The warning symbol is controlled by the Solution Tip setting in the Options dialog box on the AEC Editor tab. To hide the warning symbol for all drawings, clear the Drafting check box. This option clears all alignment and profile warning symbols from the drawing window. However, the warning symbols are still displayed in the Profile Entities vista and Profile Layout Parameters dialog box.

For more information, see AEC Editor Tab (Options Dialog Box) (page 2453).

**WARNING** Settings in the Options dialog box affect the overall behavior of AutoCAD Civil. If you clear the Solution Tip Drafting check box, the warning symbol for all alignment and profile objects is hidden in every drawing that is opened on the current installation of AutoCAD Civil.

**Turn Off the Criteria-Based Design Feature**

Disassociate the design criteria from the profile. The profile design check set and/or the design criteria file can be turned off in the Profile Properties dialog box. This option clears the warning symbols from the drawing window, Profile Entities vista, and Profile Layout Parameters dialog box.

For more information, see Applying Design Criteria to an Existing Layout Profile (page 1102).

**WARNING** If you turn off the criteria-based design feature, the profile design will not be validated against any design standards.

# Correcting Profile Design Criteria Violations

Validate the profile geometry against the specified criteria and design checks.

When a profile uses the criteria-based design feature, the profile geometry must meet the design criteria specified in the design criteria file (page 2472) and design checks (page 2472).

When a profile sub-entity violates the design criteria, a warning symbol is displayed in several locations. For information about where the warning symbols appear, see Viewing and Correcting Profile Design Criteria Violations (page 1103).

You can use the ⚠ warning symbols in the drawing window to view information about criteria and design checks that have been violated. When the cursor is hovered over a warning symbol in the drawing window, a tooltip displays information about the violation.

■ If a design criteria was violated, the tooltip displays the criteria that was violated, as well as the minimum value required to meet the criteria.

■ If a design check was violated, the tooltip displays the name and formula of the design check that was violated.

**NOTE** If a sub-entity violates more than one criteria or design check, only one warning symbol is displayed in the drawing. To clear the warning symbol, the sub-entity must be modified to meet all the design criteria and design checks.

**To correct profile design criteria violations using grips**

1 In the drawing window, hover the cursor over a ⚠ warning symbol.

   A tooltip displays information about the violation.

2 Select the profile.

3 Use the profile grips to modify the profile geometry.

   The ⚠ warning symbol disappears when the sub-entity meets the design criteria.

   **NOTE** If a sub-entity violates more than one criteria or design check, only one warning symbol is displayed on the sub-entity. To clear the warning symbol, the sub-entity must be modified to meet all the design criteria.

**To correct profile design criteria violations by entering numeric values**

1 Click the profile. Click Profile tab ➤ Modify Profile panel ➤ Geometry Editor 📝 .

**2** On the Profile Layout Tools toolbar, click ⊞ Profile Grid View.

**3** In the Profile Entities vista, click the row that contains the ⚠ warning symbol in the No. column.

The sub-entity parameters are displayed in the Profile Layout Parameters dialog box.

**4** In the Profile Layout Parameters dialog box, locate the ⚠ warning symbol in either of the following panels:

■ **Layout Parameters panel** — In the Value column, enter a numeric value that meets the value specified in the Constraints column.

■ **Design Checks panel** — Notice the design check that has been violated. Modify the profile design to meet the parameters specified in the design check.

### Quick Reference

⊞ Profile Grid View

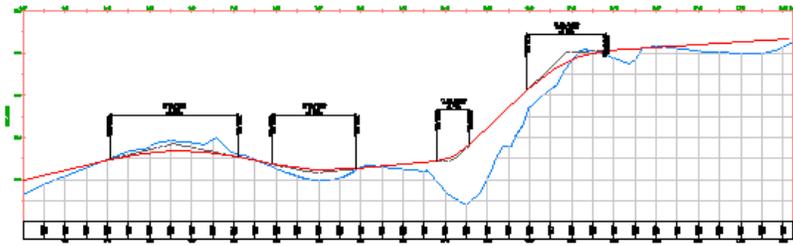
Dialog Boxes

# Working with Profile Views

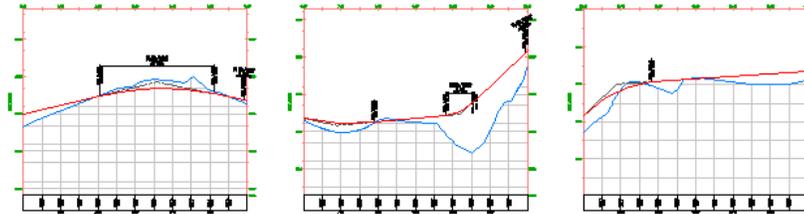
Use the profile view grid to display one or more profiles for a horizontal alignment.

You can configure data bands and profile annotations in a profile view to make it clearer or more informative for the user.

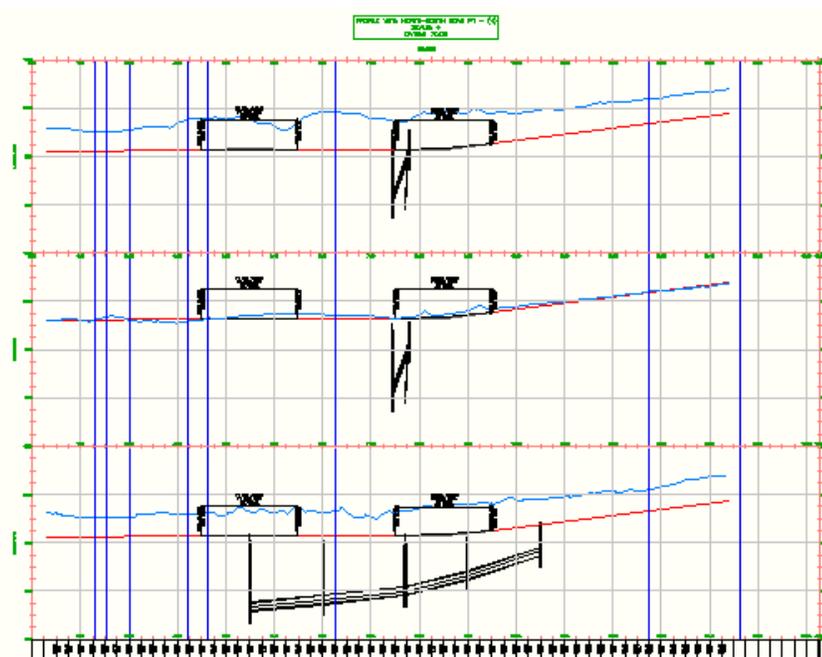
A profile can be presented in either single, multiple, or stacked profile views:

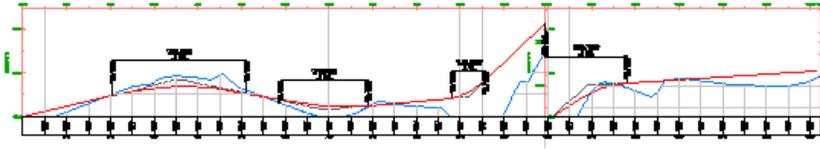
■ A single profile view is typically used to design and edit a profile. It displays the specified station range of the corresponding alignment in a single profile view grid.


