcels from objects**

**1** Make sure that the AutoCAD objects that you are converting to parcels are free of drawing errors.

**2** Click Home tab ➤ Create Design panel ➤ Parcel drop-down ➤ Create Parcel From Objects .

**3** Click objects in the drawing to select them. When you finish, press Enter.

**NOTE** You can enter **xref** to select an object from an xref. The xref command supports multiple selections.

4 In the Create Parcels (page 2005) dialog box, you can edit default settings before creating any parcels. Click OK and the parcels are created.

## Quick Reference

# Creating Parcels by Layout

Use the Parcel Layout Tools toolbar to create parcels.

The toolbar provides two types of parcel creation tools:

■ Freehand tools draw parcels as a network of lines, curves, and polylines.

■ Precise sizing tools control the angles and directions of lot lines.

You can also set default values for the parcel sizing parameters and the Automatic Layout options.

**TIP** Object Snap can be very useful when creating parcels, especially with the freehand tools. Use Object Snap to attach lines exactly to existing endpoints and vertices.

**NOTE** Using the layout tools is the only activity possible while the Parcel Layout Tools toolbar is open.

**See also:**

■ Parcel Layout Tools (page 2009)

■ Editing Parcels by Layout (page 820)

**To create parcels by layout**

1 Click Home tab ➤ Create Design panel ➤ Parcel drop-down ➤ Parcel Creation Tools  .

2 Click a parcel layout tool.

In the Create Parcels - Layout (page 2005) dialog box, you can edit default settings before creating any parcels.

3 Specify a site with which to associate the parcel or accept the default <None>. For more information, see Understanding Sites (page 719).

4 Specify a parcel style or accept the default style.

**5** Specify the Object Layer Setting.

**6** Specify the Parcel Label Set or accept the default. Click OK.

**7** Use the commands on the Parcel Layout Tools toolbar to create the parcel.

Dialog Box

Create Parcels by Layout (page 2005)

Dialog Box

Parcel Layout Tools (page 2009)

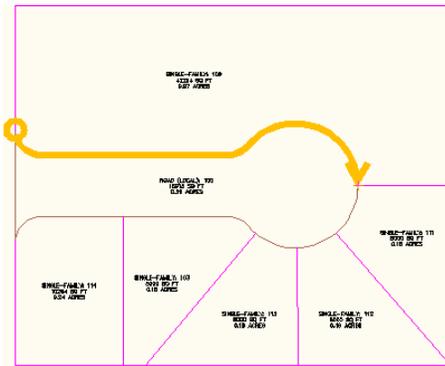
# Creating Parcels by Subdividing

Use the Parcel Layout Tools toolbar to create parcels by subdividing existing parcels.

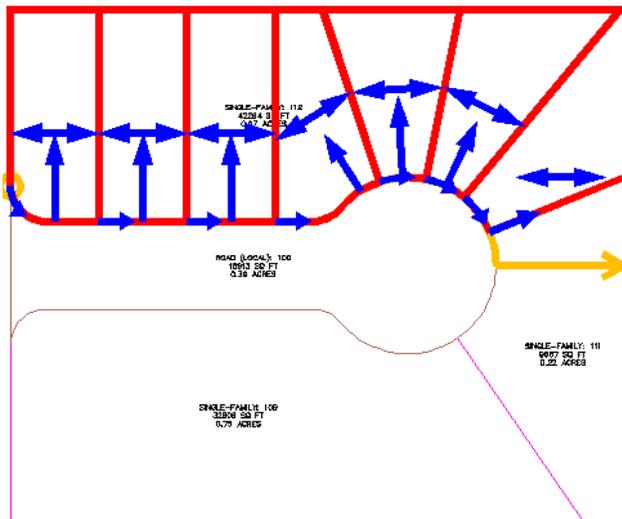
When you add a new lot line to an existing parcel, you can specify the size of the new parcel and the method with which to move the lot line. You can insert a new free-form lot line or choose one of the following types that move across the parcel in a controlled manner:

■ Slide Line. Holds either a fixed angle to the frontage or an absolute direction.

■ Swing Line. Fixed at one end and swings across the parcel frontage

When creating or editing parcels with the Parcel Layout Tools, preview graphics display the proposed solution which results from the specified layout parameters used to define parcel components such as minimum parcel frontage, width, and depth. As you use the tools to determine the design of proposed new parcels, these graphics display to illustrate the proposed solution, and you are prompted to either accept or reject the solution. When you modify the layout parameters, the graphics update dynamically while the Parcel Layout Tools toolbar is open and the parameters are being edited. For more information, see Parcel Layout Tools (page 2009).


**Proposed frontage is highlighted.**



**Preview graphics display proposed layout solution based on parcel sizing parameter values.**

**See also:**

■ Parcel Layout Tools (page 2009)

**To create parcels by subdividing with the Slide Line - Create command**

**1** Click Home tab ➤ Create Design panel ➤ Parcel drop-down ➤ Parcel Creation Tools ⊞ .

**2** On the Parcel Layout Tools toolbar, click ⏷ to expand the toolbar. Specify the Parcel Sizing and Automatic Layout parameters for the new parcel.

**3** Click ⊡ for the Slide Line - Create tool.

**4** In the Create Parcels – Layout (page 2005) dialog box, specify any changes to the default settings. Click OK.

**5** Click the Parcel Selection Area label to select the parcel or enter p and then click inside the parcel.

**6** Click the start point on the parcel frontage.

**7** Click an end point along the frontage. A preview graphic highlights the proposed frontage.

**8** Specify the angle, bearing or azimuth to place the new lot line. Preview graphics display if a solution can be obtained.

> **NOTE** When prompted for the angle, bearing or azimuth, you can press Enter to enter the default 90 degree angle.

**9** Accept the result to edit the parcel. If a solution based on the current parcel sizing parameter values is not found, you are prompted to adjust the parameters or reenter a new value for the method you are using.

**10** Optionally, continue creating lot lines by repeating Steps 5-9. When you finish, press Esc.

**To create parcels by subdividing with the Swing Line - Create command**

**1** Click Home tab ➤ Create Design panel ➤ Parcel drop-down ➤ Parcel Creation Tools .

**2** On the Parcel Layout Tools (page 2009) toolbar, click to expand the toolbar. Specify the Parcel Sizing parameters and Automatic Mode options for the new parcel.

**3** Click for the Swing Line - Create tool.

**4** In the Create Parcels – Layout (page 2005) dialog box, specify any changes to the default settings. Click OK.

**5** Select the parcel to subdivide.

**6** Click the start point on the parcel frontage.

**7** Click an end point along the frontage. A preview graphic highlights the proposed frontage.

**8** Specify the swing point. Preview graphics display if a solution can be obtained.

**9** Accept the result to subdivide the parcel. If a solution based on the current parcel sizing parameter values is not found, you are prompted to adjust the parameters, select a new point, or exit the command.

**10** Optionally, continue creating lot lines by repeating Steps 4-10. When you finish, press Esc.

### Quick Reference

Ribbon

Click Home tab ➤ Create Design panel ➤ Parcel drop-down ➤ Parcel Creation Tools

Menu

Parcels menu ➤ Edit Parcel ➤ Edit Parcel Segments

Dialog Box

Parcel Layout Tools (page 2009)

# Editing Parcels

Edit parcels to change their size, shape, or display properties.

Edit parcels in three main ways:

- Use drafting tools. Click Home tab ➤ Create Design panel ➤ Parcel drop-down ➤ Parcel Creation Tools ▧ . and use the Parcel Layout Tools (page 2009).

- Change properties and labels. Click the area label to select the parcel, then right-click and select a menu option.

- Grip edit. Click lot lines and drag their nodes to new positions.

# Locating Parcels in a Drawing

Before you can select a parcel, locate it in the drawing. Locate it by selecting the parcel in the Parcels collection in Toolspace, on the Prospector tab, and then zooming or panning to it in the drawing.

**To locate a parcel**

1 In Toolspace, on the Prospector tab click Sites ➤ Parcels.

2 Right-click a Parcel. Click Zoom To or Pan To.

   To zoom or pan to the site parcel, right-click the Parcel. Click Zoom To or Pan To.

### Quick Reference

Toolspace Shortcut Menu

   Prospector tab: Parcel ➤ Zoom To or Pan To

# Changing Parcel Appearance

Control parcel display by changing parcel styles or their label styles.

Within a given site, you can change the display order of the site parcel and the parcels that it contains.

| To change a parcels appearance by... | See this topic... |
| --- | --- |
| Editing parcel styles | Editing Parcel Styles (page 828) |
| Editing parcel label styles | Editing Parcel Label Styles (page 834) |
| Replacing parcel styles | Applying Parcel Styles (page 829) |
| Replacing parcel label styles | Applying Parcel Label Styles (page 837) |
| Changing display order | Changing Parcel Display Order (page 827) |

# Editing Parcels by Layout

Use the Parcel Layout Tools toolbar to edit parcels.

The toolbar provides tools for creating and editing parcels. For information about tools for parcel creation, see Creating Parcels by Layout (page 815).

The toolbar provides two types of parcel editing tools:

- **Precise sizing tools** control the angles and directions of lot lines.
- **Freehand tools** modify parcel geometry.

You can also modify settings for the Parcel Sizing parameters and Automatic Layout options.

Using layout tools is the only activity possible while the Parcel Layout Tools toolbar is open.

**See also:**

- Parcel Layout Tools (page 2009)

**To edit parcels by layout**

1 Click Home tab ➤ Create Design panel ➤ Parcel drop-down ➤ Parcel Creation Tools .

2 Click a parcel segment to indicate the site you will be editing.

3 Click a parcel layout tool.

When you finish, press Enter or click another tool. After pressing Enter (which puts a tool away without selecting another), you can press Enter again to continue with the same tool.

4 When you finish editing parcels, press Esc to close the toolbar. (If one of the layout tools is still in use, press Esc twice.)

Using layout tools is the only activity possible while the Parcel Layout Tools toolbar is open.

# Editing Subdivided Parcels

Use the Slide Line and Swing Line edit commands to edit subdivided parcels.

You can use the Slide Line and Swing Line edit commands to edit attached lot lines. Attached lot lines are parcel segments that were created with the Parcel Layout Tools subdivision commands.

Using layout tools is the only activity possible while the Parcel Layout Tools toolbar is open.

**See also:**

■ Parcel Layout Tools (page 2009)

**To edit parcels by subdividing with Slide Line - Edit command**

1 Click Home tab ➤ Create Design panel ➤ Parcel drop-down ➤ Parcel Creation Tools  .

2 Click  for the Slide Line - Edit tool.

3 In the Create Parcels - Layout dialog box, adjust default settings and press OK.

4 Select the attached lot line to adjust.

5 Click inside the parcel to be edited.

6 Click the start point on the parcel frontage.

7 Click an end point along the frontage. A preview graphic highlights the proposed frontage.

Specify the angle, bearing or azimuth to edit the lot line. Preview graphics display if a solution can be obtained.

**NOTE** When prompted for the angle, bearing or azimuth, you can press Enter to enter a 90 degree angle as this is the default angle.

8 Accept the result to edit the parcel. If a solution based on the current parcel sizing parameter values is not found, you are prompted to adjust the parameters or reenter a new value for the method you are using.

9 When you finish editing parcels, press Esc to close the toolbar. (If one of the layout tools is still in use, press Esc twice.)

**To edit parcels by subdividing with Swing Line - Edit command**

1 Click Home tab ➤ Create Design panel ➤ Parcel drop-down ➤ Parcel Creation Tools  .

2 Click  for the Swing Line - Edit tool.

3 In the Create Parcels - Layout dialog box, adjust default settings and press OK.

4 Select the attached lot line to adjust.

5 Click inside the parcel to be edited.

6 Click the start point on the parcel frontage.

7 Click an end point along the frontage. A preview graphic highlights the proposed frontage.

**NOTE** OSNAP must be turned off when using the Swing Line commands.

8 Specify the swing point. Preview graphics display if a solution can be obtained.

9 Accept the result to edit the parcel. If a solution based on the current parcel sizing parameters values is not found, you are prompted to adjust the parameters or reenter a new value for the method you are using.

10 When you finish editing parcels, press Esc to close the toolbar. (If one of the layout tools is still in use, press Esc twice.)

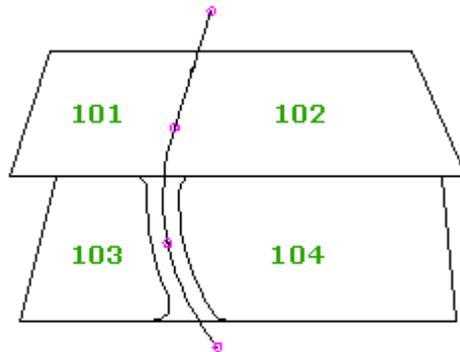
# Creating a Right of Way

Use the Create ROW command to create a right of way along an alignment.

Parcels and adjacent alignment must be in the same site. Parcel boundaries are offset a specified distance from the alignment.

Optionally, specify a radius for fillets at intersections with other objects. The following illustration shows a right of way created between parcels 103 and 104 with fillets at intersections with parcel boundaries.



The right of way is like a narrow parcel, but it is not dynamically linked to the alignment. If you move or edit the alignment you must create the right of way again.

When you run the Create ROW command, you are prompted to select one or more parcels. If an alignment is found in the site and along an edge of the selected parcels, a right of way is created in accordance with the supplied parameters.

**To create a right of way**

1   Click Home tab ➤ Create Design panel ➤ Parcel drop-down ➤ Create Right Of Way .

2   Select one or more parcels in the drawing and press Enter.

3   In the Create Right of Way (page 2020) dialog box, specify the offset distance from the alignment to the parcel boundaries.

4   If you want corner fillets at parcel boundaries along the right of way, select this option. Specify a radius.

5   If you want corner fillets at intersections with other alignments and rights of way, select this option. Specify a radius.

**6** Click OK.

# Editing Parcel Geometry and Parcel Elevations

Use the feature line editing commands to edit parcel geometry and parcel elevations.

You can access these commands by selecting a parcel and then selecting either the Edit Geometry or Edit Elevations panels to access the commands. For more information, see Editing Feature Lines (page 751).

# Parcel Settings

Parcel settings include settings for parcels, parcel commands, and parcel labels.

This section includes information about parcel settings and parcel command settings. For information about Parcel label settings, see Parcel Label Settings (page 832).

# Editing Parcel Settings

Parcel settings specify the default properties for new parcels. Edit parcel settings in the Parcel collection, in Toolspace on the Settings tab.

**To edit parcel settings**

1   In Toolspace, on the Settings tab, right-click Parcel ➤ Edit Feature Settings.

2   In the Edit Feature Settings dialog box, edit parcel settings.

### Quick Reference

# Parcel Properties

Properties define each parcel in a drawing.

Properties control everything about a parcel except its segment label styles. A site parcel has an additional property that specifies the display order of parcels within the site, including the site parcel itself.

For information about replacing parcel segment label styles, see Applying Parcel Label Styles (page 837).

# Editing Parcel Properties

Edit parcel properties to work with styles and other basic parcel attributes.

You can edit the properties of a single parcel, or a group of parcels. In each case, you can change the parcel style, area label style, and user defined properties such as parcel number and address.

Some typical editing tasks are as follows:

■   Replace a parcel's style, which governs the appearance of the parcel itself.

- Replace a parcel's area label style, which governs the appearance of its area label and the information displayed in the label.

- View information about the parcel segments.

- Specify the parcel's Point Of Beginning, which is the parcel boundary's initial node (start point of its initial segment).

- Renumber parcels to reset their starting and increment values and/or rename a parcel based on the parcel name template.

- Change parcel display order to set the properties of shared segments (such as color) when the two parcels sharing it have different properties.

Edit parcel properties by right-clicking a parcel area label in the drawing, or by right-clicking a parcel in Toolspace on the Prospector tab (or a Parcels collection for a site parcel).

**To edit properties of one parcel**

1   Click the text of the parcels area label.

    If the parcels area label is not visible, see Hiding or Showing Parcel Labels (page 842).

    If you have selected the label correctly, the label text and its anchor point are highlighted. Selecting the area label also selects the parcel.

2   Right-click and click Parcel Properties.

3   In the Parcel Properties (page 2015) dialog box, edit parcel properties.

**To edit properties of multiple parcels**

1   Click Parcel tab ➤ Modify panel ➤ Parcel Properties drop-down ➤ Parcel Properties 📑 .

2   The current site is displayed and the following prompt is displayed:

    `Start point or [Polyline/All/Site]:`

3   Do one of the following:

    - Select a start and end point to draw a path through the desired parcels.

    - Select **Polyline**, to select a polyline that crosses through the desired parcels. The polyline prompt will repeat until you hit **Enter** to end the command.

    - Select **All**, to select all parcels and open the Edit Parcel Properties (page 2008) dialog box.

    - Select **Site**, to open a Select Object (Site) dialog box with which to select another available site. After selecting a site, start back at Step 2.

4   In the Edit Parcel Properties dialog box, edit the parcel properties.

# Changing Parcel Display Order

Control parcel style display order, which is a property of the site parcel.

Display order affects the display of all parcel segments that are shared by two parcels of different styles. The style that is higher in the display order controls the actual display.

Edit the parcel style display order as a property of the site parcel, using the Composition Tab (page 2017) of the Site Parcel Properties dialog box. Access this dialog box by right-clicking either the site parcels area label or the Parcels collection in the Toolspace on the Prospector tab.

**To change parcel display order**

1   Click the site parcels area label in the drawing.

    If the parcels area label is not visible, see Hiding or Showing Parcel Labels (page 842).

    If you have selected the label correctly, the label text and its anchor point alone are highlighted. Selecting the area label also selects the parcel.

2   Right-click and click Parcel Properties.

3   In the Site Parcel Properties dialog box, click the Composition tab.

4   On the Composition tab, under Parcel Style Display Order, change the list positions of styles listed there.

    To change a styles list position, select it. Click the Up or Down Arrow. You can also drag a style to a new position. When you click Apply or OK, the parcels are redrawn, starting with the styles at the bottom of the list and working up to the top.

## Quick Reference

# Parcel Styles

Parcel styles govern how parcels are displayed in a drawing. Create, edit, or delete parcel styles in the Parcel collection in Toolspace, on the Settings tab.

You can create an entirely new parcel style, or base it on an existing style.

The default Standard parcel style is always available. If you base a new drawing on a drawing template, the styles defined in the template are available also.

## Creating Parcel Styles

Create parcel styles in the Parcel collection in Toolspace, on the Settings tab.

**To create a parcel style**

1  In Toolspace, on the Settings tab, expand the Parcel collection.

2  Right-click Parcel Styles and click New.

3  In the Parcel Styles dialog box, name the new style and define the style settings.

### Quick Reference

## Creating Parcel Styles Based on Other Styles

Create a new parcel style by copying and modifying an existing style in the Parcel collection in Toolspace on the Settings tab.

**To create a parcel style based on another style**

1 In Toolspace, on the Settings tab, expand Parcel ➤ Parcel Styles.

2 Right-click the style that the new style will be based on and click Copy.

3 In the Parcel Styles dialog box, name the new style.
The settings for the new style will be the same as the settings of the style that you copied.

4 Modify style settings.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click a parcel style ➤ Copy

Dialog Box

## Applying Parcel Styles

Apply a different style to a parcel any time that you want to change its appearance or indicate a change in the type of parcel.

The two components of a parcel style that display are the parcel segment line and the area fill. Area fill is a hatch pattern that you can apply to the entire parcel area, or use to mark a border around the inside of the parcel boundary. You can set a fill distance to define the width of the filled border.

For information about applying parcel styles during the creation process, see Default Settings for New Parcels (page 813).

**To apply a parcel style to an existing parcel**

1 In the drawing, click a parcel area label to select the parcel.
If the label is not visible, see Hiding or Showing Parcel Labels (page 842).
If you have selected the label correctly, the label text and its anchor point are highlighted.

2 Right-click, then click Parcel Properties.

3 In the Parcel Properties dialog box, click the Information tab.

4 On the Information tab, under Object Style, specify the parcel style you want to apply.

### Quick Reference

Ribbon

Select the parcel. Click Parcel tab ➤ Modify panel ➤ Parcel Properties drop-down ➤ Parcel Properties 

Object Shortcut Menu

Parcel object ➤ Parcel Properties

Toolspace Shortcut Menu

Prospector tab: Parcel ➤ Properties

Dialog Box

Parcel Properties (page 2015)

## Deleting Parcel Styles

Delete parcel styles in the Parcel collection in Toolspace on the Settings tab.

**NOTE** The Standard style can only be deleted if it is not being referenced by an existing parcel.

**To delete a parcel style**

1  In Toolspace, on the Settings tab, expand Parcel ➤ Parcel Styles.

2  Right-click the style that you want to delete, then click Delete.
   Delete is unavailable for any style that is used in the drawing.

### Quick Reference

Toolspace Shortcut Menu

# Exporting a Parcel Inverse or Mapcheck Report

You can export an inverse or mapcheck report for a single parcel, for a selection of parcels, or for all site parcels at the same time.

You can access the Export Parcel Analysis (page 2019) dialog box from three locations within the Prospector tree: the main Parcels node, from individual parcels, or by selecting multiple parcels from the Parcel list view.

To export all of the parcels in a site, you can access the Export Analysis command from the main Parcels node.

To export an individual parcel report, right-click a parcel under the Parcels node.

To export a selection of parcels, use Ctrl-click to select multiple parcels from the Parcel list view that appears below the Prospector tree when the Parcels node is selected.

To run a Mapcheck Analysis on parcel labels, select the parcel labels and click Analyze tab ➤ Ground Data panel ➤ Survey Drop-down ➤ Mapcheck. For more information, see Performing a Mapcheck Analysis (page 1608).

**To export an inverse or mapcheck report**

1   In Toolspace, on the Prospector tab, do one of the following:

■ Expand a site and right-click the Parcels node.

■ Expand a site and expand the main Parcels node, and then right-click an individual parcel.

■ Use Ctrl-click to select multiple parcels in the Parcel list view and right-click.

2   Select Export Analysis.

3   In the Export Parcel Analysis (page 2019) dialog box, specify the path to where the file will be exported and saved. Enter the path or click 🗁 to browse to a location.

4   Select the analysis type.

5   Select or clear the Enable Mapcheck Across Chord check box.

6   Select the segment order.

7   Click OK.

## Quick Reference

Dialog Box

Export Parcel Analysis Dialog Box (page 2019)

# Parcel Labels and Tables

Both parcel labels and tables display parcel information.

Labels display information within the parcel or adjacent to the component they describe. Tables are constructed with one row for each parcel or component.

Parcels always have area selection labels. Segment labels are optional. You can label parcel segments when you create them or at any time afterward.

Styles control the appearance of labels and tables and the information they contain.

### Using Labels and Tables

Display parcel information in labels only, or in both labels and tables. Parcel tables are optional, but useful for organizing data when you work with a large number of parcels.

Parcel line, curve, and area labels that are added to already created parcels are now individual objects, not sub-objects of the parcel. These parcel labels can be controlled with the AutoCAD Properties palette. The first area label that is automatically created when the parcel is created is a sub-entity of the parcel and is used to select the parcel. This parcel selection label cannot be deleted.

If you want to use parcel tables, all parcels and segments to be included in a table require a label that displays a unique table tag. This tag serves as a unique identifier for the object in the drawing and in the table. The label can include additional information, but the tag is essential.

General line and curve label styles can be applied to parcel segment labels. As a result, when creating parcel tables, you can select general line/curve label types and/or parcel segment labels. You can select any parcel

segment labels that use line/curve styles. Or you can use any line or curve label that is applied to a line, curve, feature line, or polyline segment.

For more information about parcel labels, tables, and table tags, see Parcel Label Styles (page 833), Adding Parcel Tables (page 845), and Parcel Numbering and Naming (page 849).

### More About Labels and Tables

The topics in this section provide information about labels and tables in a parcels context. For information about labels in general, see Labels and Tags (page 1463). For information about tables, see Tables (page 1555). For information about modifying labels, see Modifying Labels in a Drawing (page 1533).

# Parcel Label Settings

Parcel label settings provide default settings for parcel label styles.

Global settings apply to parcel label styles of every type; label-type settings apply only to parcel label styles of a given type, such as area label styles.

Individual label styles inherit from label-type settings, which in turn inherit from global settings. You can override inherited settings at lower levels. Also, you can block overrides by locking settings at higher levels.

If a parcel label setting is changed at a higher level, the change is propagated downward except where it is overridden. The change affects all styles that inherit it, and all labels in the drawing that use those styles.

## Editing Global Settings for Parcel Label Styles

Global settings affect parcel label styles of every type. Edit these settings in the Parcel collection in Toolspace, on the Settings tab.

### To edit global settings for parcel label styles

1  In Toolspace, on the Settings tab, right-click Parcel and click Edit Label Style Defaults.

2  In the Edit Label Style Defaults dialog box, edit label style settings.

### Quick Reference

Toolspace Shortcut Menu

  Settings tab: Parcel ➤ Edit Label Style Defaults

Dialog Box

  Edit Label Style Defaults (page 1941)

## Editing Label-Type Settings for Parcel Label Styles

Label settings affect only parcel label styles of a given type: area, line, or curve.

Change label settings in the Label Styles collection, in Toolspace on the Settings tab. The parcel label types Area, Line, and Curve, are located under the Label Styles collection. These settings inherit values and overrides from global settings.

### To edit settings for parcel label styles

1  In Toolspace, on the Settings tab, expand Parcel ➤ Label Styles.

**2** Right-click either an Area, Line, or Curve label style. Click Edit Label Style Defaults.

**3** In the Edit Label Style Defaults dialog box, edit parcel label style settings.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: Label Styles ➤ Area, Line, or Curve. Right-click ➤ Edit Label Style Defaults

Dialog Box

Edit Label Style Defaults (page 1942)

# Parcel Label Styles

Parcel label styles control the appearance of parcel labels and the information they contain.

Parcel label styles include styles for area labels and segment labels (line labels and curve labels). Specify which label styles to use when you create parcels, and when adding labels. Line and curve general label styles can also be applied to parcel segment labels.

You can create, edit, or delete parcel label styles in the Label Styles collection in Toolspace, on the Settings tab. Create an entirely new parcel label style, or create one based on an existing style.

### Specifying Label Contents

Parcel label styles specify label contents that are composed of several information components. These components are identified in the Component list on the Layout tab of the Label Style Composer dialog box (page 1942). You can add or delete information components as needed, except with segment label styles, which have a permanent Table Tag component. The Table Tag component is essential for correlating segments in the drawing with those in a segment table.

When a given information component is selected in a styles Component list, its settings are displayed below it. Edit the Content setting to specify the components information. Edit other settings to specify how the component is displayed, including its relative position. You can preview a label in the Preview pane of the Layout tab.

Labels for line and curve segments include a property to span an outside segment. Set this property to True to apply a single label to any segment that runs along the outside edge of multiple parcels. Set this property to False to label the segment for each parcel separately. Set this property on the Layout tab of the Label Style Composer dialog box.

### Segment Labels and Tags

Segment label styles (unlike area label styles) include a Display Mode value, either Label or Tag. Labels are typically used to display engineering data adjacent to each segment. They can include multiple lines of text. Tags are generally much smaller. They display a reference number and perhaps one other element such as a direction arrow. The tag numbers appear in the first column of a table that contains the engineering data. By using tags, you can eliminate parcel segment data from the drawing and organize the data in a separate table. Within a drawing, you can use labels on some segments and tags on others.

Each information component in a segment label styles label template specifies a Used In value: Label Mode, Tag Mode, or Label And Tag Modes. These settings can help you assign data to either labels, tags, or both.

**Labels, Table Tags, and Tables**

To include a segment in a table the segment must have a style with the value set to Tag for the Display Mode property. The Table Tag component must have its Used In property set to either Tag Mode or Label And Tag Modes.

Area label styles do not have a Display Mode property. You can use any piece of information as the table tag. Typically the parcel number is used, but it can be another information component. The table tag, whatever it is, must also be included in the first cell of the corresponding table row. This information is specified in the tables style. For more information, see Adding Parcel Tables (page 845).

## Creating Parcel Label Styles

Create parcel label styles in the Label Styles collection in Toolspace, on the Settings tab.

**To create a parcel label style**

1   In Toolspace, on the Settings tab, expand Parcel ➤ Label Styles.

2   Right-click a label type: Area, Line, or Curve and click New.

3   In the Label Style Composer dialog box, specify a style name and the style settings.

## Editing Parcel Label Styles

Edit parcel label styles in the Label Styles collection in Toolspace, on the Settings tab or by selecting the Edit Label Style option in the drawing.

**To edit a parcel label style**

1   In Toolspace, on the Settings tab, expand Parcel ➤ Label Styles.

2   Expand a label type: Area, Line, or Curve.

3   Right-click the label style and click Edit.

4   In the Label Style Composer dialog box, modify style settings.

OR

1   Select the segment label to edit.

2   Right-click and select Edit Label Style.

3   In the Select Style dialog box, specify a label style, create a new style, or copy or edit an existing style.

## Quick Reference

## Editing Parcel Area Label Styles

Edit parcel area label styles in the Label Styles collection in Toolspace, on the Settings tab or by selecting the right-click Edit Area Selection Label Style option in the drawing.

You can select a different label style, edit a style, or create a new one.

**To edit a parcel area selection label style**

1  In Toolspace, on the Settings tab, expand Parcel ➤ Label Styles.

2  Expand a label type: Area.

3  Right-click the label style and click Edit.

4  In the Label Style Composer dialog box, modify style settings.

OR

1  Select the area label to edit.

2  Right-click and select Edit Area Selection Label Style.

3  In the Select Style dialog box, specify a label style, create a new style, or copy or edit an existing style.

**NOTE** The Parcel Area Selection label cannot be deleted as this is an embedded object and is used to select the parcel.

## Quick Reference

■ Composition Tab (Parcel Properties Dialog Box) (page 2016)

## Displaying Parcel Area Label Properties with the List Command

Use the AutoCAD List command to display parcel area label property information.

**To display parcel area properties in the AutoCAD Text Window**

1   In the drawing, CTRL-click to select an area label.

2   In the command line, enter list.

3   The AutoCAD Text Window dialog box displays parcel properties, including diameter, area and segment information.

**To display parcel area label properties in the AutoCAD Text Window**

1   In the drawing, select an area label.

2   In the command line, enter list.

3   The AutoCAD Text Window dialog box displays the label type, and layer. For example, **AECC_PARCEL_FACE_LABEL Layer: "0"**.

## Creating Parcel Label Styles Based on Other Styles

Create a parcel label style based on another style in the Label Styles collection in Toolspace, on the Settings tab.

**To create a parcel label style based on another style**

1   In Toolspace, on the Settings tab, expand Parcel ➤ Label Styles.

2   Expand a label type: Area, Line, or Curve.

3   Right-click the label style that the new style will be based on and click Copy.

4   In the Label Style Composer dialog box, specify a name for the new style.

5   Modify style settings.

# Deleting Parcel Label Styles

Delete parcel label styles in the Label Styles collection in Toolspace, on the Settings tab.

**To delete a parcel label style**

1 In Toolspace, on the Settings tab, expand Parcel ➤ Label Styles.

2 Expand a label type: Area, Line, or Curve.

3 Right-click the style that you want to delete and click Delete.

## Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click <label style> ➤ Delete

# Applying Parcel Label Styles

A parcel area label style, which you can change at any time, is applied to parcels when they are created.

For information about applying parcel label styles during the creation process, see Default Settings for New Parcels (page 813).

Parcel area selection labels are always created and cannot be deleted. Parcel segment labels are not always applied in the creation process. Parcel segment labels are individual objects and can be placed on a layer separate from the segment being annotated. For more information on how to apply segment labels to existing parcels, see Adding Multiple Parcel Segment Labels (page 839).

**To replace a parcel label style**

1 Click a parcel label in the drawing.

If the label is not visible, see Hiding or Showing Parcel Labels (page 842).

If you have selected the label correctly, the label text and its anchor point are highlighted.

2 Right-click and click Label Properties or Properties.

3 In the AutoCAD Properties palette, replace the label style.

---

**NOTE** Use the Properties palette Label Style drop down menu to access a list of available parcel styles including the general line and curve label styles which can be used to annotate parcels.

---

# Adding or Deleting Parcel Labels

Add or delete parcel segment labels, but not area labels.

For information on how to change parcel area labels, see Applying Parcel Label Styles (page 837).

On the Toolspace Settings tab, in the General Label Style collection, set up Line and Curve label styles (page 1479) to use for the parcels.

On the Toolspace Settings tab, in the General Label Style collection, specify the default line label style (page 1476).

Use the Single Segment or Multiple Segment command to quickly label a parcel using the default label style.

Use the Add Parcel Labels option to access the Add Labels dialog box (page 1970) if you need to create or modify a style before labeling a feature line.

In the Add Labels dialog box you can specify the label types and styles to apply. You can also configure table tags and reference text object prompt methods.

You can add segment labels in the parcel creation process, or you can add them later. For information about adding segment labels during the creation process, see Default Settings for New Parcels (page 813).

## Adding Individual Parcel Segment Labels

You can label individual parcel segments with General Line and Curve label styles or Parcel Line and Curve label styles.

Parcel segment labels are independent, selectable objects. Segment labels can be placed on a layer separate from the corresponding segment. You can add segment labels automatically when you create a parcel. See Default Settings for New Parcels (page 813).

**To label parcel line segments**

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Parcel ➤ Single Segment 🏷 .

2 Select the parcel line or segment to label.

OR

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Parcel ➤ Add Parcel Labels 🏷 .

2 In the Add Labels dialog box, for Label Type, select Single Segment.

3 In the Add Labels dialog box, set Line Label Style and Curve Label Style and click Add.

> **NOTE** You can label parcel segments with either General Line and Curve label styles or with Parcel Line and Curve label styles.

4 Click a parcel segment in the drawing. The label is placed at the selected location. Click additional segments if you want.

While you select segments, the dialog box remains open. You can return to it to change styles or settings for the next sequence of clicks. After changing a label style, click Add. If you do not click Add before continuing to click segments, the style change will be ignored.

5 When you finish adding segment labels, click Close.

**Quick Reference**

## Adding Multiple Parcel Segment Labels

Add labels to multiple parcel segments in one operation.

The segments are labeled in either a clockwise or counterclockwise direction, regardless of the direction of individual segments. Labeling direction is set in the Default Options for the AddParcelSegmentLabels command.

You can add segment labels automatically when you create a parcel. See Default Settings for New Parcels (page 813).

**To label multiple parcel segments**

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Parcel ➤ Multiple Segments 🏷 .

2   Select the feature lines or segments to label.

    When parcel face is selected, a direction prompt displays. If a different supported object is selected, the direction prompt does not display.

OR

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Parcel ➤ Add Parcel Labels 🏷 .

2   In the Add Labels dialog box, for Label Type, select Multiple Segment to add labels to all segments in a parcel.

3   In the Add Labels dialog box, set Line Label Style and Curve Label Style and click Add.

    **NOTE** You can label parcel segments with either General Line and Curve label styles or with Parcel Line and Curve label styles.

4   Click a parcel area label in the drawing. Labels are added to every segment of the parcel.

    While you select segments, the dialog box remains open. You can return to it to change styles or settings for the next sequence of clicks. After changing a label style, click Add. If you do not click Add before continuing to click segments, the style change will be ignored.

5   When you finish adding segment labels, click Close.

**Quick Reference**

## Replacing Multiple Segment Labels

Use the Replace Multiple Segment command to easily replace multiple parcel segment labels.

**To replace parcel segment labels**

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Parcel ➤ Add Parcel Labels .

2   In the Add Labels dialog box, for Label Type, select Replace Multiple Segment.

3   You are prompted to select a parcel to be labelled. It will replace the labels with new ones using the current Multiple Segment label style. If the Multiple Segment label style has already been added to the selected parcel a message will be displayed and the labels will not be replaced.

   While you select parcels, the dialog box remains open. You can return to it to change styles or settings for the next sequence of commands. After changing a label style, click Add. If you do not click Add before continuing to click segments, the style change will be ignored.

4   When you finish replacing multiple segment labels, click Close.

### Quick Reference

Command Line

   AddLabels

## Adding Parcel Area Labels

Add multiple area labels to a single parcel.

You can control the display of parcel area labels separately for each viewport. A parcel can support more than one area label in addition to the embedded area selection label. With multiple area labels per parcel, you can use layer control to display a different label for each viewport with the correct orientation. You can also manage multiple parcel labels with the Edit Parcel Properties Dialog Box (page 2008).

You can add segment labels automatically when you create a parcel. See Default Settings for New Parcels (page 813).

**To add parcel area labels**

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Parcel ➤ Add Parcel Labels .

2   In the Add Labels dialog box, for Label Type, select Area.

3   The current site is displayed and the following prompt is displayed:

   `Select parcel area selection label or [STart point/Polylines/All/Site]:`

4   Do one of the following:

   ■   Select a start and end point to draw a path through the desired parcel.

- Select **Polylines**, to select a polyline that crosses through the desired parcels. The polyline prompt will repeat until you hit **Enter** to end the command.

- Select **All**, to open a Select Object (Site) dialog box with which to select another available site. After selecting a site, start back at Step 2.

- Select **Site**, to open a Select Object (Site) dialog box with which to select another available site. After selecting a site, start back at Step 2.

5 While you select parcels, the dialog box remains open. You can return to it to change styles or settings for the next sequence of commands. After changing a label style, click Add. If you do not click Add before continuing to click segments, the style change will be ignored.

6 When you finish adding area labels, click Close.

# Hiding or Showing Parcel Labels

Hide or show labels of any type by setting the Visibility property of their label styles.

For information about setting the Visibility property of label styles, see Editing Parcel Label Styles (page 834). For information about applying label styles, see Applying Parcel Label Styles (page 837).

You can set the Visibility property globally, and in that way hide or show many parcel labels at the same time. See Parcel Label Settings (page 832).

If you do not want site parcels to have area labels, assign an area label style of <none>.

## Hiding or Showing Site Parcel Area Labels

In site parcels, hide or show area labels in two ways.

Hide these labels by choosing a site area label style of <none>. As with other label types, you can also set the Visibility property of their label style to either hide or show them.

There are two types of area labels. The area selection label that is automatically created upon parcel creation cannot be deleted. You must use Ctrl-click to select it. Additional area labels that are added after the parcel is created are independent objects that can be deleted.

**To hide or show a site parcel area label**

1   In Toolspace, on the Prospector tab, expand the Sites collection.

2   Right-click a Parcels collection and click Properties.

3   In the Site Parcel Properties dialog box, click Composition. Select one of the following settings for Site Area Label Style:

**4** ■ To hide labels, set the style to *<none>*, or to a style with Visibility set to False.

■ To show labels, set the style to one with Visibility set to True.

# Parcel Table Styles

Manage parcel table styles in the Table Styles collection in Toolspace, on the Settings tab.

Parcel table styles govern how parcel tables are displayed in a drawing. You can create, edit, or delete parcel table styles.

Create an entirely new table style, or create a table style based on an existing style. When creating parcel tables, you can select general line/curve label types and/or parcel segment labels. You can label parcel segments that use line/curve label styles. Line/Curve label styles can be applied to lines, curves, feature lines, and polyline segments.

## Creating Parcel Table Styles

Create parcel table styles in the Table Styles collection in Toolspace, on the Settings tab.

**To create a parcel table style**

**1** In Toolspace, on the Settings tab, expand Parcel ➤ Table Styles.

**2** Right-click a table type: Area, Line, Curve, or Segment and click New.

**3** In the Table Style dialog box, specify a name for the new style and define the style settings.

# Adding Parcel Tables

Use parcel tables to consolidate information about the parcels and parcel segments in your drawing.

Tables provide an alternative to labels for information management. Labels can be hard to read if your parcels are small and the drawing is crowded with other data. Tables keep the information organized and separate from the drawing, but cross-referenced by small labels known as tags.

When parcel or segment information is displayed in table rows, table tags uniquely identify the parcels or segments in the drawing and in the initial cells of table rows. For example, if a line segment is labeled L234, its corresponding table row is also labeled L234.

In AutoCAD Civil, parcel tables support general line and curve label types. When creating parcel tables, you can select general line and curve label types and/or parcel segment labels.

For more information about labels, tables, and table tags, see Parcel Labels and Tables (page 831) and Parcel Label Styles (page 833).

Line/curve segments must be labeled prior to adding a table to the drawing. When you add the table, the labels are converted to tags.

You create and edit tables for most objects using the same common procedures and standard dialog boxes. The procedures included in this topic explain how to work with parcel tables. For general information about modifying tables, see Modifying Tables (page 1567).

## Adding Tables of Parcels

A table of parcels, also known as an area table, displays the data for each parcel in a separate row.

Parcel area tables can include data such as parcel perimeter, segment bearings, and street address, depending on the table style.

**To add a table of parcels**

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Parcel ➤ Add Area  .

2   In the Table Creation dialog box, specify settings as needed, except for the Selection settings.

3   To select parcels for the table, for Selection, do one of the following:
    ■   In the Label Style Name list, select one or more area label styles. When you select an area label style, you automatically select all parcels using that style.

    ■   Click the parcel selector button. Click the text of one parcel label after another. When you finish, press Enter.

4   Click OK.
    The upper-left corner of the new table is attached to your pointer.

5   Click in the drawing to set the location for the new table.

### Quick Reference

Dialog Box

Table Creation (page 2441)

## Adding Tables of Parcel Lines

A table of parcel lines displays the data for each line in a separate row.

For each line that you want to include in the line table, the Table Tag element of its label style must have the Used In property set to Tag Mode. Also, the Display Mode property of the label style must be set to Tag. See Editing Parcel Label Styles (page 834).

**To add a table of parcel lines**

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Parcel ➤ Add Line  .

2   In the Table Creation dialog box, specify settings as needed, except for the Selection settings.

3   To select segments for the table, for Selection, do one of the following:
    ■   In the Label Style Name list, select one or more segment label styles or general line/curve label styles. When you select a segment label style, you automatically select all segments using that style.

    ■   Click the segment selector button. Click one segment after another. When you finish, press Enter.

**4** Click OK.

The upper-left corner of the new table is attached to your pointer.

**5** Click in the drawing to set the location for the new table.

## Quick Reference

# Parcel Numbering and Naming

Parcels are numbered automatically when you create them. By default, parcel names are based on the parcel style name template (page 1806). You can manually renumber and/or rename them later.

Area parcels are numbered automatically in creation order, beginning with the Parcel: Next Automatic Area Counter in the Site Properties dialog box. When you renumber parcels, numbering begins with the Parcel: Next Manual Area Counter. The same concept applies to segment tags.

Tags are the label elements used as key values in parcel tables.

When numbering automatically, the increment is always 1. When numbering manually (renumbering), you can select the increment when beginning the renumbering process.

# Defining Parcel Numbering Rules

Define numbering rules for parcels, line segments, and curve segments in the Site collection in Toolspace, on the Prospector tab.

For each of these elements, you can specify the next automatic counter for numbering automatically, and the next manual counter for numbering manually (renumbering).

As numbering proceeds, the next-counter values update automatically. These values are properties of the site, and are retained from one session to the next.

**To define parcel numbering rules**

1  In Toolspace, on the Prospector tab, expand Sites.

2  Right-click a site and click Properties.

3  In the Site Properties dialog box, click the Numbering tab.

4  On the numbering tab, specify numbering rules.

**Quick Reference**

Toolspace Shortcut Menu

Dialog Box

Site Properties (page 2325)

# Numbering Area Parcels Automatically

Parcels are numbered automatically when you create them.

To display the numbered tags, you must set the Used In property of the Table Tag of the label style to Tag Mode. Also, the Display Mode property of the label style must be set to Tag. See Editing Parcel Label Styles (page 834).

Although this is not the only combination of label style properties that displays the numbered tags, it is the required combination for creating a segment table. A segment table is required for renumbering segments. See Numbering Parcel Segments (page 852).

**To number area parcels automatically**

➤ To number parcels automatically, create the parcels. They will be numbered automatically in creation order. For more information, see Creating Parcels (page 812).

# Renumbering Parcels

Renumber area parcels after they have been created.

Parcels can be renumbered based on a starting number and increment value; they can be renamed based on a name template.

**To renumber parcels**

1 Select the parcel. Click Parcel tab ➤ Modify panel ➤ Renumber/Rename.

2 In the Renumber/Rename Parcels dialog box, specify the site you want to work with and click Renumber.

3 Specify a starting number and an increment value.

**4** Optionally, click Use Name Template In Parcel Style to ensure that the name template is used to resolve the parcel name when renumbering.

**5** Click OK.

**6** Click in the drawing to select parcels using the selection jig (similar to the AutoCAD FENCE command, which selects all objects that cross the selection fence). As each parcel is selected, a temporary line is drawn and parcels faces are highlighted. When you finish picking parcels, the line disappears, enabling you to repeat the selection process for another set of parcels.

The parcel numbers, which are displayed in the parcel area labels, are updated after you exit the command.

**7** When you finish renumbering, press Enter.

### Quick Reference

# Renaming Parcels

Rename area parcels after they have been created. The parcels can be renamed automatically based on the name template.

**To rename parcels**

**1** Select the parcel. Click Parcel tab ➤ Modify panel ➤ Renumber/Rename .

**2** In the Renumber/Rename Parcels dialog box, specify the site you want to work with and click Rename.

**3** Specify a name by manually entering a string or click  to open the Name Template dialog box (page 1806) where you can update the default parcel name, using the name template.

**4** Optionally, click Use Name Template In Parcel Style to ensure that the name template is used to resolve the name when renaming.

**5** Click OK.

**6** Click in the drawing to select parcels using the selection jig (similar to the AutoCAD FENCE command, which selects all objects that cross the selection fence). As each parcel is selected, a temporary line is drawn and parcels faces are highlighted. When you finish picking parcels, the line disappears, enabling you to repeat the selection process for another set of parcels.

The parcel names, which are displayed in the parcel area labels, are updated after you exit the command.

**7** When you finish renaming, press Enter.

# Numbering Parcel Segments

Number parcel segments either before or after they have been created.

The parcel segments can be numbered automatically with the Table Tag Numbering dialog box based on a starting number and increment value.

Line/curve segments can be renumbered only if they are already labeled with a tag label.

**To number parcel segments**

1   In the Table Tag Numbering Dialog Box (page 1971), specify the starting number and increment values.

2   Create a parcel segment table of the segments that you want to number/renumber if they are not in a table already.

See Adding Tables of Parcel Segments (page 847).

3   Click Parcel tab ➤ Labels & Tables panel Renumber Tags ➤ .

4   Click one segment label after another.

Segment numbers displayed in the labels are updated as you click them. Also, the numbers displayed in the first cells of each row of the segment table are updated.

5   When you finish renumbering segments, click OK. At the command prompt, enter **E** for End.

Renumbering (page 2019)

# Using User-Defined Property Classifications with Parcels

You can use user-defined Property Classifications to organize and group specific types of user-defined properties.

For more information about User-defined Property Classifications, see User-Defined Property Classifications (page 416).

## Assigning User-Defined Properties to Parcels

Assign a User-Defined Classification to a parcel.

After you create a User-Defined Classification, you can assign it to the Parcels collection using the Site Parcels Properties dialog box (page 2017). The properties within the classification are displayed as columns in the Parcel item list view.

**To assign user-defined properties to a parcel**

1   In the drawing, define the properties within the User-Defined Classification. For more information, see Creating a User-Defined Property Classification (page 417).