■ Multiple profile views are useful for plotting shorter segments of a profile in individual profile view grids of a consistent length and vertical scale.



■ Stacked profile views are a collection of related profiles drawn in separate, vertically arranged profile views. Typically a centerline profile is contained in one profile view, and its left and right offsets are drawn in profile views that are placed above and below the centerline profile view.



A profile can be split within either a single or multiple profile view. This allows a profile view to display a profile elevation range that is greater than the specified height of the profile view.


See The Profile View Object (page 1021) for more information.

# Creating Profile Views

Create a profile view to display a surface profile and offsets.

A profile view also provides the grid on which to draw a layout profile.

You can create profiles without displaying them on a profile view. When you create a profile view, you can display any of the profiles created from a selected alignment.

The default name format for profile views is PV - (1), PV - (2), etc. You can edit the name format to suit your business requirements.

An easy-to-use wizard guides you through the process of creating single, multiple, or stacked profile views.

Use multiple profile views to create final construction documents from a design. For best results, design your profile in a single profile view, and then create multiple profile views for plotting.

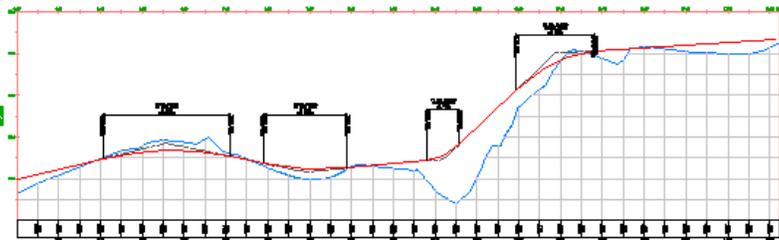
**See also:**

■ Plan Production Tools (page 1691)

## Creating a Single Profile View

Create a single profile view to display a surface profile and to design a layout profile.

Each profile view displays new or existing profiles and offsets for one horizontal alignment.



**See also:**

■ Creating Multiple Profile Views (page 1109)

■ Creating Stacked Profile Views (page 1111)

■ Creating a Superimposed Profile (page 1054)

**To create a single profile view**

1 Click Home tab ➤ Profile & Section Views panel ➤ Profile View drop-down ➤ Create Profile View .

**2** In the Create Profile View wizard (page 2145), navigate through the pages by using the links at the left or clicking Back or Next.

**NOTE** Click Create Profile View at any time to accept the current settings.

The wizard pages contain the following controls:

■ General page (page 2146) - Specify the alignment name and profile view name and description.

**NOTE** The Show Offset Profiles By Vertically Stacking Profile Views is only applicable when creating stacked profile views.

■ Station Range page (page 2146) - Specify the starting and ending stations.

■ Profile View Height page (page 2146) - Specify the profile view height and any split profile options, including split stations and styles for individual stations.

■ Profile Display Options page (page 2148) Specify the profiles to be drawn as well as their styles, labels, and layers.

■ Pipe Network Display page (page 2149) - Specify the pipe networks or parts to be drawn.

■ Data Bands page (page 2150) - Specify the data band sets and their properties.

■ Hatch Options page (page 2151) - Specify how to mark areas between two profiles on the profile view, such as where terrain must be cut or filled to create the design profile.

**3** Click Create Profile View.

**4** In the drawing window, click a location for the lower left corner (origin) of the profile view grid. The profile view is drawn.

## Quick Reference

Ribbon

Home tab ➤ Profile & Section Views panel ➤ Profile View drop-down ➤ Create Profile View 

Menu

Profiles menu ➤ Create Profile View

Command Line

CreateProfileView

Wizard

Create Profile View (page 2145)

## Creating Multiple Profile Views

Create multiple profile views to plot shorter segments of a profile in individual profile view grids of a consistent length and vertical scale.

Each profile view in the series is an independent profile view object. Each profile view object appears in Prospector, and you can modify the properties of each object independently.

**NOTE** Multiple profile views are most useful when you are creating final construction documents from your design. For best results, design your profile in a single profile view, then use the Plan Production Tools (page 1691) to create multiple profile views for plotting.

**To create multiple profile views**

1 Click Home tab ➤ Profile & Section Views panel ➤ Profile View drop-down ➤ Create Multiple Profile Views 🖼️ .

2 In the Create Multiple Profile Views wizard (page 2145), navigate through the pages by using the links at the left or clicking Back or Next.

**NOTE** Click Create Profile Views at any time to accept the current settings.

The wizard pages contain the following controls:

■ General page (page 2146) - Specify the alignment name and profile view name and description.

**NOTE** The option Show Offset Profiles By Vertically Stacking Profile Views is applicable only when creating stacked profile views.

■ Station Range page (page 2146) - Specify the starting and ending stations.

■ Profile View Height page (page 2146) - Specify the profile view height and any split profile options, including split stations and styles for individual stations.

■ Profile Display Options page (page 2148) Specify the profiles to be drawn as well as their styles, labels, and layers.

■ Pipe Network Display page (page 2149) - Specify the pipe networks or parts to be drawn.

■ Data Bands page (page 2150) - Specify the data band sets and their properties.

■ Hatch Options page (page 2151) - Specify how to mark areas between two profiles on the profile view, such as where terrain must be cut or filled to create the design profile.

■ Multiple Plot Options page (page 2152) - Specify how the multiple profile views will be laid out.

3 Click Create Profile Views.

4 In the drawing window, click a location for the origin of the profile view grid. The profile view is drawn.

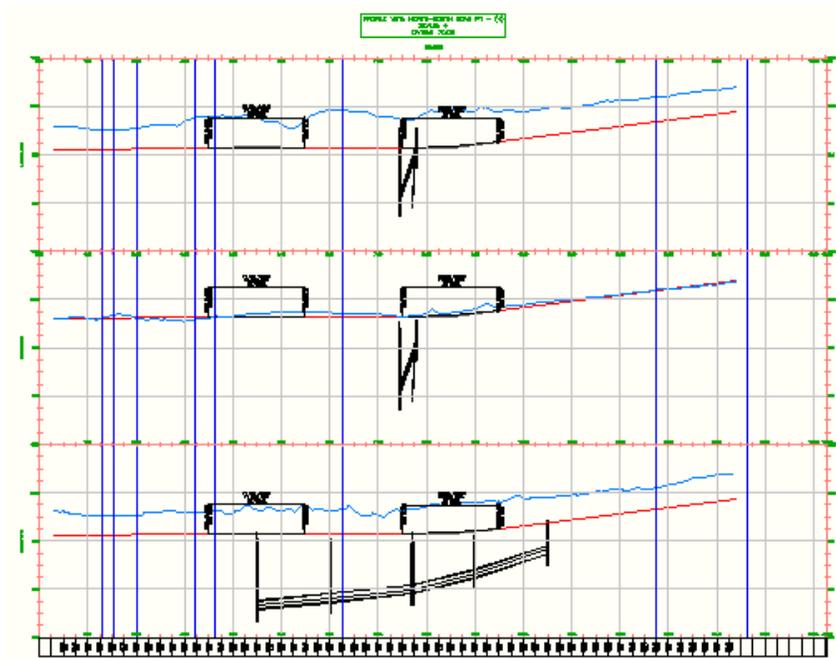
**NOTE** The profile view grid origin is determined by the Start Corner setting on the Multiple Plot Options page.