2   In Toolspace, on the Prospector tab, click the Parcels collection.

3   Right-click and click Parcel Properties.

4   In the Site Parcel Properties dialog box, click the Composition tab.

5   On the Composition tab, under User-Defined Property Classification, select the User-Defined Classification you want to assign to the Site Parcel.

6   In Toolspace, on the Prospector tab, select the parcel to which you assigned the User-Defined Classification.

7   In the parcel list view window, right-click a column heading. Select the user-defined properties you want to display in the list view window.

> **NOTE** You can arrange the display of columns in the list view by dragging column headings. For more information, see Customizing a List View (page 84).

## Parcels Command Reference

The following table lists parcel commands and briefly describes their functionality. For more information about a command, follow the link in the Description column.

| Command | Description |
| --- | --- |
| AddParcelCurveTable | Adds a parcel curve table (page 847) |
| AddParcelLabels | Adds parcel labels (page 838) |
| AddParcelLineLabel | Adds a parcel segment label, either line or curve (page 839) |
| AddParcelLineTable | Adds a parcel line table (page 847) |
| AddParcelSegmentLabels | Adds parcel segment labels (page 839) |
| AddParcelSegmentTable | Adds a parcel segment table (page 847) |

| Command | Description |
| --- | --- |
| AddParcelTable | Adds a parcel table (page 846) |
| CreateParcelByLayout | Creates a parcel by layout (page 815) |
| EditParcel | Edits parcels by layout (page 820) |
| EditParcelNumbers | Renames or renumbers parcels (page 850) |
| EditParcelTagNumbers | Edits parcel tag numbers (page 852) |
| ExportParcelAnalysis | Exports a parcel inverse or mapcheck report (page 830) |
| CreateParcelFromObjects | Creates a parcel from AutoCAD objects (page 814) |
| CreateParcelROW | Creates an automatic right-of-way (page 822) |
| ParcelPropertiesEdit | Edits parcel properties (page 825) |

# Alignments

# 23

Alignment objects can represent road centerlines, pipe networks, and other construction baselines. Creating and defining a horizontal alignment is one of the first steps in roadway, railroad, or site design. You can draw the alignment geometry as a polyline, and then create the named alignment from that geometry. For greater control, you can create an alignment object using the Alignment Layout Tools. You can also make edits to alignments using grips, or the commands on the Alignment Layout Tools toolbar, while automatically maintaining tangency between the alignment components.

For information on recommended workflows when working with alignments, see the *AutoCAD Civil Workflow Guide*.

## Understanding Alignment Objects

You create alignments as a combination of lines, curves, and spirals that are viewed as one object.

Alignments can be stand-alone objects or the parent object of profiles, sections, and corridors. If you edit an alignment, the changes are automatically reflected in any related objects.

## Overview of Alignments

In AutoCAD Civil, you create alignments as objects.

Use the Prospector and Settings tabs to manage alignments in Toolspace.

Alignments are listed in either the Alignments collection or a Site collection in the Prospector tab. From these collections, you can change alignment properties, generate reports, and export LandXML. See Alignment Collection (Prospector Tab) (page 856) for more information.

Use the Settings tab in Toolspace to manage the details of alignment object styles, label and table styles, and command settings.

Control the visual appearance of alignment components and labels through styles. You can create specific styles to use in the various phases of a project. For more information, see Alignment Styles (page 885).

When you create an alignment, you specify a style for the alignment object and styles for the alignment labels. In the Alignment Labels Dialog Box (page 1739), you can create groups of styles for alignment labels, and then save those labels as a label set to use with other alignments.

## Alignment Types

When creating an alignment, assign it a type of centerline, offset, miscellaneous, or curb return.

You can use these alignment types to categorize your data based on alignment function. Select the centerline type for a road centerline, or the miscellaneous type for other uses, such as a utility conduit. These two types are independent objects.

Offset alignments (page 2479) and curb return alignments (page 2471) can also be independent, but are often dynamically linked to other alignments. Both offset alignments and curb returns can be created automatically as components of an intersection. Offsets can also be used in widenings.

**See also:**

■ Creating Alignments (page 887)

■ Widenings (page 896)

# Alignment Object Relationships

Alignment objects can establish spatial parameters for other objects, including profiles, sections, corridors, intersections, and pipe networks.

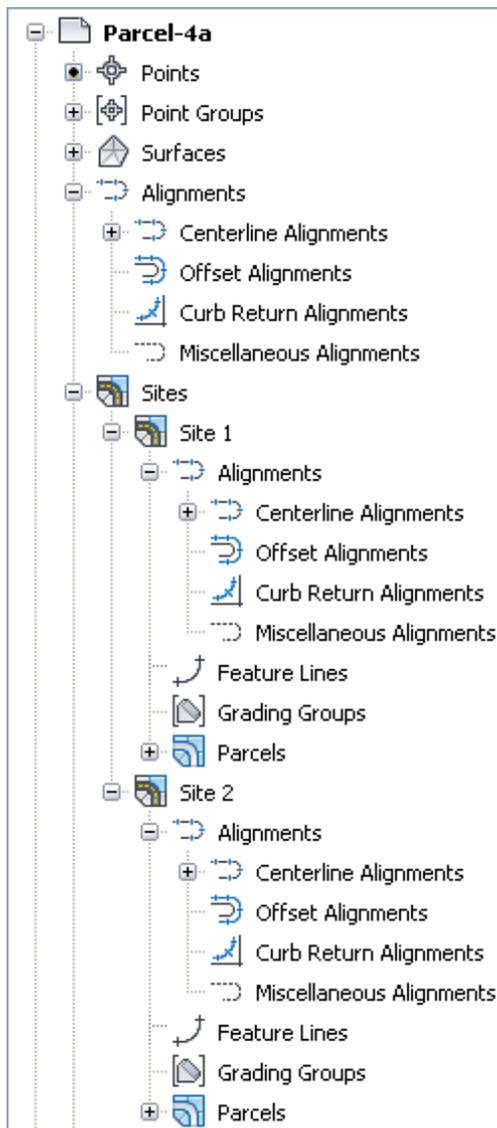
If an alignment exists in a site, its geometry interacts with that of other objects in the site, such as parcels and feature lines. For example, an alignment subdivides any parcels it intersects within the site. Any lot lines or feature lines that cross an alignment assume the same elevation at the intersection point. The elevation is set by whichever object is last edited. To prevent an alignment from interacting with other objects in a site, set the site property to <None> or move the alignment to a separate site. For more information, see Alignment and Site Interaction (page 721).

# Alignment Collection (Prospector Tab)

Use the Alignment collection in the Prospector tree to access the alignments in a drawing.

As alignment objects are created, they are displayed as named alignments, organized by type, in one of two collections:

■ The top-level Alignments collection. When alignments are in the top-level Alignments collection, they do not interact with parcels contained in Site collections. For more information, see Alignment and Site Interaction (page 721).

■ A project Site collection. An alignment object can exist in only one Site. When an alignment is in a Site collection, its geometry interacts with that of other objects in the site, such as parcels and feature lines.


**Sample alignments collections on the Toolspace Prospector tab**

Expand an Alignment collection to view the names of the alignments. Select an Alignment collection to display a detailed tabular list of Alignment information at the bottom of the Prospector tab. For more information, see The Toolspace Item View (page 82).

Right-click an individual alignment in the Alignment collection to:

■ View and edit the alignment properties

■ Move or copy an alignment to either another Site or the top-level Alignments collection

■ Zoom or pan to the alignment

■ Export the alignment to LandXML

Expand an individual alignment name to display profiles, profile views, and sample line groups that are associated with the alignment. These items are also displayed in the tabular list view at the bottom of the Prospector tab.

| For more information about... | See... |
| --- | --- |
| Profiles | Profiles Collection (Prospector Tab) (page 1022) |
| Profile Views | Profile Views Collection (Prospector Tab) (page 1022) |

# Alignment Collection (Settings Tab)

Manage alignment settings, alignment styles, alignment label styles, alignment table styles, and alignment command settings in Toolspace, on the Settings tab.

Right-click the Alignment collection to:

- Edit the alignment feature settings.

- Edit the default alignment label styles.

- Refresh the display of the settings tree.

Expand the Alignment collection to display and edit the alignment styles, label and table styles, and command settings.

**See also:**

- Alignment Settings (page 860)

- Alignment Labels and Tables (page 971)

## The Alignment Styles Collection

Use the Alignment Styles collection in the Settings tree, which lists alignment styles that are available in a drawing, to create an alignment style.

Expand the Alignment Styles collection to display a list of available alignment styles.

Right-click Alignment Style ➤ New to create an alignment style.

---

**NOTE** When you click New in a collection, the new style you create is based on installation defaults, not on the existing styles in the collection. To create a style from an existing style, right-click the style. Click Copy, and save the style with a new name.

---

Right-click an existing alignment style to display the shortcut menu commands:

| Select this command... | If you want to... |
| --- | --- |
| Edit | Change the selected style. |
| Copy | Make a copy of the selected style. |
| Delete | Delete the selected style. |
| Refresh | Update the current view. |

**See also:**

■ Alignment Styles (page 885)

## The Alignment Design Checks Collection

Use the Alignment Design Checks collection to manage the user-defined checks that verify alignment design parameters.

Alignment design checks (page 2472) can be created for Line, Curve, Spiral, or Tangent Intersection entity types. To apply a design check to an alignment, you must add it to a design check set (page 2472).

To edit, create, or copy a design check, right-click an existing design check. Click a command on the shortcut menu:

| Select this command... | If you want to... |
| --- | --- |
| Edit | Edit the design check. |
| Copy | Copy the design check. |
| Delete | Delete the selected design check. You can only delete design checks that are not referenced by a design check sets. |
| Refresh | Update the current view. |

**See also:**

■ Alignment Design Checks (page 871)

## The Alignment Label Styles Collection

Use the Alignment Label Styles collection to override default alignment label settings on the drawing level and create new styles.

Alignment labels are independent objects that are managed with the AutoCAD Properties palette. At the feature level, you can override the default label settings you established at the drawing level. You can edit or create a label style for a specific label type.

**NOTE** When you click New in a collection, the new style you create is based on installation defaults, not on the existing styles in the collection. To create a style from an existing style, right-click the style. Click Copy, and save the style with a new name.

To edit, create, or copy a label style, right-click an existing alignment label style. Click a command on the shortcut menu:

| Select this command... | If you want to... |
| --- | --- |
| Edit | Edit the current label style. |
| Copy | Copy the style. |
| Delete | Delete the selected style. You can only delete styles that are not referenced by other objects or label sets. |
| Refresh | Update the current view. |

**See also:**

- Alignment Label Styles (page 971)

## The Alignment Table Style Collection

Use the Alignment Table Style collection to create a table style or to modify an existing table style.

To edit, copy, or delete an alignment table style, right-click an alignment table style. Click a command on the shortcut menu.

---

**NOTE** When you click New in a collection, the new style you create is based on installation defaults, not on the existing styles in the collection. To create a style from an existing style, right-click the style. Click Copy, and save the style with a new name.

---

To edit, create, or copy a table style, right-click an existing alignment label style. Click a command on the shortcut menu:

| Select this command... | If you want to... |
|---|---|
| Edit | Edit the current table style. |
| Copy | Copy the style. |
| Delete | Delete the selected style. You can only delete styles that are not referenced by other objects or label sets. |
| Refresh | Update the current view. |

**See also:**

- Alignment Table Styles (page 986)

## The Alignment Command Collection

Control the settings for a specific alignment command using the Alignment Commands collection.

When you change settings for a command in the collection, the changes affect that command only.

Expand the Alignment  Commands collection, on the Settings tab, to display a list of commands for an alignment.

Right-click a command name and click Edit Command Settings to open the Edit Command Settings dialog box for the command. Change the settings as needed.

**See also:**

- Alignment Command Reference (page 1016)

# Alignment Settings

You can use alignment settings to specify the default behavior for alignment commands.

Settings are handled in a standard way throughout AutoCAD Civil. You access settings using the Settings tree. Control settings at three levels: the drawing level, the object collection (feature) level, and the command level. For more information, see Understanding Settings (page 61).

Use the Settings tree Alignment collection shortcut menu to establish defaults for all alignment commands. You can change alignment-specific settings at this level, such as Station Indexing and also override the drawing ambient settings.

Use the Commands collection under the Alignment collection to change alignment settings for a specific command. You can change alignment-specific settings at this level, or override the drawing ambient settings.

The topics in this section describe only those settings that affect alignment-related commands. The topics in this section do not cover the drawing ambient settings, which are also displayed in the Alignment Settings dialog box.

**See also:**

■ Specifying Drawing Settings (page 63)

**To edit the alignment feature settings**

1  In Toolspace, on the Settings tab, right-click the Alignment collection ➤ Edit Feature Settings.

2  In the Alignment Settings dialog box, expand the display for each setting. Click a cell in the Value column and enter a new value or specify a different style.

3  Click Apply to accept the changes and continue working in the dialog box or click OK to accept the changes and close the dialog box.

## Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click Alignment ➤ Edit Feature Settings

Dialog Box

Edit Feature Settings - Alignment Dialog Box (page 1767)

# Curve and Spiral Settings

Enter the curve settings you want to use when creating alignments using the Tangent-Tangent (With Curves) command.

You can specify default settings for curves and spirals by editing the settings in the CreateAlignmentLayout command.

While you can select various combinations of Spiral In, Curve, and Spiral Out, the A value of the spirals is controlled by the radius of the curve. The length of the spirals is controlled by changing the A Value.

## Specifying Curve and Spiral Settings

Specify default spiral type and values in the Curve and Spiral Settings dialog box or by editing the Curve and Spiral Settings for the CreateAlignmentLayout command.

The parameter values in the Curve and Spiral Settings dialog box apply only to the curves and spirals created using the Tangent-Tangent with Curves command in the current alignment. You can specify default settings for all curves and spirals by editing the settings in the CreateAlignmentLayout command.

**To change the default Curve and Spiral Settings for all instances**

1  On the Settings tab in Toolspace, expand the Alignments collection and then expand the Commands collection.

**2** Right-click CreateAlignmentLayout ➤ Edit Command Settings.

**3** In the Edit Command Settings-CreateAlignmentLayout dialog box, expand the Curve and Spiral Settings property.

**4** Specify the settings, click Apply and click OK.

> **NOTE** To save these command settings at the drawing level, on the Ambient Setting tab (page 68) select Yes in the value column for Save Command Changes To Settings.

**To change the Curve and Spiral Settings used by the tangent-tangent with curves method**

**1** Click Home tab ➤ Create Design panel ➤ Alignment drop-down ➤ Alignment Creation Tools .

**2** In the Create Alignment-Layout (page 1763) dialog box, enter creation information.

**3** On the Alignment Layout Tools toolbar, click  Curve And Spiral Settings.

**4** In the Curve and Spiral Settings (page 861) dialog box, enter curves values.

> **NOTE** The spiral type you specify in the Curve and Spiral Settings dialog box is used in all spiral commands on the Alignment Layout Tools toolbar.

Dialog Box

Alignment Layout Tools (page 1747)

## Specifying a Curve Group Index

Use each index to identify the entities that form part of a complex alignment.

The Curve Group Index identifies a curve group, such as a spiral-curve-spiral group, within an alignment.

The Curve Group Sub-Entity Index identifies each entity within a curve group.

When you label an alignment, you can use these values for alignment identification.

**To specify a curve group index**

**1** Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor .

**2** On the Alignment Layout Tools toolbar, click  Alignment Grid View.

**3** In the Alignment Entities Vista (page 1735), enter values for the Curve Group Index and the Curve Group Sub-Entity Index.

# Alignment Properties

You can use the Alignment Properties dialog box to assign a name, style, and other properties to the alignment.

You can adjust the style, stationing, design criteria, and superelevation parameters of a selected alignment. You can also view basic information about profiles and profile views that have been created for the current alignment.

Use the Superelevation tab to define the specifications for Superelevation Regions that are associated with curve groups in the alignment. Superelevation is used with the corridor model to determine the slopes of travel lanes and shoulders at each station in the model.

The Alignment Properties dialog box has the following tabs:

■ **Information**. Specifies name, description, and object style.

■ **Station Control**. Displays alignment length and raw stationing as well as options to change the station reference point, and apply station equations.

■ **Masking**. Specifies one or more regions of the alignment that can be suppressed from display.

■ **Design Criteria**. Specifies design speed options to select points in the drawing where you want to assign travel speeds to aid in design and labeling. When you assign a design speed to an alignment station, that speed is applied to all subsequent points on the alignment, unless another speed is applied at some point. This value also displays in the Superelevation Specification dialog box.
This tab also contains the options related to criteria-based design (page 2471). This optional feature allows you to specify the design criteria file, default criteria, and design check set for the alignment.

■ **Profiles**. Displays information for profiles associated with the alignment.

■ **Profile Views**. Displays information for profile views associated with the alignment.

■ **Superelevation**. Displays the data for each superelevation region after calculation.

■ **Offset Parameters**. If the alignment is a dependent offset, this tab displays properties of the offset.

■ **Curb Return Parameters**. If the alignment is a curb return, this tab displays data about the two parent alignments, offset values, and update mode.

**NOTE** Alignment label properties are controlled using the Alignment Labels Dialog Box (page 1739).

**See also:**

■ Alignment Properties Dialog Box (page 1752)

**To change alignment name, description, or style**

1 Click Alignment tab ➤ Modify panel ➤ Alignment Properties drop-down ➤ Alignment Properties  .

> **NOTE** The tab most recently opened in the Alignment Properties dialog box is displayed by default.

2 In the Alignment Properties dialog box, click the Information tab (page 1752).

3 Under Name, enter a name for the alignment.

4 Under Description, enter an optional description for the alignment.

5 In the Object Style list, select an existing alignment style.

6 Click the Style Detail button to open the Style Detail dialog box. Preview the alignment style.

**To change alignment Station Control**

1 Click Alignment tab ➤ Modify panel ➤ Alignment Properties drop-down ➤ Alignment Properties  ..

> **NOTE** The tab most recently opened in the Alignment Properties dialog box is displayed by default.

2 In the Alignment Properties dialog box, click the Station Control (page 1752) tab.

3 Under Reference Point, click  . The Alignment Properties dialog box closes.

> **WARNING** Changing the reference point location or the reference station value removes all station equations and design speeds and can adversely affect objects and data already created from the alignment. Click OK to continue or Cancel to abort this operation. Use Station Equations to change stations after you create Profiles and Cross Sections.

4 In the drawing, pick a point where you want to establish the XY coordinates for the Reference Point. The Alignment Properties dialog box is displayed again.

5 In the Reference Point box, under Station, enter a starting station value.

6 In the Station Equations box, click  . The Alignment Properties dialog box closes.

7 In the drawing, pick the point for the first station equation. The Alignment Properties dialog box is displayed again.

8 Repeat Steps 6 and 7 to add more station equations.

9 By default Station Ahead and Raw Station Back have the same value. Click the Station Ahead cell and enter a new value.

10 Click the Increase/Decrease cell to determine whether the station values from the Station Equation increases or decreases from the Station Ahead value.

**To mask an alignment**

1  Click Alignment tab ➤ Modify panel ➤ Alignment Properties drop-down ➤ Alignment Properties 🔲 .

2  In the Alignment Properties dialog box, click the Masking (page 1753) tab.

3  Click ➤ Add Masking Region.

4  Specify the start station for the mask by clicking along the alignment, entering a numeric station value, or clicking Lock to Start in the masking table.

5  Specify the end station for the mask by clicking along the alignment, entering a numeric station value, or clicking Lock to End in the masking table.

6  Optionally, enter notes about the mask in the Comment column.

**TIP** Use the Mask check box to temporarily enable or disable a mask without removing it from the list of masks.

**To change alignment design speeds or criteria**

1  Click Alignment tab ➤ Modify panel ➤ Alignment Properties drop-down ➤ Alignment Properties 🔲 .

**NOTE** The tab most recently opened in the Alignment Properties dialog box is displayed by default.

2  In the Alignment Properties dialog box, click the Design Criteria (page 1754) tab.

3  Click 🔲 .

A new row is displayed in the table.

4  In the Start Station column, enter the station at which the design speed begins.

5  For Design Speed, enter the design speed.

The default Design Speed value is specified in the alignment feature settings.

6  Repeat Steps 3 through 5 to add more design speeds.

An alignment can have unlimited numbers of design speeds, but only one speed at any given station. When a station has a design speed, that speed applies to subsequent stations until either the next station at which a design speed is set, or the alignment end station. If a single entity has multiple speeds assigned to it, the highest speed is used to validate that entity against the design criteria. The lower speed values are ignored.

**NOTE** To calculate superelevations on the Superelevation tab, you must specify design speeds.

7  On the right side of the dialog box, modify the design criteria as desired.

8  Click OK.

**NOTE** If design criteria has been associated with the alignment, the entire alignment design is validated when you click either Apply or OK.

**To view Profiles associated with the alignment**

**1** Click Alignment tab ➤ Modify panel ➤ Alignment Properties drop-down ➤ Alignment Properties .

> **NOTE** The tab most recently opened in the Alignment Properties dialog box is displayed by default.

**2** Click the Profiles tab. For more information, see Profile Data Tab (Profile Properties Dialog Box) (page 2174).

**To view Profile Views associated with the alignment**

**1** Click Alignment tab ➤ Modify panel ➤ Alignment Properties drop-down ➤ Alignment Properties .

> **NOTE** The tab most recently opened in the Alignment Properties dialog box is displayed by default

**2** Click the Profile View tab. For more information, see Profiles Tab (Profile View Properties Dialog Box) (page 2179).

# Criteria-Based Alignment Design

Use the criteria-based design feature to apply agency-specific standards to an alignment.

The criteria-based design feature provides the ability to verify that your alignment design meets the minimum standards required by your local agency.

When you use the criteria-based design feature, you can select a design criteria file (page 2472), from which you can specify the superelevation attainment method and minimum radius and transition (spiral) length tables. When you lay out the alignment, the appropriate minimum values specified in the design criteria file are displayed on the command line. You can either accept the default minimum value for a given sub-entity, or specify a new value.

Minimum transition length values are automatically generated using the specified curve radius. If there is no curve associated with the spiral, then the minimum value is the smallest acceptable spiral radius.

If the design parameters for a sub-entity violate the minimum values established in the design criteria file, a warning symbol appears both on the sub-entity in the drawing window and next to the violated value in the Alignment Entities Vista (page 1735) and Alignment Layout Parameters Window (page 1741). When you hover the cursor over a warning symbol, a tooltip displays which standard has been violated and how to correct the violation. The display of the warning symbol is controlled by the alignment style.

Some alignment design criteria are not available in table form in the design criteria file. For these criteria, you can define design checks (page 2472) to validate design standards. To apply a design check to an alignment, you must add it to a design check set (page 2472).

**NOTE** Compound spiral length is not validated against the design criteria file. You must use design checks to validate compound spiral length.

You can generate a report that documents validations or violations in the alignment design. The design criteria report identifies whether each sub-entity within a given station range violates or meets the appropriate design criteria and design checks.

# Design Criteria Files

A design criteria file contains the standards tables that specify appropriate minimum design standards for alignments or profiles.

The design criteria file (page 2472) contains the minimum design standards for alignment and profile objects. You can customize the design criteria file to support local design standards for such things as superelevation and minimum K values.

Design criteria files containing A.A.S.H.T.O. (page 2467) standards in both metric and imperial units are included with AutoCAD Civil.

If your local agency standards differ from those in the supplied design criteria files, you can use the Design Criteria Editor Dialog Box (page 1843) to customize the file to support your local standards.

**NOTE** If you use a custom a design criteria file, you must save it to a shared server to which all members of your design team have access. If you send a drawing that uses a custom design criteria file, you must send the design criteria file with the drawing.

**Alignment Design Criteria**

A design criteria file can contain the following alignment design criteria:

■ Minimum radius at a given design speed

■ Superelevation attainment method

■ Superelevation rate at a given radius

■ Minimum transition length at a given radius

**NOTE** Compound spiral length is not validated against the design criteria file. You must use design checks to validate compound spiral length.

**Profile Design Criteria**

A design criteria file can contain standards tables for minimum K values at specified design speeds. Minimum K tables for the following distances are available:

■ Stopping Sight Distance

■ Passing Sight Distance

■ Headlight Sight Distance

**See also:**

■
■
■

## Creating a Design Criteria File

Create a customized design criteria file to reflect your local standards.

If you do not want to use or modify the provided design criteria file, you can create a custom design criteria file in either of the following ways:

■ Copy the provided design criteria file. Rename the copy, and then modify the copy to reflect your design standards.

■ Create an empty design criteria file. Add your local standards using the schema that is defined in the design criteria file.

**To copy the provided design criteria file**

**1** Click an alignment or profile in the drawing

**2** Click Alignment tab ➤ Modify panel ➤ Design Criteria Editor ⬚ .

**3** In the Design Criteria Editor Dialog Box (page 1843), click ⬚ Open.

**4** In the Select A Design Criteria File dialog box, select the design criteria file you want to copy. Click Open.

**5** In the Design Criteria Editor Dialog Box (page 1843), click ⬚ Save As.

**6** In the Enter A File Name To Save dialog box, enter a new name for the design criteria file. Click Save.

> **NOTE** Design criteria files are saved in this directory: *C:\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\Data\Corridor Design Standards\<units>*. The criteria-based design feature uses the first file found in the directory. To ensure that your new file is used by default, give it a name that places it before all other files in the directory.

**7** In the Design Criteria Editor dialog box, click ⬚ Expand All to expand all nodes in the tree on the left side of the dialog box.

**8** Select the desired ⬚ table.

The table contents are displayed in the grid view on the right side of the dialog box.

**9** Edit contents of the design criteria file as desired.

■ To create new ⬚ tables and ⬚ folders in the tree view, right-click the desired node and use the commands on the shortcut menu.

■ To edit a value, double-click the value.

- To add a row to a table, click ![add icon] .

- To remove a row from a table, click ![remove icon] .

**10** Click Save And Close to save the new design criteria file and close the Design Criteria Editor dialog box.

**See also:**

- Design Criteria Files (page 867)
- Profile Standards in the Design Criteria File (page 1045)
- Superelevation Specification Variables (page 880)
- Examples of Attainment Methods (page 881)

**To create an empty design criteria file**

**1** Click an alignment or profile in the drawing

**2** Click Alignment tab ➤ Modify panel ➤ Design Criteria Editor ![icon] .

**3** In the Design Criteria Editor Dialog Box (page 1843), click ![icon]

**4** New.

An untitled design criteria file is created, with empty Units, Alignments, and Profiles folders in the tree view.

**5** In the tree view, right-click Units. Click either New Metric or New Imperial.

**6** In the grid view, specify values for the units parameters.

**7** In the tree view, right-click either the Alignments or Profiles folder. Click the desired table category.

**8** Right-click the table category folder you created in Step 5. Click the desired table.

**9** Enter a name for the table you created in Step 6.

**10** Edit contents of the table as desired.
- To edit a value, double-click the value.

- To add a row to a table, click ![add icon] .

- To remove a row from a table, click ![remove icon] .

**11** Repeat Steps 5 through 8 to add more tables to the design criteria file.

**12** In the Design Criteria Editor dialog box, click ![save icon] Save.

**13** In the Enter A File Name To Save dialog box, enter a new name for the design criteria file. Click Save.

---

**NOTE** Design criteria files are saved in this directory: *C:\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\Data\Corridor Design Standards\<units>*. The criteria-based design feature uses the first file found in the directory. To ensure that your new file is used by default, give it a name that places it before all other files in the directory.

---

**14** Click Save And Close to save the new design criteria file and close the Design Criteria Editor dialog box.

**See also:**

■ Design Criteria Files (page 867)

■ Profile Standards in the Design Criteria File (page 1045)

## Editing a Design Criteria File

Modify a design criteria file to reflect your local standards.

You use the Design Criteria Editor Dialog Box (page 1843) to edit the design criteria file.

**To edit a design criteria file**

**1** Click an alignment or profile in the drawing

**2** Click Alignment tab ➤ Modify panel ➤ Design Criteria Editor .

**3** In the Design Criteria Editor Dialog Box (page 1843), expand the desired folder in the tree on the left side of the dialog box.

**4** Select the desired table.
The table contents are displayed in the grid view on the right side of the dialog box.

**5** Edit contents of the design criteria file as desired.

■ To create new tables and folders in the tree view, right-click the desired node and use the commands on the shortcut menu.

■ To edit a value in the grid view, double-click the value.

■ To add a row to a table, click .

■ To remove a row from a table, click .

**6** Click Save And Close to save the design criteria file with your changes and close the Design Criteria Editor dialog box.

## Alignment Design Checks

Create design checks to verify the design parameters for criteria that are not included in the design criteria file.

The tables contained in the design criteria file (page 2472) contain the most commonly used criteria for alignment design. Other criteria can be checked by using mathematical expressions known as design checks (page 2472).

Design checks are created and managed in the same manner as label expressions. Use the Design Check Editor Dialog Box (page 1845), which is similar to the Expressions Dialog Box (page 1973), to create and edit design checks. To apply a design check to an alignment, you must add it to a design check set (page 2472), which is similar to an alignment label set.

You can create design checks for lines, curves, spirals, and tangent intersections, which are groups of multiple line, curve, and spiral entities.

Independent entities are checked separately from sub-entities in tangent intersection groups. To apply the same design check to both entiity types, create a separate design check for each type. For example, to enforce a minimum radius for all curves, create a curve design check for use with the independent curves and a tangent intersection design check for use with spiral-curve-spiral groups.

Design checks differ from label expressions in that they always return a true or false value. For example, you can create a design check to issue a notification if a tangent is shorter than a specified minimum tangent length.

**See also:**

- Expressions (page 1547)
- Using Alignment Label Sets (page 973)

### Design Check Examples

Following are some examples of design check syntax.

The following examples demonstrate the type of parameters that can be validated using design checks. Use the examples as a basis to create your own custom design checks.

---

**NOTE** Several design checks are included in the AutoCAD Civil templates in the Toolspace ➤ Settings ➤ Alignment and Profile ➤ Design Checks collections.

---

### Minimum Tangent Length

This design check validates that a tangent is a minimum specified length.

| | |
|---|---|
| Name | Tangent Length >= 100 |
| Type | Line |
| Formula | {Tangent Length}>=100 |
| Formula Description | Tangents must be greater than or equal to 100. |

### Minimum Tangent Length at a Design Speed

This design check validates that a minimum tangent length is used at a given design speed.

| | |
|---|---|
| Name | Tangent Length >= 100 @ 45mph |
| Type | Line |
| Formula | IF({Design Speed}>=45,Length>=100,1) |
| Formula Description | If the design speed is greater than or equal to 45, the tangent length must be greater than or equal to 100. <br><br> **NOTE** In the IF function, the ending 1 indicates that if the entity meets both the design speed and length conditions, a true value is returned. A true value means that the entity meets the design check, and no warning is issued. If the entity does not meet one or both of the conditions of the design check, a warning is issued. |

### Design Speed On Curve Radius

This design check validates that a minimum curve radius is used at a given design speed. This design check is relatively complex, and combines several formulas into a single design check.

In this example, the minimum curve radius at eight separate design speeds is validated. When applied to an alignment, the design check checks the curve design speed value, and then validates that the radius is greater than or equal to the specified value.

| | |
|---|---|
| Name | Design Speeds On Curve Radii (Multiple) |
| Type | Curve |
| Formula | IF({Design Speed}>=120,Radius>=750,<br>IF({Design Speed}>=100,Radius>=500,<br>IF({Design Speed}>=80,Radius>=300,<br>IF({Design Speed}>=70,Radius>=200,<br>IF({Design Speed}>=60,Radius>=125,<br>IF({Design Speed}>=50,Radius>=80, |

IF({Design Speed}>=40,Radius>=50,
IF({Design Speed}>=30,Radius>=30,
Radius>= 0))))))))

| Formula De-scription | If the design speed is greater than or equal to one of the specified speed values, the radius must be greater than or equal to the specified radius value for that speed. |
| --- | --- |

**Design Speed On Tangent Length**

This design check validates that the tangent length is within a specified range at a given design speed. This design check is relatively complex, and combines a several formulas into a single design check.

In this example, tangent length at five separate design speeds is validated. When applied to an alignment, the design check checks the tangent design speed value, and then validates that the tangent length is within the specified range.

| Name | Design Speeds On Tangent Lengths (Multiple) |
| --- | --- |
| Type | Line |
| Formula | IF({Design Speed}>=120,(2000>=Length)*(Length>=500), IF({Design Speed}>=100,(2000>=Length)*(Length>=400), IF({Design Speed}>=80,(1500>=Length)*(Length>=350), IF({Design Speed}>=70,(1200>=Length)*(Length>=300), IF({Design Speed}>=60,(1000>=Length)*(Length>=250),Length>=0))))) |
| Formula De-scription | If the design speed is greater than or equal to one of the specified speed values, the tangent length value must be between the maximum and minimum values specified for that speed. |

# Creating a Design Check

To create a design check, set up a mathematical formula that uses existing alignment sub-entity properties.

Use the Toolspace Settings tab to create and manage design checks. You must create separate design checks for lines, curves, spirals, and curve groups (tangent intersections). To apply a design check to an alignment, you must add it to a design check set (page 2472).

Independent entities are checked separately from sub-entities in tangent intersection groups. To apply the same design check to both entiity types, create a separate design check for each type. For example, to enforce a minimum radius for all curves, create a curve design check for use with the independent curves and a tangent intersection design check for use with spiral-curve-spiral groups.

**See also:**

- Alignment Design Checks (page 871)

**To create a design check**

**1**  In Toolspace, on the Settings tab, expand the Alignment ➤ Design Checks collection.

**2**  Right-click the entity type collection for which you want to create a design check. Click New.

Alternatively, you can expand the entity type collection for which you want to create a design check, right-click an existing design check, and click Copy.

**3**  In the Design Check Editor Dialog Box (page 1845), enter a name and description for the design check.

> **BEST PRACTICE** The name of the design check should be similar to the formula you enter in the Design Check field. When a design check is violated, only the design check name is displayed, and not the minimum acceptable value. If the formula is in the design check name, it is easier to correct the violation.

**4**  Click Insert Property. Select a property from the list.

The property appears in the Design Check field.

**5**  Add functions, constants, and logical operators to complete the design check.

Because design checks return either a true or false value, they must contain one of the following logical operators: > (greater than), < (less than), >= (greater than or equals), <= (less than or equals), != (not equals), = (equals).

> **NOTE** Do not insert anything into the { } brackets that surround the property fields.

■  Click Insert Function to insert mathematical functions like TAN.

■  Use the calculator buttons or click in the Design Check field and use your keypad to enter numbers, constants, and mathematical operators like **\*** (multiply) or / (divide).

> **NOTE** For a complete list of operators and functions, see Design Check Editor Dialog Box (page 1845).

**6**  Click OK.

> **NOTE** To apply a design check to an alignment or profile, it must be saved in a design check set. For more information, see Creating a Design Check Set (page 875) or Editing a Design Check Set (page 876).

**See also:**

Dialog Box

Design Check Editor Dialog Box (page 1845)

## Alignment Design Check Sets

Save commonly used combinations of design checks in a design check set, which is then applied to an alignment.

After you create a design check (page 2472), save it with an appropriate combination of other design checks in a design check set. A design check set can be applied to an alignment either during the alignment creation process, or through the properties of an existing alignment.

A design check set consists of design checks for a combination of design check types. For example, you can create a design check set that consists of separate design checks for minimum and maximum A values for spirals, minimum radii for curves, and minimum spiral transition lengths.

Design check sets are created and managed in the same manner as label sets. Use the Design Check Set Dialog Box (page 1848), which is similar to the Label Set Dialog Box (page 1968), to create and edit design check sets.

**NOTE** Design checks validate the type of entity for which they were created, whether the entity is independent entity or a sub-entity in a tangent intersection group. For example, a curve design check validates a curve that is part of a spiral-curve-spiral group. However, a design check that validates the properties of a curve in spiral-curve-spiral groups does not validate the same properties of a standalone curve.

## Creating a Design Check Set

Use the Design Check Set dialog box to assign design checks to the individual alignment or profile elements that you want to validate.

Create design check sets from the Alignment ➤ Design Checks ➤ Design Check Sets and Profile ➤ Design Checks ➤ Design Check Sets collections in Toolspace on the Settings tab.

**To create a design check set**

1  In Toolspace, on the Settings tab, expand either the Alignment ➤ Design Checks or Profile ➤ Design Checks collection.

2  Right-click the Design Check Sets collection. Click New.

3  In the Design Check Set dialog box, on the Information tab (page 1849), enter a name and optional description of the design check set.

4  In the Design Check Set dialog box, on the Design Checks tab (page 1849), from the Type list, select a design check type.

5  From the <type> Checks list, select a design check.

6  Click Add.

   The design check is added to the design check set and appears in the table in the dialog box.

7  Repeat Steps 4 through 6 to add other design checks to the design check set.

8  If you are creating a profile design check set, use the Apply To column to specify the type of curve (sag, crest, or both) to apply each curve check.

9  Click OK.

# Superelevation

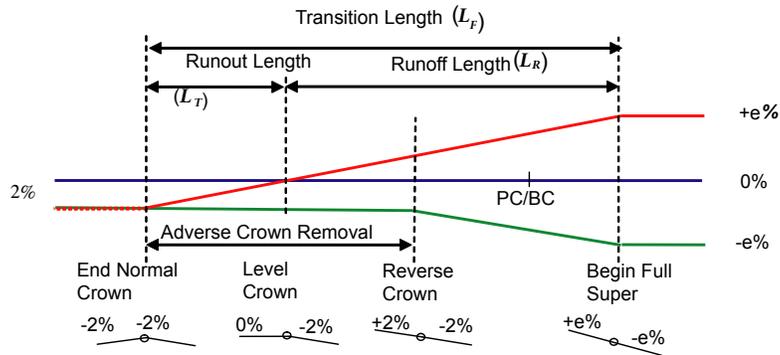
Use the Superelevation tab of the Alignment Properties dialog box to calculate and edit the superelevation specifications that you apply to roadway cross sections in the Corridor Model.

Methods of applying superelevation vary, depending on combinations of the Corridor Type and Cross Section Shape.

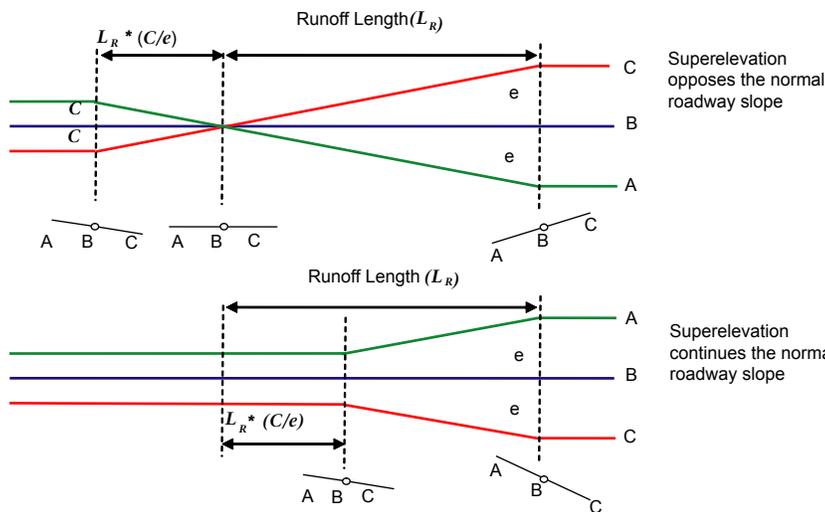
The parameters you set in the subassemblies, assemblies, and the corridor model determine how AutoCAD Civil applies these superelevation specifications.

# Superelevation on Undivided Roads

This section describes two situations for undivided roads and illustrates how superelevation is applied for each situation.

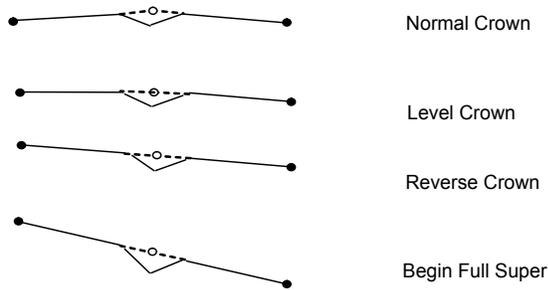
- The following illustration shows an undivided road as a corridor type and a crowned cross section shape. During superelevation, the simple crowned roadway undergoes adverse crown removal. In this illustration, the adverse crown removal is the distance from End Normal Crown to Reverse Crown:


- The following illustration shows an undivided road as the corridor type and the cross section shape is planar. There is no crown, therefore no removal of adverse crown is necessary. This type of roadway typically has a downward slope in one direction on the unsuperelevated sections. Because of this, the distance required to achieve full superelevation varies depending on whether the superelevation continues in the direction of the downward slope or superelevates in the direction opposite to the normal downward slope. This example is typical of ramps, one-way traffic roads, and some service roads.



## Superelevation on Divided Roads

This section describes two situations for divided roads and illustrates how superelevation is applied for each situation.

- The following illustration shows a divided road as the corridor type and the cross section shape is planar. The roadway undergoes adverse crown removal during superelevation:


Normal Crown

Level Crown

Reverse Crown

Begin Full Super
# Roadway Design Standards

Through the alignment properties, you can specify roadway design standards, including superelevation attainment method and minimum radius and transition length values.

Roadway design standards are contained in the design criteria file (page 2472). You can customize the design criteria file to reflect your local standards using the Design Criteria Editor Dialog Box (page 1843). For more information, see Design Criteria Files (page 867).

The XML-based design criteria file has three sections that you can use to calculate superelevation rates and superelevation transition stations on an alignment.

**Minimum Radius Tables**

A table of superelevation rates that you can apply to different types of roadways as a function of curve radius and design speed.

**Transition Length Tables**

A table of values you can use in the Superelevation Attainment Method formulas. You can use the table to calculate the distances between the critical superelevation transition points for different types of roadways as a function of curve radius and design speed. In many cases, the transition length tables provide the actual length of transition of superelevation runoff.

**Superelevation Attainment Methods**

Specifies how superelevation is applied, and the method that is used to calculate superelevation transition stations for different types of roadways. Each defined method specifies the formulas used to calculate the distances between the critical superelevation transition points. For more information, see Superelevation Specification Variables (page 880).

AutoCAD Civil supports two methods of superelevation attainment.

- Standard. Superelevation transition method that requires removal of adverse crown. This method is typically used on undivided, crowned roadways and divided roadways with crowned or planar sections.

- Planar. Superelevation transition method that does not involve removal of adverse crown. This method is typically used on undivided, planar-section roadways, such as ramps and service roads.

For more information and sample XML files, see Examples of Attainment Methods (page 881)

In the design criteria file, each attainment method, minimum radius table, and transition length table have unique, defined names. Use the Superelevation Specification Dialog Box (page 1776) to specify the name of the design criteria file.

# Superelevation Specification Variables

Use the following set of variables to calculate transition distances.

| | |
|---|---|
| {e} | The full superelevation rate. This rate is determined from the superelevation rate table, based on the design speed and curve radius. |
| {t} | The value that is read from the transition length tables, based on the design speed and the curve radius. This value may not be an actual length, but some other value, such as a transition rate from which the length can be calculated. |
| {c} | The unsuperelevated normal lane slope (positive). This value is defined by the user in the Superelevation Properties dialog box. |
| {s} | The unsuperelevated normal shoulder slope (positive). This value is defined by the user in the Superelevation Properties dialog box. |
| {w} | The nominal width from the pivot point to the outermost edge-of-traveled way. This value is defined by the user in the Superelevation Properties dialog box. |
| {l} | The length of the spiral, if a spiral is involved in the transition. This is the actual length of the spiral element in the curve group. |

The variables in the previous table are used to calculate the following distances:

| | |
|---|---|
| NCtoLC | Normal Crown point to Level Crown point (runout) |
| LCtoFS | Level Crown point to Full Super point (runoff) |
| LCtoRC | Level Crown point to Reverse Crown point |
| LCtoBC | Level Crown point to Beginning of Curve |
| NCtoFS | Normal Crown point to Full Super point (used instead of LCtoFS on undivided planar roads) for example the length of the superelevation transition |

| NCtoBC | Normal Crown point to Beginning of Curve (used instead of LCtoBC on undivided planar roads) |
| --- | --- |
| NStoNC | Normal Shoulder point to Normal Crown point (used for the Breakover Removal Method of superelevated shoulders) |

# Examples of Attainment Methods

Use this section to view examples of the XML formats you can use for various superelevation attainment methods.

**Standard Attainment Method Example**

The following example shows the XML format you can use to calculate transition stations for undivided, crowned roadways using the AASHTO standard methodology:

```
<SuperelevationAttainmentMethod name="AASHTO 2001 - Crowned Roadway">
<AttainmentStyle style="Standard"/>
<TransitionFormula type="LCtoFS" formula="{t}"/>
<TransitionFormula type="LCtoBC" formula ="2.0*{t}/3.0"/>
<TransitionFormula type="NCtoLC" formula ="{t}*{c}/{e}"/>
<TransitionFormula type="LCtoRC" formula ="{t}*{c}/{e}"/>
<TransitionFormula type="NStoNC" formula ="{t}*({s}-{c})/{e}">
<SuperelevationAttainmentMethod>
```

This example defines an attainment method whose name is "AASHTO 2001 - Crowned Roadway" which uses the standard adverse crown removal method of attaining superelevation. This example includes a calculation for the transition distance needed for shoulder breakover removal (type="NStoNC").

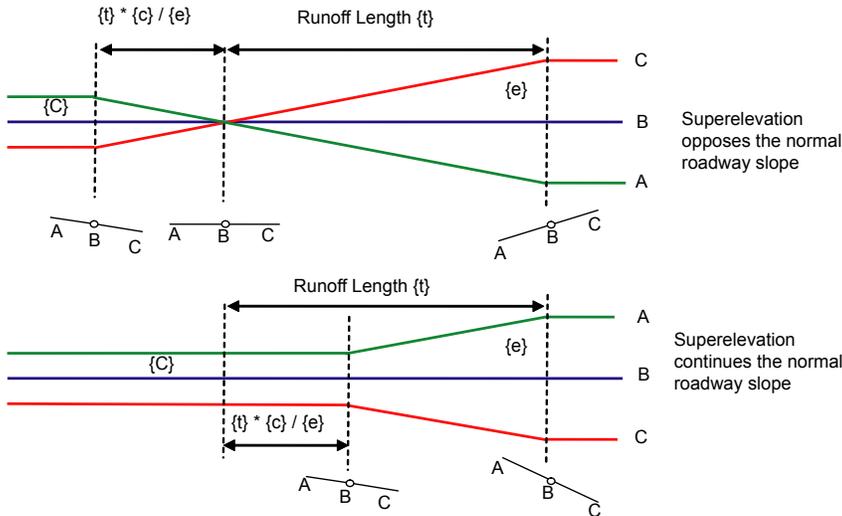
The following table describes the formulas:

| LCtoFS | The distance from the Level Crown Station to the Full Superelevation station is the value {t}, which is read from the selected transition length table. The formula assumes that the transition length table defines the runoff length. |
| --- | --- |
| | **NOTE** If there is a spiral, then LC to FS = spiral length. |
| LCtoBC | The distance from the Level Crown station to the Beginning of Curve station is 2/3 of the runoff length, {t}. |
| | **NOTE** If there is a spiral, then LC to BC = Lc to FS. |
| NCtoLC | The distance from Normal Crown station to the Level Crown Station (tangent runout) is calculated as the runoff length {t}, time the normal crown slope {c}, divided by the full superelevation rate {e}. The tangent runout length is extrapolated from the runoff length. |
| LCtoRC | The distance from the Level Crown station to the Reverse Crown station. (uses the same formula as NCtoLC) |
| NStoNC | Normal Shoulder point to Normal Crown point (used for Breakover Removal Method of superelevated shoulders) |

### Planar Transition Attainment Method Example

This example shows an undivided planar road The roadway is not crowned, and there is no adverse crown removal.