## Quick Reference

# Creating Stacked Profile Views

Create stacked profile views to display a centerline profile and related offset profiles in vertically arranged profile views.

Each profile view in the series or stack is an independent profile view object. Each profile view object appears in Prospector, and you can modify the properties of each object independently.



**To create stacked profile views**

1   Click Home tab ➤ Profile & Section Views panel ➤ Profile View drop-down ➤ Create Profile View ![icon]
    .

    OR

    Click Home tab ➤ Profile & Section Views panel ➤ Profile View drop-down ➤ Create Multiple Profile
    Views ![icon] .

**2** In the Create Profile View Wizard (page 2145) wizard, on the General page (page 2146), select the Show Offset Profiles By Vertically Stacking Profile Views check box.

The link to the Stacked Profile page (page 2147) is displayed on the left.

**3** On the General page, specify the alignment name and profile view name and description.

> **NOTE** Click Create Profile Views at any time to accept the current settings.

**4** On the Station Range page (page 2146), specify the starting and ending stations.

**5** On the Profile View Height page (page 2146), specify the profile view height and any split profile options, including split stations and styles for individual stations.

> **NOTE** If the profile elevation values are relatively consistent, under the Profile View Datum By option, select Mean Elevation. The Mean Elevation option vertically centers the profile line in the profile view, creating equal space above and below the profile line.

**6** On the Stacked Profile page, specify the number of stacked profile views, gap between the views, and the profile view style to use in the top, middle, and bottom views.

> **NOTE** The top and bottom profile views can use separate styles. All profile views between the top and bottom must be created with the same style.

**7** On the Profile Display Options page (page 2148), select a profile view from the Select Stacked View To Specify Options For list.

**8** In the Specify Profile Display Options table, specify the profiles to be drawn as well as their styles, labels, and layers.

**9** Repeat steps 7 and 8 for each profile view in the stack.

**10** On the Pipe Network Display page (page 2149), specify which pipe networks or parts will be drawn in each stacked profile view. Follow the workflow described in steps 7 through 9 to specify the options for each stacked profile view.

**11** On the Data Bands page (page 2150), specify the data band sets and their properties.

The data bands will appear at the top or bottom of the stack.

**12** For multiple, stacked profile views, on the Multiple Plot Options page (page 2152), specify how the multiple profile views will be laid out.

**13** Click Create Profile Views.

**14** In the drawing window, click a location for the origin of the stack of profile views.

> **NOTE** The profile view grid origin is determined by the Start Corner setting on the Multiple Plot Options page.

CreateMultipleProfileView

Wizard

Create Profile View (page 2145)

# Editing Profile Views

Edit profile views to change their contents, properties, and styles.

Use two dialog boxes to edit profile views:

■ Use the Profile View Properties dialog box (page 2178) to specify the name, profile view style, profile extents, included profile lines, data bands, and hatch options.

■ Use the Profile View Style dialog box (page 2185) to specify the annotation, vertical exaggeration, profile direction, grid format, and displayed elements.

You can change properties for an individual profile view. However, any changes in the Profile View Style dialog box affect all profile views that use that style. Therefore, if you must change one or more style items, create a style that can be applied where required.

Typical editing activities:

■ Add or delete profile lines.

■ Change the display style.

■ Add or delete data bands that display data such as stations, elevations, and horizontal geometry.

In the Profile View Properties dialog box, use the Draw check box to turn existing profiles on or off in the profile view. To delete a profile from the drawing, select it in the profile view and press the Delete key.

If you want to superimpose a profile from another alignment on a profile view, see Creating a Superimposed Profile (page 1054).

## Adding Profile Lines to a Profile View

Add profile lines to an existing profile view grid.

This procedure assumes that the profile lines you want to add have already been created in the drawing. To create a profile, see Creating Surface Profiles (page 1047) or Creating Layout Profiles (page 1048).

**To add profile lines to a profile view**

1 Click the profile view grid.

2 Click Profile tab ➤ Modify View panel ➤ Profile View Properties drop-down ➤ Profile View Properties ⬚ .

3 In the Profile View Properties Dialog Box (page 2178), click the Profiles tab (page 2179).

4 In the tables of profiles, select the Draw check box for each profile you want to add to the profile view.

5 Click OK.

**Quick Reference**

Dialog Box

Profile View Properties (page 2178)

# Changing a Profile View Style

Change the appearance of a profile view by changing its style.

The profile view style controls the format of the graph on which the profiles are displayed, as well as the title and annotations on the axes.

Profile view styles are useful when your project transitions to a new phase. In the design phase, you can use one profile style that has few grid elements and limited annotation. Limiting annotation and grid elements reduces drawing size and improves drawing performance. A second style can be used for plotting. The plotted profile view style can be extensively annotated and use more graph elements than the design style.

If you are working with a split profile view, the Object Style field on the Profile View Properties - Information tab (page 2178) is ignored. Use the Profile View Style fields on the Elevations tab (page 2179) to change split profile view styles.

**See also:**

■ Profile View Styles (page 1029)

**To change a profile view style**

1  In the drawing window, select the profile view.

2  Click Profile tab ➤ Modify View panel ➤ Profile View Properties drop-down ➤ Profile View Properties ⬚.

3  In the Profile View Properties dialog box, on the Information tab (page 2178), select a style from the Object Style list.

4  Click OK.

**To change a split profile view style**

1  In the drawing window, select the profile view.

2  Click Profile tab ➤ Modify View panel ➤ Profile View Properties drop-down ➤ Profile View Properties ⬚.

3  In the Profile View Properties Dialog Box (page 2178), click the Elevations tab (page 2179).

**4** In the Split Profile View area, select a different style for the desired segment by name from the Profile View Style list.

> **NOTE** The start, intermediate, and end segments can each use a different style.

## Adding Data Bands to a Profile View

Add data bands that display data such as stations, elevations, and horizontal geometry.

Place data bands along the top or bottom of a profile view grid to annotate the various profile lines with station and elevation data, vertical or horizontal geometry points, or superelevation, sectional, or pipe network data. You can also group a set of commonly used data bands into a band set that can be applied to a profile view as a single selection.

> **NOTE** The individual geometry points to label can be specified with the Profile Data band type.

**See also:**

■ Profile View Band Styles (page 1038)

■ Profile View Band Sets (page 1040)

■ Staggering Data Band Labels (page 1528)

**To add data bands to a profile view**

**1** Click the profile view grid.

**2** Click Profile tab ➤ Modify View panel ➤ Profile View Properties drop-down ➤ Profile View Properties .

**3** In the Profile View Properties Dialog Box (page 2178), click the Bands tab (page 2181).

**4** In the List Of Bands area, select either the bottom or the top of the profile view as the location for the new data band.

**5** Select a band type and style. Click Add.

If you add the Profile Data band type, use the Geometry Points to Label in Band dialog box (page 2162) to specify the individual alignment and profile points to label with the selected style.

**6** If you want to add more bands to the profile view, repeat steps 3 and 4. The List Of Bands is arranged in the same order as the actual bands on the profile view.

**7** Use the three buttons on the right side of the List Of Bands to arrange the bands as desired. You can move selected data bands up ⇧ or down ⇩ in the stack, and delete unwanted bands ✖ .

**8** Optionally, click Save As Band Set to save this arrangement of data bands as a set for reuse with other profile views. For more information, see Profile View Band Sets (page 1040).

**9** Click OK. The bands are displayed in the profile view.

## Adding Hatch Areas to a Profile View

Add hatch areas to highlight cut and fill regions along the profiles.

You can choose to hatch cut areas, fill areas, and areas with multiple surfaces as boundaries. You can also import quantity takeoff (QTO) criteria as a basis for defining hatch areas.

For each hatch area type, specify which profiles to use for upper and lower boundaries, and which shape style to use for the hatching. These styles are found on the Toolspace Settings tab ➤ General ➤ Multipurpose Styles ➤ Shape Styles.

**See also:**

■ Hatch Tab (Profile View Properties Dialog Box) (page 2182)

**To add hatch areas to a profile view**

**1** Click the profile view grid.

**2** Click Profile tab ➤ Modify View panel ➤ Profile View Properties drop-down ➤ Profile View Properties 🔲 .

**3** In the Profile View Properties Dialog Box (page 2178), click the Hatch tab (page 2182).

**4** Use the buttons on the left side to add hatch areas for Cut Area, Fill Area, Multiple Boundaries, or From Criteria.

**5** For each hatch area, review the profiles specified for upper and lower boundaries. If necessary, select different profiles from the list beside each boundary.

**6** Optionally, review the shape styles assigned to the hatch area types, and make any desired changes.

**7** Click OK. The hatch areas are displayed in the profile view.

# Using AutoCAD Object Snaps with Profiles and Profile Views

The following Object Snap modes are supported with profiles and profile views:

| Osnap | Dynamic Profile | Static Profiles | Profile Views |
|---|---|---|---|
| Endpoint | Yes | Yes | Yes (grid lines and axes) |
| Midpoint | Yes | Yes | Yes (grid lines and axes) |
| Center | No | No | No |
| Node | No | No | Yes (tick marks) |
| Quadrant | No | No | No |
| Intersec-tion | Yes | No | Yes (grid lines and axes) |

| Osnap | Dynamic Profile | Static Profiles | Profile Views |
|---|---|---|---|
| Extension | No | No | No |
| Insertion | No | No | No |
| Perpendicular | No | No | No |
| Tangent | No | No | No |
| Nearest | Yes | Yes | Yes (grid lines and axes) |
| Apparent Intersection | No | No | No |
| Parallel | No | No | No |

# Working with Projected Objects

Visualize the location of an object in relation to a surface profile or section.

Projected objects (page 2480) can display their station location and elevation.

**TIP** Before projecting an object into a view, ensure that the elevation of the object has been specified. If the object has a default elevation of 0, the profile view or section view will be vertically expanded to include the 0 elevation.

The following object types can be projected:

- **AutoCAD Civil objects:** Points, feature lines, and survey figures

- **AutoCAD objects:** points, blocks, MView blocks, 3D solids, and 3D polylines

Pipe networks have a separate procedure for projection into profile views. See Displaying Pipe Networks in Profile Views (page 1220) and Displaying Pipe Networks in Section Views (page 1221).

**Editing Projected Objects**

The station location of a projected object always reflects the location of the source object, so it can only be changed by moving the source object.

The style and elevation of projected objects can be edited on the Projections tab of the Profile View Properties (page 2178) or the Section View Properties (page 2281) dialog boxes.

The elevation of a projected object can be set to Use Object. This is a dynamic setting that ensures the elevation of the projected object and the source object are the same. If the source object is edited, the projected object reflects any changes. Elevations can also be set to match a specific surface or profile.

The elevation of some projected objects can be edited using grips. The exceptions are three object types in profile views:

- Survey figures

- Feature lines embedded in a corridor

- Feature lines dynamic to an alignment

Grip editing the vertices of feature lines or 3D polylines in a profile view also changes the elevations of the source objects in plan view. This behavior is useful for editing feature lines in relation to profiles. Grips appear on 3D polylines only if the elevation is set to **Use Object**.

Grip editing point or block objects in profile or section views does not affect the elevations of source objects, but it does break the dynamic link to the source object elevation. The Elevation Options setting changes to Manual. At any time you can change this setting to Use Object, or to match a specific surface or profile.

The object and label styles of a projected object are independent of the styles used by the source object in plan view. You can edit the styles of a projected object without affecting the source object.

**See also:**

- Adding Projected Objects to a Section View (page 1157)
- Editing Section View Properties (page 1156)
- Setting Profile View Properties (page 1042)

# Adding Projected Objects to a Profile View

Project AutoCAD or AutoCAD Civil objects from plan view into a profile view.

You can project AutoCAD points, blocks, 3D solids, and 3D polylines; you can also project AutoCAD Civil COGO points, feature lines, and survey figures.

**To project objects to a profile view**

1 Click Home tab ➤ Profile & Section Views panel ➤ Profile View drop-down ➤ Project Objects To Profile View 📊 .

2 Click one or more objects in the drawing that you want to project. Right-click or press Enter after all objects are selected.

3 Click the profile view in which you want the objects to appear.

4 In the Project Objects to Profile View dialog box (page 2192), verify the settings such as Elevation Options and Label Style, then click OK.

# Editing the Style of a Projected Object

Change the appearance of a projection, without affecting the source object.

Projected AutoCAD Civil objects use standard style editing dialog boxes for points, feature lines, and survey figures. Projected AutoCAD objects use multipurpose styles that control the appearance of different object types in profile views and section views.

**To edit a projection style**

1   In the drawing window, in a profile view or section view, select the object for which to change the style. Right-click. Click the menu option for the object type: Edit Point Style, Edit Feature Line Style, Edit Survey Figure Style, or Edit Projection Style.