The overall transition distance can be different for left-turn and right-turn curves on a road where the right edge is on the low side because the road is tilted in one direction. The following illustration shows normalized slope superelevation, where the unsuperelevated road is tilted downward from left to right. Therefore the curve to the left requires a longer transition than the curve to the right:



The Planar attainment method requires two formulas: one for curves that oppose the direction of the normal cross slope and one for curves that continue in the direction of the normal cross-slope. In the following example, the Continuing section defines the Normal Crown to Full Superelevation distance runoff length {t} (derived from the transition length tables), minus the runoff length times the normal roadway slope {c} divided by the full superelevation rate {e}. The second formula defines the distance from Normal Crown to the Beginning of Curve to be {t} times 2/3 minus {c} divided by {e}.

The Opposing section defines the overall transition distance to be the runoff length {t}. The distance to the Beginning of Curve is 2/3 {t}, and the distance between the Normal Crown and Level Crown stations is {t} * {c} / {e}

```
<SuperelevationAttainmentMethod name="Undivided Planar Roadway">
<TransitionStyle style="Planar"/>
<Continuing>
<TransitionFormula type="NCtoFS" formula="{t}-{t}*{c}/{e}"/>
<TransitionFormula type="NCtoBC" formula="{t}*(0.67-{c}/{e})"/>
</Continuing>
<Opposing>
<TransitionFormula type="LCtoFS" formula="{t}"/>
<TransitionFormula type="LCtoBC" formula="0.67*{t}"/>
<TransitionFormula type="NCtoLC" formula="{t}*{c}/{e}"/>
</Opposing>
<SuperelevationAttainmentMethod>
```

### Transitions Defined by Roadway Width and Transition Rate

Not all organizations use tables that give transition length directly. The following table defines the full

superelevation rate and the $\Delta$ as a function of design speed and curve radius. In this situation, the $\Delta$

value is used to derive the transition length based on the nominal width of the roadway. The Transition Length tables define the $\Delta$ value instead of the actual transition length.

| Radius (m) | 90 km/h | | 100km/h | | 110km/h | | 120km/h | |
|---|---|---|---|---|---|---|---|---|
| | E% | $\Delta$ | E% | $\Delta$ | E% | $\Delta$ | E% | n/a |
| 7000 | NC | n/a | NC | n/a | NC | n/a | NC | n/a |
| 5000 | NC | n/a | NC | n/a | NC | n/a | 2.0 | 0.31 |
| 3000 | 2.0 | 0.39 | 2.0 | 0.34 | 2.0 | 0.32 | 2.0 | 0.31 |
| 2500 | 2.0 | 0.39 | 2.0 | 0.34 | 2.0 | 0.32 | 2.0 | 0.31 |
| 2000 | 2.0 | 0.39 | 2.0 | 0.34 | 2.0 | 0.32 | 2.3 | 0.32 |
| 1500 | 2.0 | 0.39 | 2.0 | 0.34 | 2.2 | 0.33 | 3.0 | 0.33 |
| 1400 | 2.0 | 0.39 | 2.0 | 0.34 | 2.4 | 0.33 | 3.2 | 0.34 |
| 1300 | 2.0 | 0.39 | 2.0 | 0.34 | 2.6 | 0.33 | 3.5 | 0.34 |
| 1200 | 2.0 | 0.39 | 2.2 | 0.35 | 2.8 | 0.34 | 3.8 | 0.35 |
| 1000 | 2.0 | 0.39 | 2.6 | 0.36 | 3.7 | 0.35 | 4.5 | 0.37 |
| 900 | 2.2 | 0.40 | 2.9 | 0.37 | 3.7 | 0.36 | 5.0 | 0.38 |
| 800 | 2.5 | 0.40 | 3.3 | 0.38 | 4.2 | 0.38 | 5.7 | 0.39 |
| 700 | 2.9 | 0.41 | 3.7 | 0.39 | 4.8 | 0.39 | 6.0 | 0.40 |
| 600 | 3.4 | 0.42 | 4.4 | 0.41 | 5.6 | 0.41 | | |
| 500 | 4.0 | 0.44 | 5.2 | 0.43 | 6.0 | 0.42 | | |
| 400 | 5.0 | 0.46 | 6.0 | 0.45 | | | | |
| 300 | 6.0 | 0.48 | | | | | | |

The following example shows attainment methods and formulas for two types of roadways based on the previous table. The variable {w} is the nominal roadway width from pivot point to edge-of traveled-way, defined in the Superelevation Properties dialog box.

```
<SuperelevationAttainmentMethod name="Unspiraled ramp">
<TransitionStyle style="Planar"/>
<Continuing>
<TransitionFormula type="NCtoFS" formula="100*{e}*{w}/{t}"/>
<TransitionFormula type="NCtoBC" formula="66.7*{e}*{w}/{t}"/>
</Continuing>
<Opposing>
<TransitionFormula type="LCtoFS" formula="100*{e}*{w}/{t}"/>
<TransitionFormula type="LCtoBC" formula="66.7*{e}*{w}/{t}"/>
<TransitionFormula type="NCtoLC" formula="100*{c}*{w}/{t}"/>
<TransitionFormula type="LCtoRC" formula="100*{c}*{w}/{t}"/>
</Opposing>
</SuperelevationAttainmentMethod>
<SuperelevationAttainmentMethod name="Unspiraled 2 way roadway">
<TransitionStyle style="Standard"/>
<TransitionFormula type="LCtoFS" formula="100*{e}*{w}/{t}"/>
<TransitionFormula type="LCtoBC" formula="66.7*{e}*{w}/{t}"/>
<TransitionFormula type="NCtoLC" formula="100*{c}*{w}/{t}"/>
<TransitionFormula type="LCtoRC" formula="100*{c}*{w}/{t}"/>
<SuperelevationAttainmentMethod>
```

# Adding Superelevation Specifications

Superelevation specifications define travel lane and shoulder slopes that you can use with subassemblies when you create corridor models.

The Superelevation Specification Dialog Box (page 1776) lists each alignment curve group as a Superelevation Region. Enter superelevation data for key points on an alignment curve geometry and assign the design criteria file in this dialog box. After you calculate the superelevation, you can edit these specifications on the Superelevation tab.

**WARNING** If the horizontal geometry violates minimum standards in the look-up tables, for example, if the radius of the curve is too small for the design speed, the Event Viewer posts a warning. It is highly recommended that you set the Show Event Viewer property to Yes in the General section of the Edit Feature Settings - Alignment Dialog Box (page 1767).

**To calculate superelevation values**

1   Click Alignment tab ➤ Modify panel ➤ Alignment Properties drop-down ➤ Alignment Properties .

2   In the Alignment Properties dialog box, click the Superelevation (page 1756) tab.

3   Click  Set Superelevation Properties to open the Superelevation Specification Dialog Box (page 1776). Each curve on the horizontal alignment is listed as a Superelevation Region.

    **NOTE** Before you enter the Superelevation Specifications, you must set the appropriate design speeds on the Design Criteria tab (page 1754) in the Alignment Properties dialog box.

4   In the Design Rules section, click the Design Criteria File Name cell and browse to a design criteria file. Depending on the file you select, you can edit the Superelevation Rate Table, the Transition Length Table, and the Attainment Method.

    **NOTE** You can edit the roadway design standards to reflect your local standards. For more information, see Editing a Design Criteria File (page 870).

**5** Click OK. If there is previous superelevation data, you receive a warning that existing data will be overwritten. The Superelevation tab is populated with descriptions and values for each region.

**6** Click in a cell to make edits. Optionally, click  Add A Transition Station to add transition stations or click  Delete Transition Station to remove a transition station.

# Alignment Styles

You can use Alignment Styles to control the visual display of each alignment component.

Changes made to a style are applied to all alignments that use the style.

Use styles to control the appearance of the alignment object components, as well as the types and appearance of alignment labels.

You can create specific styles to use for the different phases of a project. For example, you can create one style to use in the design layout phase and another style to use for plotting.

Access alignment styles using these methods:

| If you want to access alignment styles... | Then... |
| --- | --- |
| In the drawing | Right-click an alignment ➤ Edit Alignment Style. |
| On the Settings tab in Toolspace | Right-click a style in the Alignment Styles folder ➤ Edit. |

**NOTE** When you click New in a collection folder, the new style you create is based on installation defaults, not on the existing styles in the collection. To create a style from an existing style, right-click the style. Click Copy and save the style with a new name.

You use the tabs in the Alignment Style dialog box to set style information:

■ Information. Specifies name, description, and creation information.

■ Design. Specifies certain grip edit behavior.

■ Markers. Specifies marker styles and marker placement options for alignment points.

■ Display. Lists the alignment components and display options as well as the choice of 2D or 3D visibility. You can display components in a 2D plan view or a 3D view using other tools, such as Orbit or Vpoint.

■ Summary. Lists all the style properties.

# Applying an Alignment Style

You can apply different styles to alignments to change the visual display of the alignment components.

You can create specific styles to use for the different phases of a project. For example, you can create one style to use in the design layout phase and another style to use for plotting.

**To apply an alignment style to an existing alignment**

1 In the drawing, click an alignment.

2 Click Alignment tab ➤ Modify panel ➤ Alignment Properties drop-down ➤ Alignment Properties .

3 In the Alignment Properties (page 863) dialog box, on the Information tab, use the Object Style list to select a style.

4 Click OK.

# Copying or Editing Alignment Styles

Copy or edit an alignment style by clicking an existing style, modifying it, and saving it with a new name.

**To copy or edit an alignment style**

1 In Toolspace, on the Settings tab, expand the Alignment Styles collection and right-click an existing style.

**2** Click Copy or Edit.

**3** In the Alignment Style dialog box, click the Information (page 1759) tab. Enter a new name and description for the alignment style.

**4** Click the Design (page 1759) tab. Specify the radius snap and the snap values.

**5** Click the Markers (page 1759) tab. Specify the display properties for the alignment.

**6** Click the Display (page 1760) tab. Specify the display properties for the alignment.

**7** To view a summary of information about the style, click the Summary (page 1760) tab.

**8** Click Apply.

Alignment Style Dialog Box (page 1758)

# Creating Alignments

Create alignments in many ways using AutoCAD Civil, such as creating them from polylines, and using the Alignment Layout Tools.

When you create an alignment, you can use the criteria-based design (page 2471) feature to ensure that your alignment design meets minimum local standards. For more information, see Criteria-Based Alignment Design (page 866).

**NOTE** You can also create alignments either from pipe networks or by importing them from LandXML files. For more information, see Creating Alignments from Pipe Network Parts (page 1196) and LandXML Import and Export (page 1673).

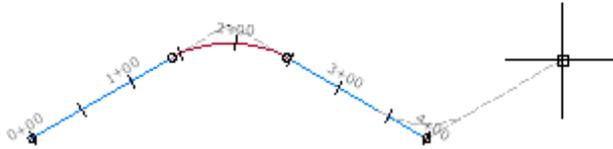
# Creating an Alignment with the Alignment Layout Tools

Create an alignment with the Alignment Layout Tools.

Use the layout command to create an alignment. Specify a unique name, site (if desired), style and label set, and criteria-based design (page 2471) options. Then, use the Alignment Layout Tools to draw the alignment.

This toolbar provides two types of alignment creation tools:

■ Freehand drawing tools for lines, curves, and spirals.

■ Constraint-based tools that define individual entities by parameters such as length and radius.


**To create an alignment using the alignment layout tools**

1  Click Home tab ➤ Create Design panel ➤ Alignment drop-down ➤ Alignment Creation Tools .

2  In the Create Alignment - Layout Dialog Box (page 1763), enter a unique name for the alignment.

3  Enter an optional description.

4  Enter a starting station value.

5  On the General tab, specify the following settings:

■ Site
Specify a site with which to associate the alignment or accept the default <None>. For more information, see Understanding Sites (page 719).

■ Alignment Style

■ Alignment Layer

■ Alignment Label Set

6  On the Design Criteria tab, specify a Starting Design Speed to apply to the alignment starting station.

This design speed is applied to the entire alignment. Additional design speeds can be applied at other stations after the alignment has been created. For more information, see Alignment Properties (page 863).

**NOTE** If you do not want to apply design criteria to the alignment, proceed to Step 8.

7  To associate design standards with the alignment, select the Use Criteria-Based Design check box.

For more information, see Criteria-Based Alignment Design (page 866).

On the Design Criteria tab, specify the following settings:

■ Use Design Criteria File
Select this check box to associate a design criteria file with the alignment. The default design criteria file location and the Default Criteria properties becomes available when you select the check box.

**NOTE** The first design criteria file found in the *C:\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\Data\Corridor Design Standards\<units>* directory is used by default when the criteria-based design feature is used.

■ Use Design Check Set
Select this check box to associate a design check set with the alignment. The design check set list becomes available when you select the check box. Select a design check set from the list.

**8** Click OK to display the Alignment Layout Tools toolbar.

**9** Use the commands on the Alignment Layout Tools toolbar to draw the alignment. For more information, see Alignment Layout Tools (page 1747) and Adding Lines, Curves, and Spirals to an Alignment (page 898).

Command Line

CreateAlignmentLayout

Dialog Box

Create Alignment - Layout Dialog Box (page 1763)

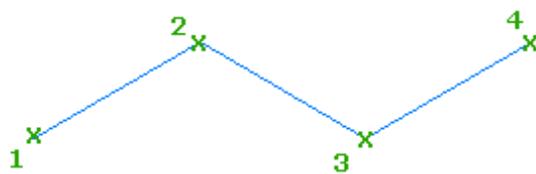
# Drawing Tangent-Tangent Alignments

Use the Alignment Layout Tools to create and edit alignments.

You can use either of the following commands to create a quick layout of the alignment. The lines and curves you create are fixed entities that can be edited without losing tangency.

**Tangent-Tangent No Curves**

Use this command to create a quick layout of an alignment. Specify tangent points of intersection (PI). Optionally add curves later.



**Tangent-Tangent With Curves**

Use this command to lay out an alignment, automatically creating curves at points of intersection (PI). Curve parameters are the current values in the Curve and Spiral Settings dialog box.

---

**TIP** You can use transparent commands when you are prompted to specify direction, radius, or length, or use station offsets to specify any points. For more information, see Transparent Commands (page 1581).

---

**See also:**

■ Curve and Spiral Settings (page 861)

**To draw an alignment using the tangent-tangent method with no curves**

1   Click Home tab ➤ Create Design panel ➤ Alignment drop-down ➤ Alignment Creation Tools .

2   In the Create Alignment-Layout (page 1763) dialog box, enter creation information.

3   On the Alignment Layout Tools toolbar, click  Tangent-Tangent (No Curves).

4   Specify the start point.

5   Continue to specify points. Press Enter to end the command, or click another command from the Alignment Layout Tools toolbar.

**To draw an alignment using the tangent-tangent method with curves**

1   Click Home tab ➤ Create Design panel ➤ Alignment drop-down ➤ Alignment Creation Tools .

2   In the Create Alignment-Layout (page 1763) dialog box, enter creation information.

3   On the Alignment Layout Tools toolbar, click  Tangent-Tangent (With Curves).

4   Specify the start point.

5   Continue to specify points. Press Enter to end the command or select another command from the Alignment Layout Tools.

   Curves are created to comply with the values in one of the following places:

   ■ If the alignment has design criteria (page 866) applied to it, the minimum radius for the current design speed is applied to the curve. If no solution can be found with the minimum radius value, the curve is not drawn.

   ■ If the alignment does not have design criteria applied to it, the default value specified in the curve and spiral settings is applied to the curve. For more information, see Curve and Spiral Settings (page 861).

**To insert a PI on a fixed line**

**1** Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✏.

**2** On the Alignment Layout Tools toolbar, click △ Insert PI.

**3** In the drawing, pick a point near a tangent, where you want to insert the PI.

**To remove a PI and combine two tangents**

**1** Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✏.

**2** On the Alignment Layout Tools toolbar, click △✗ Delete PI.

**3** In the drawing, pick a point near the PI you want to delete.

**To break apart the PI of an incoming or outgoing tangent endpoint**

**1** Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✏.

**2** On the Alignment Layout Tools toolbar, click |△\ Break-Apart PI.

**3** In the drawing, pick a point near the PI you want to break apart.

**4** Specify the distance to split the PI by picking two points or entering a value on the command line. This value is the distance each line is shortened from the PI.

**5** Specify the second point.

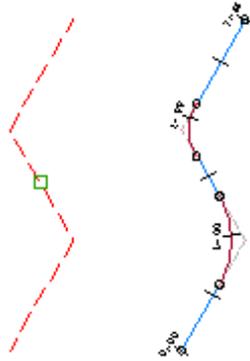
# Creating an Alignment from Graphic Entities

Create an alignment from selected lines, curves, or polylines.

This command converts a series of graphic entities to an alignment, and optionally adds curves between tangents.


**To create an alignment from graphic entities**

1 Draw one or more lines, curves, or polylines in the drawing.

2 Click Home tab ➤ Create Design panel ➤ Alignment drop-down ➤ Create Alignment From Objects ⬚.

3 Select the graphic entities.

   **NOTE** Enter XREF at the command line to select entities from within the xref drawing. See AutoCAD Help for more information about external drawing references.

4 In the Create Alignment From Objects Dialog Box (page 1760), enter a unique name for the alignment.

5 Enter an optional description.

6 Enter a starting station value.

7 On the General tab, specify the following settings:
   - Site
     Specify a site with which to associate the alignment or accept the default <None>. For more information, see Understanding Sites (page 719).

   - Alignment Style

   - Alignment Layer

   - Alignment Label Set

8 On the Design Criteria tab, specify a Starting Design Speed to apply to the alignment starting station.

   This design speed is applied to the entire alignment. Additional design speeds can be applied at other stations after the alignment has been created. For more information, see Alignment Properties (page 863).

   **NOTE** If you do not want to apply design criteria to the alignment, proceed to Step 8.

9 To associate design standards with the alignment, select the Use Criteria-Based Design check box.

   For more information, see Criteria-Based Alignment Design (page 866).

   On the Design Criteria tab, specify the following settings:
   - Use Design Criteria File
     Select this check box to associate a design criteria file with the alignment. The default design criteria file location and the Default Criteria properties become available when you select the check box.

> **NOTE** The first design criteria file found in the *C:\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\Data\Corridor Design Standards\<units>* directory is used by default when the criteria-based design feature is used.

- Use Design Check Set
  Select this check box to associate a design check set with the alignment. The design check set list becomes available when you select the check box. Select a design check from the list.

**10** Click OK.

Create Alignment From Objects Dialog Box (page 1760)

# Creating an Alignment Reference

Create a reference to an existing alignment in a data shortcut (page 2472) or a Vault project

The alignment reference is a lightweight read-only copy of the original, but it gives you access to alignment data for other objects. Before you create the alignment reference, it must exist in the current project collection on the Toolspace Prospector tab

**See also:**

- Creating Data Shortcuts (page 131)
- Using Vault (page 138)

**To create a reference to a data shortcut alignment**

**1** In Toolspace, on the Prospector tab, ensure that the correct working folder is identified on the Data Shortcuts node.

**2** Expand the Data Shortcuts ➤ Alignments collection.

**3** Right-click the desired alignment, and then click Create Reference.

The Create Alignment Reference dialog box is displayed, in which you can optionally change the properties of the reference alignment, as described in the following steps.

**4** In the Create Alignment Reference dialog box, change the source of the reference by selecting a source in the Source Alignment list.

**5** Specify a Site with which to associate the alignment or accept the default <None>. For more information, see Understanding Sites (page 719).

**6** Enter a Name for the alignment.

> **NOTE** To name the alignment, click its default name. Enter a new name, or use the name template. For more information, see Name Template Dialog Box (page 1806).

**7** Specify an Alignment Style or accept the default style.

For more information, see Alignment Styles (page 885).

**8** Click ⬚ to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

> **NOTE** If you do not select a layer, the alignment is placed on the current layer.

**9** Specify a Alignment Label Set or accept the default label set.

**10** Click OK to create the alignment reference.

The alignment name is displayed under the Alignments collection in the Prospector tree with a ⬚ next to it.

**To create a reference to an alignment in a Vault project**

**1** In Toolspace, on the Prospector tab, in Master View, expand the Projects <project name> ➤ Alignments collection.

**2** Right-click the desired alignment, and then click Create Reference.

The Create Alignment Reference dialog box is displayed, in which you can optionally change the properties of the reference alignment, as described in the following steps.

**3** In the Create Alignment Reference dialog box, change the source of the reference by selecting a source in the Source Alignment list.

**4** Specify a Site with which to associate the alignment or accept the default <None>. For more information, see Understanding Sites (page 719).

**5** Enter a Name for the alignment.

> **NOTE** To name the alignment, click its default name. Enter a new name, or use the name template. For more information, see Name Template Dialog Box (page 1806).

**6** Specify an Alignment Style or accept the default style.

For more information, see Alignment Styles (page 885).

**7** Click ⬚ to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

> **NOTE** If you do not select a layer, the alignment is placed on the current layer.

**8** Specify an Alignment Label Set or accept the default label set.

**9** Click OK to create the alignment reference.

The alignment name is displayed under the Alignments collection in the Prospector tree with a ⬚ next to it.

# Creating Offset Alignments

Create parallel alignments that are dynamically linked to an existing alignment.

In a single operation, create multiple offset alignments on one or both sides of the parent alignment. The offset distance is specified separately for left and right sides.

Left and right sides are determined from a position facing toward the end of the parent alignment.

The offset alignments retain their offset distance if the parent alignment is edited. The only geometric attribute of the offset alignments to be edited directly is offset distance.

**To create offset alignments**

1   Click Home tab ➤ Create Design panel ➤ Alignment drop-down ➤ Create Offset Alignment .

2   In the Create Offset Alignments (page 1765) dialog box, select the following attributes:
   ■ Parent alignment
   ■ Name template
   ■ Station range for the offset
   ■ Number of offsets on each side
   ■ Incremental offset distance on each side
   ■ Design Criteria (optional): design speed, criteria set

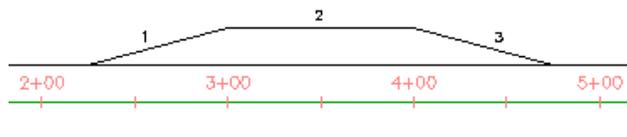
3   On the General tab, enter the site, alignment style, layer, and label set for the offset alignments.

**4** If you want to apply criteria-based design to the offset alignments, click the Design Criteria tab. Enter the required design speed. Click Use Criteria-Based Design, and then select the criteria for the design.

### Quick Reference

Ribbon

Click Home tab ➤ Create Design panel ➤ Alignment drop-down ➤ Create Offset Alignment

Command Line


CreateOffsetAlignment

Dialog Box

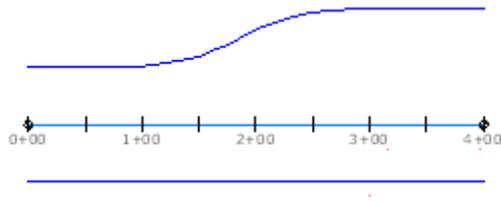
Create Offset Alignments Dialog Box (page 1765)

# Widenings

You can apply widening for a specified length along any type of alignment.

Each widening (page 2487) includes transition regions at the entry and the exit. In the figure, region 1 is the *entry transition*, and region 3 is the *exit transition*, based on the direction of the centerline alignment. Default values for the length and shape of these transitions are determined by command settings for the AddWidening command.

The transitions extend forward and back from the specified widening start and end stations. In the example shown, the widening starts at station 3+00 and the transition length is 75, so the entry transition starts at 2+25.

Curb return alignments in intersections can be edited to add widenings at one or both ends. This type of widening typically forms a turn lane at the entry to a curb return or a merge lane at the exit from a curb return.


**See also:**

■ Editing Offset Alignments and Widenings (page 1005)

■ Editing Offsets in Intersections (page 1445)

# Creating Widening

Create a widened region along an existing alignment.

Use this command to create features such as turn lanes, bus bays, and roadside parking areas.

You can add a widening to any alignment type, or to another widening. In the creation process, you specify the following attributes:

■ Whether the widening is a separate alignment, or part of the parent alignment

■ The start and end stations along the parent alignment

■ The offset width

■ The side (left or right) to widen, based on facing in the forward direction along the alignment

A widening can be part of the parent alignment only if the parent is a dynamic offset or curb return.

**See also:**

■ Editing Offset Alignments and Widenings (page 1005)

**To create a widening**

1 Click Home tab ➤ Create Design panel ➤ Alignment drop-down ➤ Create Widening .

2 Click an alignment to attach the widening to. This is also known as the parent alignment.

3 Specify whether to create the widening as a new alignment, or part of the parent alignment.

4 Specify start and end stations for the widening, either by clicking on the parent alignment or entering numeric station values.

5 Specify the offset width.

6 Specify whether the widening is offset to the left or right of the parent alignment. The widening is created, and its default parameters are displayed in the Offset Parameters window.

## Quick Reference

Ribbon

Click Home tab ➤ Create Design panel ➤ Alignment drop-down ➤ Create Widening

Command Line

AddWidening

# Adding Lines, Curves, and Spirals to an Alignment

Use the constraint-based commands on the Alignment Layout Tools toolbar, to add a fixed entity (page 2474), a free entity (page 2474), or a floating entity (page 2474) (lines, curves, spiral-curve-spiral groups and spirals) to the alignment.

The Alignment Layout Tools toolbar provides you with an infinite number of ways to solve various problems by using different constraints.

Using the constraint-based commands, you can fit an alignment by working inward from two known points at the beginning and end of the design area. You can also create alignment entities in sequential order.

With the established tangency rules, you can edit the parameters of any alignment entity in real-time and still maintain tangency.

# Entity Descriptions

This section contains descriptions of fixed, free, and floating alignment entities.

**Fixed Entity**

A fixed entity has the following characteristics:

■ It is defined by specifying parameters, such as points or radius.

■ Its parameters are fixed in their position. Only you can change the parameters that define this entity.

■ It is not dependent on any other entity to define its geometry or to maintain tangency, but its length can be affected by another entity that is attached to it.

■ It can be initially created with a tangency association. Fixed entities that start from the beginning of another fixed entity can be initially tangent to the other entity, but the tangency is not maintained when either entity is edited.

**Floating Entity**

A floating entity has the following characteristics:

■ It is defined by the parameters that you specify and is always tangent to one entity.

■ It is always tangent to the entity it is attached to. A floating entity cannot be attached to a free entity, but a free entity can be attached to a floating entity.

■ It can be attached only to another floating entity or a fixed entity.

■ It is dependent on being tangent to one other entity to define its geometry.

**Free Entity**

A free entity has the following characteristics:

■ It is defined by the parameters that you specify and is always tangent to an entity before and an entity after.

■ It must have at least two other entities to add to.

■ It is dependent on two other entities to define its geometry.

■ It can only be attached between either two fixed entities, two floating entities, or one fixed and one floating entity, but in any order.

# Adding Lines

Add fixed, free, or floating lines to build constraint-based alignment geometry for the areas of your design that require maintaining tangency.

In most cases the length of the line automatically adjusts to meet the tangency point of the next or previous entity.

After clicking a button on the Alignment Layout Tools toolbar, follow the command prompts on the command line.

**TIP** You can use transparent commands when you are prompted to specify direction, radius, or length, or use station offsets to specify any points. For more information, see Transparent Commands (page 1581).

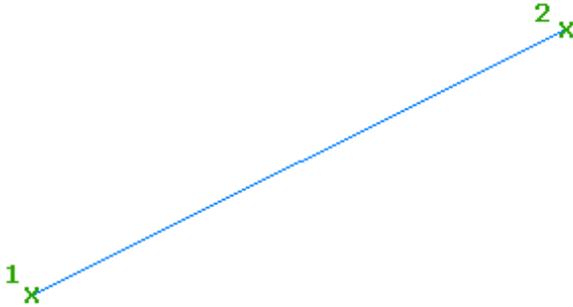
## Adding Fixed Lines

Add fixed lines to build constraint-based alignment geometry for the areas of your design that require maintaining tangency.

After clicking a button on the Alignment Layout Tools toolbar, follow the command prompts on the command line.

## Adding a Fixed Line Between Two Points

Add a fixed line between two points.

The entity position is not affected by edits to adjacent entities.


**To add a fixed line (two points)**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✐ .

2 On the Alignment Layout Tools toolbar, click ✐ Fixed Line (Two Points).

3 Specify the start point.

4 Specify the end point. A line preview is displayed.

**TIP** Edit the line direction or location by moving either point or move the line using the middle grip.

### Quick Reference

Ribbon

Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✏️

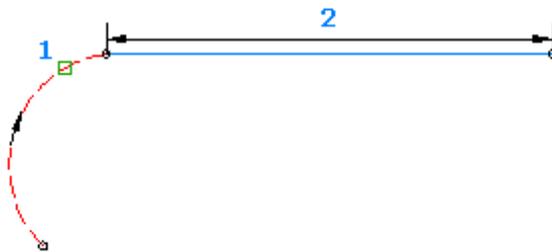
Alignment Layout Tools Toolbar icon

✏️ Fixed Line (Two Points)

## Adding a Fixed Line with a Specified Length to a Curve End

Add a fixed line of a specified length to the end of an existing curve.

The direction of the line matches the direction of the attachment curve (1). The specified line length (2) is affected only if a floating or free entity is attached to it.



The line is tangent to the end of the selected fixed or floating entity when it is created. If you edit the line or the entity it is attached to, tangency is not maintained.

**To add a fixed line (from curve end, length)**

1   Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✏️ .

2   On the Alignment Layout Tools toolbar, click ✏️ Fixed Line (From Curve End, Length).

3   Select an entity end for the start point and direction.

4   Specify the length. A line preview is displayed.

By specifying the start point at the end of an entity, a direction, and length, you create a fixed two-point line alignment entity. The result is a line through two points.

**TIP** You can edit either of the two points or the middle grip, but the initial tangency will not be maintained.

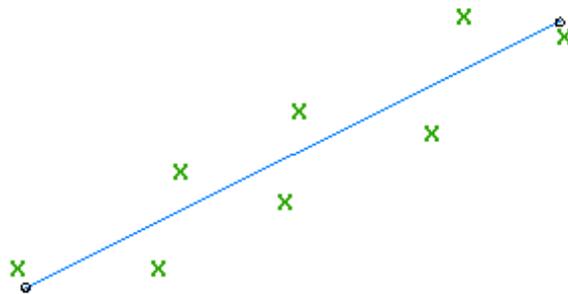
## Adding a Fixed Line by Best Fit

Add the most probable fixed line through a series of using a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen.

Regression points can be added, removed, or modified after the entity has been created.



**See also:**

■ Editing Best Fit Alignment Entities (page 1003)

**To create a fixed line by best fit from AutoCAD Civil points**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor .

2 On the Alignment Layout Tools toolbar, click Fixed Line - Best Fit.

3 In the Line By Best Fit Dialog Box (page 1989), select From COGO Points.

4 Select two or more AutoCAD Civil points. Enter G to select a point group or N to enter points by number.

As you select points in the drawing window, an X marks each regression point and a temporary, dashed line is displayed in real time.

5 Press Enter to complete the command.

6 In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**7** Create the line:

- Click ![icon] to create the line and keep the Regression Data vista open.

- Click ![icon] to create the line and close the Regression Data vista.

**To create a fixed line by best fit from AutoCAD points**

**1** Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ![icon] .

**2** On the Alignment Layout Tools toolbar, click ![icon] Fixed Line - Best Fit.

**3** In the Line By Best Fit Dialog Box (page 1989), select From AutoCAD Points.

**4** Select two or more AutoCAD points.

As you select points in the drawing window, an X marks each regression point and a temporary, dashed line is displayed in real time.

**5** Press Enter to complete the command.

**6** In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**7** Create the line:

- Click ![icon] to create the line and keep the Regression Data vista open.

- Click ![icon] to create the line and close the Regression Data vista.

**To create a fixed line by best fit from existing entities**

**1** Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ![icon] .

**2** On the Alignment Layout Tools toolbar, click ![icon] Fixed Line - Best Fit.

**3** In the Line By Best Fit Dialog Box (page 1989), select From Entities. Specify the tessellation and mid-ordinate tolerance settings.

**4** Select one or more of the entities listed on the command line.

---

**NOTE** You can select several types of entities listed on the command line.

---

As you select entities in the drawing window, an X marks each regression point and a temporary, dashed line is displayed in real time.

**5** If you selected a profile object, specify the starting and ending station in the Specify Station Range Dialog Box (page 1992).

**6** Press Enter to complete the command.

**7** In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**8** Create the line:

- ■ Click ![save icon] to create the line and keep the Regression Data vista open.

- ■ Click ![checkmark icon] to create the line and close the Regression Data vista.

**To create a fixed line by best fit by clicking on screen**

**1** Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ![icon].

**2** On the Alignment Layout Tools toolbar, click ![icon] Fixed Line - Best Fit.

**3** In the Line By Best Fit Dialog Box (page 1989), select By Clicking On The Screen.

**4** Select a starting point and at least one other point.

> **NOTE** You can use OSNAP or transparent commands to select points.

As you select points in the drawing window, an X marks each regression point and a temporary, dashed line is displayed in real time.

**5** Press Enter to complete the command.

**6** In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**7** Create the line:

- ■ Click ![save icon] to create the line and keep the Regression Data vista open.

- ■ Click ![checkmark icon] to create the line and close the Regression Data vista.

Regression Data Vista (page 1990)

## Adding Floating Lines

Add floating lines to build constraint-based alignment geometry for the areas of your design that require maintaining tangency during edits.

After clicking a button on the Alignment Layout Tools toolbar, follow the command prompts on the command line.

## Adding a Floating Line through a Point from a Curve

Add a floating line from a point on an existing curve to a specified point.

The direction of the attachment curve (1) and the location of the pass-through point (2) determine the attachment point.

**To add a floating line (from curve, through point)**

1  Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✎ .

2  On the Alignment Layout Tools toolbar, click ⌒ Floating Line (From Curve, Through Point).

3  Select the end of the curve to which you want to add the floating line.

4  Specify the end point.

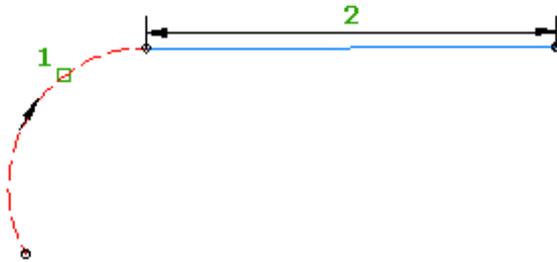
Command Line

EditAlignment

## Adding a Floating Line of a Specified Length to a Curve End

Adds a floating line, with a specified length, to the end of a curve.

The direction of the attachment curve (1) determines the line direction.



This type of entity always starts at the end of the entity it is attached to. The line is always tangent to the end of a fixed or floating curve. Unlike an entity where the location is defined by a pass-through point, this type of entity is not pinned to a location in the drawing. Therefore, the entity geometry moves with the entity to which it is attached.

**To add a floating line (from curve end, length)**

1   Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✎ .

2   On the Alignment Layout Tools toolbar, click ⟋ Floating Line (From Curve End, Length).

3   Select the end of the curve to which you want to add the floating line.

4   Specify a length by picking two points in the drawing, or by entering a length value on the command line.

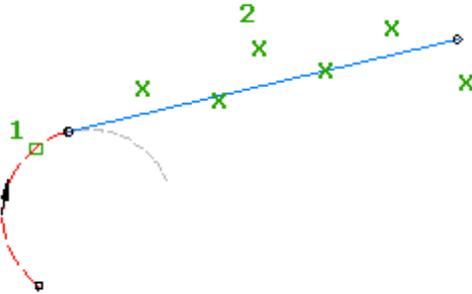
## Adding a Floating Line by Best Fit

Adds the most probable floating line from a point on an existing entity through a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen.

The direction of the attachment curve (1) and the path through the selected regression points (2) determines the location of the attachment point.



**See also:**

■ Editing Best Fit Alignment Entities (page 1003)

**To create a floating line by best fit using AutoCAD Civil points**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor 📝 .

2 On the Alignment Layout Tools toolbar, click 📏 Floating Line - Best Fit.

3 Select a curve entity for the start point and direction.

 If you select the beginning of the curve entity, the best fit line will precede the curve entity. If you select the end of the curve entity, the best fit line will succeed the curve entity.

4 In the Line By Best Fit Dialog Box (page 1989), select From COGO Points.

5 Select one or more AutoCAD Civil points. Enter G to select a point group or N to enter points by number.

 As you select points in the drawing window, an X marks each regression point and a temporary, dashed line is displayed in real time.

6 Press Enter to complete the command.

7 In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

 As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

8 Create the line:

 ■ Click 💾 to create the line and keep the Regression Data vista open.

 ■ Click ✔ to create the line and close the Regression Data vista.

**To create a floating line by best fit from AutoCAD points**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor .

2 On the Alignment Layout Tools toolbar, click  Floating Line - Best Fit.

3 Select a curve entity for the start point and direction.

If you select the beginning of the curve entity, the best fit line will precede the curve entity. If you select the end of the curve entity, the best fit line will succeed the curve entity.

4 In the Line By Best Fit Dialog Box (page 1989), select From AutoCAD Points.

5 Select one or more AutoCAD points.

As you select points in the drawing window, an X marks each regression point and a temporary, dashed line is displayed in real time.

6 Press Enter to complete the command.

7 In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

8 Create the line:

■ Click  to create the line and keep the Regression Data vista open.

■ Click  to create the line and close the Regression Data vista.

**To create a floating line by best fit from existing entities**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor .

2 On the Alignment Layout Tools toolbar, click  Floating Line - Best Fit.

3 Select a curve entity for the start point and direction.

If you select the beginning of the curve entity, the best fit line will precede the curve entity. If you select the end of the curve entity, the best fit line will succeed the curve entity.

4 In the Line By Best Fit Dialog Box (page 1989), select From Entities. Specify the tessellation and mid-ordinate tolerance settings.

5 Select one or more of the entities listed on the command line.

**NOTE** You can select several types of entities listed at the command line.

As you select entities in the drawing window, an X marks each regression point and a temporary, dashed line is displayed in real time.

6 If you selected a profile object, specify the starting and ending station in the Specify Station Range Dialog Box (page 1992).

7 Press Enter to complete the command.

8 In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**9** Create the line:

- ■ Click ![save icon] to create the line and keep the Regression Data vista open.

- ■ Click ![check icon] to create the line and close the Regression Data vista.

**To create a floating line by best fit by clicking on screen**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ![icon] .

2 On the Alignment Layout Tools toolbar, click ![icon] Floating Line - Best Fit.

3 Select a curve entity for the start point and direction.

   If you select the beginning of the curve entity, the best fit line will precede the curve entity. If you select the end of the curve entity, the best fit line will succeed the curve entity.

4 In the Line By Best Fit Dialog Box (page 1989), select By Clicking On The Screen.

5 Select at least one other point.

   **NOTE** You can use OSNAP or transparent commands to select points.

   As you select points in the drawing window, an X marks each regression point and a temporary, dashed line is displayed in real time.

6 Press Enter to complete the command.

7 In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

   As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

8 Create the line:

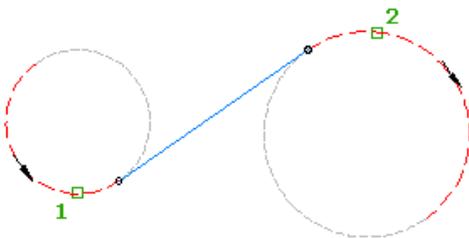
## Adding Free Lines

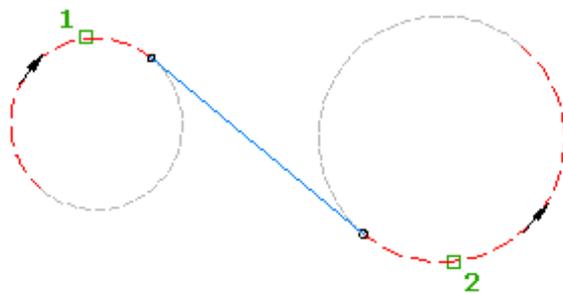
Add free lines to build constraint-based alignment geometry for the areas of your design that require maintaining tangency between two curves.

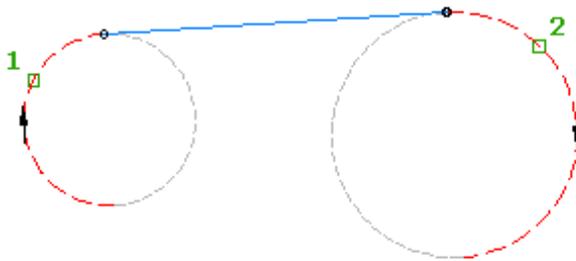
After clicking a button on the Alignment Layout Tools toolbar, follow the command prompts on the command line.

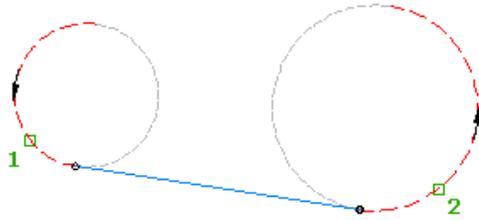
## Adding a Free Line Between Two Curves

Add a free line between two existing curves.

This entity maintains tangency to both attachment curves (2). There are four possible solutions for this entity, depending on the direction of the curves.








**To add a free line (between two curves)**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor 📝 .

2 On the Alignment Layout Tools toolbar, click 📐 Free Line (Between Two Curves).

3 Specify the curve entity from which you want to add the free line.

4 Specify the curve entity to which you want to add the free line.

📐 Free Line (Between Two Curves)

# Adding Curves

Add fixed, free, or floating curves to build constraint-based alignment geometry for the areas of your design that require maintaining tangency.

After clicking a button on the Alignment Layout Tools toolbar, follow the command prompts on the command line.

**TIP** You can use transparent commands when you are prompted to specify direction, radius, or length, or use station offsets to specify any points. For more information, see Transparent Commands (page 1581).

## Adding Fixed Curves

Add a fixed curve through three specified pass-through points.

These commands are similar to an AutoCAD arc, but have a third point along the arc.

## Adding a Fixed Curve with Three Points

Add a fixed three-point curve by specifying three points.

The entity position is not affected by edits to adjacent entities.

**To add a fixed curve (with three points)**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor 📝 .

2 On the Alignment Layout Tools toolbar, click 🌰 Fixed Curve (Three Point).

3 Specify the start point.

4 Specify the second point.

5 Specify the next point.

**TIP** Edit the curve by moving any of the three points.

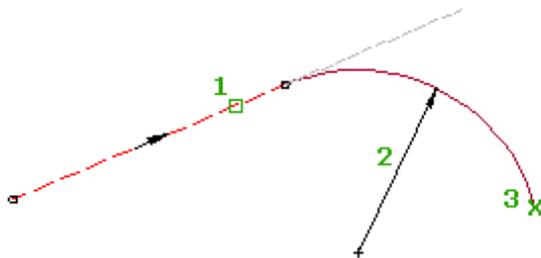
## Adding Floating Curves

Add floating curves to build constraint-based alignment geometry for the areas of your design that require maintaining tangency.

## Adding a Floating Curve with a Radius and a Through Point to an Entity

Add a floating curve, defined by a specified radius and angle range, from an existing entity to a specified end point.

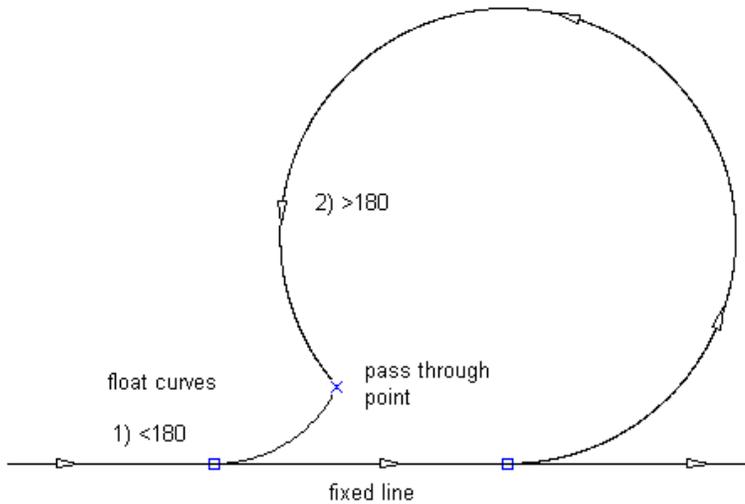
This curve supports both compound and reverse solutions.



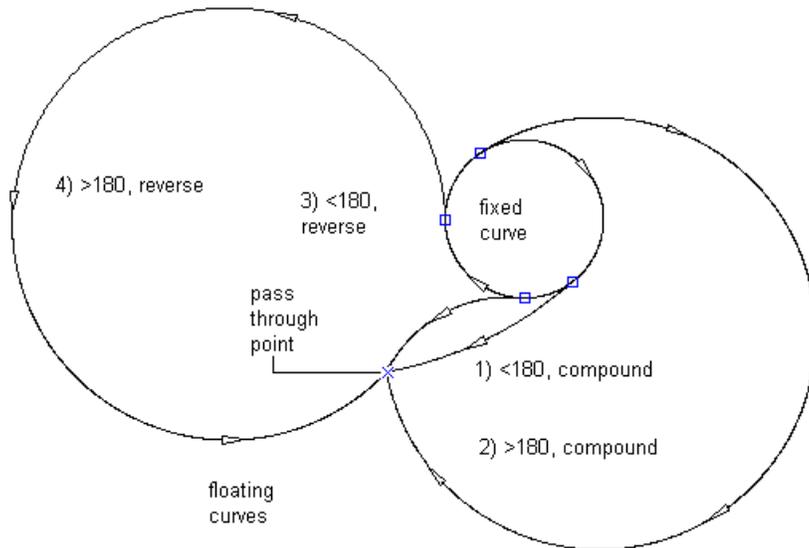
---

**TIP** You can use transparent commands when you are prompted to specify direction, radius, or length, or use station offsets to specify any points. For more information, see Transparent Commands (page 1581).

---

The following illustration shows a floating curve attached to a fixed line and two possible solutions for a given radius and point:


The following illustration shows a floating compound curve attached to a curve and four possible solutions for a given radius and pass-through point. The illustration also shows variables for greater than and less than 180 degrees and compound and reverse variables:



**To add a floating curve (from entity, radius, through point)**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor .

2 On the Alignment Layout Tools toolbar, click  Floating Curve (From Entity, Radius, Through Point).

3 Select the end of the entity to which you want to add the floating curve.

4 Specify a radius.

Specify a new value, or press Enter to accept the value that is displayed on the command line.

■ If the alignment has design criteria (page 866) applied to it, the minimum value for the current design speed is displayed.

- If the alignment does not have design criteria applied to it, the default value specified in the curve and spiral settings is displayed. For more information, see Curve and Spiral Settings (page 861).

**5** Specify whether the curve solution angle is either greater than or less than 180 degrees. A preview curve is displayed.

**NOTE** If the attachment entity is a curve, you are prompted to specify either a compound curve or a reverse curve.

**6** Specify the pass-through point.

## Adding a Floating Curve by Best Fit

Add the most probable floating curve through a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen.

The location of the curve start point on the attachment entity (1) is determined by the path through the selected regression points (2).

**See also:**

■ Editing Best Fit Alignment Entities (page 1003)

**To create a floating curve by best fit using AutoCAD Civil points**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ⬚ .

2 On the Alignment Layout Tools toolbar, click ⬚ Floating Curve - Best Fit.

3 Select an entity for the start point and direction.

If you select the beginning of the entity, the best fit curve will precede the entity. If you select the end of the entity, the best fit curve will succeed the entity.

4 In the Curve By Best Fit Dialog Box (page 1989), select From COGO Points.

5 Select two or more AutoCAD Civil points. Enter G to select a point group or N to enter points by number.

As you select points in the drawing window, an X marks each regression point and a temporary, dashed curve is displayed in real time.

**NOTE** You must select at least two non-collinear regression points.

6 Press Enter to complete the command.

7 In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

8 Create the curve:

■ Click ⬚ to create the curve and keep the Regression Data vista open.

■ Click ✔ to create the curve and close the Regression Data vista.

**To create a floating curve by best fit using AutoCAD points**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ⬚ .

2 On the Alignment Layout Tools toolbar, click ⬚ Floating Curve - Best Fit.

3 Select an entity for the start point and direction.

If you select the beginning of the entity, the best fit curve will precede the entity. If you select the end of the entity, the best fit curve will succeed the entity.

4 In the Curve By Best Fit Dialog Box (page 1989), select From AutoCAD Points.

5 Select two or more AutoCAD points.

As you select points in the drawing window, an X marks each regression point and a temporary, dashed curve is displayed in real time.

**NOTE** You must select at least two non-collinear regression points.

6 Press Enter to complete the command.

**7** In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**8** Create the curve:

■ Click [icon] to create the curve and keep the Regression Data vista open.

■ Click [icon] to create the curve and close the Regression Data vista.

**To create a floating curve by best fit using existing entities**

**1** Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor [icon] .

**2** On the Alignment Layout Tools toolbar, click [icon] Floating Curve - Best Fit.

**3** Select an entity for the start point and direction.

If you select the beginning of the entity, the best fit curve will precede the entity. If you select the end of the entity, the best fit curve will succeed the entity.

**4** In the Curve By Best Fit Dialog Box (page 1989), select From Entities. Specify the tessellation and mid-ordinate tolerance settings.

**5** Select one or more of the entities listed on the command line.

**NOTE** You can select several types of entities listed on the command line.

As you select entities in the drawing window, an X marks each regression point and a temporary, dashed curve is displayed in real time.

**NOTE** You must select at least two non-collinear regression points.

**6** If you selected a profile object, specify the starting and ending station on the Specify Station Range Dialog Box (page 1992).

**7** Press Enter to complete the command.

**8** In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**9** Create the curve:

■ Click [icon] to create the curve and keep the Regression Data vista open.

■ Click [icon] to create the curve and close the Regression Data vista.

**To create a floating curve by best fit by clicking on screen**

**1** Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor [icon] .

**2** On the Alignment Layout Tools toolbar, click [icon] Floating Curve - Best Fit.

**3** Select an entity for the start point and direction.

If you select the beginning of the entity, the best fit curve will precede the entity. If you select the end of the entity, the best fit curve will succeed the entity.

**4** In the Curve By Best Fit Dialog Box (page 1989), select By Clicking On The Screen.

**5** Select at least two points.

---

**NOTE** You can use OSNAP or transparent commands to select points.

---

As you select points in the drawing window, an X marks each regression point and a temporary, dashed curve is displayed in real time.

---

**NOTE** You must select at least two non-collinear regression points.

---

**6** Press Enter to complete the command.

**7** In the Panorama window, use the Regression Data (page 1990) vista to make changes to the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**8** Create the curve:

- Click ![save icon] to create the curve and keep the Regression Data vista open.

- Click ![check icon] to create the curve and close the Regression Data vista.

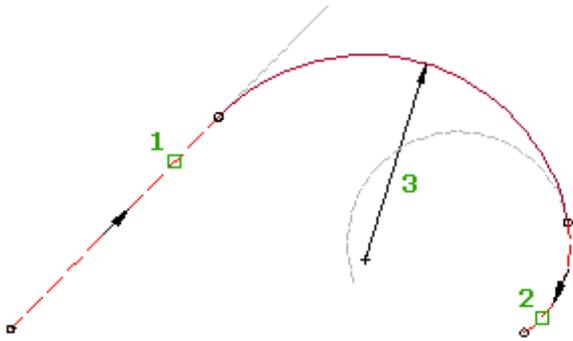
## Adding Free Curves

Add free curves to build constraint-based alignment geometry for the areas of your design that require maintaining tangency.

These entity types are very similar to the AutoCAD "fillet" command, but give you added control.

## Adding a Free Curve Fillet with a Specified Radius Between Two Entities

Add a free curve, with a specified angle range and radius, between two entities.

This entity is defined by the attachment entities (1, 2), radius (3), solution angle, and whether the required solution is compound or reverse. The solution can vary greatly, depending on how you define the constraints.


The following illustration shows a free curve fillet between two fixed lines. There are two solutions based on the included angle of the curve:

The following illustration shows a free curve fillet between two fixed clockwise curves:

2) compound & >180

1) compound & <180

cw
fixed
curve

cw

reverse to curve 2 & <180

4) reverse to curve 1,
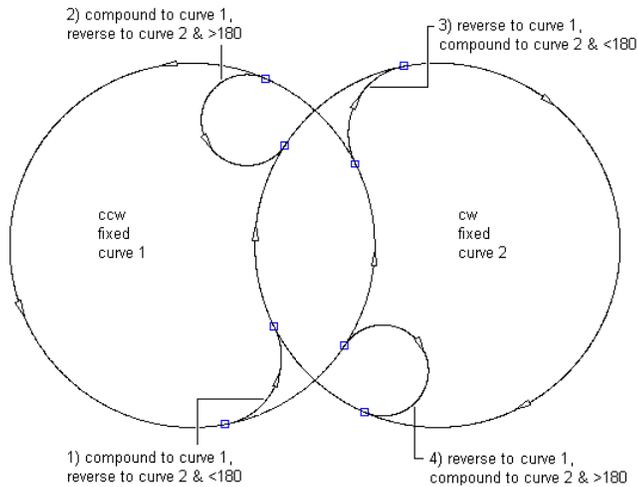
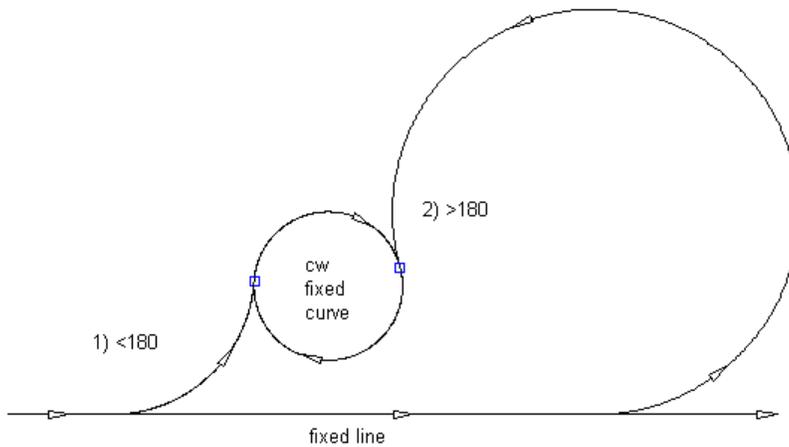
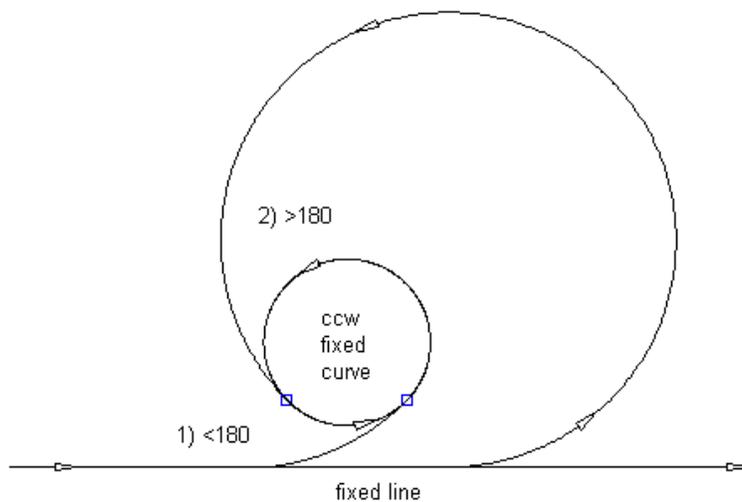
compound to curve 2 & >180


The following illustration shows a free curve fillet between a line and a clockwise curve (on the left) with a specified radius:


The following illustration shows a free curve fillet between a line and a counter-clockwise curve (on the left) with a specified radius:


**To add a free curve fillet (between two entities, radius)**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor .

2 On the Alignment Layout Tools toolbar, click  Free Curve Fillet (Between Two Entities, Radius).

3 Specify the entity (line, curve) from which you want to add the free curve.

4 Specify the entity (line, curve) to which you want to add the free curve.

   **NOTE** The entity before and the entity after must have the same direction.

5 Specify whether the curve solution angle is either greater than or less than 180 degrees.

6 Specify the radius or [curveLen/Tanlen/Chordlen/midOrd/External].

   Specify a new value, or press Enter to accept the value that is displayed on the command line.

   ■ If the alignment has design criteria (page 866) applied to it, the minimum value for the current design speed is displayed.

■ If the alignment does not have design criteria applied to it, the default value specified in the curve and spiral settings is displayed. For more information, see Curve and Spiral Settings (page 861).

To display a curve preview you must pick a point in the drawing or enter a coordinate value, then a rubber band is drawn to the cursor from the selected point and the curve preview is displayed.

7 Specify the second point. You can enter a 2D coordinate point or use a transparent command. For more information, see Transparent Commands (page 1581).

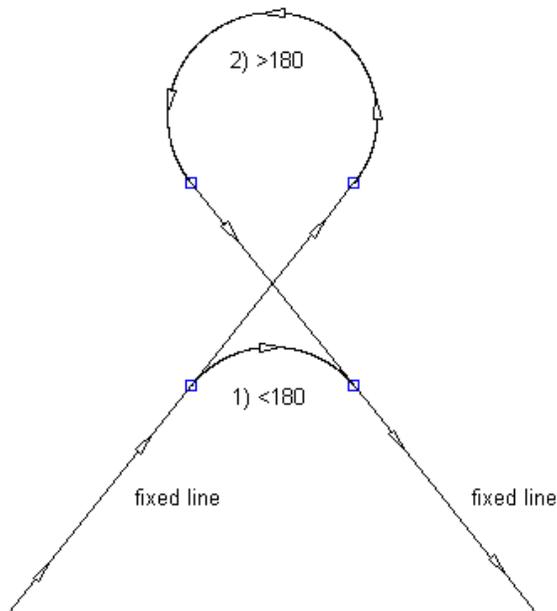
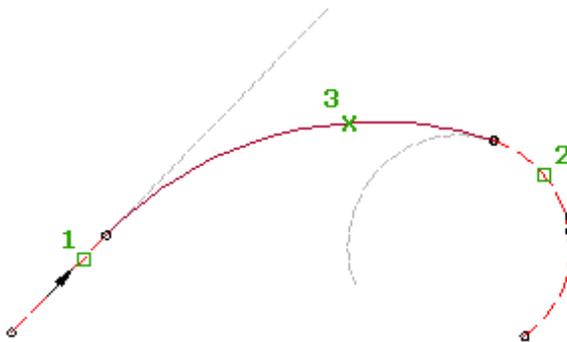
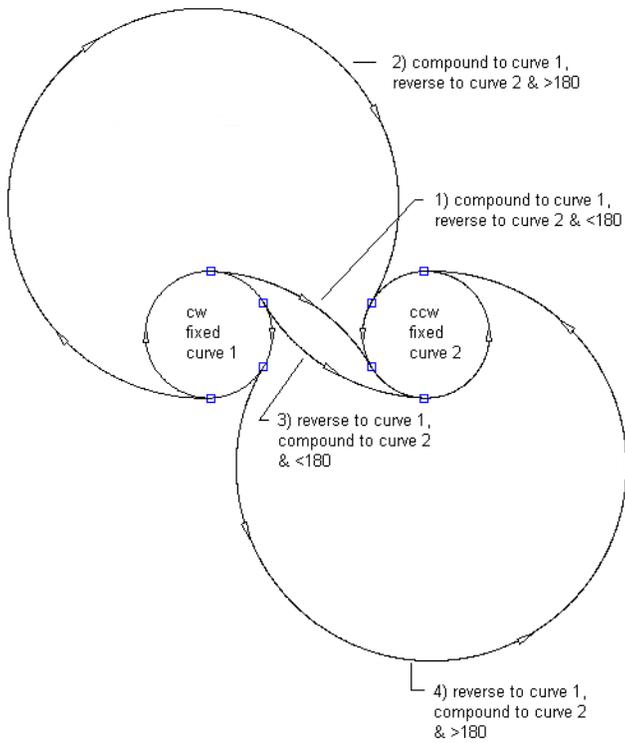
## Adding a Free Curve Fillet with a Through Point Between Two Entities

Add a free curve, with a specified pass-through point, between two entities.

You can add this entity between two lines, two curves, or a line and a curve. The attachment entities (1, 2) and pass-through point (3) determine the curve radius and length. You cannot edit the radius and length for this type of curve.





**TIP** You can use transparent commands when you are prompted to specify direction, radius, or length, or use station offsets to specify any points. For more information, see Transparent Commands (page 1581).


**To add a free curve fillet (between two entities, through point)**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ![icon] .

**2** On the Alignment Layout Tools toolbar, click ⌃ Free Curve Fillet (Between Two Entities, Through Point).

**3** Select the entity from which you want to add the free curve.

**4** Select the entity to which you want to attach the free curve. A curve preview is displayed.

**5** Specify the pass-through point. You can enter a 2D coordinate point or use a transparent command. For more information, see Transparent Commands (page 1581).

# Adding Spirals

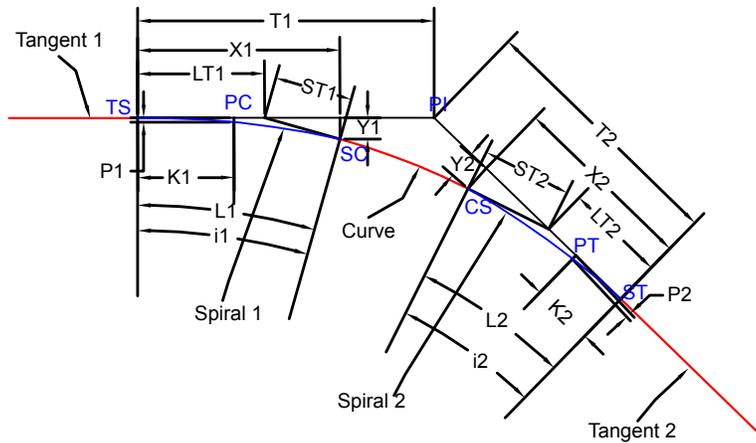
Use the Spiral commands to add fixed, free, or floating spirals to the alignment geometry.

## Spiral Definitions

Various transition curves are used in civil engineering to gradually introduce curvature and superelevation between both tangents and circular curves as well as between two circular curves with different curvature.

In its relationship to other tangents and curves, each spiral is either an incurve (page 2476) or an outcurve (page 2479).

The two most commonly used parameters by engineers in designing and setting out a spiral are L (spiral length) and R (radius of circular curve).

The following illustration shows the various parameters of a spiral:


| Spiral Parameter | Description |
|---|---|
| i1 | The central angle of spiral curve L1, which is the spiral angle. |
| i2 | The central angle of spiral curve L2, which is the spiral angle. |
| T1 | The total tangent distance from PI to TS. |
| T2 | The total tangent distance from PI to ST. |
| X1 | The tangent distance at SC from TS. |
| X2 | The tangent distance at CS from ST. |
| Y1 | The tangent offset distance at SC from TS. |
| Y2 | The tangent offset distance at CS from ST. |
| P1 | The offset of the initial tangent into the PC of the shifted curve. |
| P2 | The offset of the initial tangent out to the PT of the shifted curve. |
| K1 | The abscissa of the shifted PC referred to the TS. |
| K2 | The abscissa of the shifted PT referred to the ST. |
| LT1 | The long tangent spiral in. |
| LT2 | The long tangent spiral out. |
| ST1 | The short tangent spiral in. |
| ST2 | The short tangent spiral out. |
| | Other Spiral Parameters |

| A1 | The A value equals the square root of the spiral length multiplied by the radius. A measure of the flatness of the spiral. |
|---|---|
| A2 | The A value equals the square root of the spiral length multiplied by the radius. A measure of the flatness of the spiral. |

Formula

$$\text{Flatness of spiral} = A = \sqrt{LR}$$

### Compound Spiral

Compound spirals provide a transition between two circular curves with different radii. As with the simple spiral, this allows for continuity of the curvature function and provides a way to introduce a smooth transition in superelevation.

### Clothoid Spiral

While AutoCAD Civil supports several spiral types, the clothoid spiral is the most commonly used spiral type. The clothoid spiral is used world wide in both highway and railway track design.

First investigated by the Swiss mathematician Leonard Euler, the curvature function of the clothoid is a linear function chosen such that the curvature is zero (0) as a function of length where the spiral meets the tangent. The curvature then increases linearly until it is equal to the adjacent curve at the point where the spiral and curve meet.

Such an alignment provides for continuity of the position function and its first derivative (local azimuth), just as a tangent and curve do at a Point of Curvature (PC). However, unlike the simple curve, it also maintains continuity of the second derivative (local curvature), which becomes increasingly important at higher speeds.

Formula

Clothoid spirals can be expressed as: $\theta = \dfrac{l^2}{2RL}$

Flatness of spiral: $A = \sqrt{LR}$

Total angle subtended by spiral: $i_s = \dfrac{L}{2R}$

Tangent distance at spiral-curve point from tangent-spiral point is:

$$X = L*[1 - \frac{L^2}{40R^2} + \frac{L^4}{3456R^4} - ...]$$

Tangent offset distance at spiral-curve point from tangent-spiral point is:

$$Y = \frac{L^2}{6R}[1 - \frac{L^2}{56R^2} + \frac{L^4}{7040R^4} - ...]$$

### Bloss Spiral

Instead of using the clothoid, the Bloss spiral with the parabola of fifth degrees can be used as a transition. This spiral has an advantage over the clothoid in that the shift P is smaller and therefore there is a longer transition, with a larger spiral extension (K). This factor is important in rail design.

Formula

Bloss spirals can be expressed as:

$$\theta = \frac{l^3}{RL^2} - \frac{l^4}{2RL^3}$$

Other key expressions:

Tangent distance at spiral-curve point from tangent-spiral point is:

$$X = L - \frac{L^3}{43.8261R^2} + \frac{L^5}{3696.63R^4}$$

Tangent offset distance at spiral-curve point from tangent-spiral point is:

$$Y = \frac{3L^2}{20R} - \frac{L^4}{363.175R^3}$$

## Sinusoidal Curves

These curves represent a consistent course of curvature and are applicable to transition from 0 through 90 degrees of tangent deflections. However, sinusoidal curves are not widely used because they are steeper than a true spiral and are therefore difficult to tabulate and stake out.

Formula

Sinusoidal curves can be expressed as:

$$\theta = \frac{l^2}{2RL} + \left(\frac{L}{4\pi^2 R}\right)\left[\cos\left(\frac{2\pi l}{L}\right) - 1\right]$$

Differentiating with *l* we get an equation for *l*/*r*, where *r* is the radius of curvature at any given point:

$$r = \frac{2\pi LR}{2\pi l - L * SIN\left(\frac{2\pi l}{L}\right)}$$

## Sine Half-Wavelength Diminishing Tangent Curve

This form of equation is commonly used in Japan for railway design. This curve is useful in situations where you need an efficient transition in the change of curvature for low deflection angles (in regard to vehicle dynamics.)

Formula

Sine Half-Wavelength Diminishing Tangent curves can be expressed as:

$$y = \frac{X^2}{R}\left[\frac{a^2}{4} - \frac{1}{2\pi^2}\{1 - \cos a\pi\}\right]$$

$$a = \frac{x}{X}$$

where and x is the distance from the start to any point on the curve and is measured along the (extended) initial tangent; *X* is the total X at the end of the transition curve.

Other key expressions:

Tangent distance at spiral-curve point from tangent-spiral point is:

$$X = L - \left( \frac{2\pi^2 - 9}{48\pi^2} \right) * \frac{L^3}{R^2} = L - 0.0226689447 \frac{L^3}{R^2}$$

Tangent offset distance at spiral-curve point from tangent-spiral point is:

$$Y = \left[ \frac{1}{4} - \frac{1}{\pi^2} \right] * \frac{X^2}{R} = 0.14867881635766 \frac{X^2}{R}$$

**Cubic Spiral (JP)**

This spiral is developed for requirements in Japan. Some approximations of the clothoid have been developed to use in situations to accommodate a small deflection angle or a large radius. One of these approximations, used for design in Japan, is the Cubic Spiral (JP).

Formula

Cubic Spirals (JP) can be expressed as:

$$y = \frac{x^3}{6RX}$$

Where X = Tangent distance at spiral-curve point from tangent-spiral point

This formula can also be expressed as:

$$\tan \theta_s = \frac{x^2}{2RX}$$

Where $\theta$ is central angle the spiral (illustrated as i1 and i2in the illustration)

Other key expressions:

Tangent distance at spiral-curve point from tangent-spiral point is:

$$X = L * \left[ \frac{10}{10 + (\tan \theta_s)^2} \right]$$

Tangent offset distance at spiral-curve point from tangent-spiral point is:

$$TotalY = \frac{X^2}{6R}$$

**Cubic Parabolas**

Cubic parabolas converge less rapidly than cubic spirals, which makes their use popular in railway and highway design. While they are less accurate than cubic spirals, cubic parabolas are preferred by highway and railway engineers because they are expressed in Cartesian coordinates and are easy to set out in the field.

Formula

When $\theta$ -> zero -> we can assume that cos $\theta$ = 1, then $x = l$.

Further, if we assume that sin $\theta = \theta$ , then

$x = l$ and *TotalX = (approximately) L*

Substituting this approximation helps us obtain the following equation:

$$y = \frac{x^3}{6RL}$$

All other parameters are the same as the clothoid spiral.

Minimum Radius of Cubic Parabola

The radius at any point on a cubic parabola is:

$$r = \frac{\sqrt{RL}}{\sqrt{2\sin\theta\cos^5\theta}}$$

A cubic parabola attains minimum *r* at:

$$\tan\theta = \frac{1}{\sqrt{5}}$$

So $r_{min} = 1.39\sqrt{RL}$

A cubic parabola radius decreases from *infinity* to $r_{min} = 1.39\sqrt{RL}$ at 24 degrees, 5 minutes, 41 seconds and from then onwards starts to increase again. This makes cubic parabolas useless for deflections greater than 24 degrees.

**Bi-Quadratic (Schramm) Spirals**

Bi-quadratic (Schramm) spirals have low values of vertical acceleration. They contain two second-degree parabolas whose radii vary as a function of curve length.

Simple Curve Formula

Curvature of the first parabola:

$$\frac{1}{r} = \frac{2 * l^2}{RL^2} \quad \text{for} \quad 0 \le l \le \frac{L}{2}$$

Curvature of the second parabola:

$$\frac{1}{r} = \frac{4 * L * l - L^2 - 2 * l^2}{RL^2} \quad \text{for} \quad \frac{L}{2} \le l \le L$$

This curve is specified by the user-defined length (L) of the transition curve.

Compound Curve Formulas

Curvature of the first parabola:

$$\frac{1}{r} = \frac{1}{r_1} + \frac{2 * l^2}{L^2}\left(\frac{1}{R_2} - \frac{1}{R_1}\right) \text{ for } 0 \leq l \leq \frac{L}{2}$$

Curvature of the second parabola:

$$\frac{1}{r} = \frac{1}{r_2} - \left(\frac{L-l}{L}\right)^2 * \left(\frac{1}{R_2} - \frac{1}{R_1}\right) \text{ for } \frac{L}{2} \leq l \leq L$$

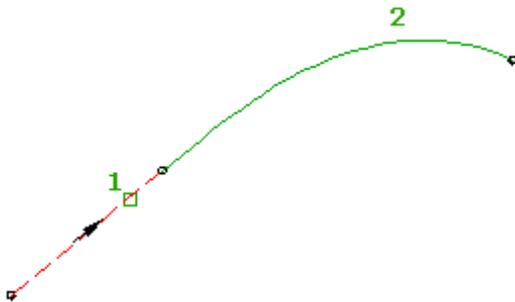
## Adding Fixed Spirals

Use the Alignment Layout Tools to add a fixed spiral to the end of an existing entity.

## Adding a Fixed Spiral

Add a fixed spiral to the end of a fixed or floating entity.

Depending on the desired solution, a fixed spiral can be defined by various parameters, which cannot be edited after creation. When the attachment entity (1) is edited, the defining parameter (2) does not change.



**To add a fixed spiral**

1   Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✐ .

2   On the Alignment Layout Tools toolbar, click ⊚ Fixed Spiral.

   The current spiral definition is displayed on the command line. For more information about changing the default spiral definition, see Specifying Curve and Spiral Settings (page 861)

3   Select the entity for a start point and a direction.

4   Specify the spiral type: either Compound, Incurve, Outcurve, or Point.

5   Specify the curve direction: either Clockwise or Counterclockwise.

6   Specify a start radius by either picking two points in the drawing or entering a value on the command line.

   **NOTE** If the alignment has design criteria (page 866) applied to it, the minimum radius and spiral length values for the current design speed are displayed on the command line. Specify new values, or press Enter to accept the minimums.

**7**  Specify a length by either picking two points in the drawing or entering a value on the command line, or specify the A value.

**8**  Specify the end radius by picking two points in the drawing or entering a value on the command line.

  ◎ Fixed Spiral

## Adding Free Spirals

Use the free spiral commands to create spiral solutions as a transition between two curves with different radii.

## Adding a Free Spiral Between Two Entities

Add a free spiral between two fixed or floating entities.

A free spiral has only one geometric solution, so you cannot specify its length or A value. The solution depends on the type of attachment entities (1, 2), and the order in which they are selected.

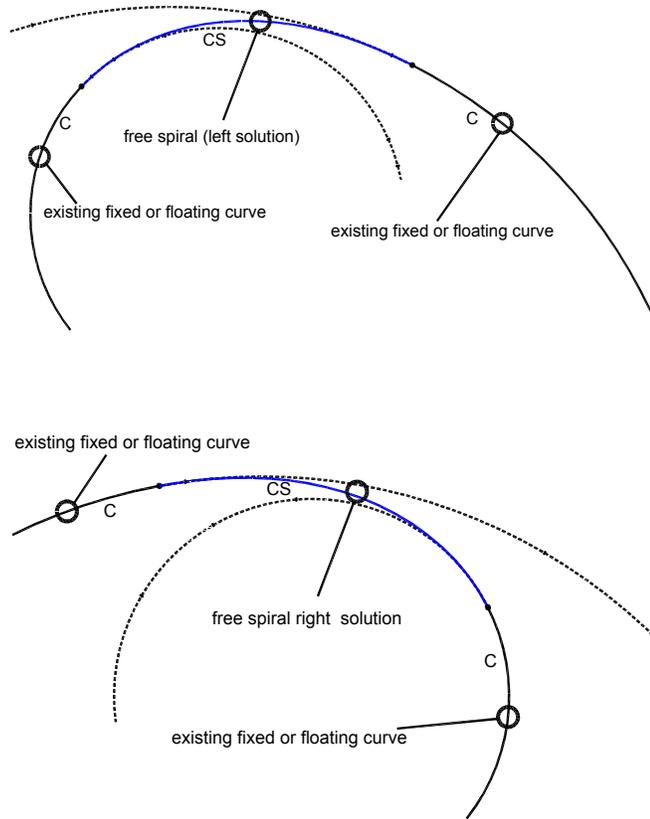
## Adding a Free Spiral Between Two Curves

Use this command in situations where you need to create a single compound spiral solution as a transition between two curves with different radii.

Because free spirals have only one geometric solution, you cannot specify length or A value. The program makes the calculation.

**IMPORTANT** Adding a free spiral between two curves is only supported for Clothoid and Bloss spiral types.

The following illustrations show a free spiral between two curves. The solution depends on the selection order of the curve that the spiral is being attached to. The first illustration shows a left solution, where the inner circle was selected first. The second illustration shows a right solution, where the inner circle was selected second:



**To add a free spiral (between two curves)**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✎ .

2 On the Alignment Layout Tools toolbar, click ┆ Free Spiral (Between Two Entities).

   The current spiral definition is displayed on the command line. For more information about changing the default spiral definition, see Specifying Curve and Spiral Settings (page 861).

3 Select the entity before and the entity after to add the spiral to.

   The solution depends on the order in which you select the curves that the spiral is being attached to. For a solution where the spiral is coming from the left, select the inner circle first. For a solution where the spiral is coming from right, select the inner circle second.

Free Spiral (Between Two Entities)

## Adding a Free Spiral Between Two Lines

Add a free spiral between two lines in situations where you want the spirals to maintain tangency to the lines they are attached to.

For this solution, the spirals are simple, incurve, or outcurve.

The following illustration shows a free spiral between two lines. The possible solutions include:

- simple spiral (page 2482) incurve
- simple spiral outcurve

**To add a free spiral (between two lines)**

1  Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor .

2  On the Alignment Layout Tools toolbar, click  Free Spiral (Between Two Entities).

   The current spiral definition is displayed at the command line. For more information about changing the default spiral definition, see Specifying Curve and Spiral Settings (page 861).

3  Select the entity before and the entity after to add the spiral to.

4  Specify the spiral type as either Incurve or Outcurve.

5  Specify the spiral length or the A value.

Free Spiral (Between Two Entities)

## Adding a Free Spiral Between a Line and a Curve

Add a free spiral between a line and curve in situations where you want the spiral to maintain the radius of the curve it is attached to, even if the curve is edited.

For this solution, the spirals are simple because the radius of the spiral at the line end is infinite (as opposed to a compound spiral, where the radius at each end is finite). This solution between a line and a curve is valid for all spiral types because all spirals types support the simple spiral.

The two possible solutions depend on which entity you select first, either the line or the curve.

The following illustration shows a free spiral between a line and a curve, where the line was selected first:

**To add a free spiral (between a line and a curve)**

1  Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor 📝 .

2  On the Alignment Layout Tools toolbar, click  Free Spiral (Between Two Entities).

   The current spiral definition is displayed at the command line. For more information about changing the default spiral definition, see Specifying Curve and Spiral Settings (page 861).

3  Select the line before and the curve after to add the spiral to.

⌐ Free Spiral (Between Two Entities)

## Adding a Free Compound Spiral-Spiral Between Two Curves

Add a free spiral-spiral group between two curves that are in the same direction but have different radii.

The spirals have finite radii on either end. Spiral parameters and attachment points are automatically calculated. If either of the attachment curves (1, 2) are edited, the spiral-spiral group maintains tangency.

By default, the two spirals have equal lengths and A values. Both values can be modified at the time of creation by specifying a ratio of A1/A2 or L1/L2.

The spiral radii are identical at the spiral-spiral intersection point. The radius value is determined by the total deflection angle and the two spiral lengths. The radius value cannot be edited.

**To add a free compound spiral-spiral (between two curves)**

1   Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✎ .

2   On the Alignment Layout Tools toolbar, click ⌐ Free Compound Spiral-Spiral (Between Two Curves). The current spiral definition is displayed at the command line. For more information about changing the default spiral definition, see Specifying Curve and Spiral Settings (page 861).

3   Specify the entity before and the entity after to which you want to add the spiral.

4   Optionally, enter a value for the ratio of A1 to A2, or select Length and enter a value for the ratio of L1 to L2. Otherwise, the A values and lengths of each spiral will be equal.

**NOTE** If the curves are in the same direction, a compound solution is given. Enter Yes at the command line to accept the solution, or enter No to restart the command. There is no solution if the curves cross, or for concentric curves.

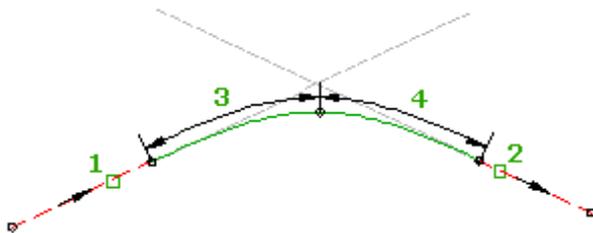
## Adding a Free Compound Spiral-Spiral Between Two Tangents

Add a free compound spiral-spiral group, with a specified parameter, between two tangents.

You specify either the length (3, 4) or A value for each spiral. The spiral radii match at the spiral-spiral intersection point. If either of the attachment tangents (1, 2) are edited, the spiral parameters that you specified do not change.



**To add a free compound spiral-spiral (between two tangents)**

**1** Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor 🖊 .

**2** On the Alignment Layout Tools toolbar, click ⟋ Free Compound Spiral-Spiral (Between Two Tangents).

**3** Select the tangent (the First Entity) from which you want to add the spiral group.

**4** Select the tangent (the Next Entity) to which you want to add the spiral group.

**5** Specify the length or A value of the first spiral (the spiral in).

Specify a new value, or press Enter to accept the value that is displayed on the command line.

- If the alignment has design criteria (page 866) applied to it, the minimum value for the current design speed is displayed.

- If the alignment does not have design criteria applied to it, the default value specified in the curve and spiral settings is displayed. For more information, see Curve and Spiral Settings (page 861).

6 Specify the length or A value of the second spiral (the spiral out).

7 Specify whether the solution is greater or less than 180 degrees.

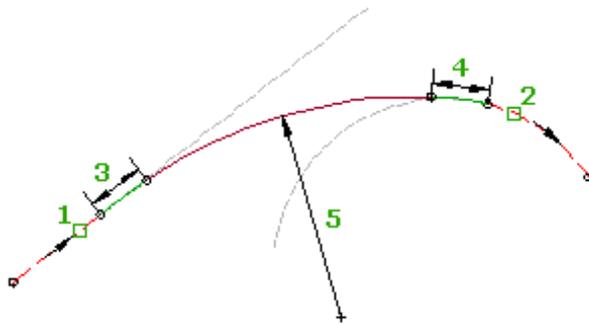
🔵 Floating Reverse Curve With Spirals (From Curve, Two Points)

## Adding Spiral-Curve-Spirals

Add a free spiral-curve-spiral group between two entities.

The type of spirals created (simple vs. compound) depends on the types of entities you attach it to. When the attachment entities (1, 2) are edited, the spiral lengths (3, 4) and curve radius (5) do not change. The attachment points and the curve length adjust to accommodate edits to the attachment entities.


The Spiral-Curve-Spiral command is similar to the command that adds a free curve by radius between two entities. However, this command adds a transition spiral in and a transition spiral out. The curve group for this command is the same as the automatic curve group that is created when you use the Tangent-Tangent command. However, with this command you can create an SCS curve group between curves.

You cannot grip edit the spiral-curve-spiral curve group, but you can edit the entities to which the SCS group is attached. Make edits to the spiral or curve parameters in the Alignment Layout Parameters (page 1741) dialog box or the Alignment Entities (page 1735) vista.

### SCS curve group between two tangents

An SCS curve group placed between two tangents creates two simple spirals.

### SCS curve group between a curve and a tangent

An SCS curve group placed between a tangent and a curve results in the simple spiral attached to the tangent and a compound spiral attached to the curve.

### SCS curve group between two curves

An SCS curve group placed between two curves creates two compound spirals. The SCS curve group should only be placed in a configuration where the attachment to either curve forms a compound curve-curve situation.

### To add a free spiral-curve-spiral (between two entities)

1   Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✎ .

2   On the Alignment Layout Tools toolbar, click ⤳ Free Spiral-Curve-Spiral (Between Two Entities).

3   Select the entity from which you want to add the spiral-curve-spiral.

4   Select the entity to which you want to add the spiral-curve-spiral.

5   Select the spiral-in length by picking two points in the drawing or by entering a spiral-in A value. Specify a new value, or press Enter to accept the value that is displayed on the command line.

   ■ If the alignment has design criteria (page 866) applied to it, the minimum value for the current design speed is displayed.

   ■ If the alignment does not have design criteria applied to it, the default value specified in the curve and spiral settings is displayed. For more information, see Curve and Spiral Settings (page 861).

6   Select the spiral-out length or enter a spiral-out A value.

7   Specify whether the curve solution angle is either greater than or less than 180 degrees.

8   Enter a radius value or select two points in the drawing to specify the radius. To display a curve preview you must either pick a point in the drawing or enter a coordinate value. Then, rubber band is drawn to the cursor from the selected point and the curve preview is displayed.

---

NOTE If you enter an A value for either the spiral-in or the spiral-out value, then the curve preview is not displayed when you specify the radius.

Free Spiral-Curve-Spiral (Between Two Entities)

## Adding Complex Free Curve Groups Between Tangents

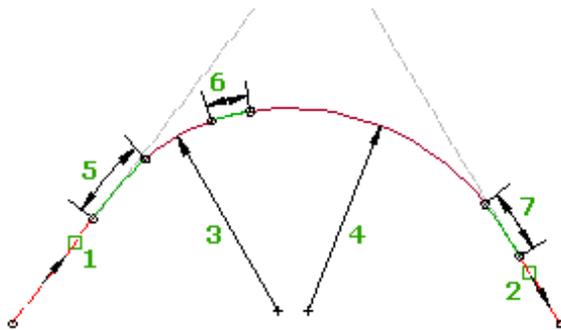
Use the Alignment Layout Tools to add complex curve groups to your alignment. Complex curve groups consist of multiple curves and spirals and are available in compound and reverse solutions.

Complex free curve groups are defined by the radius of each curve and the length or A value of each spiral. Additionally, a second parameter must be specified for either of the two curves.

## Adding a Free Compound Spiral-Curve-Spiral-Curve-Spiral Between Two Tangents

Add a free spiral-curve-spiral-curve-spiral group between two tangents.

When the attachment tangents (1, 2) are edited, the curve radii (3, 4) and spiral lengths (5, 6, 7) do not change. The attachment points and the curve lengths adjust to accommodate edits to the attachment tangents. The length of any of the spirals can be zero.



The compound Spiral-Curve-Spiral-Curve-Spiral (SCSCS) group is placed between two tangents. This group is similar to the spiral-curve-spiral (SCS) group, but it has a second curve and spiral at the end of the group.

The SCSCS group accepts zero as a spiral length, which allows you to create a multiple curve group with or without spirals. Any of the spirals in this group can have a zero length. A spiral with zero length is effectively omitted from the group. The following combinations are possible by specifying zero as the spiral length: SCSCS, SCSC, CSCS, CSC, SCCS, SCC, CCS, CC.

You cannot grip edit the SCSCS group, but you can edit the tangents to which it is attached. The point of intersection (PI) of the original tangents is maintained, which causes the entire curve group to react to

changes to either tangent. You can edit the spiral or curve parameters directly in either the Alignment Layout Parameters (page 1741) dialog box or the Alignment Entities (page 1735) vista. If a spiral in the group has zero length specified, the spiral parameters are still displayed.

**To add a free spiral-curve-spiral-curve spiral between two tangents**

1   Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✎ .

2   On the Alignment Layout Tools toolbar, click ⟲ Free Compound Spiral-Curve-Spiral-Curve-Spiral (Between Two Tangents).

3   Select the tangent (the First Entity) from which you want to add the curve group.

4   Select the tangent (the Next Entity) to which you want to add the curve group.

5   Specify the length or A value of the first spiral.

---

**NOTE**  You can specify length by picking two points in the drawing. Zero is an acceptable length for any of the spirals in this curve group.

---

6   Specify the radius of the first curve.

7   Specify the length or A value of the second spiral.

8   Specify the radius of the second curve.

9   Specify the length or A value of the third spiral.

10   Enter a second parameter for one of the curves.

You can specify an extended tangent length, start point on a tangent, subtended angle, or pass-through point. Enter C to switch the curve for which you will enter the parameter.

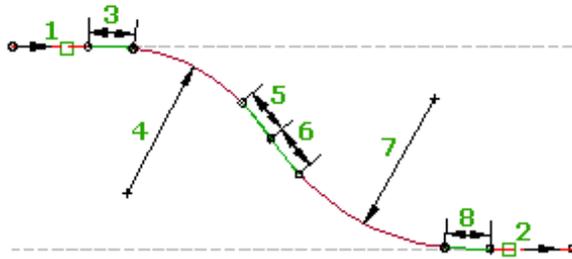
⟲ Free Compound Spiral-Curve-Spiral-Curve-Spiral (Between Two Tangents)

# Adding a Free Reverse Spiral-Curve-Spiral-Spiral-Curve-Spiral Between Two Tangents

Add a free reverse spiral-curve-spiral-spiral-curve-spiral group between two tangents that are nearly parallel.

This group consists of two successive spiral-curve-spiral groups in opposing directions. When the attachment tangents (1, 2) are edited, the curve radii (4, 7) and spiral lengths (3, 5, 6, 8) do not change. The attachment points and the curve lengths adjust to accommodate edits to the attachment tangents.


You cannot grip edit the reverse SCSSCS group, but you can edit the tangents to which it is attached. You can edit the spiral or curve parameters directly in either the Alignment Layout Parameters (page 1741) dialog box or the Alignment Entities (page 1735) vista.

**To add a free reverse spiral-curve-spiral-spiral-curve-spiral between two tangents**

1   Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✏ .

2   On the Alignment Layout Tools toolbar, click 🖉 Free Reverse Spiral-Curve-Spiral-Spiral-Curve-Spiral (Between Two Tangents).

3   Select the tangent (the First Entity) from which you want to add the curve group.

4   Select the tangent (the Next Entity) to which you want to add the curve group.

5   Specify the length or A value of the first spiral (the spiral in).

   **NOTE**   You can specify length by picking two points in the drawing.

6   Specify a radius for the first curve.

7   Specify the length or A value of the second spiral (the spiral out).

8   Specify the length or A value of the third spiral (the spiral in).

9   Specify a radius for the second curve.

10   Specify the length or A value of the fourth spiral (the spiral out).

11   Enter a second parameter for one of the curves.
   You can specify a start point on a tangent, subtended angle, or pass-through point. Enter C to switch the curve for which you will enter the parameter.

# Alignment Labels and Tables

Use the label and table styles to control the appearance and behavior of alignment labels and tables in a drawing.

When you create alignments, they are labeled automatically with the labels specified in the Alignment Labels dialog box. The labels are applied along the alignment at specific points, for example, the major and minor stations.

With the Add Labels command, you specify the following parameters as you label the alignment:

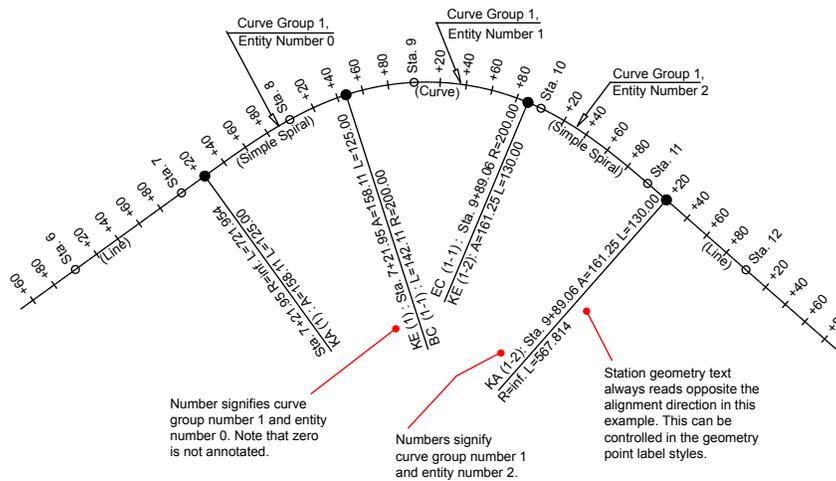
■ Label type, such as station offset, segment, and tangent intersection

■ Label and marker styles

■ Points along the alignment

You can also use commands to insert alignment tables into a drawing. Alignment tables organize and consolidate the information about the alignment. When you insert a table into the drawing, full labels are converted to tags, and the detailed alignment information is inserted into the table.

The topics in this section describe what is unique to alignment labels and tables. For a general overview of labels, see Labels and Tags (page 1463). For an overview of tables, see Tables (page 1555).



**Alignment labels**

# Alignment Label Styles

Manage alignment label styles by specifying which label styles to use when you create alignment label sets, as well as which styles to use with the Add Alignment Labels command.

In Toolspace, on the Settings tab, the Alignment collection contains the Label Styles collection. The Label Styles collection contains sub-folders for labels sets, individual types of alignment labels, and alignment table styles. You can right-click a specific type of alignment label, such as for major stations and minor stations, and either edit the default label settings or create a label style.

The types of alignment label styles that you can create and use:

| Use this type of alignment label style... | To label... |
|---|---|
| Major Station | Stations at major intervals, which use the default format of sta = <station> <units>. For example, sta = 1000 ft. |
| Minor Station | Stations at intervals that divide the major stations. To add minor station labels, you must have major station labels. |
| Geometry Point | Locations at which alignment geometry changes, which use the default format of <Geometry point>: <station>. For example, CS: 3+27+65. |
| Profile Geometry Point | Locations of profile points on the alignment geometry. |
| Station Equation | Points added on the Station Control tab of the Alignment Properties dialog box. |
| Design Speeds | Points added on the Design Speeds tab of the Alignment Properties dialog box. |
| Superelevation Critical Points | Stations at which the superelevation cross slope changes. |
| Station Offset | A point either on or adjacent to an alignment that lists station and offset information from the alignment to the point picked. |
| Line | Properties of a line entity within an alignment object. |
| Curve | Properties of a curve entity within an alignment object. |
| Spiral | Properties of a spiral entity within an alignment object. |
| Tangent Intersection | Properties of a tangent-tangent intersection (PI) and either the associated free curve or free Spiral-Curve-Spiral (SCS) group. This label type can also be applied to either individual curve or spiral entities (even within an SCS group). |

# Labeling Alignment Stations

Station labels display reference information about specific points along the length of an alignment.

AutoCAD Civil supports the following alignment station label types:

■ Major Stations

■ Minor Stations

■ Geometry Points

■ Profile Geometry Points

- Station Equations

- Design Speeds

- Superelevation Critical Points

When you create an alignment, you select a label set, which is a predefined collection of label types with associated styles. You can modify the station labels in an existing alignment, and then optionally save the changes as a label set.

## Using Alignment Label Sets

One step in creating an alignment is selecting the Alignment Label Set.

## Using Label Sets

Use the Alignment Labels dialog box to assign styles to the individual elements that you want to label on the alignment. Then save the group of labels as a label set.

For example, you can create a label set that only includes major and minor station types, and another label set that includes major and minor stations, and also geometry points, station equations, and design speeds. You can determine the style, start station, and end station for each type of individual label in the label set.

A label set can contain multiple instances of a label type. You can assign different label styles to the individual geometry points in the Geometry Points, Profile Geometry Points, and Superelevation Critical Points label types. For example, you can create a label set that contains multiple occurrences of the Geometry Points label type. One occurrence can label the Alignment Beginning and Alignment End points using a style. A second occurrence of the Geometry Points label type can label the Tangent-Tangent Intersect and Tangent-Curve Intersect points using a different style.