    OR

    In Toolspace, on the Settings tab, expand General ➤ Multipurpose Styles ➤ Projection Styles. Right-click the style you want to change. Click Edit.

2   In the Projection Styles dialog box, make changes as required.

## Quick Reference

Ribbon

# Profile Command Reference

Use commands for quick access to profile functionality.

The following table lists the profile-related AutoCAD Civil commands and briefly describes their functionality.

| Command | Description |
| --- | --- |
| AddProfilePVI | Adds a point of vertical intersection (PVI) (page 1093)to an existing profile. |
| CreateProfileFromCorridor | Creates a profile from a corridor feature line (page 1372). |
| CreateProfileFromFile | Creates a profile from a specified text file (page 1050). |
| CreateProfileFromSurface | Opens the Create Profile from Surface dialog box (page 2144), which is the starting point for creating a surface profile from a horizontal alignment. |
| CreateProfileLayout | Creates a layout profile (page 1047) on an existing profile view. |
| CreateProfileReference | Creates a profile reference (page 1055). |
| CreateQuickProfile | Creates a quick profile (page 1058). |
| DeleteProfilePVI | Deletes a specified PVI (page 1093) from a profile line. |
| DesignCriteriaEditor | Opens the Design Criteria Editor dialog box (page 867). |
| EditProfileLabels | For the specified profile, opens the Profile Labels dialog box (page 2167). |
| EditProfileLayout | For the specified profile, opens the Profile Layout Tools dialog box (page 2170). |
| EditProfileProperties | For the specified profile, opens the Profile Properties dialog box (page 2174). |
| SuperimposeProfile | Creates a superimposed profile (page 1054). |

# Profile View Command Reference

Use commands for quick access to profile view functionality.

The following table lists the AutoCAD Civil commands for profile views and briefly describes their functionality.

| Command | Description |
| --- | --- |
| AddProfileViewDepthLbl | Adds a depth label  (page 1037)that shows the spatial relationship between two specified points on a profile view. |
| AddProfileViewLabels | Opens the Add Labels dialog box. (page 1037) |
| AddProfileViewStaElevLbl | Adds a station elevation label (page 1037) to a profile view that shows the station and elevation data for a specified point, which can be anywhere on the profile view grid. |
| CreateMultipleProfileView | Opens the Create Multiple Profile Views Wizard (page 2145). |
| CreateProfileView | Opens the Create Profile View wizard (page 2145). |
| CreateProfileViewStyle | Opens the Profile View Style dialog box (page 2185). |
| EditProfileViewStyle | Opens the Profile View Style dialog box (page 2185) |
| ProjectObjectsToProf | Adds projected objects to a profile view, opening the Project Objects to Profile View Dialog Box (page 2192) dialog box. |
| RemoveFromProfileView | Removes a projected object from a profile view. |

# Sections

# 25

Use sections (also referred to as cross sections) to provide a view of the terrain cut at an angle across a linear feature, such as a proposed road.

Typically, sections are cut across horizontal (plan) alignments at a specified station interval using specified swath widths. These sections are then plotted, individually for a station, or as a group for a range of stations.

AutoCAD Civil handles the creation, management, and plotting of sections with the following components:

■ **Sections**. Terrain elevations that cut across surfaces, including corridor surfaces, which are associated with a specified sample line group. Elevations are sampled at each of the sample line XY vertices and also at locations where the vertical plane defined by the sample line intersects with surface edges.

■ **Section Views**. For each sample line, views displaying some or all of the sections sampled at that sample line. This graphical view has both horizontal limits based on the length of corresponding sample line and vertical values based on the minimum and maximum elevations from the set of sections it is displaying.

**NOTE** Before creating sections, a surface and one or more horizontal alignments must exist.

For more information, see Creating and Editing Sample Lines and Sections (page 1142).

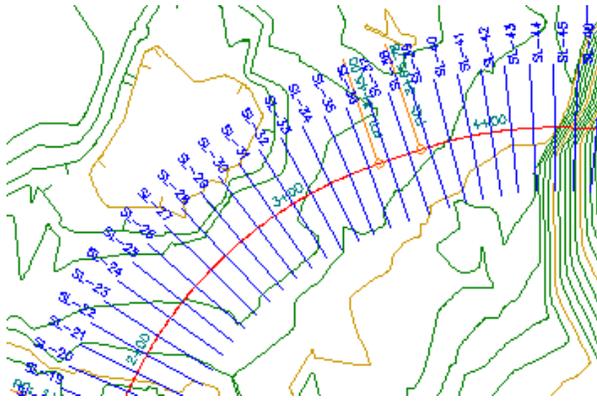
## Understanding Sections

You can use sections to examine existing and proposed surface elevations sampled across an alignment at defined station intervals.

In AutoCAD Civil, section data is defined and displayed using sample lines, sections, and section views, all of which are managed through a collection called a sample line group. An alignment can have more than one sample line group associated with it, each having a unique set of sample lines and sections.

For overview information about AutoCAD Civil objects, see Understanding Objects and Styles (page 51).

## Sample Line Object

Use a sample line as a linear plan object representing the direction along which sections are cut for a set of specified surfaces.


Sample lines are linear objects that are used to cut sections across an alignment. Sample lines have their own styles and can be labeled (for example, SL-29). A set of sample lines makes up a named collection called a sample line group. A sample line group centrally manages the display styles and label styles for a number of sample lines, sections, section views, and mass haul lines and mass haul views.

Sample line groups related to an alignment are displayed in the Toolspace Prospector tree under that alignment.

# Section Object

Use a section object to examine surface elevations along a sample line (across an alignment). In AutoCAD Civil, each section is an object.

Sections cut across a linear feature, to a specified distance to the left and right. Typically, sections are cut at given stations along a horizontal alignment.

A section is an object containing elevation data along a sample line. Each surface that intersects the vertical plane defined by the sample line results in a section object. The type of section object is defined by the elevation source, such as the TIN surface. Sections can also be extracted from corridor surfaces, corridors, and pipe networks along a sample line.

When you create sample lines along an alignment, the section objects are also created for a specified set of existing or proposed surfaces. The default set of surfaces to sample at each sample line are specified through a sample line group. To plot the sections in the drawing, create individual section views or multiple section views.

A section object is defined by the following components:

■ Vertices or grade break points, where a grade line ends and another line might begin

■ Line segments, which detail the grade of the surface between two grade break points

For example, if a section is sampled from a TIN surface, then the grade breaks are extracted at the point where the (vertical plane defined by) sample lines intersect with the TIN edges. Elevation between these two line segments is linearly interpolated and joined with a straight line (assuming that the sample line between these two points is also a straight line).

### Corridor Section Object

The corridor section object is a special type of section object that displays assemblies as applied in a corridor at a specified (corridor) station. While surface-created sections are usually line items with a series of lines joining various grade breaks, corridor-created sections can display closed shapes and multiple layers.