After you save a label set, you can reuse it by importing it to the alignment.

Label sets include the following label types:

- Major Stations

- Minor Stations

- Geometry Points

- Profile Geometry Points

- Station Equations

- Design Speeds

- Superelevation Critical Points

For more information about modifying labels, see Modifying Labels in a Drawing (page 1533). For more information about which properties of different label types can be modified, see Managing Layout Properties for Label Styles (page 1492).

**NOTE** To change the label type defaults, right-click the <Label Type> collection on the Settings tree in Toolspace and select Edit Label Style Defaults. For more information, see Default Settings for All Labels in a Label Type (page 1476).

**To add labels to a label set**

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Add/Edit Station Labels
   ◈ .

2  Select an alignment in the drawing to open the Alignment Labels dialog box.

3  In the Type list, select the type of label that you want to add.

> **NOTE** To add minor station labels, you must have at least one major station label type added to the label set.

4  In the Style list, select a style for the label type.

5  Click Add.

> **TIP** To delete a label, select the label type and click. You cannot delete a major station if it has a minor station.

6  If you select either the Geometry Points, Profile Geometry Points, or Superelevation Critical Points label type, select the specific points to label.

7  In the Style column, either click the icon to change the style or accept the label style selection.

8  In the Increment column, either enter a value to determine the increment distance between major station labels, or accept the default.

9  In the Start Station column, either clear the check box and enter a new starting station value or accept the default.

10  In the End Station column, either clear the check box and enter a new end station value or accept the default.

> **NOTE** The default start and end stations for each label type are the beginning and end of the alignment. To change either the start station or end station, clear the check box, and enter new start station and end station values.

11  In the Geometry Points To Label column, click ⊡ to update the points to label.

> **NOTE** The Geometry Points To Label column is only available for the Geometry Points, Profile Geometry Points, and Superelevation Critical Points label types.

12  Repeat Steps 2 through 10 to add more label types to the label set.

## Saving Alignment Label Sets

Create and save any number of alignment label sets to use during different phases in a project.

Copy and edit label sets from the Label Style collection in Toolspace on the Settings tab.

**To save a label set**

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Add/Edit Station Labels
   ◈ .

2  Select an alignment in the drawing to open the Alignment Labels dialog box.

3  In the Alignment Labels dialog box, determine the label types you want to save in the label set.

**4** Click Save Label Set. The Alignment Label Set dialog box is displayed.

**5** On the Information tab (page 1771), enter a name and optional description for the label set.

**6** Optionally, on the Labels tab (page 1772), change values.

## Importing Label Sets

Create and save any number of alignment label sets. Import the labels sets during different phases in a project.

**To import a label set**

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Add/Edit Station Labels
.

**2** Select an alignment in the drawing to open the Alignment Labels dialog box.

**3** In the Alignment Labels dialog box, click Import Label Set.

**4** In the Select Style Set dialog box, either select an existing label set or copy, edit, or create a label set.

## Editing Alignment Station Labels

After an alignment has been created, you can change the type and style of the station labels.

If you label an alignment created through an xref, the labels you add exist in the current drawing. If you detach the xref, labels created in the current drawing will be lost.

You can save a collection of alignment station label types and styles as a label set, which can be applied to other alignments.

**To edit alignment station labels**

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Add/Edit Station Labels
.

**2** Select an alignment in the drawing to open the Alignment Labels dialog box.

**3** In the Alignment Labels dialog box, do any of the following procedures, and then click OK.

**To add a station label type to the alignment**

**1** In the Type list, select the type of label that you want to add.

> **NOTE** To add minor station labels, you must have at least one major station label type added to the label set.

**2** In the Style list, select a style for the label type.

**3** Click Add.

**4** If you select either the Geometry Points, Profile Geometry Points, or Superelevation Critical Points label type, select the specific points to label.

**To delete a station label type from the alignment**

To delete a label, select the label type and click ✖ . You cannot delete a major station if it has a minor station.

**To change the parameters of an existing station label type**

1  In the Style column, either click the icon to change the style or accept the label style selection.

2  In the Increment column, either enter a value to determine the increment distance between major station labels, or accept the default.

3  In the Start Station column, either clear the check box and enter a new starting station value or accept the default.

4  In the End Station column, either clear the check box and enter a new end station value or accept the default.

> **NOTE** The default start and end stations for each label type are the beginning and end of the alignment. To change either the start station or end station, clear the check box, and enter new start station and end station values.

5  In the Geometry Points To Label column, click ⊡ to update the points to label.

> **NOTE** The Geometry Points To Label column is only available for the Geometry Points, Profile Geometry Points, and Superelevation Critical Points label types.

Command Line

EditAlignmentLabels

Dialog Box

Alignment Labels Dialog Box (page 1739)
Alignment Geometry Points Dialog Box (page 1739)
Profile Geometry Points Dialog Box (page 1775)
Superelevation Critical Points Dialog Box (page 1775)

## Labeling Geometry Points

Use different styles to label specific alignment, profile, or superelevation critical geometry points along an alignment.

You can apply separate label styles to specific points in the geometry point label types. You can determine which points to label, and then apply different styles to each point type.

For example, you can create a label set that contains multiple occurrences of the Geometry Points label type. One occurrence can label the Alignment Beginning and Alignment End points using a style. A second occurrence of the Geometry Points label type can label the Tangent-Tangent Intersect and Tangent-Curve Intersect points using a different style.

Geometry point label types include:

- Geometry Points

- Profile Geometry Points

- Superelevation Critical Points

    **NOTE** Superelevation critical labels are not dynamically linked to the parent alignment. If the alignment geometry changes, the superelevation critical labels must be updated manually.

    **TIP** Superelevation critical point labels can also display a diagram that represents the cross section at each superelevation transition point. For more information, see Adding Superelevation Cross-Section Diagrams Along an Alignment (page 978).

**To add geometry point labels**

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Add/Edit Station Labels
  .

2 Select an alignment in the drawing to open the Alignment Labels dialog box.

3 In the Alignment Labels Dialog Box (page 1739) dialog box, in the Type list, select the type of geometry point label that you want to add.

  Select either Geometry Points, Profile Geometry Points, or Superelevation Critical Points.

4 In the Style list, select a style for the label type.

  This style is used by the geometry points you specify in Step 5.

5 Click Add.

6 In the <label type> Points dialog box, select the specific points to label.

    **NOTE** If you selected Profile Geometry Points, you must specify a profile to reference in the Profile Geometry Points Dialog Box (page 1775) dialog box.

7 In the Start Station column, either clear the check box and enter a new starting station value or accept the default.

8 In the End Station column, either clear the check box and enter a new end station value or accept the default.

    **NOTE** The default start and end stations for each label type are the beginning and end of the alignment. To change either the start station or end station, clear the check box, and enter new start station and end station values.

9 Repeat Steps 1 through 7 to add more geometry point labels.

  You can add multiple instances of each label type. Each instance can label different geometry points and use a different label style and range of stations.

    **NOTE** In the Geometry Points To Label column, click  to update the points to label.

Superelevation Critical Points Dialog Box (page 1775)

## Adding Superelevation Cross-Section Diagrams Along an Alignment

Add block diagrams that represent the cross section at each superelevation transition point.

To add superelevation cross-section diagrams, compose a separate label style for each of the Superelevation Critical Points that you want to label. Use the Alignment Labels dialog box to add each of the point label styles to the alignment. You can save the collection of superelevation critical point labels as a label set, which you can apply to other alignments.

**To add superelevation cross-section diagrams along an alignment**

1   Compose a label style for each type of superelevation critical point that you want to label.

   Each style must contain a block component that refers to an appropriate representation of the cross section at that type of geometry point. Optionally, each style can include text, tick, and line components.

   For information about composing a label style, see Creating New Label Styles (page 1477).

2   Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Add/Edit Station Labels .

3   Select an alignment in the drawing to open the Alignment Labels dialog box.

4   In the Alignment Labels Dialog Box (page 1739), in the Type list, select Superelevation Critical Points.

5   In the Superelevation Label Style list, select a style for the superelevation critical geometry point.

6   Click Add.

7   In the Superelevation Critical Points Dialog Box (page 1775), click  Deselect All. Select the superelevation critical points that correspond to the style you selected in Step 4. Click OK.

8   In the Start Station column, either clear the check box and enter a new starting station value, or accept the default.

9   In the End Station column, either clear the check box and enter a new end station value, or accept the default.

> **NOTE** The default start and end stations for each label type are the beginning and end of the alignment. To change either the start station or end station, clear the check box, and enter new start station and end station values.

**10** Repeat Steps 3 through 8 to add the remaining superelevation critical points.

**11** Add other alignment label types as desired.

**12** Optionally, click Save Label Set to save the current label configuration as a label set.
For more information, see Saving Alignment Label Sets (page 974).

Command Line

EditAlignmentLabels

Dialog Box

Alignment Labels Dialog Box (page 1739)
Superelevation Critical Points Dialog Box (page 1775)

## Displaying Stations in Station Index Format

Use the Station Index Format to label a station value as a count that is relative to a distance.

This distance is referred to as a station index increment. Specify the station index increment in the Alignment Labels dialog box. Format the station index label using the Label Style Composer Dialog Box (page 1942).

**To display stations in station index format**

**1** In Toolspace, on the Settings tab, right-click a station label type. Click either Edit or New.

**2** In the Label Style Composer, click the Layout tab.

**3** Under Text, click ⋯ in the Contents Value column.

**4** In the Text Component Editor, click the Format Value column. Select Station Index Format from the list.

**5** Specify other modifiers as necessary.

**6** Click ⇨ to insert the property into the Text Component Editor window.

**7** Click OK.

## Changing the Station Character Display

Use the Station Character setting to change the display of the character in station labels.

The following station character formats are available:

- 10+50.00
- 10-50.00
- 10_50.00
- 1050.00
- 10/50.00
- 10C50.00
- 10K50.00

**To change the display of the station character**

1  In Toolspace, on the Settings tab, right-click a station label type. Click either Edit or New.

2  In the Label Style Composer, click the Layout tab.

3  Under Text, click ⬚ in the Contents Value column.

4  In the Text Component Editor, in the preview pane, select the station value property formula.

5  In the Properties list, select Station Value.

6  Click the Station Character Value column. Select the desired character from the list.

7  Specify other modifiers as necessary.

8  Click ⇨ to insert the property into the Text Component Editor window.

9  Click OK.

# Adding Descriptive Geometry Point Text

Use the Abbreviations tab in the Drawing Settings dialog box to compose labels that include geometric property information about the entities that come before and after geometry points.

**See also:**

- Abbreviations Tab (Drawing Settings Dialog Box) (page 1855)

**To add descriptive geometry point text**

1  In Toolspace, on the Settings tab, right-click the drawing and click Edit Drawing Settings. Click the Abbreviations Tab (Drawing Settings Dialog Box) (page 1855).

2  In the Alignment Geometry Point Entity Data section, select the entity endpoint type. Click ⬚ in the Value column to modify the label for that type.

3  In the Text Component Editor, select a property from the list and select modifiers as necessary.

4  Click ⇨ to insert the property into the Text Component Editor window.

5  Insert other properties and modifiers as necessary. Click OK.

6  Repeat Steps 2-5 to format other alignment endpoint entities listed on the Abbreviations tab.

**7** In Toolspace, on the Settings tab, right-click a <geometry point label>. Click either Edit or New.

**8** In the Label Style Composer, click the Layout tab.

**9** Under Text, click [...] in the Contents Value column.

**10** In the Properties list, select Geometry Point Entity Before Data. Click ⇨ .

**11** In the Properties list, select Geometry Point Entity After Data. Click ⇨ .

**12** Click OK.

The text you compose on the Abbreviations tab for the alignment endpoint entities is included in the labels that display before and after the geometry point.

# Labeling Alignment Line, Curve, and Spiral Entities

You can label components along an alignment by using specified label styles.

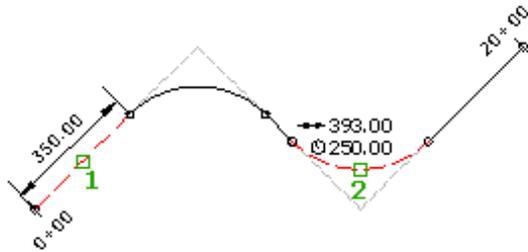
To place the label, specify the alignment and the component in the drawing, such as a line, curve, or spiral segment. Select either a single segment or intersection or label the whole alignment using the multiple options.

For more information about modifying labels, see Modifying Labels in a Drawing (page 1533). For more information about modifying label properties, see Managing Layout Properties for Label Styles (page 1492).

## Adding Labels to Single Segments in Alignments

Add single segment labels to the lines, curves, or spirals with Line, Curve, and Spiral label styles.

Labels are placed on each line (1), curve (2) or spiral entity that you select.



**To label alignment line segments**

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Single Segment ✎ .

**2** Select a location on the alignment line or segment to label.

**3** In the Label Type list, select Single Segment.

**4** Specify label styles for Line, Curve, and Spiral.

**5** Click Add. In the drawing, select the alignment.

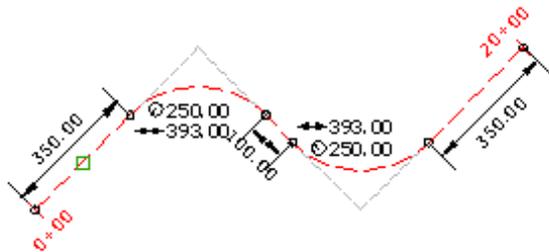
**6** In the drawing, select the segments you want to label.

**Quick Reference**

## Adding Multiple Segment Labels to Alignments

Automatically label all lines, curves, and spirals in the alignment with Line, Curve, and Spiral label styles.

Labels are placed on each line, curve, and spiral entity in the selected alignment.



**To label multiple alignment line segments**

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Add Alignment Labels ✎ .

2  In the Add Labels dialog box, verify that Alignments is displayed in the Feature list.

3  In the Label Type list, select Multiple Segment.

4  Specify label styles for Line, Curve, and Spiral.

5  Click Add. In the drawing, select the alignment.
   Labels are displayed on all lines, curves, and spirals in the alignment.

**Quick Reference**

Command Line

AddAlignLabels

# Labeling Station Offset and Tangent Intersection Points in Alignments

You can label a station offset or a tangent intersection with specified offset and marker label styles.

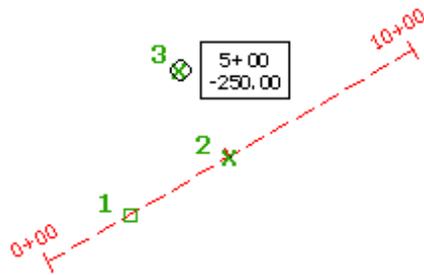
You can label individual tangent-intersection points or use the multiple tangent intersection command and label all points. The multiple tangent intersection command labels the PI points of all intersecting tangents, along with the PI point for any curves, or spiral-curve-spiral groups.

**NOTE** You cannot label fixed spirals with the multiple tangent intersection label command.

## Adding Station Offset Labels - Relative Point

Add station offset labels at selected points along the alignment. You must also specify a style for the point marker.

For the selected alignment (1), you specify the desired station (2) and offset distance (3). If the alignment is moved, the label moves with it and maintains the relative station and offset location.



**NOTE** If you move the alignment, labels that you add using the station offset labels command move with the associated point.

**To add station offset labels for relative points**

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Station/Offset  .

2   Select the station and offset distance to label.

## Quick Reference

Ribbon

Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Station/Offset 

Menu

Click Alignments menu ➤ Add Alignment Labels ➤ Station/Offset

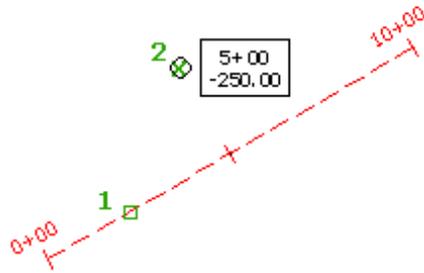
Command Line

AddAlignOffLbl

## Adding Station Offset Labels - Fixed Point

Add station offset labels at fixed points in the drawing. Because the Station Offset label uses a point marker to locate the station offset point, you must also specify a Marker Style.

For the selected alignment (1), you specify the XY location of the desired point (2). If the alignment is moved, the point's X-Y location is maintained, but the labels update to show new station and offset distances.



**NOTE** If you edit the alignment, labels that you add using the Station/Offset - Fixed Point command do not move.

**To add station offset labels at a fixed point**

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Station/Offset – Fixed ✎ .

2  Select the point location to label.

### Quick Reference

Menu

Click Alignments menu ➤ Add Alignment Labels ➤ Station/Offset - Fixed Point

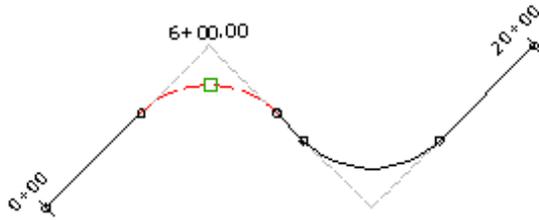
Command Line

AddAlignOffXYLbl

## Adding Tangent Intersection Labels

Add tangent intersection labels to selected intersections on the alignment.

You can label the intersection point, or label the properties of a curve or a spiral-curve-spiral group at the tangent intersection.

---


**NOTE** Complex free curve groups (compound SCSCS and reverse SCSSCS) do not support tangent intersection labels. For more information on complex curve groups, see Adding Complex Free Curve Groups Between Tangents (page 968).

---

**To add tangent intersection labels**

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Tangent Intersection 🏷 .

2 Select the tangent intersection to label.

## Quick Reference

Ribbon

Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Tangent Intersection 🏷

Menu

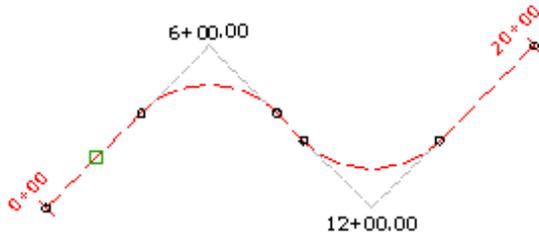
Click Alignments menu ➤ Add Alignment Labels ➤ Tangent Intersection

Command Line

AddAlignTangentIntLbl

## Adding Multiple Tangent Intersection Labels

Add multiple tangent intersection labels at every point of intersection (PI) on the alignment, including the actual point of intersection of two tangents, as well as the virtual locations of the PI for curves and spiral-curve-spiral groups.

Labels are placed at all tangent intersection points for the selected alignment.


**NOTE** Complex free curve groups (compound SCSCS and reverse SCSSCS) do not support PI labels. For more information on complex curve groups, see Adding Complex Free Curve Groups Between Tangents (page 968).

**To add multiple tangent intersection labels**

1   Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Alignment ➤ Multiple Tangent Intersection 🏷 .

2   Select the tangent intersections to label.

# Alignment Table Styles

Manage alignment table styles, which define the type of information that is placed in the alignment table on the Settings tab.

The types of alignment table styles that you can create and use:

| This Alignment table style... | Places the following alignment information in the table... |
| --- | --- |
| Line | Geometric information for points on any solved line portion of the alignment |
| Curve | Geometric information for points on any solved curve portion of the alignment |
| Spiral | Geometric information for points on any solved spiral portion of the alignment |

| This Alignment table style... | Places the following alignment information in the table... |
|---|---|
| Segment | Combines geometric information for lines, curves, and spirals into one table |

# Adding Alignment Tables

Create alignment tables that contain information about the alignment components, such as lines, curves, spirals, and segments.

Alignment segments must be labeled before you add a table to the drawing. When you add the table, the labels are converted to tags.

Use alignment tables to present alignment data in a concise format and to reduce the labels to compact tags that reference the table rows.

You create and edit tables for most objects using the same common procedures and standard dialog boxes. The procedures in this topic explain how to access the alignment table creation commands, and provide links to reference information about the Table Creation dialog box. For information about modifying tables, see Modifying Tables (page 1567).

**To create a line table**

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Alignment ➤ Add Line ⊞ .

2  In the Table Creation (page 2441) dialog box, select a Table Style and a Table Layer.

3  Specify the label styles or select labels in the drawing to create a tag child style for the labels.

4  Select the Apply check box.

5  Select the Split Table check box and enter values.

6  Under Behavior, select either Static or Dynamic.

7  Click the upper left corner in the drawing where you want the table to display.

**To create a curve table**

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Alignment ➤ Add Curve ⊞ .

2  In the Table Creation (page 2441) dialog box, select a Table Style and a Table Layer.

3  Specify the label styles or select labels in the drawing to create a tag child style for the labels.

4  Select the Apply check box.

5  Select the Split Table check box and enter values.

6  Under Behavior, select either Static or Dynamic.

7  Click the upper left corner in the drawing where you want the table to display.

**To create a spiral table**

1  Click Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Alignment ➤ Add Spiral.

2  In the Table Creation (page 2441) dialog box, select a Table Style and a Table Layer.

3  Specify the label styles or select labels in the drawing to create a tag child style for the labels.

**4** Select the Apply check box.

**5** Select the Split Table check box and enter values.

**6** Under Behavior, select either Static or Dynamic.

**7** Click the upper left corner in the drawing where you want the table to display.

**To create a segment table**

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Alignment ➤ Add Segment ⊞ .

**2** In the Table Creation (page 2441) dialog box, select a Table Style and a Table Layer.

**3** Specify the label styles or select labels in the drawing to create a tag child style for the labels.

**4** Select the Apply check box.

**5** Select the Split Table check box and enter values.

**6** Under Behavior, select either Static or Dynamic.

**7** Click the upper left corner in the drawing where you want the table to display.

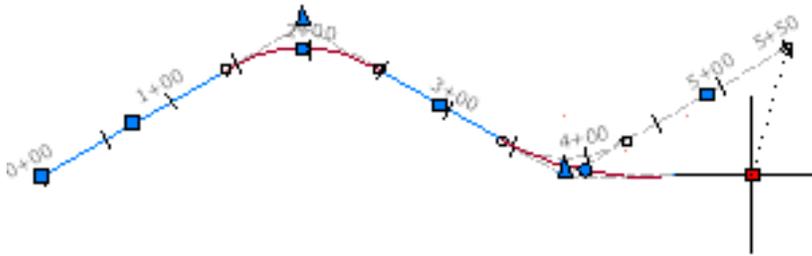
# Editing Alignments

Edit an alignment by modifying the geometry or parameter values.

You can grip edit an alignment, modify geometric values, or add constraint-based line, curve, and spiral entities.


You use the Alignment Layout Tools toolbar, Alignment Layout Parameters dialog box, and Alignment Entities vista to edit an alignment. These dialog boxes remain open if you either grip edit or deselect the alignment, or enter another command.

If you select an alignment for editing and then select a second alignment, the second alignment becomes the active alignment. The most recently selected alignment has the focus of the Alignment Layout Tools toolbar and the Alignment Entities vista. The last object selected becomes the current object and has focus of the alignment editing tools.

**See also:**

■　Alignment Properties (page 863)

## Selecting Alignment Entities

Select an entire alignment, a single sub-entity, or a range of sub-entities.

When a single sub-entity is selected, the Alignment Layout Parameters dialog box displays the parameters of the selected entity.

After you have selected an alignment entity (sub-entity), you can edit it using various tools.

If the Alignment Entities  (page 1735) vista and Alignment Layout Tools (page 1747) toolbar is open, selecting a sub-entity or range of sub-entities in an alignment causes the selected sub-entities to display in the Alignment Entities vista. Selecting sub-entities or ranges of sub-entities in a different alignment causes that range of selected sub-entities to display in the Alignment Entities vista and have focus of the Alignment Layout Tools toolbar. The last object selected becomes the current object and has focus of the alignment editing tools.

**To select an entire alignment**

1　Click an alignment in the drawing.

　　Grips appear along the alignment.

2　Use the desired tools to edit the alignment:

| To Edit the alignment... | see this topic: |
| --- | --- |
| by adding constraint-based sub-entities | Editing Alignment Points of Intersection (page 992) |

| To Edit the alignment... | see this topic: |
|---|---|
| by entering precise attribute values | Editing Alignment Entity Layout Parameters (page 994) |
| using grips | Editing Alignments Using Grips (page 996) |

**To select a single alignment sub-entity**

1   Ctrl+click an alignment sub-entity in the drawing.

2   Edit the alignment sub-entity by either manipulating the grips (page 996) or entering specific attribute values (page 994).

**NOTE** The Alignment Entities Vista (page 1735) displays only the selected sub-entity attributes.

**To select a range of alignment sub-entities**

1   In the drawing window, Ctrl+click the first alignment sub-entity in the desired range.

2   Ctrl+click the last alignment sub-entity in the range.

3   Right-click one of the selected sub-entities and select Edit Alignment Geometry.

4   Click  Alignment Grid View on the Alignment Layout toolbar (page 1747).

5   Edit the alignment sub-entities by either manipulating the grips (page 996) or entering specific attribute values (page 994)

**NOTE** The Alignment Entities vista displays only the attributes of the sub-entities in the range.

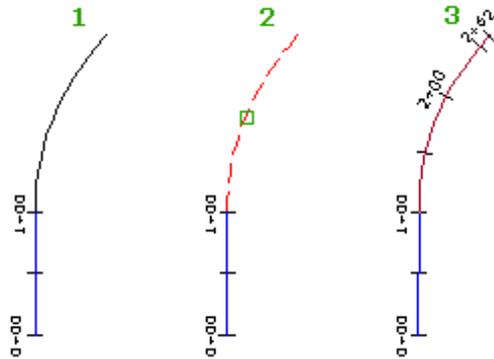
# Converting an AutoCAD Line or Arc to an Alignment Sub-Entity

Create a fixed two-point line or three-point curve alignment entity from an AutoCAD line or arc.

The new sub-entity becomes part of the solved alignment geometry if either of the following two conditions are met:

■ Before it is converted, it must be attached to an unattached end point of another solved entity in the alignment.

■ After it has been converted, it can be joined to the solved alignment geometry using the alignment layout tools.



This command is useful when you must add an AutoCAD line or arc onto an existing alignment. AutoCAD lines and arcs can be created using the best fit entities or other lines and curves commands. See Lines and Curves (page 559) for more information.

**To convert an AutoCAD line or arc to an alignment sub-entity**

1 Create an alignment or find an existing one.

2 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor 🖉 .

3 On the Alignment Layout Tools toolbar, click Convert AutoCAD Line And Arc.

4 Select the AutoCAD entity.

5 If necessary, reverse the direction of the alignment sub-entity. See Reversing Alignment Sub-Entity Direction (page 1012) for more information.

NOTE If the sub-entity you converted is hidden behind the source AutoCAD entity, use Shift+spacebar to select it. Hover the cursor over the white AutoCAD entity. Press and hold Shift, then press the spacebar to highlight the alignment sub-entity. Click to select the alignment sub-entity, then release the Shift key. Click the alignment sub-entity again to select it and continue with the command.

# Editing Alignment Points of Intersection

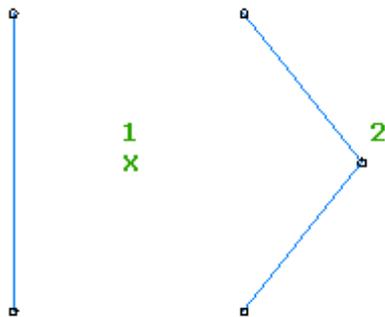
Edit an alignment geometry by working with the points of intersection (PI).

You can access the PI commands on the Alignment Layout Tools (page 1747) toolbar.

## Adding a Point of Intersection to an Alignment

Break a fixed line into two adjacent fixed lines by creating a point of intersection (PI) at a specified point.

When you select a point (1), the new PI (2) is created. At the new PI, endpoints are created for the new lines, which maintain tangency to one another.



**To add a PI to an alignment**

1   Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor.

2   On the Alignment Layout Tools toolbar, click ⛰ Insert PI.

3   In the drawing window, click the location for the new PI.

### Quick Reference

Ribbon

Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor

Alignment Layout Tools Toolbar icon

⛰ Insert PI

## Deleting a Point of Intersection from an Alignment

Create a single tangent from two adjacent tangents by removing their point of intersection (PI).

When the PI (1) is deleted (2), the tangent endpoints are removed.

**To delete a PI from an alignment**

1   Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor 🖉 .

2   On the Alignment Layout Tools toolbar, click △✗ Delete PI.

3   In the drawing window, click a point near the PI that you want to remove.

## Breaking Apart an Alignment Point of Intersection

Separate the point of intersection (PI) where the endpoints of two fixed or floating tangents meet.

When you break a PI (1), the tangent endpoints are separated by a specified distance (2). When a PI is broken (3), the second tangent is no longer part of the solved alignment geometry.

**To break apart an alignment PI**

**1** Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✎ .

**2** On the Alignment Layout Tools toolbar, click ⌁ Break-Apart PI.

**3** In the drawing window, click a point near the PI that you want to break apart.

**4** Specify the distance that you want to break apart the PI.

⌁ Break-Apart PI

## Editing Alignment Entity Layout Parameters

Use the Alignment Entities vista and Alignment Layout Parameters dialog box to display and edit parameters of alignment entities that are part of the solved alignment geometry.

The Alignment Entities vista displays a form that is like a spread sheet, where each row represents an alignment entity and each column represents a parameter. You can right-click a column heading to display options for customizing the display of detail in the column views.

You can use the alignment grid view, which is also known as the Alignment Entities vista, to quickly scroll through all the sub-entities that make up the alignment. You can select a sub-entity in the Alignment Entities vista, and then edit it in the Alignment Layout Parameters dialog box. Attributes in the Alignment Entities vista and Alignment Layout Parameters window are automatically updated as the alignment is edited.

You can use the Alignment Layout Parameters dialog box to display and edit the many attributes for a single alignment sub-entity. The parameters that are displayed are dependent upon the constraints you used to create the entity.

The Alignment Layout Parameters dialog box contains up to three panels. The Layout Parameters panel, which displays the geometric parameters of the selected sub-entity, is always present. In this panel, the Value column lists the actual value of each sub-entity Parameter. If the alignment was created using the criteria-based design (page 2471) feature, the Constraint column lists the value to which a Parameter is constrained by the specified design criteria. Use the Value and Constraint columns together to view whether the sub-entity parameters meet the specified design criteria. If the alignment was not created using the criteria-based design feature, the Constraint column is not available.

Two additional panels may be present on the Alignment Layout Parameters dialog box if the alignment has design criteria applied to it. If the alignment has a design criteria file (page 2472) associated with it, the criteria from the file are displayed in the Design Criteria panel. If the alignment has a design check set (page 2472) associated with it, the name and contents of the design check set are displayed in the Design Checks panel.

If any of the parameters violate either a design check or the standards specified in the design criteria file, a ⚠ warning symbol appears next to the violation. For more information, see Viewing and Correcting Alignment Design Criteria Violations (page 1008).

**NOTE** The attributes of a curve or other alignment entity that you can edit depends on the method you used to create the entity. Generally speaking, you can edit the numeric value of a parameter if the parameter was used to define the entity. For all other parameters, numeric values are calculated and displayed but cannot be edited.

**See also:**

■  Editing Best Fit Alignment Entities (page 1003)

**To edit alignment layout parameters using the Alignment Entities vista and Alignment Layout Parameters dialog box**

1  Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor 📝 .

2  On the Alignment Layout Tools toolbar, click ▦ Alignment Grid View.

   The Alignment Entities Vista (page 1735) displays the attributes of only the selected alignment entities. If you select another entity using Ctrl+click, it is added to the list.

3  On the Alignment Layout Tools toolbar, click ▦ Sub-Entity Editor.

   The Alignment Layout Parameters Window (page 1741) displays detailed attributes of a single alignment entity that is highlighted on the Alignment Entities vista. Selecting another entity in the Alignment Entities vista causes the new entity's attributes to display in the Alignment Layout Parameters dialog box.

   **NOTE** You can edit only values that are available. You cannot edit unavailable (shaded) text in either the Alignment Entities vista or Alignment Layout Parameters dialog box.

# Editing Alignments Using Grips

Use grips to change the vertical curves and tangents in an alignment graphically.

Use editing grips to relocate or modify curves and tangents using visual design cues. If you created alignment entities using the constraint-based tools, some editing grips are not available.

Grips are oriented in the direction of the WCS (World Coordinate System) in which the object currently is displayed. The exception is constrained grips, which indicate a particular constraint direction.

| Use this grip... | To do this... |
| --- | --- |
| ■<br><br>AT END OF LINE OR CURVE | Move an unconstrained pass-through point on a line or curve. On a line, moving this grip affects the length and angle of the line. On a curve, moving this grip does not affect the radius of the curve to which it belongs, but it can affect the radius of another attached entity. |
| ■<br><br>AT CENTER OF LINE | Move an entire line. Moving this grip only affects the line location. |
| ▶<br><br>AT END OF LINE OR CURVE | Change the constrained length of a line or curve. This grip appears on lines and curves that have a directly editable length and is aligned with the vector at the end of the line or curve. Moving this grip does not affect the radius of a curve or angle of a line. |
| ●<br><br>AT CURVE CENTER POINT | Change the center point of a circle. Moving a center point changes only the center point. |
| ◆<br><br>AT PASS-THROUGH POINT | Change the pass-through point and radius of a curve or circle. Moving a pass-through point affects the radius of the curve. |
| ▲<br><br>AT POINT OF INTERSECTION | Change where two tangent points meet. This grip is oriented up with the top pointing toward the Y axis of the world coordinate system. |

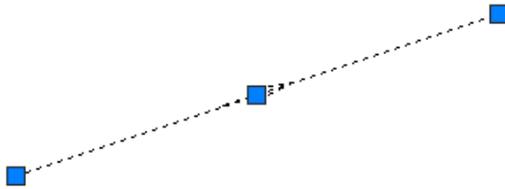
| Use this grip... | To do this... |
|---|---|
| <br>AT PASS-THROUGH POINT | Change the radius or through point of the curve. The triangle grip appears on curves that have a directly editable radius and is oriented in and constrained to the direction of the change. The circle grip changes the pass-through point and radius of the curve. |

When a grip is selected, you can use either dynamic input or the Alignment Entities (page 1735) vista and Alignment Layout Parameters (page 1741) dialog box to enter precise attribute values for the grip.

**To use grips to edit a fixed line**

1 In the drawing, click an alignment containing a fixed line.

Grips for a fixed line with two pass-through points:



2 Use the grips to edit the line:

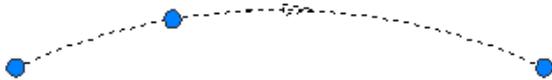
- Use the end grips to adjust the line length and pass-through point.

- Use the center grip to move the location of the line.

**To use grips to edit a fixed curve with three pass-through points**

1 In the drawing, click an alignment containing a fixed curve through three points.

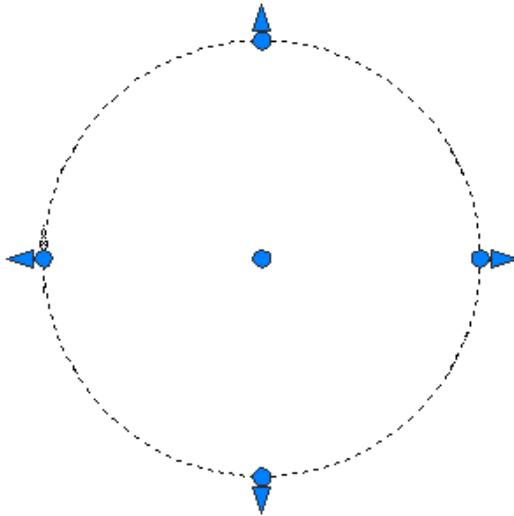
Grips for a fixed curve with three pass-through points:



2 Move any grip to change a pass-through point, which changes the radius of the curve.

**To use grips to edit a fixed curve with a center point and radius**

1 In the drawing, click an alignment that contains a fixed curve with a center point and radius.

Grips on a fixed curve with a center point and radius:


**2** Use the grips to edit the curve:

■ Move a triangular grip to change the radius.

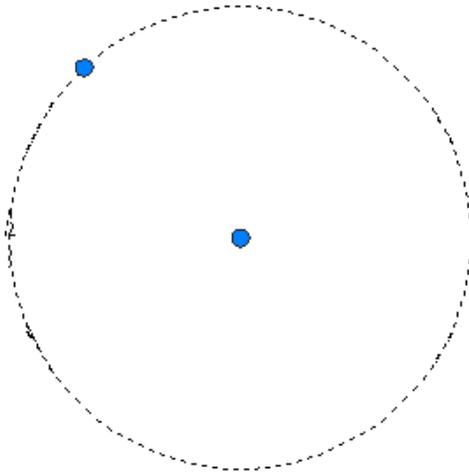
■ Move the center grip to change the center point of the circle.

■ Move a circular grip on the circle to change a pass-through point.

**To use grips to edit a fixed curve with a center point and a pass-through point**

**1** In the drawing, click an alignment that contains a fixed curve with a center point and a pass-through point.

Grips for a fixed curve with a center point and a pass-through point:



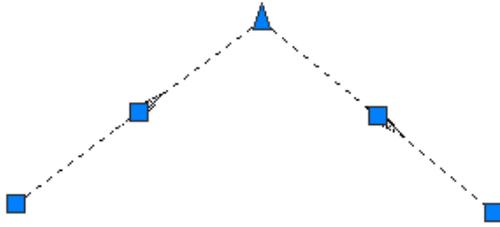
**2** Use the grips to edit the curve:

■ Move the center grip to change the center point of the circle.

■ Move the grip on the circle to change the pass-through point.

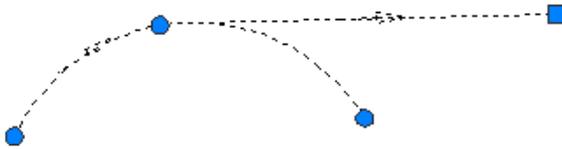
**To use grips to edit fixed or floating intersecting lines**

**1** In the drawing, click an alignment that contains either a fixed or a floating line.

PI (point of intersection) grip where the endpoints of a fixed or floating line meet:


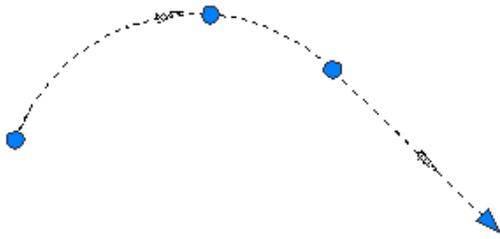
**2** Move the PI grip in any direction to edit the shared endpoints of the two lines.

**To use grips to edit a floating line with a pass-through point**

**1** In the drawing, click an alignment that contains a floating line with a pass-through point.
Grip for a floating line with a pass-through point:


**2** Move the square grip to edit the endpoint of the line.

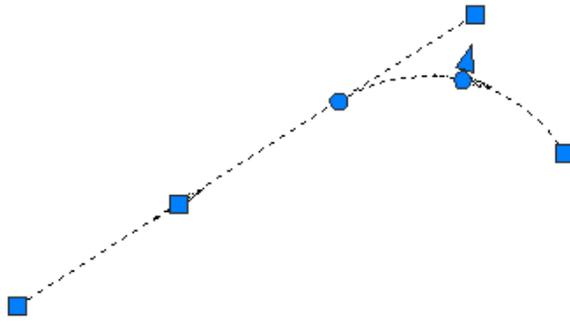
**To use grips to edit a floating line attached to an entity end**

**1** In the drawing, click an alignment that contains a floating line attached to an entity.
Grips for a floating line attached to an entity:


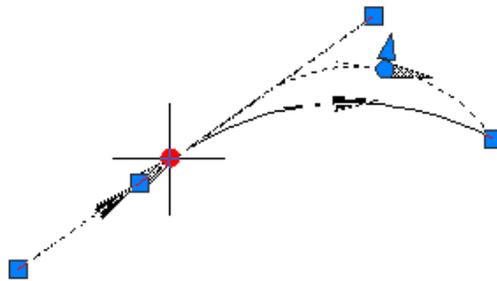
**2** Move the triangular grip to change the length of the line.

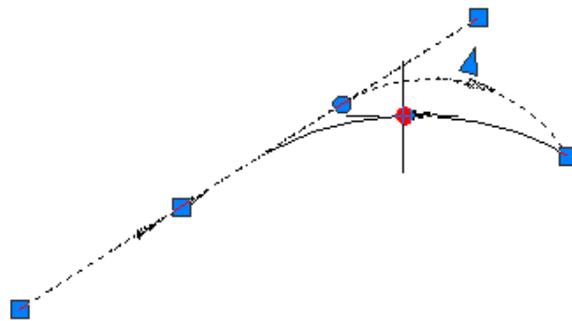
**NOTE** You cannot move the triangular grip to the beginning of the line grip. Zero length lines are not permitted.

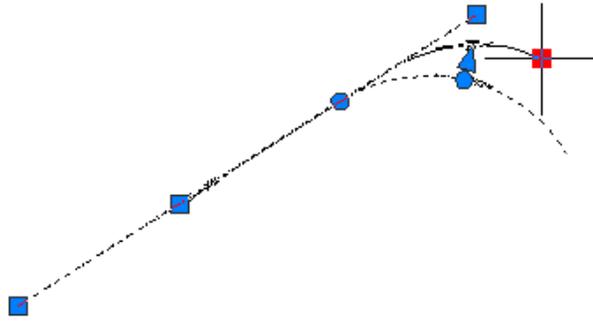
**To use grips to edit a floating curve with a pass-through point and radius**

**1** In the drawing, click an alignment that has a floating curve with a pass-through point and radius.
Grips for a floating curve with a pass-through point:


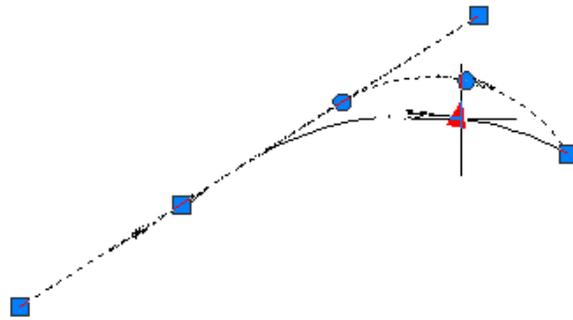
**2** Use the grips to edit the curve.

- Moving the first circular grip, located at the PC/PT point of the curve, relocates the point of tangency (PT). Use this grip to create a compound or reverse curve with another curve attached to the same entity.
  Changing a curve using the PC/PT grip:


- Moving the second circular grip, located at the mid-point of the curve, modifies the radius while changing the pass-through point.
  Changing a curve using the midpoint grip:


- Moving the square grip at the end of the curve changes the pass-through point of the curve while holding the curve radius.
  Changing a curve using the end grip:


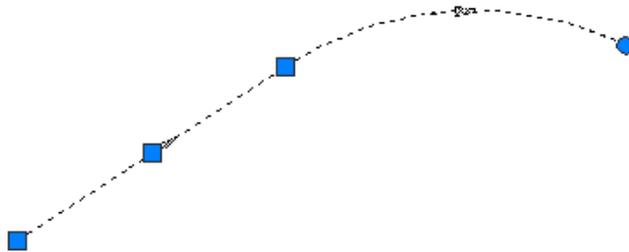
- Moving the triangular grip changes the radius while holding the pass-through point.
  Changing a curve using the radius grip:



**To use grips to edit a floating curve attached to an entity end with a pass-through point**

1   In the drawing, click an alignment that contains a floating curve attached to an entity end with a pass-through point.

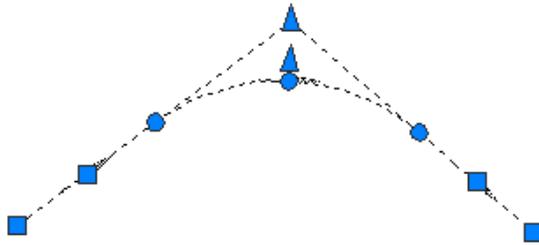
   Grips for a floating curve attached to an entity end with a pass-through point:



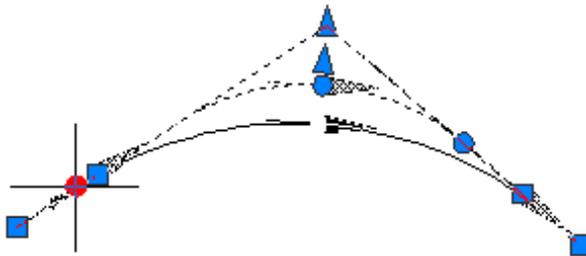
2   Move the circular grip to change the pass-through point at the end of the curve. Moving the pass-through point also changes the radius.

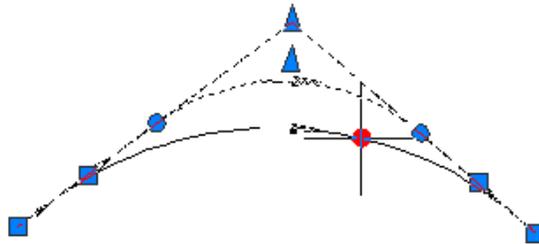
**To use grips to edit a free curve by radius**

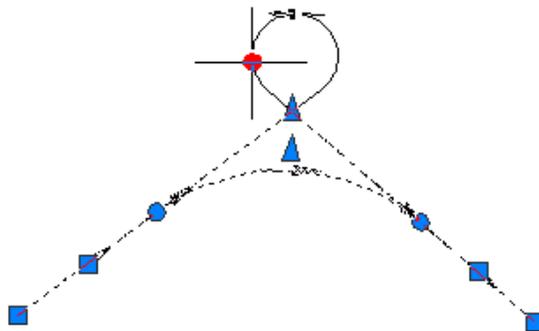
1   In the drawing, click an alignment that has a free curve. Move any grip to modify the curve radius.

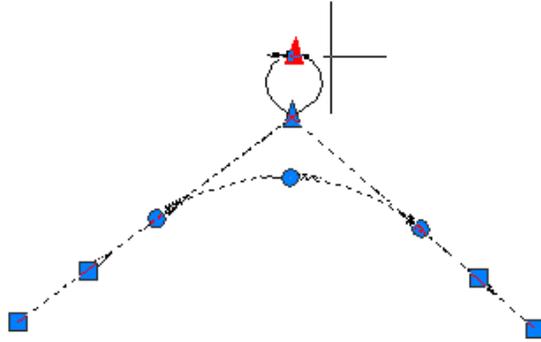
   Grips for changing the curve radius:


**2** Use the grips to edit the curve:

- Move the circular grips along tangent entities to adjacent PC/PT points on the opposite end of the same tangent to create reverse or compound solutions.
  Endpoint grips for dragging the beginning or end of the curve along the attachment entity:


- Move the circular, mid-point grip to modify the pass-through point and radius for the curve. Move the triangular grip to modify the radius for the curve while holding the pass-through point. By moving either of these grips, you can create a curve of less than or greater than 180 degrees. Changing the radius to less than 180 degrees:


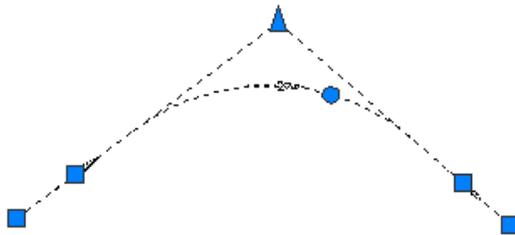
Changing the radius to greater than 180 degrees using the circular pass-through point grip:


Changing the radius to greater than 180 degrees using the triangular radius grip:


**To use grips to edit a free curve with a pass-through point**

**1** In the drawing, click an alignment with a free curve and a pass-through point.

Grips for a free curve with a pass-through point:



**2** Move the circular grip to change the pass-through point of the curve. This pass-through point is maintained when you edit the attached entities.

# Editing Best Fit Alignment Entities

Modify the regression data for alignment entities that were created by best fit.

The regression data can be modified, and then applied to the entity. If the entity is grip edited, it can be resynchronized with the original regression data.

The Regression Data vista displays the source regression data from which the best fit entity was created. The regression data can be modified either before or after the entity has been created. The information in the Regression Data vista can be changed, and then applied to the entity. If the entity parameters are changed outside the Regression Data vista, the entity can be synchronized to the current regression data.

The Alignment Entities vista displays a form that is like a spread sheet, where each row represents an alignment entity and each column represents a parameter. When an entity is created by best fit, Best Fit is displayed

in the Constraint2 column. Click  in this column to edit the source regression data.

Regression data is not dynamically linked to the best fit entity. If the entity is edited,  appears in both the Regression Data and Alignment Entities vistas.

**NOTE** You can edit only values that are available, you cannot edit unavailable (shaded) text.

**Editing Floating Best Fit Entities**

The manner in which a best fit floating entity reacts to edits to the attachment entity depends on whether the best fit entity is synchronized with the best fit sample data:

■ If the floating best fit entity is synchronized with the best fit sample data, it will maintain tangency when the attachment entity is edited. The floating best fit entity geometry will change to adapt to changes to the attachment entity, and continue to honor the regression points.

■ If the floating best fit entity is not synchronized with the best fit sample data, it will behave as a normal floating entity. The floating best fit entity will remain tangent to the attachment entity, and its geometry will not change to honor the regression points.

**To edit best fit regression data**

1   Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor .

2   On the Alignment Layout Tools toolbar, click  Edit Best Fit Data For All Entities.

> **NOTE** You can also open the Regression Data vista from the Alignment Entities vista. In the Constraint2 column, click  .

3   In the Regression Data vista, edit the regression data as needed.
    You can add, edit, or remove regression points.

4   Click  to apply the changes and close the Regression Data vista.

**To synchronize a best fit alignment entity to the regression data**

1   Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor .

2   On the Alignment Layout Tools toolbar, click  Edit Best Fit Data For All Entities.

3   In the Regression Data vista, click  Synchronize Entity To Best Fit Sample Data.

> **NOTE** You can also synchronize the entity to the regression data from the Alignment Entities vista. In the Constraint2 column, click  .

# Editing Offset Alignments and Widenings

You can edit the parameters of an offset alignment or widening, split it into sections, and attach additional widenings.

Two editing methods are available:

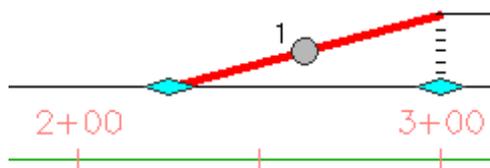
■   Edit values in the Offset Parameters dialog box

■   Grip editing

### Editing Offset Parameters

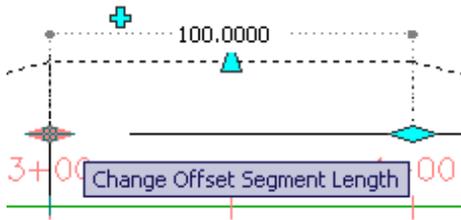
This editing method offers precise control of the dimensions and shape of an offset alignment or widening. Parameters for each region of the object are displayed in a tabular format in the Offset Parameters (page 1773) dialog box.

When you click on the top heading for a region, the region is highlighted in the drawing.



**Example of a highlighted region**

### Grip Editing

This editing method enables you to use freehand controls to reshape an offset or widening. Dimensions are also available in tooltips.


**Examples of tooltips for grip editing**

The various grips and their use are described in the following table.

| Grip | Function |
|---|---|
|  | Adjusts the width of the widening. |
|  | Adjusts the length of a region along the alignment. |
|  | Adds a widening by splitting the current offset or widening into two regions of equal length. |
|  | On a transition, switches the available grip set from transition grips to widening grips. |
|  | Adjusts the length of a transition. |

**To edit offset parameters**

1  Click the offset alignment. Click Offset Alignment tab ➤ Modify panel ➤ Offset Parameters .

2  In theOffset Parameters (page 1773) dialog box, modify station values, transition types, or other parameters.

**To grip edit an offset or widening**

1  Click the offset alignment or widening. Grips appear along the object.

2  Click the grip that adjusts the offset or widening as desired.

Right-click alignment or widening. Click Edit Offset Parameters

Command Line

EditOffsetAlignParameters

# Applying Design Criteria to an Existing Alignment

Use the Alignment Properties dialog box to apply design criteria to an existing alignment.

The criteria-based design feature provides the ability to verify that your alignment design meets the minimum standards required by your local agency.

For more information, see Criteria-Based Alignment Design (page 866).

**To apply design criteria to an existing alignment**

1   Click the alignment. Click Alignment tab ➤ Modify panel ➤ Alignment Properties
    drop-down ➤ Alignment Properties  .

2   In the Alignment Properties dialog box, click the Design Criteria (page 1754) tab.

    **NOTE** To use criteria-based design, an alignment must have at least one design speed.

3   In the Design Speeds section, click  Add Design Speed.

4   Specify the Start Station and Design Speed values.

5   Repeat Steps 3 and 4 to specify design speeds at other stations.

    An alignment can have unlimited numbers of design speeds, but can have only one speed at any given station. When a station has a design speed setting, that setting applies to either the remainder of the alignment or the next station at which a design speed is set. If a single entity has multiple speeds assigned to it, the highest speed is used to validate that entity against the design criteria. The lower speed values are ignored.

6   On the right side of the dialog box, select the Use Criteria-Based Design check box.

7   Specify the following settings:

    ■   Use Design Criteria File
        Select this check box to associate a design criteria file with the alignment. The default design criteria file location and the Default Criteria properties become available when you select the check box.

        **NOTE** The first design criteria file found in the *C:\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\Data\Corridor Design Standards\<units>* directory is used by default when the criteria-based design feature is used.

    ■   Use Design Check Set
        Select this check box to associate a design check set with the alignment. The design check set list becomes available when you select the check box. Select a design check set from the list.

8   Click OK.

    **NOTE** The entire alignment design is validated when you click either Apply or OK.

Alignment Properties Dialog Box (page 1752)

# Viewing and Correcting Alignment Design Criteria Violations

Use the warning symbols to verify whether the alignment design meets the specified criteria and design checks.

When an alignment uses the criteria-based design feature, the alignment geometry must meet the design criteria specified in the design criteria file (page 2472) and design checks (page 2472).

When an alignment sub-entity violates the design criteria, a warning symbol is displayed in the following locations:

■ The drawing window — The ⚠ warning symbol is displayed on each sub-entity that violates the design criteria.

> **NOTE** The size of the warning symbol does not adjust automatically. After zooming in or out, enter REGEN to resize the warning symbols.

■ The Alignment Entities vista — The ⚠ warning symbol is displayed in the No. column of the sub-entity that violates the design criteria. If a criteria in the design criteria file was violated, the warning symbol is also displayed next to the specific criteria and parameter value that violates the design criteria.

■ The Alignment Layout Parameters dialog box — If a criteria in the design criteria file was violated, the ⚠ warning symbol is displayed in the Design Criteria panel next to the Property that was violated, and in the Layout Parameters panel next to the Parameter that was violated. If a design check was violated, the ⚠ warning symbol is displayed in the Design Checks panel next to the design check that was violated.

You can use the ⚠ warning symbols in the drawing window to view information about criteria and design checks that were violated. When the cursor is hovered over a warning symbol in the drawing window, a tooltip displays information about the violation. If a design criteria was violated, the tooltip displays the criteria that was violated, as well as the minimum value required to meet the criteria. If a design check was violated, the tooltip displays the name of the design check that was violated.

> **BEST PRACTICE** The name of the design check should be similar to the formula you enter in the Design Check field. When a design check is violated, only the design check name is displayed, and not the minimum acceptable value. If the formula is in the design check name, it is easier to correct the violation.

**NOTE** If a sub-entity violates more than one criteria or design check, only one warning symbol is displayed in the drawing. To clear the warning symbol, the sub-entity must be modified to meet all the design criteria and design checks.

## Turning Off the Alignment Warning Symbol

Change the visibility of the warning symbol that indicates violations in the alignment design.

There are several ways to turn off the warning symbol. The following methods are listed in the order in which they are recommended.

### Modify the Alignment Geometry

Edit the alignment design to meet the specified design criteria. This option clears the warning symbols from the drawing window, Alignment Entities vista, and Alignment Layout Parameters dialog box.

The criteria-based design feature does not validate portions of the alignment that have the design speed set to zero.

**NOTE** If a sub-entity violates more than one criteria or design check, only one warning symbol is displayed in the drawing. To clear the warning symbol, the sub-entity must be modified to meet all the design criteria and design checks.

For more information, see Correcting Alignment Design Criteria Violations (page 1010).

### Change the Alignment Style

Turn off the Warning Symbol display component in the current alignment style. Alternatively, create a separate alignment style that has the Warning Symbol display component turned off. This option clears the warning symbols from the drawing window for alignments that use that style. The warning symbols are still displayed in the Alignment Entities vista and Alignment Layout Parameters dialog box.

For more information, see Alignment Styles (page 885).

### Turn Off the AutoCAD Civil Solution Tip

The warning symbol is controlled by the Solution Tip setting in the Options dialog box on the AEC Editor tab. To hide the warning symbol for all drawings, clear the Drafting check box. This option clears all alignment and profile warning symbols from the drawing window. However, the warning symbols are still displayed in the Alignment Entities vista and Alignment Layout Parameters dialog box.

For more information, see AEC Editor Tab (Options Dialog Box) (page 2453).

**WARNING** Settings in the Options dialog box affect the overall behavior of AutoCAD Civil. If you clear the Solution Tip Drafting check box, the warning symbol for all alignment and profile objects will be hidden in every drawing that is opened on the current installation of AutoCAD Civil.

### Turn Off the Criteria-Based Design Feature

Disassociate the design criteria from the alignment. The alignment design check set and/or the design criteria file can be turned off in the Alignment Properties dialog box. This option clears the warning symbols from the drawing window, Alignment Entities vista, and Alignment Layout Parameters dialog box.

For more information, see Applying Design Criteria to an Existing Alignment (page 1007).

**WARNING** If you turn off the criteria-based design feature, the alignment design will not be validated against any design standards.

# Correcting Alignment Design Criteria Violations

Validate the alignment geometry against the specified criteria and design checks.

When an alignment uses the criteria-based design feature, the alignment geometry must meet the design criteria specified in the design criteria file (page 2472) and design checks (page 2472).

When an alignment sub-entity violates the design criteria, a warning symbol is displayed in several locations. For information about where the warning symbols appear, see Viewing and Correcting Alignment Design Criteria Violations (page 1008).

You can use the ⚠ warning symbols in the drawing window to view information about criteria and design checks that were violated. When the cursor is hovered over a warning symbol in the drawing window, a tooltip displays information about the violation.

- If a design criteria was violated, the tooltip displays the criteria that was violated, as well as the minimum value required to meet the criteria.

- If a design check was violated, the tooltip displays the name and formula of the design check that was violated.

**NOTE** If a sub-entity violates more than one criteria or design check, only one warning symbol is displayed in the drawing. To clear the warning symbol, the sub-entity must be modified to meet all the design criteria and design checks.

**To correct alignment design criteria violations using grips**

1  In the drawing window, hover the cursor over a ⚠ warning symbol.

   A tooltip displays information about the violation.

2  Select the alignment.

3  Use the alignment grips to modify the alignment geometry.

   The ⚠ warning symbol disappears when the sub-entity meets the design criteria.

   **NOTE** If a sub-entity violates more than one criteria or design check, only one warning symbol is displayed on the sub-entity. To clear the warning symbol, the sub-entity must be modified to meet all the design criteria.

**To correct alignment design criteria violations by entering numeric values**

1  Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✎ .

2  On the Alignment Layout Tools toolbar, click ▦ Alignment Grid View.

3  In the Alignment Entities vista, click the row that contains the ⚠ warning symbol in the No. column.

   The sub-entity parameters are displayed in the Alignment Layout Parameters dialog box.

4  In the Alignment Layout Parameters dialog box, locate the ⚠ warning symbol in either of the following panels:

   - **Layout Parameters panel** — In the Value column, enter a numeric value that meets the value specified in the Constraints column.

■ **Design Checks panel** — Notice that the design check that has been violated. Modify the alignment design to meet the parameters specified in the design check.

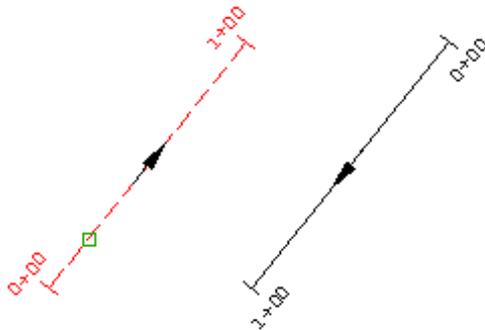
Dialog Box

# Reversing Alignment Direction

Use this command to reverse the direction and stationing of an alignment.

All objects that are dependent on the alignment (such as profiles) will also be updated.



When you create an alignment, you can control the direction of the alignment, regardless of the direction the polyline was drawn. If you create an alignment using the Create Alignment From Polyline command, the alignment direction starts from the nearest endpoint you click the polyline. If you create an alignment using the Create Alignment By Layout command, the alignment direction is determined by the direction in which you draw the alignment. If you must change the direction of the alignment, you can use the Reverse Alignment Direction command. However, it is important to note that all objects that are dependent on the alignment (Profiles, Sample Lines, Sections, and Corridor objects, Superelevation) will change as well.

You can only change the direction of an alignment that is continuous.

You can also reverse the direction of an individual fixed, unattached alignment sub-entity. See Reversing Alignment Sub-Entity Direction (page 1012) for more information.

**To reverse the direction of an alignment**

➤ Click the alignment. Click Alignment tab ➤ Modify panel ➤ ▼ ➤ Reverse Direction ⇄.

### Quick Reference

Ribbon

Click the alignment. Click Alignment tab ➤ Modify panel ➤ ▼ ➤ Reverse Direction ⇄

Menu

Alignments menu ➤ Reverse Alignment Direction

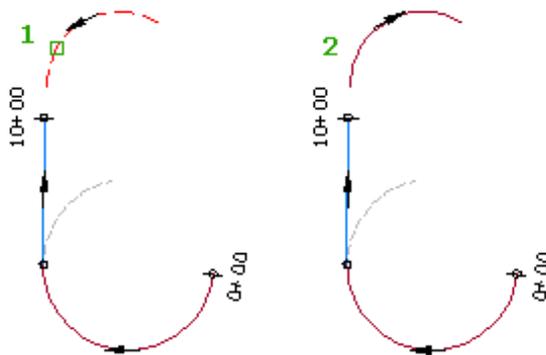
Command Line

ReverseAlignmentDirection

# Reversing Alignment Sub-Entity Direction

Reverse the direction of a fixed, unconnected line or curve entity.

This command works only on fixed entities that are not part of the solved alignment geometry. To reverse the direction of the entire alignment, use the ReverseAlignDirection command.



See Reversing Alignment Direction (page 1011) for more information.

When you add an alignment sub-entity to an existing alignment, the sub-entity direction is determined by the direction in which it was drawn. If the sub-entity direction is different from the alignment, the sub-entity cannot become part of the solved alignment geometry. The sub-entity cannot be included in the alignment stationing or labeling unless its direction matches the alignment's.

**To reverse the direction of an alignment sub-entity**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor ✎ .

**2** On the Alignment Layout Tools (page 1747) toolbar, click ⇙ Reverse Sub-Entity Direction.

**3** Click the alignment sub-entity in the drawing window.

# Using AutoCAD Object Snaps with Alignment Objects

You can use AutoCAD object snaps (OSNAPs) with the alignment object. Although there are differences, alignment OSNAPs function in a manner consistent with OSNAPs to AutoCAD lines, curves, and polylines.

Node snaps apply to all pass-through points and all points of intersection.

**OSNAPs that apply to line segments**

Use OSNAPs with some alignment components. Alignment line components can have solved and unsolved segments, depending on whether they are fixed, free, or floating.(Yes indicates that OSNAPs do apply; No indicates that OSNAPs do not apply.)

| Line Segments | Solved Segments | Unsolved Segments |
| --- | --- | --- |
| Endpoint | Yes | No |
| Midpoint | Yes | No |
| Center | Yes | No |
| Node | Yes | No (Exception: Node does apply to visible pass-through points.) |
| Quadrant | Yes | No |
| Intersection | Yes | No |
| Extension | Yes | No |
| Insertion | Yes | No |
| Perpendicular | Yes | No |

| Line Segments | Solved Segments | Unsolved Segments |
|---|---|---|
| Tangent | Yes | No |
| Nearest | Yes | No |
| Apparent Intersection | Yes | No |
| Parallel | Yes | No |

**OSNAPs that apply to curve segments**

Use OSNAPS with some curve segments. Curves can have solved or unsolved segments depending on whether they are fixed, free, or floating curves.

(Yes indicates that OSNAPS apply; No indicates they do not apply.)

| Curve Segments | Solved Segments | Unsolved Segments |
|---|---|---|
| Endpoint | Yes | No |
| Midpoint | Yes | No |
| Center | Yes | No |
| Node | Yes | No (Exception: Node does apply to visible pass-through points.) |
| Quadrant | No | No |
| Intersection | Yes | No |
| Extension | Yes | No |
| Insertion | Yes | No |
| Perpendicular | Yes | No |
| Tangent | Yes | No |
| Nearest | Yes | No |
| Apparent Intersection | Yes | No |
| Parallel | Yes | No |

**OSNAPs that apply to spiral segments**

(Yes indicates that OSNAPS apply; No indicates they do not apply.)

| Spiral Segments | Solved Segment | Unsolved Segments |
|---|---|---|
| Endpoint | Yes | No |
| Midpoint | Yes | No |

| Spiral Segments | Solved Segment | Unsolved Segments |
| --- | --- | --- |
| Center | Yes | No |
| Node | Yes | No |
| Quadrant | No | No |
| Intersection | Yes | No |
| Extension | Yes | No |
| Insertion | Yes | No |
| Perpendicular | Yes | No |
| Tangent | Yes | No |
| Nearest | Yes | No |
| Apparent Intersection | Yes | No |
| Parallel | Yes | No |

# Deleting Alignment Entities

Use one of several methods to delete an alignment or alignment sub-entity.

The dependencies for deleting an alignment or alignment sub-entity are explained in the following topics.

# Deleting an Alignment

Delete an alignment from either the drawing window or the Toolspace Prospector tab.

If other objects were created from an alignment, you cannot use Prospector to delete the alignment. You can delete the alignment from the drawing window, but the dependant objects will also be deleted. Depending on the object type, the objects can also be deleted from Prospector.

For example, a profile and corridor can be created from an alignment. If you right-click the alignment in the Prospector, the Delete option is not available. If you select the alignment in the drawing window and press Delete, the corridor and profile are cleared from the drawing window. The profile is also deleted from Prospector because it is a child of the alignment object. The corridor object is still present in Prospector because the alignment was only one of the objects from which it was created. You can add another alignment to the corridor as a baseline, and then rebuild the corridor.

**To delete an alignment from the drawing window**

1   Select an alignment in the drawing.

2   Press Delete.

**To delete an alignment from the Prospector**

1   In Toolspace, on the Prospector tab, select the alignment object.

2   Right-click. Click Delete.

# Deleting an Alignment Sub-Entity

Delete a specified alignment entity.

You can delete an alignment sub-entity only if no other sub-entities use it as a defining parameter. The following points are the basic conditions for deleting the different types of alignment sub-entities:

- A fixed entity cannot be deleted if it has a floating or free entity attached to it.

- A floating entity cannot be deleted if it has either a floating or free entity attached to it.

- Free entities are not used to define the geometry of other entities. You can delete a free entity at any time.

**To delete an alignment sub-entity from the Alignment Layout Tools toolbar**

1 Click the alignment. Click Alignment tab ➤ Modify panel ➤ Geometry Editor .

2 On the Alignment Layout Tools toolbar, click Delete Sub-Entity.

3 Click the sub-entity in the drawing.

4 Press Enter to end the Delete Sub-Entity command.

**To delete an alignment sub-entity using the Delete key**

1 Ctrl+click an alignment sub-entity in the drawing.

**NOTE** For more information about selecting alignment sub-entities, see Selecting Alignment Entities (page 989).

2 Press Delete.

## Quick Reference

# Alignment Command Reference

You can use AutoCAD Civil commands when you work with alignments. The following table lists the alignment-related AutoCAD Civil commands and briefly describes their functionality.

For more information about a command, follow the link in the Description column.

| Command | Description |
| --- | --- |
| AddAlignmentCurveTable | Adds an alignment curve table (page 987) |
| AddAlignLabels | Opens the Add Labels dialog box (page 971) |
| AddAlignmentLineTable | Adds an alignment line table (page 987) |
| AddAlignmentSegmentTable | Adds an alignment segment table (page 987) |
| AddAlignmentSpiralTable | Adds an alignment spiral table (page 987) |
| AddAlignOffLbl | Labels fixed station offsets (page 984) |
| AddAlignOffXYLbl | Labels multiple station offsets (page 983) |
| AddAlignSegLbl | Labels multiple segment labels (page 982) |
| AddAlignSegLbls | Labels multiple segment labels (page 982) |
| AddAlignTangentIntLbl | Labels single tangents intersections (page 984) |
| AddAlignTangentIntLbls | Labels multiple tangent intersections (page 985) |
| AddWidening | Adds a widened region to an existing alignment (page 896) |
| CreateAlignmentEntities | Opens the Create Alignment from Objects dialog box (page 1760) |
| CreateAlignmentLayout | Opens the Create Alignment-Layout dialog box (page 887) |
| CreateAlignmentReference | Creates an alignment reference in the current drawing (page 893) |
| CreateOffsetAlignment | Creates one or more offset alignments based on an existing alignment (page 895) |
| DesignCriteriaEditor | Opens the Design Criteria Editor dialog box (page 867) |
| EditAlignment | Opens the Alignment Layout Tools toolbar (page 988) |
| EditAlignmentLabels | Opens the Alignment Labels dialog box (page 973) |
| EditAlignmentTagNumbers | Renumbers alignment entity label tags (page 1544) |

| Command | Description |
| --- | --- |
| EditOffsetAlignParameters | Edits the parameters of an offset alignment or widening (page 1005) |
| ReverseAlignmentDirection | Reverses an alignment direction (page 1011) |

# Profiles

# 24

The main purpose of a profile is to show surface elevations along a horizontal alignment.

Use profiles to visualize the terrain along a route of interest or across a particular region.

For information on recommended workflows when working with profiles, see the *AutoCAD Civil Workflow Guide*.

## Understanding the Profile Object

There are several types of profiles: surface profiles, layout profiles, superimposed profiles, quick profiles, and corridor profiles.

- A surface profile—often called an existing ground (EG) profile—is extracted from a surface, showing the changes in elevation along a particular route.

- A layout profile, by contrast, is a designed object that shows the proposed elevation changes to be constructed. The layout profile—often called a design profile or finished grade (FG) profile—is typically used for a roadway or other graded site. For a road, the layout profile can include slopes and curves that are designed for safe driving at a particular speed.

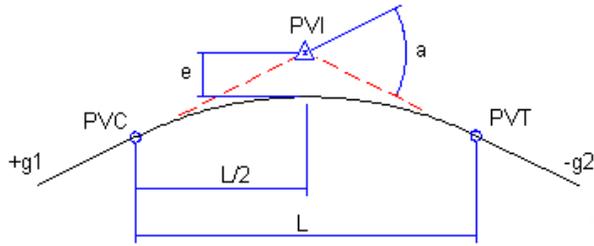
- A superimposed profile is a profile of an alignment superimposed onto profile views of different alignments. These profiles are always dynamic and update when changes are made in the originating profile/alignment.

- A quick profile is a temporary object that shows the elevations along any existing line or series of selected points.

- A corridor profile is created from a corridor feature line, such as an edge of pavement. This profile is displayed on the profile view of the baseline alignment from which it is derived.

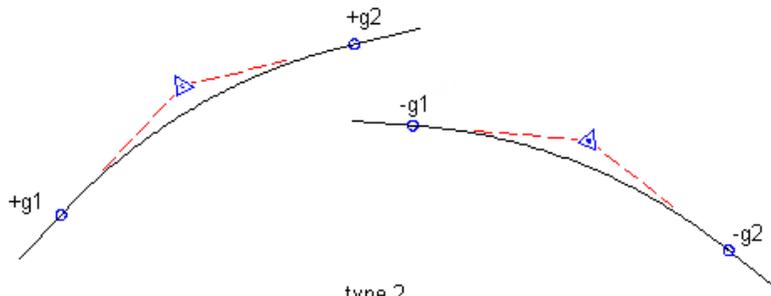
Layout profiles use two types of curves: crest curves and sag curves. Crest curves are placed on hilltops or wherever the grade changes to a lesser value. There are three types of crest curves: a positive to negative grade transition, positive to positive, and negative to negative:

**Sample Crest Curves**



type 1

g1 and g2 - tangent grades in percent
a - algebraic difference
L - length of vertical curve

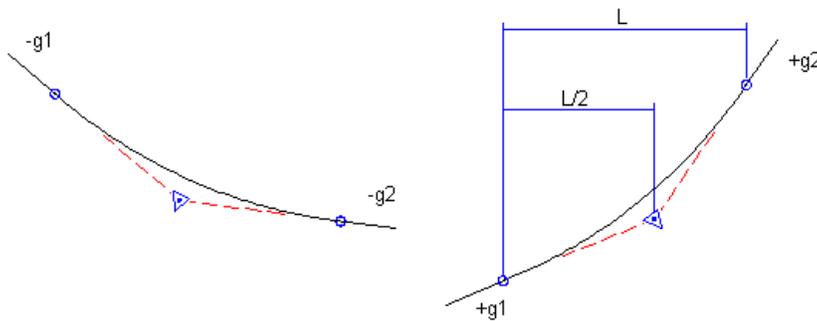


type 2

Sag curves are placed in valleys or wherever the grade changes to a greater value. There are three types of sag curves: a negative to positive grade transition, negative to negative, and positive to positive:

**Sample Sag Curves**

type 3



type 4

An offset profile is another type of profile commonly used in road design. While the road centerline provides the main horizontal alignment, various lines offset from the centerline mark other linear features, such as

edges of pavement, ditches, and sidewalks. Profiles along these offsets can be analyzed in relation to each other and to the centerline profile for a more complete view of the surface along a corridor. Offset profiles are created and managed independently from any offset alignments that may exist, though both can be used together in the design process.

When you create a surface profile, you specify whether it is dynamic or static. A dynamic profile automatically changes if the surface elevation changes. Such changes can occur if you move the horizontal alignment or edit the surface. A static profile represents the terrain at the time it is created, and does not respond to changes in the surface.

Profiles are displayed as graphed lines in a grid known as a profile view. Typically, you create a profile view to display surface profiles. Then, you draw layout profiles on the same grid to show elevation differences between the two surfaces. Profiles can be created and saved in a drawing, and displayed later when a profile view is created.

You can use a quick profile to view surface elevations along an object or through a selection of points. This quick profile is for temporary use and is not saved in the drawing. For more information, see Creating a Quick Profile (page 1058).

# The Profile View Object

Use a profile view to display profiles as graphed lines on a grid.

When you create a profile view, you specify which existing profiles to display on the grid. Use these profiles as a reference for drawing new layout profiles on the grid.

A profile view can include one or more related profiles, along with multiple data bands along the X-axis, above or below the grid. Data bands annotate the profiles with stationing, elevation, horizontal geometry, and other data that assists engineering analysis.

You typically use a profile view to display several profiles along a proposed route for a road, pipe, fence, or a similar structure. Use profile views to compare elevations of several surfaces or design profiles along the alignment.

Within a profile view, you can superimpose the profile of another alignment. For example, in the profile view for a road, you can superimpose the profile of a culvert that occupies the same corridor. By superimposing a profile, you can analyze culvert elevations in relation to the same alignment stations used for the road surfaces.

A profile view can include projected objects (page 2480) from the drawing that you want to see in relation to a profile. See Adding Projected Objects to a Profile View (page 1119) for more information.

If you design a road, pipeline, or a similar structure across the landscape, and you want to compare the feasibility of several possible routes, a profile view of each route can help with the comparison.

AutoCAD Civil allows profiles to split to fit within a specified profile view height and displayed in either single or multiple profile views. See Working with Profile Views (page 1106) for more information.

# Profile Object Relationships

A profile object is the child of a horizontal alignment. The horizontal alignment must exist to define the route of a profile across the terrain.

If you edit a horizontal alignment after creating dynamic surface profiles along its length, the profiles automatically change.

A profile view object is also dependent on a horizontal alignment. The length of the alignment can control the horizontal extents of the profile view grid, and the alignment stationing controls the annotation of horizontal axes. The vertical extents of the profile view have an optional relationship with one of the profiles in the profile view. You can set the vertical extents to a fixed value, but normally they are dynamically

linked to one of the profiles. The dynamic link ensures that the profile view always has several grid lines above and below the profiles.

A profile view can contain projected objects such as points, feature lines, or AutoCAD blocks. These objects exist in plan view and are projected into a profile view so that you can visualize them in relation to a profile.

# Profiles Collection (Prospector Tab)

Use the Profiles collection to access profiles in drawings.

As profiles are created, they are displayed as named objects in the Toolspace Prospector tab under the Profiles collection.

Right-click the Profiles collection to do any of the following:

- Export site data to LandXML. (page 1682)
- Recursively refresh the Profiles collection and list view.

If one or more profiles exist in the current drawing, expand the Profiles collection in Toolspace on the Prospector tab. The Profiles collection displays the names of all profiles associated with a particular horizontal alignment, as well as a tabular list of the profiles.

Right-click an individual profile name to do any of the following:

- Review or change properties (page 1024) of the profile.
- Export profile data to LandXML (page 1682).
- Delete the profile from the drawing.
- Refresh the display of the profile in the Prospector tab.

# Profile Views Collection (Prospector Tab)

Use the Profile Views collection to access profile views in drawings.

As profile views are created, they are displayed as objects under the Profile Views collection.

Right-click the Profile Views collection to refresh the Profile Views collection and list view.

If one or more profile views exist in the current drawing, expand the Profile Views collection in Toolspace on the Prospector tab. The Profile Views collection displays the names of all profile views associated with a particular horizontal alignment, as well as a tabular list of the profile views.

Right-click an individual profile view name to:

- Review or change properties (page 1024) of the profile view.
- Delete the profile view.
- Refresh the display of the profile view in the Prospector tab.

# Profile Collection (Settings Tab)

Use the Profile collection on the Settings tree to manage profile settings, profile styles, profile label styles, and profile command settings.

Right-click the Profile collection to do any of the following:

- Edit the profile feature settings.

- Edit the profile label style defaults.

- Refresh the display of the Profile collection in the Prospector tab.

Expand the Profile collection to display and edit the styles and command settings that are available for profiles.

| For more information about... | See... |
| --- | --- |
| Profile Settings | Profile Settings (page 1025) |
| Profile Styles | Profile Styles (page 1027) |
| Profile Label Styles | Managing Profile Label Styles (page 1034) |
| Profile Commands | Profile Command Reference (page 1121) |

## Profile View Collection (Settings Tab)

Use the Profile View collection on the Settings tree to manage settings, styles, label styles, band styles, and command settings for profile views.

Right-click the Profile View collection to do any of the following:

- Edit the profile view feature settings

- Edit the profile view label style defaults

- Refresh the display of the Profile Views collection in the Prospector tab

Expand the Profile Views collection to display and edit the styles and command settings that are available for profile views.

| For more information about... | See... |
| --- | --- |
| Profile View Styles | Profile View Styles (page 1029) |
| Profile View Label Styles | Profile Labels and Label Styles (page 1033) |
| Data Band Styles | Profile View Band Styles (page 1038) |
| Profile View Commands | Profile View Command Reference (page 1121) |

## Profile Shortcut Menu

Use the profile shortcut menu for quick access to common functions.

When you right-click a profile in the drawing, the shortcut menu is displayed.

The following table explains the items on the menu that are specific to profiles. Other selections on the menu are standard AutoCAD options.

| Use this menu item... | To... |
| --- | --- |
| Profile Properties | Open the Profile Properties Dialog Box (page 2174) for the selected profile. |
| Edit Profile Style | Open the Profile Style Dialog Box (page 2176). |

| Use this menu item... | To... |
| --- | --- |
| Edit Profile Geometry | Open the Profile Layout Tools (page 2170). |
| Superimposed Options | Open the Superimpose Profile Options Dialog Box (page 2193). Available for superimposed profiles only. |
| Edit Labels | Open the Profile Label Set Dialog Box (page 2167) |
| Inquiry | Open the Inquiry Tool Dialog Box (page 2462) with a Profile inquiry selected |

## Profile View Shortcut Menu

Use the profile view shortcut menu for quick access to common functions.

When you right-click a profile view grid in the drawing, the shortcut menu is displayed.

The following table explains the items on the menu that are specific to profile views. Other selections on the menu are standard AutoCAD options.

| Use this menu item... | To... |
| --- | --- |
| Profile View Properties | Open the Profile View Properties Dialog Box (page 2178). |
| Edit Profile View Style | Open the Profile View Style Dialog Box (page 2185). |
| Inquiry | Open the Inquiry Tool Dialog Box (page 2462) with a Profile inquiry selected. |

## Projected Object Shortcut Menu

Use the shortcut menu for a projected object for quick access to object properties.

When you right-click a projected object (page 2480)in a profile view, the shortcut menu is displayed. The only menu selection specific to the projection is Projection Object Properties. It opens the Projections tab (page 2183) of the Profile View Properties dialog box.

## Profile Properties

When you create a profile, you set the properties, including its name, style, station range, and labeling.

Use the Profile Properties Dialog Box (page 2174) to review or edit the name and other information for an existing profile. The three tabs correspond to general types of properties: information, profile data, and design criteria.

**See also:**

■ Setting Profile Properties (page 1041)

## Profile View Properties

By specifying properties, you control the content and format of a profile view.

Set these properties when you create a profile view. At any time, you can use the Profile View Properties Dialog Box (page 2178) to make changes. The tabs on this dialog box correspond to general types of properties: Information, Stations, Elevations, Profiles, Bands, and Hatch. Additional tabs for Projections and Pipe Networks appear if the profile view includes these objects.

**See also:**

- Setting Profile View Properties (page 1042)

# Settings for Profiles and Profile Views

You can review and edit the default style and name format settings for profiles and profile views. You can also review and edit default settings for profile and profile view commands.

Settings are handled in a standard way throughout AutoCAD Civil through the Settings tree at three levels: drawing, feature, and command. For more information, see Understanding Settings (page 61).

# Profile Settings

You can review and edit the default style and name format settings for profiles and profile commands.

Settings are handled in a standard way throughout AutoCAD Civil, and accessed in Toolspace on the Settings tab. Control settings at three levels: the drawing, the feature, and the command. For more information, see Understanding Settings (page 61).

On the Settings tab, use the Profile collection shortcut menu to establish default settings for all profiles. At this level, you can either change profile-specific settings or override the drawing ambient settings.

Use the Profile Commands collection under the Profile collection to change settings for a specific command. At this level, you can either change settings for profile commands or override the settings at the profile feature level.

**NOTE** Overrides to the drawing ambient settings at the Profile collection level and the Profile Command collection level affect only the specified level. The drawing level settings are not changed. For more information, see The Commands Collections (Settings Tree) (page 97).

This section describes only the default styles and name format settings for profile commands. It does not cover the drawing ambient settings, even though these settings are displayed in the Edit Feature Settings dialog box. For more information about the drawing ambient settings, see Specifying Drawing Settings (page 63).

For more information about profile view settings, see Profile View Settings (page 1026).

**To change profile settings**

1 In Toolspace, on the Settings tab, do one of the following:
   - Right-click the Profile collection and click Edit Feature Settings
   - In the Profile collection, open the Commands folder, right-click the command for which you want to change settings. Click Edit Command Settings.

   In the Edit Feature (or Command) Settings dialog box, profile feature-level settings are marked with ⌄ . Profile command-level settings are marked with ⊞✓ .

2 Expand the default styles and default name format to see the current settings.

**3** In the Value column, click the entry you want to change. A small Browse button appears on the right side of the cell.

**4** Click the Browse button to open a dialog box where you can modify the value.

**5** In the Edit Feature (or Command) Settings dialog box, click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click Profile collection ➤ Edit Feature Settings

# Profile View Settings

You can review and edit the default style and name format settings for profile views and profile view commands.

Settings are handled in a standard way throughout AutoCAD Civil, and accessed in Toolspace on the Settings tab. You can control settings at three levels: the drawing, the feature, and the command. For more information, see Understanding Settings (page 61).

On the Settings tab, use the Profile View collection shortcut menu to establish default settings for all profile views. At this level, you can change settings specific to profile views, which will override the drawing ambient settings for profile view.

Use the Commands collection under the Profile View collection to change settings for a specific command. At this level, you can change settings specific to profile view commands or override the settings at the level of the profile view feature.

---

**NOTE** Overrides to the drawing ambient settings at the Profile View collection level and the Profile View Command collection level affect only the specified level. The drawing level settings are not changed. For more information, see The Commands Collections (Settings Tree) (page 97).

---

This section describes only the default styles and name format settings for profile view commands. It does not cover the drawing ambient settings, even though these settings are displayed in the Edit Feature Settings dialog box. For more information about the drawing ambient settings, see Specifying Drawing Settings (page 63).

For more information about profile settings, see Profile Settings (page 1025).

**To change profile view settings**

**1** In Toolspace, on the Settings tab, do one of the following:

■ Right-click the Profile View collection and click Edit Feature Settings

■ In the Profile View collection, open the Commands folder, right-click the command for which you want to change settings. Click Edit Command Settings.

In the Edit Feature (or Command) Settings dialog box, profile view feature-level settings are marked

with ⌄ . Profile view command-level settings are marked with ▦✔ .

**2** Expand the default styles and default name format to see the current settings.

**3** In the Value column, click the entry you want to change. A small Browse button is displayed on the right side of the cell.

**4** Click the Browse button to open a dialog box where you can modify the value.

**5** In the Edit Feature (or Command) Settings dialog box, click OK.

### Quick Reference

Toolspace Shortcut Menu

Edit Feature Settings - Profile View Dialog Box (page 2159)

# Styles and Display of Profiles and Profile Views

Styles control the way a profile and profile view are displayed in a drawing. Profiles have label styles that control the appearance and behavior of their labels in a drawing.

# Profile Styles

You can use styles to control profile appearance in model, profile, and section views.

Use the Toolspace Settings tree to manage profile styles. All objects have an object style collection on the Settings tab that you can use to create, edit, copy, and delete the styles for that object. For more information, see The Object Style Collection (Settings Tree) (page 94).

To examine the properties of an existing style, follow the procedure for Creating and Editing Profile Styles (page 1027).

A profile object can reference two style types:

- **Profile Style.** This style controls the visibility of profile components and their rendering in both 2 and 3 dimensions.

- **Profile Label Style**. This style controls the appearance and content of labels for stations, lines, curves, and geometry points along the profile. For more information, see Profile Labels and Label Styles (page 1033).

## Creating and Editing Profile Styles

Use the Toolspace Settings tab to create or edit a profile style.

Create a style by adjusting the default settings, or by copying an existing style and changing its properties to suit your requirements.

You can choose markers for key geometry points on layout profiles.

Set the style properties on the following tabs in the Profile Style dialog box:

- **Information.** Specify the style name and description. See also Information Tab (Style Dialog Box) (page 1801).

- **Design.** Specify the tessellation distance to control the accuracy of rendering profile curves in 3D view.

- **Markers.** Specify the markers for locations on layout profiles such as PVI points, pass-through points, and profile start and end.

- **Display.** Specify the display attributes of profile components, including visibility, layer, color, linetype, line weight, linetype scale, and plot style. See also Display Tab (Style Dialog Box) (page 1801).

- **Summary**. Provides a concise display of the style properties. See also Summary Tab (Style Dialog Box) (page 1803).

**TIP** Any style changes you make apply to all existing profiles in the drawing that use the style. To change the style of some profiles but not all, consider creating a separate style.

**See also:**

- Profile Style Dialog Box (page 2176)

**To create a profile style**

1 In Toolspace, on the Settings tab, expand the Profile Styles collection. Right-click and click New.

2 In the Profile Style dialog box (page 2176), specify the name of the style and other settings as required.

3 Click OK.

**To copy a profile style**

1 In Toolspace, on the Settings tab, expand the Profile Styles collection. Identify the style you want to copy as a basis for the new style.

2 Right-click the style name and click Copy.

3 In the Profile Style dialog box (page 2176), change the name of the style and other settings as required.

4 Click OK.

**To edit a profile style**

1 In Toolspace, on the Settings tab, expand the Profile Styles collection. Identify the style you want to edit.

2 Right-click the style name and click Edit.

3 In the Profile Style dialog box (page 2176), change settings as required.

4 Click OK.

# Profile View Styles

You can use profile view styles to control the appearance of the graph that displays a profile.

Use the Toolspace Settings tab to manage profile view styles. All objects have an object style collection on the Settings tab that you use to create, edit, copy, and delete the styles for that object. For more information, see The Object Style Collection (Settings Tree) (page 94).

To examine the properties of an existing style, follow the procedure for creating and editing profile view styles (page 1030).

A profile view object can reference the following style types:

- **Profile View Style.** This style controls the format of the graph on which the profiles are displayed, as well as the title and annotations on the axes. For more information, see Creating and Editing Profile View Styles (page 1030).

- **Label Style.** This style controls the format of two types of manually placed labels along the profile: station elevation and depth (elevation difference and/or grade between any two points). For more information, see Profile Labels and Label Styles (page 1033).

- **Band Style.** This style controls the format of data bands above and below the profile view. Data bands show station elevations, horizontal geometry, vertical geometry, superelevation, sectional data, and pipe data. For more information, see Profile View Band Styles (page 1038).
  For convenience, you can define a group of band styles as a band style set (page 1040). Then, apply the entire set of band styles to a profile view with a single action, rather than applying each band style separately.

- **Projection Style.** This multipurpose style controls the appearance of objects projected into profile views or section views.

- **Shape Style.** This multipurpose style controls the appearance of hatching for cut and fill areas between surfaces and profiles.

## Creating and Editing Profile View Styles

Use the Toolspace Settings tab to create or edit a profile view style.

You can choose which elements to display, and change the appearance of the graph, grid, title, axes ticks, and text.

The main properties are set on the following tabs in the Profile View Style dialog box:

- **Information.** Specify style name and description. See also Information Tab (Style Dialog Box) (page 1801).

- **Graph.** Specify profile view direction and vertical scale factor

- **Grid.** Specify grid clipping, padding, and offset options

- **Title Annotation.** Specify content and appearance of titles for the overall profile view and individual axes

- **Horizontal Axes.** Specify ticks, tick justification, tick and grid spacing, and annotation of the horizontal axes

- **Vertical Axes.** Specify ticks, tick justification, tick and grid spacing, and annotation of the vertical axes

- **Display.** Specify display attributes for profile view components, including visibility, layer, color, linetype, line weight, linetype scale, and plot style. See also Display Tab (Style Dialog Box) (page 1801).

- **Summary.** Provides a concise display of the style properties. See also Summary Tab (Style Dialog Box) (page 1803).

Before editing a style to change its properties, remember that any changes you make apply to all profile views that use the style. To change the style of some profile views but not all, consider creating a separate style.

**See also:**

- Profile View Style dialog box (page 2185)

**To create a profile view style**

1   In Toolspace, on the Settings tab, expand the Profile View Styles collection. Right-click and click New.

2   In the Profile View Style dialog box (page 2185), specify the name of the style and other settings as required.

3   Click OK.

**To copy a profile view style**

1   In Toolspace, on the Settings tab, expand the Profile View Styles collection. Identify the style you want to copy as a basis for the new style.

2   Right-click the style name and click Copy.

3   In the Profile View Style dialog box (page 2185), change the name of the style and other settings as required.

4   Click OK.

**To edit a profile view style**

1   In Toolspace, on the Settings tab, expand the Profile View Styles collection. Identify the style you want to edit.

2   Right-click the style name and click Edit.

3   In the Profile View Style dialog box (page 2185), change settings as required.

4   Click OK.

## Creating and Editing Projection Styles

Use these general styles to control the display of AutoCAD objects projected into profile views and section views.

Within a style, the settings for the appearance of an object type in profile views are independent from the settings for section views.

The appearance of AutoCAD Civil projected objects is controlled by styles for the particular object type: points, feature lines, and survey figures.

**See also:**

- Display Tab (Point Style Dialog Box) (page 2117)
- Display Tab (Feature Line Style Dialog Box) (page 1898)
- Display Tab (Survey Figure Style Dialog Box) (page 2393)

**To create a projection style**

1 In Toolspace, on the Settings tab, expand the General ➤ Multipurpose Styles collection. Right-click Projection Styles and click New.

2 In the Projection Styles dialog box (page 1807), specify the name of the style and other settings as required.

3 Click OK.

**To copy a projection style**

1 In Toolspace, on the Settings tab, expand the General ➤ Multipurpose Styles collection. Identify the style you want to copy as a basis for the new style.

2 Right-click the style name and click Copy.

3 In the Projection Styles dialog box (page 1807), change the name of the style and other settings as required.

4 Click OK.

**To edit a projection style**

1 In Toolspace, on the Settings tab, expand the General ➤ Multipurpose Styles collection. Identify the style you want to edit.

2 Right-click the style name and click Edit.

3 In the Projection Styles dialog box (page 1807), change settings as required.

4 Click OK.

Command Line

EditProjectionStyle

# Profile Labels and Label Styles

You can label profiles and profile views using different label types.

**Profile labels**

When you create a layout profile, you can automatically label it using label styles you specify in the Create Profile - Draw New dialog box (page 2142). For other types of profiles, add labels using the Edit Labels command.

Profile label styles can be configured to mark any of the following standard points along the profile:

- Major and minor stations of the parent horizontal alignment

- Horizontal geometry points

- Grade breaks

- Lines

- Sag curves

- Crest curves

You can save profile label styles as a profile label set and apply the labels to a profile as a group.

**See also:**

- Staggering Profile and Section Labels (page 1527)

**Profile view labels**

After creating a profile view, use the Add Labels dialog box (page 1970) to manually add labels to particular points of interest anywhere on the profile view grid. These labels can be of three types:

- Station Elevation, showing the station and elevation of a point.

- Depth, showing the elevation difference between two points, and other data such as slope and distance.

- Projection, showing the station and elevation of a projected object (page 2480).

**Profile view bands**

Place data bands along the top or bottom of a profile view grid to annotate the various profile lines with station and elevation data, vertical or horizontal geometry points, or superelevation, sectional, or pipe network data. You can also group a set of commonly used data bands into a band set that can be applied to a profile view as a single selection.

The topics in this section describe unique properties of profile labels. For a general overview of labels, see Understanding Labels (page 1466).

## Editing Profile Labels

Edit the set of labels used on a profile line.

Edit the settings for each label type, and import or save label sets.

Editing the labels on a profile does not affect instances of the same profile in other profile views.