This sectional design is accomplished using subassembly and assembly objects. Subassemblies are design elements that define sectional geometry of a specified part or element used in typical sections. Assemblies

are collections of subassemblies that form shapes of typical sections. These assemblies can be displayed at each station in a section view. Each station is created along the alignment at either a baseline or a controlling offset of that corridor.

For more information, see Assemblies and Subassemblies (page 1377) and Corridors (page 1327).

**Pipe Network Section Object**

The pipe network section object is a special type of section object. It shows pipe networks at a specified station. While surface-created sections are usually line items with a series of lines joining various grade breaks, pipe-created sections can display closed (pipe) shapes.

For more information, see Pipe Networks (page 1185).

# Section View Object

Create section view objects to display sectional data in the drawing.

The section view object displays sectional data (both existing and finished ground/designed) along a sample line, at any given station along a horizontal alignment. A section view shows a section created from either a surface (TIN or corridor), a corridor (which is an assembly at a specified station), or a pipe network. Bands can also be displayed above or below the section view.

A section view, which is very similar to a profile view, is essentially a grid or graph with specific characteristics that are controlled by a section view style. Section views that relate to a sample line are stored in the Prospector tree in Toolspace under that sample line. Individual section views are accessible in Toolspace using the item view. If you delete a sample line in the drawing, section views under that sample line are also deleted.

A section view can include projections of other objects in the drawing that you want to see in relation to a section. See Adding Projected Objects to a Section View (page 1157) for more information.

# Section Object Relationships

Since sample line geometry controls where surfaces are sampled to create section objects, sample lines are the parent of the section object.

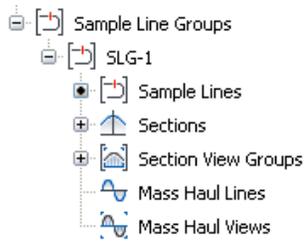
You create one or more section views along a sample line to graphically represent section objects at that location across an alignment. Thus, each section and section view are children of a sample line. Each sample line is associated with a sample line group, which is in turn associated with an alignment.

Profiles are longitudinal sections cut along a linear feature and are also children of the parent alignment. For more information, see Profiles (page 1019).

# Sample Line Groups Collection (Prospector Tab)

Use the Sample Line Groups ⊡ collection to access the sample lines, sections, section views, mass haul lines, and mass haul views in a drawing.

As sample line groups are created, they are displayed as named sample line groups, such as SLG-1, in the Sample Line Groups collection.

Sample lines, in turn, are displayed as named sample lines, such as SL-1, in the named sample line groups, which are located in the Sample Line Groups collection:


If one or more sample line groups have been added to the current drawing, expand the Sample Line Groups collection to view the names of the sample line groups. A tabular list of the sample line groups is displayed in the item view at the bottom of the Prospector tab.

Select Sample Lines of an individual sample line group to display the sample line group's named sample lines in the item view at the bottom of the Prospector tab. Similarly, expand the subordinate sections, section views, mass haul lines and mass haul views collections to display in the item view the individual sections, section views, mass haul lines and mass haul views. For more information, see The Toolspace Item View (page 82).

Right-click a named sample line group to:

■ Access the sample line group's properties (page 2257).

■ Zoom or pan to the extents of the sample line group.

■ Refresh the view of the Sample Line Groups collection.

## Sections Collection (Prospector Tab)

Use the Sections ⬆ collection to access the sections in a drawing.

As section objects are created, they are displayed as named sections, such as SLG-1-SL-1-EG(1), in the Sections collection for each named sample line.

If one or more sections has been added to the current drawing, expand the Sections collection to view the names of the sections. A tabular list of the various types of sections is displayed in the Prospector list view. These may include:

■ Surface sections 

■ Corridor sections 

■ Corridor surface sections 

■ Pipe network sections 

■ Material list sections 

When each type of section is selected, a tabular list of individual sections of that type is displayed in the item view at the bottom of the Prospector tab. For more information, see The Toolspace Item View (page 82).

## Section View Groups Collection (Prospector Tab)

Use the Section View Groups ⬆ collection to access the section views in a drawing.

As individual section view objects are created, they are displayed as named section views, such as 0+00.00(1), in the item view under Individual Section Views in the Section View Groups collection for each named sample line.

As multiple section view objects are created, they are displayed as named section views, in the item view under their parent section view group in the Section View Groups collection.

For more information, see The Toolspace Item View (page 82).

## Sample Line Collection (Settings Tab)

Use this collection in the Toolspace Settings tree to manage sample line settings, sample line styles, sample line label styles, and sample line command settings.

Right-click the Sample Line collection to:

■ Edit the sample line feature settings

■ Edit the sample line label style defaults

■ Refresh the display of the sample line settings collection

For more information about the contents of this shortcut menu, see "The Object Collection (Settings Tree)".

Expand the Sample Line collection to display and edit the styles and command settings that are available for sample lines.

| For information about... | See... |

# Sample Line, Section, and Section View Settings

You can change the default style and name format settings for sample lines, sections, and section views.

Settings are handled in a standard way throughout AutoCAD Civil via the Settings tree at three levels: drawing, feature, and command. For more information, see Understanding Settings (page 61).

## Sample Line Settings

To establish default settings for all sample lines, in the Settings tree, right-click the Sample Line collection.

To change settings for the CreateSampleLine command, expand the Commands collection in the Sample Line collection and right-click the CreateSampleLine command.

The default styles and name format settings for sample line commands are described in this topic. Drawing ambient settings are described in Specifying Drawing Settings (page 63).

**To change sample line settings**

1  In Toolspace, on the Settings tab, right-click the Sample Line collection. Click Edit Feature Settings.

   In the Edit Feature Setting - Sample Line dialog box, note that appears next to the settings for default styles and default name format, marking them as specific to sample lines.

2  Expand the default styles and the default name format to see the current settings.

3  In the Value column, click the entry you want to change.

4  Click to open a dialog box. Modify the value.

5  In the Edit Feature Settings - Sample Line dialog box, click OK.

### Quick Reference

Toolspace Shortcut Menu

   Settings tab: right-click Sample Line collection ➤ Edit Feature Settings

Dialog Box

   Edit Feature Settings - Sample Line (page 2243)

# Section Settings

You can change the default style and name format settings for sections.

To establish default settings for all sections, in the Settings tree, right-click the Section collection.

The default styles and name format settings for sections are described in this topic. Drawing ambient settings are described in Specifying Drawing Settings (page 63).

**To change section settings**

1  In Toolspace, in the Settings tree, right-click the Section collection. Click Edit Feature Settings.

   In the Edit Feature Settings - Section dialog box, note that appears next to the settings for default styles and the default name format, marking them as specific to sections.