Profile labels that display curve and tangent dimensions have editing grips that you can use to move labels.

Use the Profile Labels dialog box (page 2167) to numerically edit the position of labels, change the style of a label, or save your changes as a label style.

Label styles ensure convenience and consistency. A particular profile may require different labels. After the labels are edited, save the modified label set for reuse with other profiles.

**See also:**

■ Staggering Profile and Section Labels (page 1527)

**To edit profile labels**

1 Do one of the following:

■ Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Add/Edit Profile Labels ✎ . Select a profile in the drawing to open the Profile Labels dialog box.

■ Click the profile line you want to edit. Right-click and click Edit Labels

2 In the Profile Labels dialog box (page 2167), review the existing labels and their attributes. Do any of the following:

■ Add or remove labels of any type.

■ Change the style for a label type.

■ Import a standard set of labels.

■ Save your modified labels as a set to use again.

■ Stagger labels to avoid label collisions. For more information, see Staggering Profile and Section Labels (page 1527).

3 Click Apply to see your changes on the profile line.

4 Click OK to save the changes.

Dialog Box

Profile Labels (page 2167)

## Managing Profile Label Styles

Use the Toolspace Settings tab to create and edit profile label styles.

The types of profile label styles that you can create:

| This type of profile label style... | Labels... |
| --- | --- |
| Major Stations | Stations along the profile at major intervals |
| Minor Stations | Stations along the profile at minor intervals |
| Horizontal Geometry Points | Locations where the horizontal alignment geometry changes, such as the start of a curve |
| Lines | Lines that form the tangents of a profile |
| Grade Breaks | Locations where the vertical grade changes |
| Sag Curves | Sag curves in the profile |
| Crest Curves | Crest curves in a profile |

When you need a new profile label style, it is usually easiest to find an existing style that is similar to what you need, then copy it and make the required changes. You can also create a style and change whatever default values are not suitable.

You can group several profile label styles into a label set. Apply the label set to a profile as a single setting. An existing label set can be edited or copied to create a new one.

Label spacing is an important design consideration for surface profiles. Wherever they cross uneven surfaces, this type of profile can have many short tangents and closely spaced grade breaks. As a result, labels for these features can overlap and become unreadable when they require more horizontal space than is available. To address this condition for one label type, the Profile Labels dialog box (page 2167) provides a weeding setting that suppresses grade break labels within a specified distance of each other.

Profile label styles are created and edited using the Label Style Composer. For more information, see Overview of the Label Style Composer (page 1473).

**To copy a profile label style**

1   In Toolspace, on the Settings tab, expand the Profile, Label Styles, and specific label style collection.

2   Right-click the name of the label style you want to copy, and click Copy. The Label Style Composer dialog box (page 1942) is displayed.

3   Change settings as required to produce the style you want. Specify a name for the style.

4   Click OK to save the style.

**To edit a profile label style**

1   In Toolspace, on the Settings tab, expand the Profile and Label Styles collections. Click a specific label style collection.

2   Right-click the name of the label style you want to edit and click Edit. The Label Style Composer dialog box (page 1942) is displayed.

3   Change settings as required.

4   Click OK to save the style.

**To create a profile label style**

1  In Toolspace, on the Settings tab, expand the Profile and Label Styles collections.

2  Right-click the collection of label style you want to create and click New. The Label Style Composer dialog box (page 1942) is displayed.

3  Change settings as required. Specify a name for the new style.

4  Click OK to save the style.

**To create a profile label set**

1  In Toolspace, on the Settings tab, expand the Profile, Label Styles, Label Sets collections.

2  Do one of the following:
   ■ Right-click the Label Sets collection and click New.
   ■ To copy an existing set as a starting point, right-click the set and click Copy

3  In the Label Set dialog box (page 1771), on the Information tab, specify a name for the label set. Optionally, specify a description.

4  On the Labels tab (page 1772), specify the individual labels to include in the set, and settings for each one.

5  Click OK to save the new set.

## Managing Profile View Label Styles

Use the Settings tab on Toolspace to create and edit profile view label styles.

Profile view labels are added manually to mark points of interest on a profile view. The following types of profile view labels are available:

■ **Station Elevation** labels show the elevation and station value at a specified point anywhere in the profile view.

■ **Depth** labels show the elevation difference between two specified points, and other selected data, such as slope and distance.

■ **Projection** labels show data about a projected object (page 2480), such as the elevation and station value.

Create and edit the styles for profile view labels using the Label Style Composer.

If a profile view contains projected objects, label styles for these objects are managed as feature settings for the profile view object.

**See also:**

■ Overview of the Label Style Composer (page 1473)

■ Edit Feature Settings - Profile View Dialog Box (page 2159)

**To copy a profile view label style**

1  In Toolspace, on the Settings tab, expand the Profile View, Label Styles, and specific label style collections.

2  Right-click the name of the label style you want to copy. Click Copy. The Label Style Composer dialog box (page 1942) is displayed.

**3** Change settings as required. Specify a name for the style.

**4** Click OK to save the style.

**To edit a profile view label style**

**1** In Toolspace, on the Settings tab, expand the Profile View, Label Styles, and specific label style collections.

**2** Right-click the name of the label style you want to edit. Click Edit. The Label Style Composer dialog box (page 1942) is displayed.

**3** Change settings as required.

**4** Click OK to save the style.

**To create a profile view label style**

**1** In Toolspace, on the Settings tab, expand the Profile View, Label Styles, and specific label style collections.

**2** Right-click the name of the label style you want to create, and click New. The Label Style Composer dialog box (page 1942) is displayed.

**3** Change settings as required. Specify a name for the new style.

**4** Click OK to save the style.

## Adding Profile View Labels

Manually place profile view labels at points of interest anywhere on a profile view.

You can label any point to show station and elevation, to show the relationship between two points, or to mark the location of a projected object (page 2480).

Station Elevation labels show the elevation and station value at any specified point in the profile view.

Depth labels show the elevation difference between two specified points, and other selected data, such as slope and distance.

Projection labels show information about an object projected into the profile view, such as its elevation and station.

Projection labels cannot be used with projected feature lines or 3D polylines that appear as lines in a profile view.

---

**TIP** To label points on a feature line projected into a profile view, use Station Elevation or Depth labels.

---

**To add a profile view station elevation label**

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Profile View ➤ Station Elevation .

**2** Select the station and elevation to label.

**To add a profile view depth label**

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Profile View ➤ Depth .

**2** Click any two locations. Labels are displayed, showing the depths, grade, or other data about the relationship between the two points.

**To add a projection label**

➤ Select the projected object. Right-click and click Add Label.

# Profile View Band Styles

Use the Toolspace Settings tab to create and edit profile view band styles.

Profile view band styles control the location and content of data bands.

Use the Profile View Properties dialog box (page 2178) to specify which data band styles to use and where to place them on the profile view.

Data band labels are label objects that can be manipulated like other AutoCAD Civil label objects. For more information, see Editing Data Band Labels (page 1529).

The types of data band styles that you can create:

| This type of data band style... | Provides this type of annotation... |
|---|---|
| Profile Data | Stations, elevation of one or two profiles at each station, and elevation difference between two profiles at the station |
| | **NOTE** The individual geometry points to label can be specified with the Profile Data band type. For more information, see Adding Data Bands to a Profile View (page 1115). |
| Vertical Geometry | Geometric details of vertical tangents and curves |
| Horizontal Geometry | Geometric details of horizontal tangents, curves, and spirals |

| This type of data band style... | Provides this type of annotation... |
| --- | --- |
| Superelevation | Critical transition stations and transition diagrams for the superelevation at curves |
| Sectional Data | Sampled station, material, typical section details, incremental distance and volume, balanced volume information |
| Pipe Data | Location and key dimensions of pipe network parts, offset, elevation, direction |

When you need a new data band style, it is usually easiest to find an existing style that is similar to what you need, then copy it and make the required changes. You can also create one and change whatever default values are not suitable.

The notes in this section describe what is unique to profile data bands. For a general overview of labels, see Understanding Labels (page 1466).

**See also:**

- Adding Data Bands to a Profile View (page 1115)
- Staggering Data Band Labels (page 1528)

**To copy a data band style**

1  In Toolspace, on the Settings tab, expand the Profile View, Band Styles, and specific band style collections.

2  Right-click the name of the band style you want to copy. Click Copy. The Profile Data Band Style Dialog Box (page 2164) is displayed.

3  On the Information tab (page 2164), enter a new name for the style. Optionally, add a description.

4  On the Band Detail tab (page 2165), compose the band title and modify any settings for the band title and layout.

5  On the right side of the Band Details tab, select a label location. Click Compose Label to define the property fields annotated by the band. For more information, see Layout Tab (Label Style Composer Dialog Box) (page 1944).

6  On the Display tab (page 2166), modify any display settings for the band components.

7  On the Summary tab, review all settings for the style. Make any corrections.

8  Click OK to save the style.

**To edit a data band style**

1  In Toolspace, on the Settings tab, expand the Profile View, Band Styles, and specific band style collections.

2  Right-click the name of the band style you want to change. Click Edit. The Profile Data Band Style dialog box (page 2164) is displayed.

3  Review the settings on the Information tab (page 2164), the Band Details tab (page 2165), and the Display tab (page 2166). Make any changes.

4  On the Summary tab, review all settings for the style. Make any corrections.

5  Click OK to save the style.

**To create a data band style**

**1** In Toolspace, on the Settings tab, expand Profile View and Band Styles.

**2** Right-click the name of the band type for which you want to create a style. Click New. The Profile Data Band Style dialog box (page 2164) is displayed.

**3** On the Information tab (page 2164), enter a new name for the style. Optionally, add a description.

**4** On the Band Details tab (page 2165), compose the band title and modify any settings for the band title and layout.

**5** On the right side of the Band Details tab, select a label location and click Compose Label to define the property fields annotated by the band. For more information, see Layout Tab (Label Style Composer Dialog Box) (page 1944).

**6** On the Display tab (page 2166), modify any display settings for the band components.

**7** On the Summary tab, review all settings for the style. Make any corrections.

**8** Click OK to save the style.

# Profile View Band Sets

Use a data band set to manage a group of band styles that you want to apply to other profile views.

**See also:**

■  Adding Data Bands to a Profile View (page 1115)

**To create a band set**

**1** In Toolspace, on the Settings tab, expand Profile View and Band Styles.

**2** Right-click the Band Sets folder, and click New. The Band Set dialog box (page 2139) is displayed.

**3** On the Information tab (page 2139), enter a name and optional description for the band style set.

**4** On the Bands tab (page 2140), in the List Of Bands area, specify the Location where you want to place the bands.

**5** In the Band Type field, select the type of band to add to the set.

**6** In the Select Band Style field, select an existing band style or use one of the style buttons to create a style.

**7** Click Add to add the band type to the List Of Bands.

**8** Repeat steps 4 to 7 to add more bands to the set.

**9** Use the three band position buttons on the right side of the List of Bands to put the data bands in the desired order and to delete unwanted bands.

**10** Click OK to save the band style set.

**To edit a band set**

**1** In Toolspace, on the Settings tab, expand the Profile View, Band Styles, and Band Sets collections.

**2** Right-click the name of the set you want to edit. Click Edit. The Band Set dialog box (page 2139) is displayed.

**3** Change content as required. Click OK to save the modified set.

**To copy a band set**

**1** In Toolspace, on the Settings tab, expand the Profile View, Band Styles, and Band Sets collections.

**2** Right-click the name of the set you want to copy. Click Copy. The Band Set dialog box (page 2139) is displayed.

**3** On the Information tab (page 2139), enter a new name. Optionally, enter a description.

**4** Change other content as required. Click OK to save the new set.

# Properties of Profiles and Profile Views

Several aspects of profile data and display are controlled by properties.

# Setting Profile Properties

Set properties of individual profiles either from the Toolspace Prospector tab, or from a profile view.

You can edit some of the properties, including those for design criteria.

Profile properties are organized on three tabs of the Profile Properties (page 2174) dialog box: information, profile data, and design criteria.

### Information

The profile name, description, and object style. By changing the style here you can instantly change the displayed appearance for the profile.

### Profile Data

Each profile is one of the following types: surface, layout, superimposed, or corridor.

A surface profile can be either static or dynamic. The elevation data in a dynamic profile changes to respond to changes in the parent alignment or surface. A static profile displays the elevation data at a particular time, and does not respond to changes in other objects.

### Design Criteria

A design criteria file (page 2472) and design check set (page 2472) can be applied to the profile if the parent alignment has a design speed applied. The criteria-based design feature enables you to verify that a profile design meets the minimum standards required by your local agency. These options are available if the Use Criteria-Based Design check box is selected.

**See also:**

■ Criteria-Based Profile Design (page 1044)

**To set profile properties**

**1** In Toolspace, on the Prospector tab, expand the Alignments collection, identify the parent alignment for the profile you want to work with, and then expand the Profiles collection for that alignment.

**2** Select the profile, right-click, and then click Properties. The Profile Properties (page 2174) dialog box opens.

**3** After setting properties, click OK.

## Quick Reference

Dialog Box

Profile Properties Dialog Box (page 2174)

# Setting Profile View Properties

Set properties of profile views either from the Toolspace Prospector tab, or from the drawing window.

You can change the station range, grid, displayed profiles, and annotation of objects in the profile view.

Profile view properties are organized on several tabs of the Profile View Properties (page 2178) dialog box: information, stations, elevations, profiles, bands, hatch, projections, and pipe networks.

**Information tab**

View or edit the profile view name, description, and object style.

**Stations tab**

Set the range of stations displayed in the profile view.

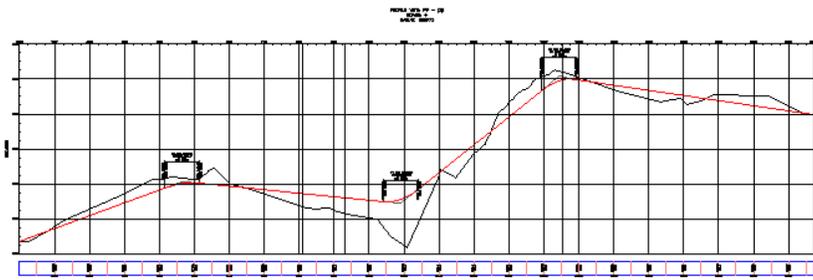
**Elevations tab**

Set the range of elevations displayed in the profile view. If the profile view is split, you can use this tab to specify the stations and styles for the split segments. See The Profile View Object (page 1021) for more information about split profile views.

**Profiles tab**

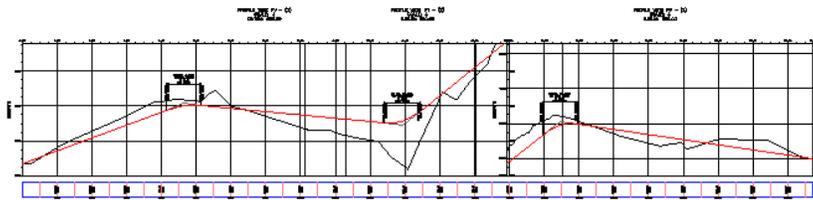
Specify which profiles to display in the profile view and whether the view is clipped to the extents of a specific profile. You can edit the description, change the update mode (dynamic or static), layer, and style

for each profile in the current view. You can also specify whether to split the profile view, which reduces its vertical size.



**Profile view without split**

The sample profile view before splitting shows an elevation range of 60 feet.



**Profile view with split**

The split profile view is more compact, with an elevation range of about 38 feet. At the split station, a separate elevation scale is provided for each part of the profile view.

### Bands tab

Specify which data bands to include in the profile view and whether they are placed along the top or bottom of the grid. The following data band types are available for displaying profile data: profile data, vertical geometry, horizontal geometry, superelevation for a specified horizontal alignment, sectional data, and pipe network data.

### Hatch tab

Specify the style and location of hatching between surfaces, which shows cut regions and fill regions in the vertical design.

### Pipe Networks tab

Specify which pipes or structures to display in the profile view as well as their styles, style overrides, and layer placement. The Pipe Networks tab is displayed only when there is one or more pipe networks in the drawing.

### Projection tab

Specify objects from plan view to project into the profile view, includings AutoCAD objects and AutoCAD Civil objects. You can also specify the object display styles, elevation options, and elevation values. The Projections tab is displayed only when projected objects (page 2480) exist in the profile view.

**See also:**

■ Setting Profile Properties (page 1041)

**To set profile view properties**

1   Click the profile view you want to modify.

2   Click Profile View tab ➤ Modify View panel ➤ Profile View Properties drop-down ➤ Profile View Properties ⬚ .

3   In the Profile View Properties (page 2178) dialog box, set properties, and then click OK.

# Criteria-Based Profile Design

Use the criteria-based design feature to apply agency-specific standards to a profile.

The criteria-based design feature provides the ability to verify that your profile design meets the minimum standards required by your local agency.

When you use the criteria-based design feature, you can select a design criteria file (page 2472), from which you can specify the minimum K value table. If the parent alignment also uses design criteria, the design criteria file applied to the alignment is applied for the profile by default. You can specify a separate design criteria file for the profile either during creation or in the profile properties.

When you lay out the profile, the appropriate minimum values specified in the design criteria file are displayed on the command line. You can either accept the default minimum value for a given sub-entity, or specify a new value.

Agency standards, which are typically based on superelevation and design speed requirements, are contained in the customizable design criteria file. When you create the profile, the minimum standards from the design criteria file ensure that the vertical curves comply with the minimum standards required by your local agency.

If the design parameters for a sub-entity violate the minimum values established in the design criteria file, a warning symbol appears both on the sub-entity in the drawing window and next to the violated value in the Profile Entities Vista (page 2166)and Profile Layout Parameters Dialog Box (page 2168). When you hover the cursor over a warning symbol, a tooltip displays which standard has been violated and how to correct the violation. The display of the warning symbol is controlled by the profile style.

Some profile design criteria are not available in table form in the design criteria file. For these criteria, you can define design checks (page 2472) to validate design standards. A design check must be saved in a design check set (page 2472) to be applied to a profile.

You can generate a report that documents validations or violations in the profile design. The design criteria report identifies whether each sub-entity within a given station range meets the appropriate design criteria and design checks.

**See also:**

■ Creating Layout Profiles (page 1048)

■ Applying Design Criteria to an Existing Layout Profile (page 1102)

■ Viewing and Correcting Profile Design Criteria Violations (page 1103)

## Profile Standards in the Design Criteria File

The design criteria file contains the standards tables that specify design standards for alignments and profiles.

The design criteria file (page 2472) contains A.A.S.H.T.O. (page 2467) standards tables for minimum K values at specified design speeds. Minimum K tables for Stopping Sight Distance, Passing Sight Distance, and Headlight Sight Distance are provided. If your local agency standards differ from the standards in the supplied design criteria file, you can use the Design Criteria File Editor dialog box (page 1843) to customize the file to support your local standards.

By default, the profile uses the design criteria applied to the parent alignment. You can accept the default, or select a different design criteria file for the profile.

The design criteria file contains standards for both alignment and profile objects. The Design Criteria Editor dialog box is used to modify the standards for both objects.

**NOTE** Design criteria files can be created only with the Design Criteria Editor dialog box. Existing design criteria data cannot be used unless it is input to an XML file using the Design Criteria Editor dialog box.

**See also:**

■ Design Criteria Files (page 867)

■ Creating a Design Criteria File (page 868)

■ Editing a Design Criteria File (page 870)

■ Criteria-Based Profile Design (page 1044)

■ Criteria-Based Alignment Design (page 866)

## Profile Design Checks

Create design checks to verify the design parameters for criteria that are not included in the design criteria tables.

The tables contained in the design criteria file (page 2472) contain A.A.S.H.T.O. (page 2467) standards tables for Stopping Sight Distance, Passing Sight Distance, and Headlight Sight Distance minimum K values at specified design speeds. Other criteria can be checked by using mathematical expressions, which are known as design checks (page 2472).

Design checks are created and managed in the same manner as label expressions. Use the Design Check Editor dialog box (page 1845), which is similar to the Expressions dialog box (page 1973), to create and edit design checks. To apply a design check to a profile, you must add it to a design check set (page 2472).

**NOTE** When you add curve design checks to a design check set, you must specify whether to apply it to sag curves, crest curves, or both.

Design checks differ from label expressions in that they always return a true or false value. For example, you can create a design check to issue a notification if a tangent is shorter than a specified minimum tangent length.

**See also:**

■ Design Check Examples (page 871)

■ Creating a Design Check (page 873)

■ Editing a Design Check (page 875)

■ Expressions (page 1547)

## Profile Design Check Sets

Save commonly used combinations of design checks in a design check set, which is then applied to a profile.

After you create a design check (page 2472), save it with an appropriate combination of other design checks in a design check set. A design check set can be applied to a profile either during the profile creation process, or through an existing profile's properties.

A design check set consists of design checks for a combination of design check types. For example, you can create a design check set that consists of separate design checks for minimum and maximum K values for sag and crest curves.

Design checks are created and managed in the same manner as label expressions. Use the Design Check Editor dialog box (page 1845), which is similar to the Expressions dialog box (page 1973), to create and edit design checks. To apply a design check to a profile, you must add it to a design check set (page 2472).

# Creating Profiles

Using profiles, you can view changes in elevation along a horizontal alignment.

In addition to the centerline profile, you can create offset profiles for features such as road edges or ditches.

Create a profile view to see one or more of the profiles associated with a horizontal alignment. Use the profile view of a surface as a guide for creating the layout profile of a designed surface, such as a road. On a profile view, you can also superimpose the profile of a different horizontal alignment that is in the same area.

To work most effectively with profiles, learn how to combine the create, copy, edit, and superimpose operations to get the profiles you need for terrain analysis and design.

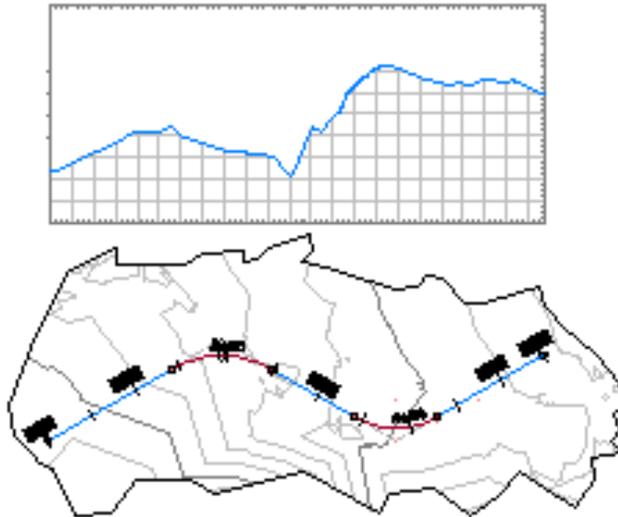
In addition, you can use quick profiles to view and evaluate elevation information at locations where there is no alignment. Quick profiles are temporary objects that are useful for evaluating elevation information along a line, polyline, feature or lot line, survey figure, or along a series of points you select.

# Creating Surface Profiles

You can create surface profiles to show surface elevations along an alignment.

You can create a surface profile either from a horizontal alignment on a surface or from a surface profile file.

When you create a centerline profile, you can create one or more offset profiles at the same time. Use the Draw in Profile View option to display the profile in the drawing.



**To create profiles from a surface**

1 Click Home tab ➤ Create Design panel ➤ Profile drop-down ➤ Create Surface Profile ⬚ .

2 In the Create Profile from Surface dialog box (page 2144), in the Alignment list, select the horizontal alignment to use for the profile.

3 Ensure that the surface you want to use is listed in the Select Surfaces list. If multiple surfaces are listed, use Ctrl + click to select one or more of them from which to create profiles.

4 Optionally, in the Station Range area, specify start and end stations if you want the profile to cover a distance less than the entire length of the horizontal alignment.

5 Click Add to add the centerline profile to the Profile List.

6 Optionally, select the Sample Offsets check box. Enter the offset distances in the field if you want the profile to include one or more offsets from the centerline of the horizontal alignment. Use positive numbers to specify right offsets, and negative numbers for left offsets. Use commas to separate the values. Example: 20,-20,30,40

7 Optionally, click Add to add the offset profiles to the Profile List.

8 In the table, review the data for each profile line and make corrections as required. Optionally, add or delete profiles in the Profile list.

9 Do one of the following:
   ■ If you want to draw the profile in a profile view, click Draw In Profile View, and then go to the create profile view procedure (page 1108).

■ Click OK. The profiles you created are saved. If the alignment has one or more profile views associated with it, the profiles you created are added to the views.

Dialog Box

Create Profile from Surface (page 2144)

# Creating Layout Profiles

Create layout profiles to represent designed elevations along an alignment.

You typically draw a layout profile on the grid of a profile view, using the surface profile as a guide.

A profile view grid must exist in the drawing to use this command. Create curves and tangents by freehand sketching or by entering numeric values.

You can create a layout profile with tangents, and then optionally add curves at the points of vertical intersection (PVI).

You can create a profile from an external ASCII file that contains a series of stations along an alignment, the elevation of each station, and optionally, the length of curve at the station.

Curve attributes are set by the Curve Settings command. These curves maintain tangency when edited.

Several methods are available for drawing a layout profile:

■ Use the  Draw Tangents command to specify points of vertical intersection (PVIs) for a series of straight tangents. Later you can add free curves (page 1084) with specific parameters between the tangents.

■ Use the  Draw Tangents With Curves command to specify PVIs for the tangents, automatically creating curves between the tangents using the parameters you specify in the Vertical Curve Settings Dialog Box (page 2194).

■ Use the constraint-based profile design commands (page 1059) to create a profile one sub-entity at a time.

When you are prompted for point locations, you can use the Transparent Commands (page 1581) to specify points in the profile.

To create a more detailed design using a specific parameter or other constraints, or to create curves without first creating tangents, use the constraint-based tools included on the Profile Layout Tools toolbar. For more information, see Adding Tangents and Curves to a Layout Profile (page 1059).

The criteria-based design (page 2471) feature allows a layout profile to be validated against local design standards. You can select a design criteria file (page 2472) and/or a design check set (page 2472) using either the Create Profile - Draw New dialog box (page 2142) when you create the layout profile, or the Design Criteria tab (page 2175) of

the Profile Properties dialog box after it has been created. For more information, see Criteria-Based Profile Design (page 1044).

**To create a layout profile**

1   Click Home tab ➤ Create Design panel ➤ Profile drop-down ➤ Profile Creation Tools ⬚ .

2   Click the profile view in which to draw the layout profile.

3   In the Create Profile - Draw New dialog box (page 2142), enter a unique Name for the profile. Optionally, enter a Description.

4   On the General tab (page 2142), specify the following settings:

   ■   Profile Style

   ■   Profile Layer

   ■   Profile Label Set

   ---

   **NOTE** If you do not want to apply design criteria to the profile, proceed to step 6.

   ---

5   If you would like to associate design standards with the profile, on the Design Criteria tab (page 2143), select the Use Criteria-Based Design check box.

   For more information, see Criteria-Based Profile Design (page 1044).

   On the Design Criteria tab, specify the following settings:

   ■   Use Design Criteria File
      Select this check box to associate a design criteria file with the profile. The default design criteria file location and the Default Criteria properties becomes available when you select the check box.

   ■   Use Design Check Set
      Select this check box to associate a design check set with the profile. The design check set list becomes available when you select the check box. Select a design check set from the list.

6   Click OK to display the Profile Layout Tools toolbar.

7   Use the commands on the Profile Layout Tools (page 2170) toolbar to draw the profile.

   You can use any of the following methods to lay out a profile:

   ■   Use the ⬚ Draw Tangents command to specify points of vertical intersection (PVIs) for the tangents, and then add free curves (page 1084) with specific parameters between the tangents.

   ■   Use the ⬚ Draw Tangents With Curves command to specify PVIs for the tangents, automatically creating curves between the tangents using the parameters you specify in the Vertical Curve Settings dialog box (page 2194).

   ■   Use various Profile Layout Tools (page 2170) to create separate entities and then join them together.

   ---

   **TIP** When you are prompted for point locations, you can use the Transparent Commands (page 1581) to specify points in the profile.

   ---

   When you use Use the ⬚ Draw Tangents With Curves command, curves are created to comply with the values in one of the following places:

   ■   If the profile has design criteria (page 866) applied to it, the minimum K value for the current design speed is applied to the curve. If no solution can be found with the minimum K value, the curve is not drawn.

■ If the profile does not have design criteria applied to it, the default curve length or K value specified in the vertical curve settings is applied to the curve. For more information, see Vertical Curve Settings dialog box (page 2194).

**To create a profile from a profile file**

1 Click Home tab ➤ Create Design panel ➤ Profile drop-down ➤ Create Profile From File 🔲.

2 Browse to the text file (a text file uses the *.txt* extension).

3 Click the text file and click Open. If the file is correctly formatted, it is read into the system and the Create Profile - Draw New dialog box is displayed.

4 In the Create Profile - Draw New dialog box (page 2142), review and revise any settings you want to change for the profile name, description, and styles.

5 Click OK to save the profile in the drawing.

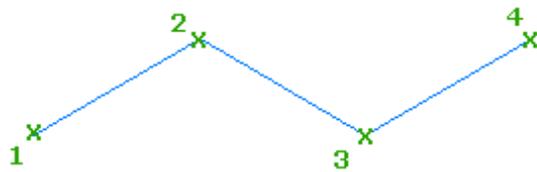
## Drawing Tangent-Tangent Profiles

Use the Profile Layout Tools to create and edit profiles.

You can use either of the following commands to create a quick layout of the profile. The lines and curves you create maintain tangency when you edit them.

**Draw Tangents Without Curves**

Use this command to create a quick layout of the profile. Specify tangent start and end points (1 through 4), then add curves at the points of intersection as necessary. The tangents are fixed, so you can edit them and they always maintain tangency.


**Draw Tangents With Curves**

Use this command to create a quick layout of the profile, with curves automatically created at points of intersection. Specify tangent start and end points (1 through 4), and curves are created at the points of intersection (2, 3) based on the values you enter in the Curve Settings dialog box. You can edit the tangents and curves and they always maintain tangency.

**TIP** You can use transparent commands when you are prompted to specify direction, radius, or length, or use station offsets to specify any points. For more information, see Transparent Commands (page 1581).

**See also:**

■ Editing PVIs (page 1093)

**To draw a profile using the tangent-tangent method with no curves**

1  Click Home tab ➤ Create Design panel ➤ Profile drop-down ➤ Profile Creation Tools .

2  In the Create Profile-Layout (page 1763) dialog box, enter creation information.

3  On the Profile Layout Tools toolbar, click  Draw Tangents Without Curves.

4  Specify the start point.

5  Continue to specify points. Press Enter to end the command, or click another command from the Profile Layout Tools toolbar.

**To draw a profile using the tangents with curves**

1  Click Home tab ➤ Create Design panel ➤ Profile drop-down ➤ Profile Creation Tools .

**2** In the Create Profile-Layout (page 1763) dialog box, enter creation information.

**3** On the Profile Layout Tools toolbar, click ⛤ Draw Tangents With Curves.

**4** Specify the start point.

**5** Continue to specify points. Press Enter to end the command or select another command from the Profile Layout Tools.

Curves are created to comply with the values in one of the following places:

■ If the profile has design criteria (page 866) applied to it, the minimum radius for the current design speed is applied to the curve. If no solution can be found with the minimum radius value, the curve is not drawn.

■ If the profile does not have design criteria applied to it, the default value specified in the curve and spiral settings is applied to the curve. For more information, see Curve and Spiral Settings (page 861).

## Setting Curve Parameters

Enter the curve settings you want to use when creating profiles or parcels using the Draw Tangents With Curves command.

You can specify default settings for curves by editing the Profile Creation settings in the CreateProfileLayout command.

## Specifying Curve Settings

Specify default curve types and values in the Vertical Curve Settings dialog box or by editing the Profile Creation settings for the CreateProfileLayout command.

The parameter values in the Vertical Curve Settings dialog box apply only to the curves created using the Draw Tangents with Curves command in the current profile. You can specify default settings for all curves by editing the settings in the CreateProfileLayout command.

**To change the default CurveSettings**

**1** On the Settings tab in Toolspace, expand the Profiles collection and then expand the Commands collection.

**2** Right-click CreateProfileLayout ➤ Edit Command Settings.

**3** In the Edit Command Settings-CreateProfileLayout dialog box, expand the Profile Creation property.

**4** Specify the settings, click Apply, and click OK.

> **NOTE** To save these command settings at the drawing level, on the Ambient Setting tab (page 68)select Yes in the value column for Save Command Changes To Settings.

**To change the curve settings when you draw a profile using the tangent with curves method**

**1** Click Home tab ➤ Create Design panel ➤ Profile drop-down ➤ Profile Creation Tools .

**2** In the Create Profile - Draw New (page 2142) dialog box, enter creation information.

**3** On the Profile Layout Tools toolbar, click Curve Settings.

**4** In the Vertical Curve Settings (page 2194) dialog box, enter curves values.

> **NOTE** The curve type you specify in the Vertical Curve Settings dialog box is used in all curve commands on the Profile Layout Tools toolbar.

Curve Settings

Dialog Box

Vertical Curve Settings Dialog Box (page 2194)

# Format Requirements of Profile Files

Use profile files to record layout data for points of vertical intersection (PVIs) in a profile.

A profile file is a simple text file in ASCII format. The file contains a series of stations along an alignment, the elevation of each station, and optionally, the length of curve at the station. Each line can include up to three information elements, separated by spaces:

**1** **Station**. An element required for each line. Plus characters (+) cannot be used.

**2** **Elevation**. A required element.

**3** **Curve length**. An optional element. However it cannot be used on the first or last line of the file. All vertical curves must be parabolic.

Sample file lines:

```
0 100.23
50 104.2
100 109.0 40.0
150 102.63
200 98.12 35.0
250 102.45
300 105.8
```

In this example, only the third and fifth PVIs include curves (lengths of 40.0 and 35.0). Use these other format requirements for each profile file:

■ The first and last lines must not contain curve information.

■ The first line must provide the station and elevation for the first station.

■ Stations must be in ascending order.

■ No leading blank lines or headers.

■ No blank lines; a blank line is read as the end of the file.

■ No blank spaces at the beginning of any line.

■ The last item must be the elevation for the last station.

## Creating a Superimposed Profile

In a profile view, display the profile of another alignment that is adjacent to the main horizontal alignment.

Use this option to show one profile in relation to another, such as a ditch in relation to a road centerline.

The general process is first to create separate profile views to display the two profiles. Then identify one profile as the source profile to display in the other profile view, which is known as the destination profile view. In the example of a ditch and a road centerline, let us assume that the ditch is the source profile and the profile view for the road is the destination. When you superimpose the ditch profile on the profile view of the road, you see the ditch elevations with reference to the stations along the road centerline.

When you superimpose a profile, you can set some options in the Superimpose Profile Options dialog box (page 2193)

**To superimpose a profile**

1 Identify the source profile you want to superimpose. Ensure that each profile appears in a profile view.

2 Click Home tab ➤ Create Design panel ➤ Profile drop-down ➤ Create Superimposed Profile 📉 .

3 In the drawing, click the source profile line.

4 Click the grid of the destination profile view.

5 Optionally, on the Limits tab (page 2194), specify a limited range of stations to superimpose.

**NOTE** If you want the superimposed profile station range to remain fixed, then select the Select Start and Select End checkboxes and the superimposed profile will not react to changes in the station range of the source alignment. If the Select Start and Select End boxes are not selected, then the start and end of the superimposed profile locks to the start and end of the source alignment. If the start or end of the source alignment changes, the superimposed profile updates dynamically.

6 Optionally, on the Accuracy tab (page 2194), specify different mid-ordinate distances for curve tessellation.

**7** Click OK.

### Quick Reference

# Creating a Corridor Profile

In a profile view, display a profile derived from a corridor feature line.

Profiles derived from corridor feature lines are static and are displayed with a ⚲ in the Profile collection in the Prospector tree.

For information on creating a corridor profile, see Exporting Corridor Feature Lines as Profiles (page 1372).

# Creating a Profile by Reference

Create a reference to an existing profile in a data shortcut (page 2472) or a Vault project.

The profile reference is a lightweight read-only copy of the original, but it gives you access to profile data for other objects. Before you create a profile reference in the current drawing, the reference object or data shortcut must exist in the current project collection on the Toolspace Prospector tab.

When a profile reference is created, a reference to the profile's parent alignment is also created in the drawing. AutoCAD Civil automatically looks for the correct alignment reference in the source drawing when creating the profile reference.

**See also:**

■ Creating Data Shortcuts (page 131)

■ Using Vault (page 138)

**To create a reference to a data shortcut profile**

**1** In Toolspace, on the Prospector tab, ensure that the correct project folder is identified on the Data Shortcuts node.

**2** Expand the Data Shortcuts ➤ Alignments collection.

**3** Expand the parent alignment of the profile you want to reference.

**4** Right-click the desired profile, and then click Create Reference.

The Create Profile Reference dialog box is displayed, in which you can optionally change the properties of the reference profile, as described in the following steps.

**5** In the Create Profile Reference dialog box, change the source of the reference by selecting a source in the Source Profile list.

**6** Change the source parent alignment by selecting an alignment from the Source Alignment list.

**7** Enter a Name for the profile.

> **NOTE** To name the profile, click its default name. Enter a new name, or use the name template. For more information, see Name Template Dialog Box (page 1806).

**8** Specify a Profile Style or accept the default style.
For more information, see Profile Styles (page 1027).

**9** Click  to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

> **NOTE** If you do not select a layer, the profile is placed on the current layer.

**10** Specify a Profile Label Set or accept the default label set.

**11** Click OK to create the profile reference.
A reference to the parent alignment is also created. The alignment name is displayed under the

Alignments collection in the Prospector tree with a  next to it. Expand the alignment name and the Profiles collection to view the profile reference.

**To create a reference to a profile in a Vault project**

**1** In Toolspace, on the Prospector tab, in Master View, expand the Projects <project name> ➤ Alignments collection.

**2** Expand the parent alignment of the profile you want to reference.

**3** Right-click the desired profile, and then click Create Reference.
The Create Profile Reference dialog box is displayed, in which you can optionally change the properties of the reference profile, as described in the following steps.

**4** In the Create Profile Reference dialog box, change the source of the reference by selecting a source in the Source Profile list.

**5** Change the source parent alignment by selecting an alignment from the Source Alignment list.

**6** Enter a Name for the profile.

> **NOTE** To name the profile, click its default name. Enter a new name, or use the name template. For more information, see Name Template Dialog Box (page 1806).

**7** Specify a Profile Style or accept the default style.
For more information, see Profile Styles (page 1027).

**8** Click  to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

> **NOTE** If you do not select a layer, the profile is placed on the current layer.

**9** Specify a Profile Label Set or accept the default label set.

**10** Click OK to create the profile reference.

A reference to the parent alignment is also created. The alignment name is displayed under the Alignments collection in the Prospector tree with a ↗ next to it. Expand the alignment name and the Profiles collection to view the profile reference.

# Copying a Profile

Copy a layout profile or a static surface profile. Use the copy to create a profile or replace an existing one.

Profile copying operations allow you to create a profile that is based on another. For example, you can create an offset profile for a road edge or ditch that is a specific elevation below the road centerline. In this case, you can copy the centerline profile, then change the elevation of the copy to create the offset profile.

After copying a profile, you can raise or lower the copy to create an initial line for a related profile. For example, to place a ditch five feet lower than a centerline, copy the centerline profile and lower the copy five feet to create a ditch profile.

### Troubleshooting a Copied Profile

When you try copying a profile, you may receive the following error message:

*Station xx+xx: Either outside of alignment limits, or within gap created by a station equation.*

To resolve this issue, create a profile that extends beyond the station limits of the defined parent alignment. You will not be able to copy a selected station range of PVIs if you select a start or end station that is outside the limits of the parent horizontal alignment. Instead, copy the entire profile and then remove the unwanted PVIs manually.

### To copy a profile

1 Click the profile you want to copy.

2 Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

3 In the Profile Layout Tools dialog box (page 2170), click  Copy Profile.

4 In the Copy Profile Data Dialog Box (page 2141), check the data displayed in the Source Profile Information area to ensure that this is the correct profile to copy.

5 Click the PVI range you want to copy: either All PVIs or those within a range of stations.

6 If you clicked Station Range, specify the start and end stations.

7   In the Destination Profile Options area, specify what to do with the copy of the profile: either Create New Profile or Overwrite Existing Profile.

8   If you clicked Overwrite Existing Profile, select the profile to overwrite.

9   To overwrite all properties of the existing profile, select Overwrite All Properties.

10  Click OK to create the copy of the profile. The copy is initially named according to the naming template, like any new profile. You can change the name. The copy is displayed in the current profile view, superimposed on its source profile. It also appears in the Toolspace Prospector tab, in the list of profiles for the parent alignment.

### Quick Reference

## Creating a Quick Profile

View surface elevation data along an object or between two points.

Use the quick profile functionality to generate elevation data using a few quick steps before you create a detailed design.

You can create quick profiles along many object types:

■   2D or 3D lines or polylines

■   Lot lines

■   Feature lines

■   Survey figures

■   A series of points

These profiles are not saved with the drawing.

You can control which surfaces are sampled in the quick profile, the style used to display the profile of each surface, and the profile view style.

To create a profile that you can use again, create an alignment at the location of interest and use it to generate a standard profile.

After you create a quick profile, extract information from it using the Inquiry tool. You can select and move a quick profile. Use the object shortcut menu to change the style of one of its profiles or the profile view.

**NOTE** To simplify working with quick profiles, open two viewports before you create a quick profile. Use one viewport to display the plan view and the other viewport to display the quick profiles.

**To create a quick profile from an object**

**1** Click Home tab ➤ Create Design panel ➤ Profile drop-down ➤ Quick Profile  .

On the command line, you are prompted to pick an object.

**2** In the drawing, select a line, polyline, lot line, feature line, or survey figure.

**3** In the Create Quick Profiles dialog box, select the surfaces you want to sample, and the profile and profile view styles.

**4** Optionally, if you selected a 3D object, select Draw 3D Entity Profile to display elevation data for the object in the quick profile and a profile style for the 3D object elevation data.

**5** Click OK.

**6** In the drawing window, click a location for the lower left corner (origin) of the profile view grid.

The quick profile is drawn.

**To create a quick profile by selecting points**

**1** Click Home tab ➤ Create Design panel ➤ Profile drop-down ➤ Quick Profile  .

On the command line, you are prompted to pick an object.

**2** Enter p (points).

**3** In the drawing, select a point, and then a second point.

**4** Optionally, select additional points as required.

**5** Press Enter.

**6** In the Create Quick Profiles dialog box, select the surfaces you want to sample, and the profile and profile view styles.

**7** In the drawing window, click a location for the lower left corner (origin) of the profile view grid.

The quick profile is drawn.

# Adding Tangents and Curves to a Layout Profile

You can add fixed, floating, or free tangents and curves to a layout profile.

Use constraint-based commands on the Profile Layout Tools (page 2170) toolbar to refine the layout profile design to meet your project objectives.

**NOTE** When drawing or editing constraint-based profile entities, ensure that the Profile Layout Tools (page 2170) toolbar is set to △╱ Entity Based mode.

The three entity type describes the way an entity is defined and edited:

■ Fixed entities are defined by specifying parameters, such as pass-through points, tangent slope, and curve radius. The entities are fixed in position and must be edited directly. Except for its length, the geometry of a fixed entity is not dependent on adjacent entities. If an adjacent entity is edited, the geometry of the fixed entity is not affected.

■ Floating entities are defined by specifying parameters and an entity to attach to. Floating entities are always tangent to the entity they are attached to, and are dependent on the other entity to define their geometry.

■ Free entities are defined by attachment to two entities, before and after. The free entity always remains tangent to the two adjacent entities, and its geometry is defined by these adjacent entities.

# Adding Vertical Tangents

Add fixed, free, or floating vertical tangents to build constraint-based profile geometry.

To access the vertical tangent creation commands, click the arrow next to the tangent creation command displayed on the toolbar. The ╱ Draw Fixed Tangent By Two Points command is displayed by default.

After clicking a button on the Profile Layout Tools toolbar, follow the command prompts on the command line.

**TIP** You can use transparent commands to specify a station and elevation when you are prompted to select a point. For more information, see Transparent Commands (page 1581).

## Adding Fixed Vertical Tangents

Add fixed vertical tangents to build constraint-based profile geometry.

Fixed entities are defined by specifying parameters, such as points or minimum radius. The parameters are fixed in their position and must be edited directly.

The position of a fixed entity is not affected by edits to adjacent entities.

Except for its length, the geometry of a fixed entity is not dependent on adjacent entities.

## Adding a Fixed Vertical Tangent with Two Points

Add a fixed vertical tangent by specifying two points that the line will pass through.

**To add a fixed vertical tangent with two points**

1 Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor 🖉 .

2 On the Profile Layout Tools (page 2170) toolbar, click ╱ Draw Fixed Tangent By Two Points.

3 Specify the start point.

**4** Specify the next point.

## Adding a Fixed Vertical Tangent by Best Fit

Add a fixed, two-point vertical tangent entity by best fit to a profile. You can define the best fit entity using a series of AutoCAD Civil points or clicks on screen.

The following illustration shows a fixed vertical tangent created by best fit. The Xs indicate the data points that were used to create the entity.

**NOTE** Each best fit profile entity is drawn to the vertical scale set in the profile view style. To create an accurate best fit entity, set the profile view style Vertical Exaggeration value to 1.000 to match the horizontal scale of the profile view. For more information, see Creating and Editing Profile View Styles (page 1030).

**See also:**

■ Editing Best Fit Profile Entities (page 1100)

**To add a fixed vertical tangent by best fit from AutoCAD Civil points**

**1** Set the profile view style Vertical Exaggeration value to 1.0000. See Creating and Editing Profile View Styles (page 1030) for more information.

**2** Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

**3** In the Profile Layout Tools (page 2170) toolbar, click  Fixed Tangent - Best Fit.

**4** In the Tangent by Best Fit dialog box (page 1989), select From COGO Points.

**5** In plan view, select two or more points. Enter G to select a point group or N to enter points by number.

As the points are selected in plan view, an X marks each regression point and a temporary, dashed tangent is displayed in the profile view.

**6** Press Enter to complete the command.

**7** In the Panorama window, use the Regression Data vista (page 1990) to modify the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**8** Create the tangent:

■ Click  to create the tangent and keep the Regression Data vista open.

■ Click  to create the tangent and close the Regression Data vista.

**To add a fixed vertical tangent by best fit by clicking on screen**

**1** Set the profile view style Vertical Exaggeration value to 1.0000. See Creating and Editing Profile View Styles (page 1030) for more information.

**2** Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

**3** In the Profile Layout Tools (page 2170) toolbar, click  Fixed Tangent - Best Fit.

**4** In the Tangent by Best Fit dialog box (page 1989), select By Clicking On The Screen.

**5** Select a starting point and at least one other point.

**NOTE** You can use OSNAP or transparent commands to select points.

As you select points in the drawing window, an X marks each regression point and a temporary, dashed tangent is displayed in real time.

**6** Press Enter to complete the command.

**7** In the Panorama window, use the Regression Data vista (page 1990) to modify the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**8** Create the tangent:

■ Click  to create the tangent and keep the Regression Data vista open.

■ Click  to create the tangent and close the Regression Data vista.

**To add a fixed vertical tangent by best fit from existing entities**

**1** Set the profile view style Vertical Exaggeration value to 1.0000. See Creating and Editing Profile View Styles (page 1030) for more information.

**2** Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor  .

**3** In the Profile Layout Tools (page 2170) toolbar, click  Fixed Tangent - Best Fit.

**4** In the Tangent by Best Fit dialog box (page 1989), select By Clicking On The Screen. Specify the tessellation and mid-ordinate tolerance settings.

**5** Select one of the entities listed on the command line.

---

**NOTE** You can select several types of entities listed on the command line.

---

**6** If you selected a profile entity, specify the starting and ending station on the Specify Station Range dialog box (page 1992).

**7** Repeat steps 5 and 6 to select other entities from which to create the best fit tangent.

As you select entities in the drawing window, an X marks each regression point and a temporary, dashed tangent is displayed in real time.

**8** Press Enter to complete the command.

**9** In the Panorama window, use the Regression Data vista (page 1990) to modify the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**10** Create the tangent:

■ Click  to create the tangent and keep the Regression Data vista open.

■ Click  to create the tangent and close the Regression Data vista.

1 Set the profile view style Vertical Exaggeration value to 1.0000. See Creating and Editing Profile View Styles (page 1030) for more information.

2 Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor  .

3 In the Profile Layout Tools (page 2170) toolbar, click  Float Tangent - Best Fit.

4 Select an existing fixed or floating profile entity to which to attach the best fit tangent.

5 In the Tangent by Best Fit dialog box (page 1989), select From COGO Points.

6 In plan view, select two or more points. Enter G to select a point group or N to enter points by number.

   As the points are selected in plan view, an X marks each regression point and a temporary, dashed tangent is displayed in the profile view.

7 Press Enter to complete the command.

8 In the Panorama window, use the Regression Data vista (page 1990) to modify the regression points.

   As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

9 Create the tangent:

   ■ Click  to create the tangent and keep the Regression Data vista open.

   ■ Click  to create the tangent and close the Regression Data vista.

**To add a floating vertical tangent by best fit by clicking on screen**

**1** Set the profile view style Vertical Exaggeration value to 1.0000. See Creating and Editing Profile View Styles (page 1030) for more information.

**2** Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

**3** In the Profile Layout Tools (page 2170) toolbar, click Float Tangent - Best Fit.

**4** Select an existing fixed or floating profile entity to which to attach the best fit tangent.

**5** In the Tangent by Best Fit dialog box (page 1989), select By Clicking On The Screen.

**6** Select at least one point in the drawing.

> **NOTE** You can use OSNAP or transparent commands to select points.

As you select points in the drawing window, an X marks each regression point and a temporary, dashed tangent is displayed in real time.

**7** Press Enter to complete the command.

**8** In the Panorama window, use the Regression Data vista (page 1990) to modify the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**9** Create the tangent:

- Click to create the tangent and keep the Regression Data vista open.

- Click to create the tangent and close the Regression Data vista.

**To add a floating vertical tangent by best fit from existing entities**

**1** Set the profile view style Vertical Exaggeration value to 1.0000. See Creating and Editing Profile View Styles (page 1030) for more information.

**2** Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

**3** In the Profile Layout Tools (page 2170) toolbar, click Float Tangent - Best Fit.

**4** Select an existing fixed or floating profile entity to which to attach the best fit tangent.

**5** In the Tangent by Best Fit dialog box (page 1989), select From Entities. Specify the tessellation and mid-ordinate tolerance settings.

**6** Select one of the entities listed on the command line.

> **NOTE** You can select several types of entities listed on the command line.

**7** If you selected a profile entity, specify the starting and ending station on the Specify Station Range dialog box (page 1992).

**8** Repeat steps 6 and 7 to select other entities from which to create the best fit tangent.

As you select entities in the drawing window, an X marks each regression point and a temporary, dashed tangent is displayed in real time.

**9** Press Enter to complete the command.

**10** In the Panorama window, use the Regression Data vista (page 1990) to modify the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**11** Create the tangent:

■ Click 🖫 to create the tangent and keep the Regression Data vista open.

■ Click ✔ to create the tangent and close the Regression Data vista.

## Vertical Curve Design

Designing vertical curves in layout profiles requires that you understand the concepts described in this topic.

**Curve Types**

- **Taylor Pohlman Parabolic**. Most vertical curves in road design are symmetrical parabolic curves for a good reason. The parabolic curve is the natural vertical curve followed by any projectile. A properly designed symmetrical parabola minimizes the inertial forces on a vehicle traveling along the curve. Highway curves are often designed with reference to curve tables, such as those provided by the American Association of State Highway and Transportation Officials (A.A.S.H.T.O. (page 2467)). These tables can be used only with symmetrical parabolic curves.

Quadratic parabolas are preferred in vertical designs as they have a constant rate of change of grade along the curve. Quadratic parabolas are a very close approximation to circular curves at flat grades and are usually used in vertical design. This quality makes them very easy to stake out. Substituting these values we get the quadratic parabola equation for vertical curve as:

$$y = \frac{g_1}{100} x + \frac{(g_2 - g_1)}{200L} x^2$$

- g1 is the grade of tangent in

- g2 is the grade of tangent out

- L is the horizontal length of the curve that is fit between these two tangents

Since the rate of grade change is constant over the length of the curve, the parabolic curve parameter can be expressed as:

$$K = \frac{L}{|g_1 - g_2|}$$

- Circular. These curves are easier to lay out and construct. This type is often used for the design of railways or roads that are traveled at low speeds.

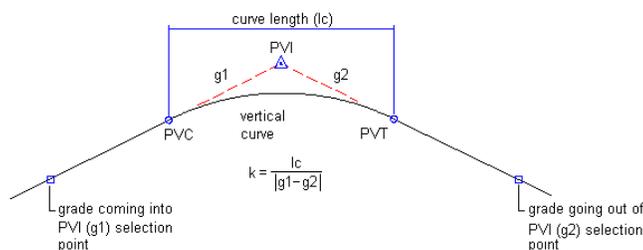
- Asymmetrical parabolic. These curves are the least common type. This curve type consists of two different parabolic curves that meet at the midpoint of the vertical curve.

**K-Value**

This value represents the horizontal distance along which a 1% change in grade occurs on the vertical curve. It expresses the abruptness of the grade change in a single value. Speed tables or other design tools often provide a target minimum K value.

The criteria-based design (page 1044) feature automatically validates profile curve design against local design standards. A.A.S.H.T.O. tables defining minimum K values at given speeds are provided in the customizable design criteria file. Curves that violate your design standards can be corrected by using the Profile Layout Parameters dialog box (page 2168) to either adjust K value directly, or change curve length and tangent grade to meet the criteria.

**K-value formula**



**Stopping Sight Distance**

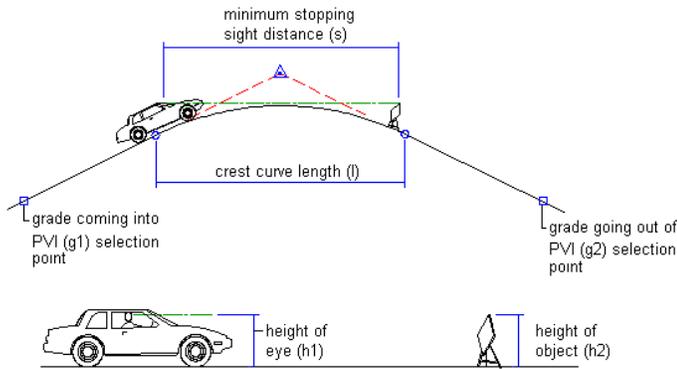
This design method for crest curves provides a minimum curve length. The curve must be long enough so that the driver of a standard vehicle can always see an object before it gets within the maximum stopping distance for the designed speed of travel.

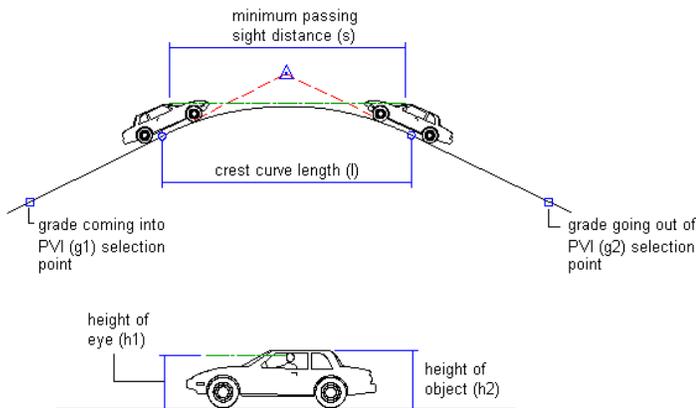
### Diagram of stopping sight distance

### Passing Sight Distance

This design method for crest curves provides a minimum curve length. The curve must be long enough so that the driver of a standard vehicle can always see an oncoming vehicle within a safe distance for the designed speed of travel.

### Diagram of passing sight distance

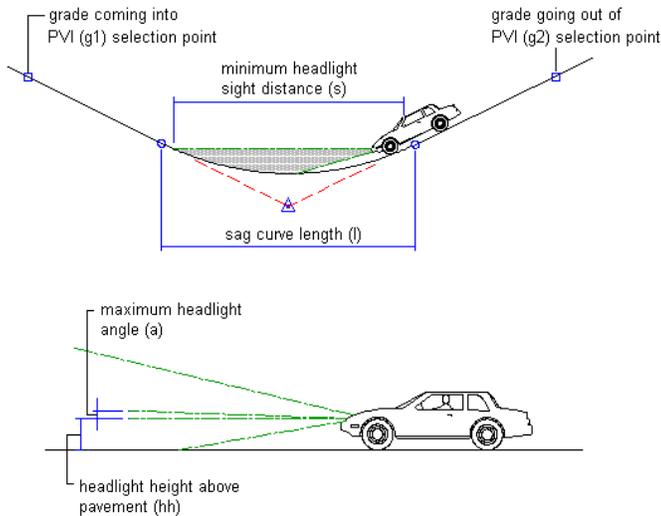




### Headlight Sight Distance

This design method for sag curves provides a minimum curve length. The curve must be long enough so that in dark driving conditions, the headlights of a standard vehicle illuminate the road a safe distance beyond the stopping distance for the designed speed of travel.

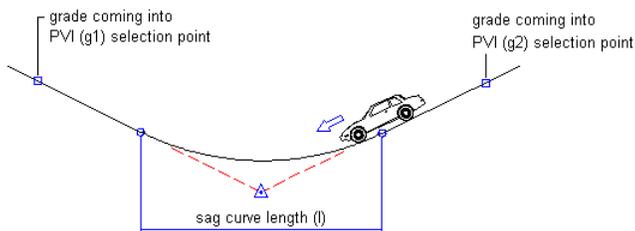
**Diagram of headlight sight distance**



**Rider Comfort**

This design method for sag curves provides a minimum curve length. The curve must be long enough so that people in a standard vehicle do not experience excessive inertial force as they travel through the curve at the designed speed.

**Diagram of rider comfort design**



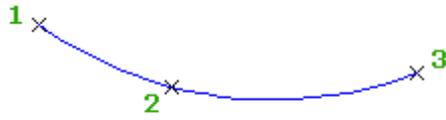
# Adding Fixed Vertical Curves

Add fixed vertical curves to build constraint-based profile geometry.

Fixed entities are defined by specifying parameters, such as points or minimum radius. The parameters are fixed in their position and must be edited directly. If an adjacent entity is edited, the geometry of the fixed entity is not affected. Except for its length, the geometry of a fixed entity is not dependent on adjacent entities.

# Adding a Fixed Vertical Curve with Three Points

Add a fixed vertical curve by specifying three pass-through points.

The illustration shows a fixed curve from start point 1 through specified points 2 and 3.


**To add a fixed vertical curve with three points**

1 Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor ![icon].

2 On the Profile Layout Tools toolbar, click ![icon] Fixed Vertical Curve (Three Points).

3 Specify the start point.

4 Specify the second point.

5 Specify the end point.

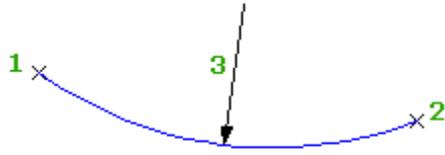
## Adding a Fixed Vertical Curve with Two Points and a Parameter

Specify two pass-through points and a K value or minimum radius.

The illustration shows a fixed curve defined by a start point (1), end point (2), and a minimum radius (3):


**To add a fixed vertical curve with two points and a parameter**

1　Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor ✎ .

2　On the Profile Layout Tools toolbar, click 🔔 Fixed Vertical Curve (Two Points, Parameter).

3　Specify a start point.

4　Specify an end point.

5　Do one of the following:
   - To specify a crest curve, press Enter.
   - To specify a sag curve, enter S (sag).

6　Do one of the following:
   - Specify a K value.
   - To specify a minimum radius for the curve parabola, enter R (radius), and then specify the radius.

     **NOTE** If the profile was created using the criteria-based design (page 2471) feature, a default value is displayed on the command line. Minimum K values at given design speeds are specified in the design criteria file (page 2472). Minimum curve length and radius are calculated from the minimum K value at the current design speed.

Floating entities are defined by specifying parameters and an entity to attach to. Floating entities are always tangent to the entity it is attached to, and are dependent on the other entity to define its geometry.

# Adding a Floating Vertical Curve with a Pass-Through Point and a Parameter

Add a floating vertical curve by specifying a pass-through point and a parameter.

The illustration shows a floating curve from an existing entity (1) to a pass-through point (2) and a minimum radius (3). This curve type can also be drawn from a specified K value.

**To add a floating vertical curve with a pass-through point and a parameter**

1   Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor  .

2   On the Profile Layout Tools toolbar, click  Floating Vertical Curve (Through Point, Parameter).

3   Select the fixed or floating entity to which you want to attach the curve.

**4** Specify a pass-through point.

**5** If selected a parabola in step 3, specify whether the resulting curve should be either a crest or sag.

**6** Do one of the following:

- To specify a K value, enter the K value.

- To specify a minimum radius for the curve parabola, enter R (radius), and then specify the radius.

> **NOTE** If the profile was created using the criteria-based design (page 2471) feature, a default value is displayed on the command line. Minimum K values at given design speeds are specified in the design criteria file (page 2472). Minimum curve length and radius are calculated from the minimum K value at the current design speed.

## Adding a Floating Vertical Curve by Best Fit

Add a floating, three-point curve entity by best fit to a profile. You can define the best fit entity using a series of AutoCAD Civil points, existing entities, or clicks on screen.

The illustration shows a floating vertical curve created from entity 1 by best fit. The Xs indicate data points used to create the entity.

**NOTE** Each best fit profile entity is drawn to the vertical scale set in the profile view style. To create an accurate best fit entity, set the profile view style Vertical Exaggeration value to 1.000 to match the horizontal scale of the profile view. For more information, see Creating and Editing Profile View Styles (page 1030).

**See also:**

■ Editing Best Fit Profile Entities (page 1100)

**To add a floating vertical curve by best fit from AutoCAD Civil points**

1 Set the profile view style Vertical Exaggeration value to 1.0000. See Creating and Editing Profile View Styles (page 1030) for more information.

2 Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

3 In the Profile Layout Tools (page 2170) toolbar, click Floating Vertical Curve - Best Fit.

4 Select an existing fixed or floating profile entity to which to attach the best fit tangent.

   If you select the first half of the profile entity, the best fit entity will precede the profile entity. If you select the second half of the profile entity, the best fit entity will succeed the profile entity.

5 In the Curve by Best Fit dialog box (page 1989), select From COGO Points.

6 In plan view, select two or more points. Enter G to select a point group or N to enter points by number.

   As the points are selected in plan view, an X marks each regression point and a temporary, dashed curve is displayed in the profile view.

7 Press Enter to complete the command.

8 In the Panorama window, use the Regression Data vista (page 1990) to modify the regression points.

   As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

9 Create the curve:

   ■ Click to create the curve and keep the Regression Data vista open.

   ■ Click to create the curve and close the Regression Data vista.

**To add a floating vertical curve by best fit by clicking on screen**

1 Set the profile view style Vertical Exaggeration value to 1.0000. See Creating and Editing Profile View Styles (page 1030) for more information.

2 Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

3 In the Profile Layout Tools (page 2170) toolbar, click Floating Vertical Curve - Best Fit.

4 Select an existing fixed or floating profile entity to which to attach the best fit tangent.

   If you select the first half of the profile entity, the best fit entity will precede the profile entity. If you select the second half of the profile entity, the best fit entity will succeed the profile entity.

5 In the Curve by Best Fit dialog box (page 1989), select By Clicking On The Screen.

6 Select at least two points in the drawing.

   **NOTE** You can use OSNAP or transparent commands to select points.

As you select points in the drawing window, an X marks each regression point and a temporary, dashed curve is displayed in real time.

**7** Press Enter to complete the command.

**8** In the Panorama window, use the Regression Data vista (page 1990) to modify the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**9** Create the curve:

- ■ Click ![icon] to create the curve and keep the Regression Data vista open.

- ■ Click ![icon] to create the curve and close the Regression Data vista.

**To add a floating vertical curve by best fit from existing entities**

**1** Set the profile view style Vertical Exaggeration value to 1.0000. See Creating and Editing Profile View Styles (page 1030) for more information.

**2** Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor ![icon] .

**3** In the Profile Layout Tools (page 2170) toolbar, click ![icon] Floating Vertical Curve - Best Fit.

**4** Select an existing fixed or floating profile entity to which to attach the best fit tangent.

If you select the first half of the profile entity, the best fit entity will precede the profile entity. If you select the second half of the profile entity, the best fit entity will succeed the profile entity.

**5** In the Curve by Best Fit dialog box (page 1989), select By Clicking On The Screen. Specify the tessellation and mid-ordinate tolerance settings.

**6** Select one of the entities listed on the command line.

**NOTE** You can select several types of entities listed on the command line.

**7** If you selected a profile entity, specify the starting and ending station on the Specify Station Range dialog box (page 1992).

**8** Repeat steps 6 and 7 to select other entities from which to create the best fit curve.

As you select entities in the drawing window, an X marks each regression point and a temporary, dashed curve is displayed in real time.

**9** Press Enter to complete the command.

**10** In the Panorama window, use the Regression Data vista (page 1990) to modify the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**11** Create the curve:

- ■ Click ![icon] to create the curve and keep the Regression Data vista open.

- ■ Click ![icon] to create the curve and close the Regression Data vista.

## Adding Free Vertical Curves

Add free vertical curves to build constraint-based profile geometry.

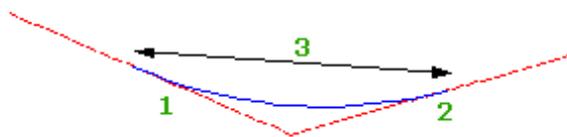
Free entities are defined by attachment to two entities, on which the free entity is dependent to define its geometry.

## Adding a Free Vertical Curve with a Parameter

Add a free vertical curve between two entities by specifying a parameter.

Specify a K value, length, or radius to define the curve.

The illustration shows a free curve between entities 1 and 2, specified with a length parameter 3.



**To add a free vertical curve with a parameter**

1   Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

2   On the Profile Layout Tools toolbar, click  Free Vertical Curve (Parameter).

3   Select the first fixed or floating entity to which you want to attach the curve.

4   Select the second fixed or floating entity to which you want to attach the curve.

**5** Enter one of the following parameters to complete the curve definition:

- Length: Enter L

- K Value: Enter K

- Radius: Enter R

---

**NOTE** If the profile was created using the criteria-based design (page 2471) feature, a default value is displayed on the command line. Minimum K values at given design speeds are specified in the design criteria file (page 2472). Minimum curve length and radius are calculated from the minimum K value at the current design speed.

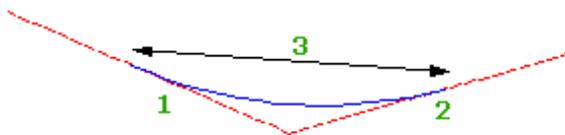
## Adding a Free Parabolic Vertical Curve

Add a free parabolic vertical curve.

Specify the curve by length, a pass-through point, or a K value.

The illustration shows a free curve between entities 1 and 2, specified with a length parameter 3.



**To add a free parabolic vertical curve**

**1** Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor  .

**2** On the Profile Layout Tools toolbar, click ⊟ Free Vertical Parabola (PVI Based).

**3** In the profile view, select a location near the PVI to which you want to add a curve.

**4** Enter one of the following parameters to complete the curve definition:

- Length: Enter L.

- Pass-Through Point: Enter P

- K Value: Enter K.

**NOTE** If the profile was created using the criteria-based design (page 2471) feature, a default value is displayed on the command line. Minimum K values at a given design speed are specified in the design criteria file (page 2472). Minimum curve length and radius are calculated from the minimum K value at the current design speed.

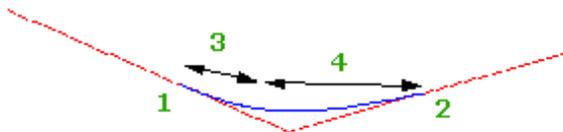
## Adding a Free Asymmetrical Vertical Curve

Add a free asymmetrical vertical curve.

You specify the length of the curve before the PVI and the length of the curve after the PVI.

The illustration shows an asymmetrical curve between tangents 1 and 2, with curve lengths 3 and 4.


**To add a free asymmetrical vertical curve**

1   Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor ![icon].

2   On the Profile Layout Tools toolbar, click ![icon] Free Asymmetrical Parabola (PVI Based).

3   In the profile view, select a location near the PVI to which you want to add a curve.

4   Specify the length of the curve before the PVI by entering a value or by selecting two points in the drawing window.

    If the first length you specify is too large for the asymmetric curve, you cannot enter the length for the second curve. The length of the first curve must be less than the station distance between the PVI you select and the station value of the previous PVI (or end station of the previous curve.)

5   Specify the length of the curve after the PVI by entering a value or by selecting two points in the drawing window.

    **NOTE**  If the profile was created using the criteria-based design (page 2471) feature, a default value is displayed on the command line. Minimum K values at given design speeds are specified in the design criteria file (page 2472). Minimum curve length and radius are calculated from the minimum K value at the current design speed.

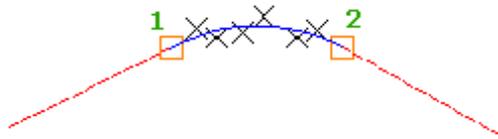
## Adding a Free Vertical Curve by Best Fit

Add a free, three-point curve entity by best fit to a profile. You can define the best fit entity using a series of AutoCAD Civil points, existing entities, or clicks on screen.

The illustration shows a free vertical curve created by best fit between endpoints 1 and 2. The Xs indicates data points used to create the entity.



**NOTE** Each best fit profile entity is drawn to the vertical scale set in the profile view style. To create an accurate best fit entity, set the profile view style Vertical Exaggeration value to 1.000 to match the horizontal scale of the profile view. For more information, see Creating and Editing Profile View Styles (page 1030).

**See also:**

- Editing Best Fit Profile Entities (page 1100)

**To add a free vertical curve by best fit from AutoCAD Civil points**

1  Set the profile view style Vertical Exaggeration value to 1.0000. See Creating and Editing Profile View Styles (page 1030) for more information.

2  Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor 🖉 .

3  In the Profile Layout Tools (page 2170) toolbar, click ⛰ Free Vertical Curve - Best Fit.

4  Select an existing fixed or floating profile entity (the First Entity) from which to attach the best fit tangent.

5  Select an existing fixed or floating profile entity (the Next Entity) to which to attach the best fit tangent.

6  In the Curve by Best Fit dialog box (page 1989), select From COGO Points.

7  In plan view, select one or more points. Enter G to select a point group or N to enter points by number.

   As the points are selected in plan view, an X marks each regression point and a temporary, dashed curve is displayed in the profile view.

8  Press Enter to complete the command.

9  In the Panorama window, use the Regression Data vista (page 1990) to modify the regression points.

   As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

10  Create the curve:

   - Click 💾 to create the curve and keep the Regression Data vista open.

■ Click ✔ to create the curve and close the Regression Data vista.

**To add a free vertical curve by best fit by clicking on screen**

1 Set the profile view style Vertical Exaggeration value to 1.0000. See Creating and Editing Profile View Styles (page 1030) for more information.

2 Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor 📝 .

3 In the Profile Layout Tools (page 2170) toolbar, click 🔺 Free Vertical Curve - Best Fit.

4 Select an existing fixed or floating profile entity (the First Entity) from which to attach the best fit curve.

5 Select an existing fixed or floating profile entity (the Next Entity) to which to attach the best fit curve.

6 In the Curve by Best Fit dialog box (page 1989), select By Clicking On The Screen.

7 Select one or more points in the drawing.

**NOTE** You can use OSNAP or transparent commands to select points.

As you select points in the drawing window, an X marks each regression point and a temporary, dashed curve is displayed in real time.

8 Press Enter to complete the command.

9 In the Panorama window, use the Regression Data vista (page 1990) to modify the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

10 Create the curve:

■ Click 💾 to create the curve and keep the Regression Data vista open.

■ Click ✔ to create the curve and close the Regression Data vista.

**To add a free vertical curve by best fit from existing entities**

1 Set the profile view style Vertical Exaggeration value to 1.0000. See Creating and Editing Profile View Styles (page 1030) for more information.

2 Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor 📝 .

3 In the Profile Layout Tools (page 2170) toolbar, click 🔺 Free Vertical Curve - Best Fit.

4 Select an existing fixed or floating profile entity (the First Entity) from which to attach the best fit tangent.

5 Select an existing fixed or floating profile entity (the Next Entity) to which to attach the best fit tangent.

6 In the Curve by Best Fit dialog box (page 1989), select By Clicking On The Screen. Specify the tessellation and mid-ordinate tolerance settings.

7 Select one of the entities listed on the command line.

**NOTE** You can select several types of entities listed on the command line.

**8** If you selected a profile entity, specify the starting and ending station on the Specify Station Range dialog box (page 1992).

**9** Repeat steps 7 and 8 to select other entities from which to create the best fit curve.

As you select entities in the drawing window, an X marks each regression point and a temporary, dashed curve is displayed in real time.

**10** Press Enter to complete the command.

**11** In the Panorama window, use the Regression Data vista (page 1990) to modify the regression points.

As you highlight a row in the Regression Data vista, the corresponding regression point in the drawing window is highlighted in red.

**12** Create the curve:

■ Click ![save icon] to create the curve and keep the Regression Data vista open.

■ Click ![check icon] to create the curve and close the Regression Data vista.

# Editing Layout Profiles

Use the profile layout tools to edit curves, tangents, and points of vertical intersection (PVIs) on layout profiles.

You can edit a layout profile by manipulating grips or by entering specific values that reflect road design criteria.

Selecting either the ![icon] PVI Based or ![icon] Entity Based button on the Profile Layout Tools (page 2170) toolbar has three effects:

■ Updates the tools available on the Profile Layout Tools toolbar

■ Changes the data shown in the Profile Entities vista (page 2166)

■ Changes the data shown in the Profile Layout Parameters Dialog Box (page 2168)

For information on profile tools for creating and editing profiles, specifying curve settings, and displaying the profile editors, see Profile Layout Tools (page 2170).

**TIP** You can use transparent commands when you are prompted to specify direction, radius, or length, or use station offsets to specify any points. For more information, see Transparent Commands (page 1581).

# Selecting Profile Sub-entities

Select an entire profile or a range of sub-entities in order to precisely edit them.

Select an entire profile by clicking it. Select an individual profile sub-entity or range or sub-entities by Ctrl+clicking.

After you have selected a profile entity, you can use a variety of editing tools.

If the Profile Entities vista (page 2166) and Profile Layout Tools (page 2170) toolbar are open, selecting a sub-entity or range of sub-entities in a profile causes the selected sub-entities to display in the Profile Entities vista. Selecting sub-entities or ranges of sub-entities in a different profile causes that range of selected sub-entities to display in the Profile Entities vista and have focus of the Profile Layout Tools toolbar. The last object selected becomes the current object and has focus of the profile editing tools.

**To select an entire profile**

1 Click the profile.

Grips are displayed along the profile.

2 Use the desired tools to edit the profile:

| To Edit the profile by... | see this topic: |
| --- | --- |
| adding constraint-based fixed, free, or floating tangents and curves | Adding Tangents and Curves to a Layout Profile (page 1059) |
| changing the profile at the points of vertical intersection | Editing PVIs (page 1093) |
| deleting profile sub-entities | Deleting Profile Sub-entities (page 1097) |
| using grips or entering precise parameter values | Editing Profile Curve and Tangent Parameter Values (page 1098) |

**To select a single profile sub-entity**

1 In the drawing window, click the profile.

2 Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor ![icon] .

3 In the Profile Layout Tools toolbar (page 2170), click ![icon] Entity Based to enable the profile entity editing tools.

4 In the Profile Layout Tools toolbar, click ![icon] Profile Grid View.

The Profile Entities vista (page 2166) displays attributes for all profile sub-entities.

5 In the drawing window, Ctrl+click the desired profile sub-entity.

The selected sub-entity is highlighted in the drawing, and the Profile Entities vista displays attributes for only the selected profile sub-entity.

**6** Edit the profile sub-entity by entering specific attribute values in the Profile Entities vista.

See Editing Profile Curve and Tangent Parameter Values (page 1098) for more information.

**NOTE** The Profile Entities vista (page 2166) displays the attributes of only the selected sub-entity.

**To select a range of profile sub-entities**

**1** Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor ▧ .

**2** In the Profile Layout Tools toolbar (page 2170), click ⟋ Entity Based to enable the profile entity editing tools.

**3** In the Profile Layout Tools toolbar, click ▦ Profile Grid View.

The Profile Entities vista (page 2166) displays attributes for all profile sub-entities.

**4** In the drawing window, Ctrl+click the profile sub-entity at the beginning of the desired range.

The selected sub-entity is highlighted in the drawing, and the Profile Entities vista displays attributes for only the selected profile sub-entity.

**5** In the drawing window, Ctrl+click the profile sub-entity at the end of the desired range.

The selected range of sub-entities is highlighted in the drawing, and the Profile Entities vista displays attributes for only the selected profile sub-entities.

**6** Edit the profile sub-entities by entering specific attribute values in the Profile Entities vista.

See Editing Profile Curve and Tangent Parameter Values (page 1098) for more information.

**NOTE** The Profile Entities vista (page 2166) displays the attributes of only the selected sub-entities.

▦ Profile Grid View

Dialog Box

Profile Layout Tools (page 2170)

# Editing PVIs

Manage the elevations and grades along a layout profile or static surface profile by editing the points of vertical intersection (PVIs).

Adjusting the number and location of PVIs allows you to make major changes to a layout profile, such as removing vertical curves and changing tangent grades.

You can lock a PVI at a specific station and elevation so that it cannot be moved by edits to adjacent entities. This is often done in intersections, where a side road profile is locked to the crown and edge-of-pavement elevations of the main road. If you unlock a dynamic PVI for one road in an intersection, you break the link to the profile of the other road.

You can also move PVIs with editing grips. For more information about the use of editing grips, see Editing Profile Curve and Tangent Parameter Values (page 1098).

**To insert a PVI**

1   Click the profile. Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

2   In Profile Layout Tools (page 2170), click  Insert PVI.

3   Specify a point along the profile for the location of the new PVI. Specify the point either by clicking the point or by entering **'pse** and providing a numeric value.

4   Optionally, add other PVIs by repeating Step 4.

5   Right-click to finish.

**To insert multiple PVIs (bulk data entry)**

1   Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

2   In Profile Layout Tools (page 2170), click  Insert PVIs - Tabular.

3   To place a curve at each inserted PVI, click the desired curve type in the Insert PVIs dialog box (page 2164). Otherwise, click None. The choice made here applies to all PVIs inserted at this time.

4   Click the first Station cell to activate it. Enter station and elevation values for each PVI. Press Enter after each value to move the cursor to the next field. To change a value after entering it in the table, click the cell and modify the entry.

5   After all values are entered, check the table to ensure that each value is correct.

6   Click OK to insert the set of PVIs.

**To delete a PVI**

1   Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

2   In Profile Layout Tools dialog box (page 2170), click  Delete PVI.

3   In the profile view, click near the PVI you want to delete. The PVI is removed, and the tangents are adjusted to connect the adjacent PVIs or endpoints.

**To lock a PVI**

1   Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

2   In theProfile Layout Tools dialog box (page 2170), select the PVI based display option.

3   Click  Profile Grid View.

4   Find the PVI to lock, and optionally edit its location by changing numeric data in the table.

**5** Click the open lock icon in the table row for the PVI. The icon changes to a closed lock state, and some values in the table are dimmed to indicate they cannot be edited.

**To unlock a PVI**

**1** Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

**2** In the Profile Layout Tools dialog box (page 2170), select the PVI based display option.

**3** Click  Profile Grid View.

**4** Click the closed lock icon in the table row for the PVI. The icon changes to an open lock state, and additional values in the table can be edited.

**TIP** You can also unlock a PVI by clicking the lock icon in the profile view.

**To move a PVI**

**1** Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

**2** In Profile Layout Tools (page 2170), click  Move PVI.

**3** In the drawing window, click near the PVI that you want to move.

**4** Click the new location for the PVI. The PVI is immediately moved to the new location. The adjacent tangents are adjusted accordingly.

**5** To move additional PVIs, repeat steps 4 and 5.

**To raise or lower a series of PVIs**

**1** Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

**2** In Profile Layout Tools (page 2170), click  Raise/Lower PVIs.

**3** In the "Raise/Lower PVI Elevations dialog box", enter the elevation distance to raise or lower the PVIs. A positive number raises the PVIs and a negative number lowers them.

**4** Click the PVI Range you want to move: either All PVIs or those within a range of stations.

**5** If you clicked Station Range, specify the start and end stations.

**6** Click OK to move the PVIs.

# Converting AutoCAD Entities to Profile Sub-entities

Convert an AutoCAD line or spline to a profile sub-entity.

AutoCAD lines and curves can be created using the best fit entities or similar commands. See Lines and Curves (page 559) for more information.

The converted sub-entity becomes part of the solved profile geometry if either of the following two conditions are met:

■ Before it is converted, it must be attached to an unattached end point of another solved entity in the profile.

■ After it has been converted, it may be joined to the solved profile geometry using the profile layout tools.

**To convert an AutoCAD entity to a profile sub-entity**

1   Create a profile view or select an existing profile view.

2   Set the profile view style vertical exaggeration to 1. For more information, see Creating and Editing Profile View Styles (page 1030).

3   Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

4   On the Profile Layout Tools (page 2170) toolbar, click Convert AutoCAD Line And Spline.

5   Select the AutoCAD entity.

**NOTE** If the sub-entity you converted is hidden behind the source AutoCAD entity, use Shift+spacebar to select it. Hover the cursor over the white AutoCAD entity. Press and hold Shift, then press the spacebar to highlight the profile sub-entity. Click to select the profile sub-entity, then release the Shift key. Click the profile sub-entity again to select it and continue with the command.

# Deleting Profile Sub-entities

Use the Profile Layout Tools dialog box (page 2170) to remove tangents and curves from a layout profile.

When you delete a curve, the tangents on either side of the curve are preserved. If the tangents were joined when they were created, the tangents are joined at the PVI after the curve is deleted.

---

**NOTE** You cannot delete a tangent that has a curve attached to it. **Before deleting a tangent,** you must first delete the PVI and any dependent curves and tangents.

---

You can delete profile sub-entities either using the Profile Layout Tools dialog box (page 2170) or selecting the sub-entity and pressing Delete.

**To delete a sub-entity from the Profile Layout Tools dialog box**

1  Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor  .

2  In the Profile Layout Tools dialog box (page 2170), click  Delete Entity.
   If you do not see the button, click

    Entity Based to change to an entity-based view.

3  In the drawing window, select a sub-entity to delete.

**To delete a sub-entity using the Delete key**

1  Ctrl+click the profile sub-entity you want to delete.

2  Press Delete.

# Editing Profile Curve and Tangent Parameter Values

Use the Profile Entities vista and Profile Layout Parameters dialog box to display and edit parameters of profile entities that are part of the solved profile geometry.

The Profile Entities vista displays a form that is like a spread sheet, where each row represents either a profile entity or PVI and each column represents a parameter. Use the △ PVI Based and △ Entity Based buttons on the Profile Layout Tools toolbar to change the type of data that is displayed on the Profile Entities vista. In the Profile Entities vista, you can right-click a column heading to display options for customizing the display of detail in the column views.

The purpose of Profile Entities vista is to let you quickly scroll through the entities that make up the profile. The list displays only the entities that have been selected (page 1092) in the drawing window. When you select a row, the details for the corresponding entity are displayed in the Profile Layout Parameters dialog box.

The Profile Layout Parameters dialog box enables you to view and change the many attributes for a single profile sub-entity. The Profile Layout Parameters dialog box contains up to three panels. The Layout Parameters panel, which displays the geometric parameters of the selected sub-entity, is always present. In this panel, the Value column lists the actual value of each sub-entity Parameter. If the profile was created using the criteria-based design (page 2471) feature, the Constraint column lists the value to which a Parameter is constrained by the specified design criteria. Use the Value and Constraint columns together to view whether the sub-entity parameters meet the specified design criteria. If the profile was not created using the criteria-based design feature, the Constraint column is not available.

Two additional panels may be present on the Profile Layout Parameters dialog box if the profile has design criteria applied to it. If the profile has a design criteria file (page 2472) associated with it, the criteria from the file are displayed in the Design Criteria panel. If the profile has a design check set (page 2472) associated with it, the name and contents of the design check set are displayed in the Design Checks panel.

---

**NOTE** The attributes of a curve or other profile entity that you can edit depends on the method you used to create the entity. Generally speaking, you can edit the numeric value of a parameter if the parameter was used to define the entity. For all other parameters, numeric values are calculated and displayed but cannot be edited.

---

**See also:**

■ Vertical Curve Design (page 1068)

■ Editing Best Fit Profile Entities (page 1100)

**To edit profile layout parameters using the Profile Entities vista and Profile Layout Parameters dialog box**

1   Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor ⬇ .

2   In the Profile Layout Tools (page 2170), click 📝 Profile Layout Parameters and 🔲 Profile Grid View.

3   Specify the type of data to display in the Profile Entities vista:

   ■ To display PVI data, click △ PVI Based.

   ■ To display entity data, click △ Entity Based.

   The Profile Entities vista (page 2166) displays the attributes of the selected profile entities. The Profile Layout Parameters dialog box (page 2168) is empty.

4   In the Profile Entities vista, select the specific PVI, entity, or sub-entity you want to analyze. The parameters of the selected the entities are displayed in the Profile Layout Parameters dialog box. Editable values are in black text (not shaded).

**5** To display a range of entities in the Profile Entities vista, Ctrl+click the entity at the end of the desired range.

The selected range of entities is displayed on the Profile Entities vista. Highlighting a row displays the parameters of that entity in the Profile Layout Parameters dialog box.

**NOTE** Selecting another profile causes the Profile Layout Tools dialog box, Profile Entities vista, and Profile Layout Parameters dialog box to become active for the new profile. See Selecting Profile Sub-entities (page 1092) for more information about profile sub-entity selection.

**6** Review and edit the data as required. To edit another PVI, entity sub-entity, or range, repeat Steps 5 and 6.

**7** When finished, close the Profile Layout Parameters dialog box and Profile Layout Tools toolbar.

## Editing Layout Profiles Using Grips

Use grips to graphically change the vertical curves and tangents in a profile.

Use editing grips to relocate or modify curves and tangents using visual design cues. If you created profile entities using the constraint-based tools, some editing grips are not available. For example, if you attach a floating curve to a fixed or floating tangent, the editing grip is not available for editing the PVI of the two entities.

**NOTE** When a grip is selected, you can use either dynamic input or the Profile Entities (page 2166) and Profile Layout Parameters (page 2168) dialog boxes to enter precise attribute values for the grip.

**To grip edit layout profiles**

1  Click a profile object in a profile view. If the profile type is static, editing grips appear on the tangents and vertical curves. Grip behavior depends on the type of grip:

| Grip Type | Behavior |
|---|---|
| ▲ at point of vertical intersection (PVI) | Moves the PVI, changing grades and lengths of adjacent tangents.<br>Preserves curve length and radius.<br>Use with ORTHO mode turned on to move PVI horizontally or vertically. |
| ▶ at end of tangent | Adjusts the tangent length while preserving the grade.<br>Modifies the grade of adjacent tangent.<br>Preserves curve length and radius. |
| ■ at end of tangent | Adjusts the tangent length and grade simultaneously.<br>Modifies the grade of adjacent tangent. |
| ■ at tangent mid-point | Moves the entire tangent, without changing the length or grade.<br>Changes the location of adjacent PVIs and the grade of adjacent tangents.<br>Preserves the radius and length of adjacent curves. |
| ● at curve endpoint | Moves the endpoint along the tangent, without affecting the tangent grades or PVI location.<br>Changes position of both curve endpoints so that midpoint remains near PVI.<br>Changes the curve length and radius. |
| ● at curve midpoint | Moves a pass-through point for the curve, changing the curve length, radius, and position of both endpoints as required.<br>PVI location is not affected.<br>After the curve is edited, this grip moves to the new midpoint. |

2  Identify the grip you want to move, then click it once. The grip changes color from cyan to red.

3  Drag the grip to its new location, and click to place it there. The grip follows your mouse pointer, within the constraints imposed by the grip type.

**NOTE** When a grip is selected, you can use either dynamic input or the Profile Entities vista (page 2166) and Profile Layout Parameters dialog box (page 2168) to enter precise attribute values for the grip.

# Editing Best Fit Profile Entities

Use the Regression Data and Profile Entities vistas to edit parameters of profile entities that were created by best fit.

The Regression Data vista displays the source regression data from which the best fit entity was created. The regression data can be modified either before or after the entity has been created. The information in the Regression Data vista can be changed, and then applied to the entity. If the entity parameters are changed outside the Regression Data vista, the entity can be synchronized to the current regression data.

The Profile Entities vista displays a form that is like a spread sheet, where each row represents a profile entity and each column represents a parameter. When an entity is created by best fit, Best Fit is displayed in the Constraint2 column. Click [...] in this column to edit the source regression data.

Regression data is not dynamically linked to the best fit entity. If the entity is edited, ▽ appears in both the Regression Data and Profile Entities vistas.

**NOTE** You can edit only values that are available, you cannot edit unavailable (shaded) text.

**Editing Floating Best Fit Entities**

The manner in which a best fit floating entity reacts to edits to the attachment entity depends on whether the best fit entity is synchronized with the best fit sample data.

■ If the floating best fit entity is synchronized with the best fit sample data, it maintains tangency when the attachment entity is edited. The floating best fit entity geometry changes to adapt to changes to the attachment entity, and continue to honor the regression points.

■ If the floating best fit entity is not synchronized with the best fit sample data, it behaves as a normal floating entity. The floating best fit entity remains tangent to the attachment entity, and its geometry will not change to honor the regression points.

**To edit best fit regression data**

1 Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

2 On the Profile Layout Tools toolbar, click Edit Best Fit Data For All Entities.

**NOTE** You can also open the Regression Data vista from the Profile Entities vista. In the Constraint2 column, click [...] .

3 In the Regression Data vista, edit the regression data as needed.
You can add, edit, or remove regression points.

4 Click ✔ to apply the changes and close the Regression Data vista.

**To synchronize a best fit profile entity to the regression data**

1 Select the profile that contains the best fit entity.

2 Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor .

3 On the Profile Layout Tools toolbar, click Edit Best Fit Data For All Entities.

4 In the Regression Data vista, click ▽ Synchronize Entity To Best Fit Sample Data.

**NOTE** You can also synchronize the entity to the regression data from the Profile Entities vista. In the Constraint2 column, click ▽ .

## Applying Design Criteria to an Existing Layout Profile

Use the Profile Properties dialog box to apply design criteria to an existing profile.

The criteria-based design feature provides the ability to verify that your profile design meets the minimum standards required by your local agency.

For more information, see Criteria-Based Profile Design (page 1044).

**To apply design criteria to an existing profile**

1   Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Profile Properties drop-down ➤ Profile Properties  .

2   In the Profile Properties dialog box, click the Design Criteria tab (page 2175).

   **NOTE** To apply design criteria to a profile, there must be at least one design speed applied to the profile from which the profile was created.

3   Select the Use Criteria-Based Design check box.

4   Specify the following settings:
   ■   Use Design Criteria File
       Select this check box to associate a design criteria file with the profile. The design criteria file field and the Default Criteria properties become available when you select the check box.

       **NOTE** The design criteria file that is applied to the parent alignment is used by default. A separate design criteria file can be applied to the profile.

■ Use Design Check Set
Select this check box to associate a design check set with the profile. The design check set list becomes available when you select the check box. Select a design check set from the list.

**5** Click OK.

> **NOTE** The entire profile design is validated when you click either Apply or OK.

# Viewing and Correcting Profile Design Criteria Violations

Use the warning symbols to verify whether the profile design meets the specified criteria and design checks.

When a profile uses the criteria-based design feature, the profile geometry must meet the design criteria specified in the design criteria file (page 2472) and design checks (page 2472).

When a profile sub-entity violates the design criteria, a warning symbol is displayed in the following locations:

■ The drawing window — The ⚠ warning symbol is displayed on each sub-entity that violates the design criteria.

> **NOTE** The size of the warning symbol does not adjust automatically. After zooming in or out, enter REGEN to resize the warning symbols.

■ The Profile Entities vista — The ⚠ warning symbol is displayed in the No. column of the sub-entity that violates the design criteria. If a criteria in the design criteria file was violated, the warning symbol is also displayed next to the specific criteria and parameter value that violates the design criteria.

■ The Profile Layout Parameters dialog box — If a criteria in the design criteria file was violated, the ⚠ warning symbol is displayed in the Design Criteria panel next to the Property that was violated, and in the Layout Parameters panel next to the Parameter that was violated. If a design check was violated, the ⚠ warning symbol is displayed in the Design Checks panel next to the design check that was violated.

You can use the ⚠ warning symbols in the drawing window to view information about criteria and design checks that were violated. When the cursor is hovered over a warning symbol in the drawing window, a tooltip displays information about the violation. If a design criteria was violated, the tooltip displays the criteria that has been violated, as well as the minimum value required to meet the criteria. If a design check was violated, the tooltip displays the name of the design check that has been violated.

**BEST PRACTICE** The name of the design check should be similar to the formula you enter in the Design Check field. When a design check is violated, only the design check name is displayed, and not the minimum acceptable value. If the formula is in the design check name, it is easier to correct the violation.

**NOTE** If a sub-entity violates more than one criteria or design check, only one warning symbol is displayed in the drawing. To clear the warning symbol, the sub-entity must be modified to meet all the design criteria and design checks.

## Turning Off the Profile Warning Symbol

Change the visibility of the warning symbol that indicates violations in the profile design.

There are several ways to turn off the warning symbol. The following methods are listed in the order in which they are recommended.

### Modify the Profile Geometry

Edit the profile design to meet the specified design criteria. This option clears the warning symbols from the drawing window, Profile Entities vista, and Profile Layout Parameters dialog box.

**NOTE** If a sub-entity violates more than one criteria or design check, only one warning symbol is displayed in the drawing. To clear the warning symbol, the sub-entity must be modified to meet all the design criteria and design checks.

For more information, see Correcting Profile Design Criteria Violations (page 1105).

### Change the Profile Style

Turn off the Warning Symbol display component in the current profile style. Alternatively, create a separate profile style that has the Warning Symbol display component turned off. This option clears the warning symbols from the drawing window for profiles that use that style. The warning symbols are still displayed in the Profile Entities vista and Profile Layout Parameters dialog box.

For more information, see Profile Styles (page 1027).

### Turn Off the AutoCAD Civil Solution Tip