2  Expand the default styles and the default name format to see the current settings.

3  In the Value column, click the entry you want to change.

4  Click to open a dialog box. Modify the value.

5  In the Edit Feature Settings - Section dialog box, click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: right-click Section collection ➤ Edit Feature Settings

Dialog Box

Edit Feature Settings - Section (page 2245)

## Section View Settings

You can change the default style and name format settings for section views and section view commands.

To establish default settings for all section views, in the Settings tree, right-click the Section View collection.

To change settings for a specific command, use the Commands collection in the Section View collection.

The default styles and name format settings for section view commands are described in this topic. Drawing ambient settings are described in Specifying Drawing Settings (page 63).

---

**NOTE** Overrides to the drawing ambient settings at the Section View collection level and the Command collection level affect only the specified level. The drawing level settings are not changed. For more information, see The Commands Collections (Settings Tree) (page 97).

---

**To change section view settings**

1   In Toolspace, in the Settings tree, right-click the Section View collection. Click Edit Feature Settings.

   In the Edit Feature Settings - Section View dialog box, note that 🏠 appears next to the settings for the default styles and the default name format, marking them as specific to section views.

2   Expand the default styles and the default name format to see the current settings.

3   In the Value column, click the entry you want to change.

4   Click ⊡ to open a dialog box. Modify the value.

5   In the Edit Feature Settings - Section View dialog box, click OK.

## Sample Line, Section, and Section View Styles and Display

Styles control the way a sample line, section, and section view is displayed in a drawing. Sample lines, sections, and sections views have label styles that control the appearance and behavior of their labels in a drawing.

# Sample Line, Section, and Section View Styles

Use styles to control how sample lines, sections, and section views are displayed in a drawing.

In AutoCAD Civil, all objects have a standard object style grouping on the Settings tree, called an object style collection. You use this to create, edit, copy, and delete the styles for that object. For more information, see The Object Style Collection (Settings Tree) (page 94).

## Creating and Editing Sample Line Styles

Use the Toolspace Settings tree to create, copy, edit, or delete a sample line style.

Create a new style by copying an existing style. Then change its properties to suit your requirements. Use the Sample Line Style dialog box (page 2264) tabs to specify the main properties.

---

**NOTE** Before editing an existing sample line style to change its properties, remember that any changes you make will apply to all sample lines that use the style. If you want to change the style of some sample lines but not all, consider creating a new style.

---

**To create a new sample line style**

1   In Toolspace, in the Settings tree, expand the Sample Line Styles collection.

2   Do one of the following:
    ■   Right-click Sample Line Styles collection. Click New.

    ■   Right-click the existing style to use as a template. Click Copy.

3   In the Sample Line Style dialog box (page 2264), enter or change the name of the style and other settings as required.

4   Click OK.

**To copy an existing sample line style**

1   In Toolspace, in the Settings tree, expand the Sample Line Styles collection.

2   Right-click the existing style. Click Copy.

3   In the Sample Line Style dialog box (page 2264), change the name of the style and other settings as required.

4   Click OK.

**To edit a sample line style**

1   In Toolspace, in the Settings tree, expand the Sample Line Styles collection.

2   Right-click the existing style. Click Edit.

3   In the Sample Line Style dialog box (page 2264), change settings as required.

4   Click OK.

**To delete a sample line style**

1   In Toolspace, in the Settings tree, expand the Sample Line Styles collection.

2   Right-click the style to delete. Click Delete.

3   In the confirmation dialog box, click Yes.

## Creating and Editing Section Styles

Use the Toolspace Settings tree to create, copy, edit, or delete a section style.

Create an entirely new style, or create a new style by copying an existing style. Change its properties to suit your requirements. Use the Section Style dialog box (page 2274) tabs to specify the main properties.

---

**NOTE** Before editing an existing section style to change its properties, remember that any changes you make will apply to all sections that use the style. To change the style of some sections, but not all, consider creating a new style.

---

**To create a new section style**

1  In Toolspace, in the Settings tree, expand the Section Styles collection.

2  Do one of the following:
   ■ Right-click Section Styles collection. Click New.

   ■ Right-click the existing style you want to use as a template. Click Copy.

3  In the Section Style dialog box (page 2274), change the name of the style and other settings as required.

4  Click OK.

**To copy an existing section style**

1  In Toolspace, in the Settings tree, expand the Section Styles collection.

2  Right-click the existing style. Click Copy.

3  In the Section Style dialog box (page 2274), change the name of the style and other settings as required.

4  Click OK.

**To edit a section style**

1  In Toolspace, in the Settings tree, expand the Section Styles collection.

2  Right-click the existing style. Click Edit.

3  In the Section Style dialog box (page 2274), change settings as required.

4  Click OK.

**To delete a section style**

1   In Toolspace, in the Settings tree, expand the Section Styles collection.

2   Right-click the existing style to delete. Click Delete.

3   In the confirmation dialog box, click Yes.

## Quick Reference

Toolspace Shortcut Menu

EditCrossSectionStyle

Dialog Box

Section Style (page 2274)

## Creating and Editing Section View Styles

Use the Toolspace Settings tree to create, copy, edit, or delete a section view style.

Create an entirely new style, or create a new style by copying an existing style. Then change its properties to suit your requirements. Use the Section View Style dialog box (page 2288) tabs to specify the main properties.

---

**NOTE** Before editing an existing section view style to change its properties, remember that any changes you make will apply to all section views that use the style. To change the style of some section views, but not all, consider creating a new style.

---

Section view styles control the format of the graph on which the sections are displayed, as well as the title and annotations on the axes.

Label styles control the format of labels for offset elevations at any point in a section view and depth/grade between any two selected points in a section view (see Using Section Labels (page 1137)).

Band styles control the format of section bands, which can appear above and/or below the section view.

For convenience, define a group of band styles as a band set. The entire set of band styles can then be applied to a section view with a single step, rather than applying each band style separately.

Group plot styles control the layout of the graph on which multiple section views are displayed. It also controls the spacing between sheets (if plotted "by page") and overall plot area.

For more information, see Group Plot Style dialog box. (page 2251)

Sheet styles control the way a cross section sheet, which contains multiple section views, is displayed. They also specify the individual plot area and visibility of sheet components.

For more information, see Sheet Style Dialog Box (page 2296).

Projection styles control the appearance of AutoCAD point, solid, polyline, and block objects projected into profile views or section views.

**To create a new section view style**

**1** In Toolspace, in the Settings tree, expand the Section View Styles collection.

**2** Do one of the following:
- Right-click Section View Styles collection. Click New.
- Right-click the existing style to use as a template. Click Copy.

**3** In the Section View Style dialog box (page 2288), enter or change the name of the style and other settings as required.

**4** Click OK.

**To copy an existing section view style**

**1** In Toolspace, in the Settings tree, expand the Section View Styles collection.

**2** Right-click the existing style. Click Copy.

**3** In the Section View Style dialog box (page 2288), change the name of the style and other settings as required.

**4** Click OK.

**To edit a section view style**

**1** In Toolspace, in the Settings tree, expand the Section View Styles collection.

**2** Right-click the existing style. Click Edit.

**3** In the Section View Style dialog box (page 2288), change settings as required.

**4** Click OK.

**To delete a section view style**

**1** In Toolspace, in the Settings tree, expand the Section View Styles collection.

**2** Right-click the existing style to delete. Click Delete.

**3** In the confirmation dialog box, click Yes.

**To edit a section view group plot style**

**1** Select the section view whose group plot style you want to edit.

**2** Click Section tab ➤ Modify View panel ➤ View Group Properties drop-down ➤ Edit Group Plot Style .

**3** In the Group Plot Style dialog box (page 2251), change settings as required.

**4** Click OK.

**To update a section view group's layout**

**1** Select a section view whose group layout may be modified by a style change.

**2** Click Section tab ➤ Modify View panel ➤ Update Group Layout .
The layout of the section view group is updated to reflect any style changes.

## Quick Reference

## Creating and Copying Projection Styles

Use these general styles to control the display of AutoCAD objects projected into profile views and section views.

Within a style, the settings for the appearance of an object type in section views are independent from the settings for profile views.

**To create a projection style**

1   In Toolspace, on the Settings tab, expand the General ➤ Multipurpose Styles collection. Right-click Projection Styles and click New.

2   In the Projection Styles dialog box (page 1807), specify the name of the style and other settings as required.

3   Click OK.

**To copy a projection style**

1   In Toolspace, on the Settings tab, expand the General ➤ Multipurpose Styles collection. Identify the style you want to copy as a basis for the new style.

2   Right-click the style name and click Copy.

3   In the Projection Styles dialog box (page 1807), change the name of the style and other settings as required.

4   Click OK.

## Quick Reference

## Editing Projected Object Styles

Change the appearance of a projected object, without affecting the source object.

Projected AutoCAD Civil objects use standard style editing dialog boxes for points, feature lines, and survey figures. Projected AutoCAD objects use multipurpose styles that control the appearance of different object types in profile views and section views.

**To edit a projection style**

1 In Toolspace, on the Settings tab, expand the General ➤ Multipurpose Styles collection. Identify the style you want to edit.

2 Right-click the style name and click Edit.

3 In the Projection Styles dialog box (page 1807), change settings as required.

4 Click OK.

**To edit the style of a projected object**

1 In the drawing window, in a section view, select the object whose style you want to change.

2 Right-click, and click the menu option for the object type:
   - Edit Point Style
   - Edit Feature Line Style
   - Edit Survey Figure Style
   - Edit Projection Style

3 In the styles dialog box, make changes as required.

# Sample Line, Section, and Section View Labels

You can use sample line, section, and section view label styles to control the appearance and behavior of labels in a drawing.

This information describes what is unique to sample line, section, and section view labels. For a general overview of labels, see Labels and Tags (page 1463).

## Using Sample Line Labels

Use the Toolspace Settings tree to create and edit sample line label styles, which are used to label sample line objects.

Specify which label styles to use when you create sample lines.

**To add sample line labels automatically based on the default label style**

**1** In the Toolspace Settings tree, right-click Sample Line and click Edit Feature Settings.

**2** In the Edit Feature Settings - Sample Line dialog box (page 2243) click Default Styles ➤ Sample Line Label Style.

**3** Click in the Value column and click ⊡ .

**4** In the Sample Line Label Style dialog box (page 1805), set the default label style.

Sample line labels are displayed when you add sample lines to the drawing.

You can select a sample line label style in the Sample Line Labels dialog box, or create or edit a style in the Label Style Composer.

**To edit sample line labels**

**1** Select a sample line in the drawing.

**2** Click Sample Line tab ➤ Labels & Tables panel ➤ Edit Labels ✎ .

**3** In the drawing, select a sample line to open the Sample Line Labels dialog box (page 2261).

**4** Edit the label in the Label Style Composer dialog box (page 1942).

## Quick Reference

Command Line

EditSampleLineLabels

Dialog Boxes

Sample Line Labels (page 2261)
Label Style Composer (page 1942)

## Using Section Labels

Use the Toolspace Settings tree to create and edit section label styles.

When you create sections, specify which label styles to use. Sections can be labeled automatically when created, using the specified label set. After creating a section, you can also add labels.

Use either the Section Labels dialog box (page 2270) or the Section View Properties dialog box (page 2281)to add labels.

You can select a section label style in the Section Labels or Section View Properties dialog box, or create or edit a style in the in the Label Style Composer.

Types of section label styles:

| This type of section label style... | Labels... |
| --- | --- |
| Major Offset | Offsets, elevations, and instantaneous grades at major increments. |
| Minor Offset | Offsets, elevations, and instantaneous grades at minor increments. |
| Segments | Section segment labels for each segment (line) of a section object. A user-specified weeding factor is supported, thus avoiding close annotation. |
| Grade Breaks | Grade break labels applied at every grade break point for a section. A user-specified weeding factor is supported, thus avoiding close annotation. |
| Label Set | The default set of label styles to use for sections when a section view object is created. |

For a general overview of labels, see Labels and Tags (page 1463).

**To add section labels**

1  In the drawing, zoom to a section view.

2  Do one of the following:
   ■ Click the desired section line. Right-click and click Edit Labels.
   ■ Click the desired section view grid. Right-click and click Section View Properties. On the Sections tab, click the Labels column.

   The Section Labels dialog box (page 2270) is displayed.

3  In the Section Labels dialog box, for Type, select the label type in the list, either: Major Offset, Minor Offset, Segments, or Grade Breaks.

4  Optionally, for Section <Label Style> Label Style, select the label style in the list or use the standard controls to create a new style, copy or edit the current style selection, create a child of the current style selection, or pick a style from the drawing.

5  Click Add.
   The specified label type is added to the set.

6  Review the label set in the table and make the required adjustments. Click OK.
   The labels are displayed along the section line in the section view.

**To edit section labels**

1  Click the section line you want to edit.

2  Do one of the following:
   ■ Click Section tab ➤ Labels panel ➤ Edit Section Labels 🖋 .
   ■ Right-click and click Edit Labels.

**3** In the Section Labels dialog box (page 2270), review the existing labels and their attributes. Do any of the following:

- Add or remove labels of any type.

- Change the style for a label type.

- Import a standard set of labels.

- Save your modified labels as a set to use again.

- Stagger labels to avoid label collisions. For more information, see Staggering Profile and Section Labels (page 1527).

**4** Click Apply to see your changes on the section line.

**5** Click OK to save the changes.

## Quick Reference

Ribbon

Select the section line. Section tab ➤ Labels panel ➤ Edit Section Labels 

Object Shortcut Menu

Click section, right-click ➤ Edit Labels

Command Line

EditSectionLabels

Dialog Box

Section Labels (page 2270)

## Using Section View Labels

Use the Toolspace Settings tree to create and edit section view label styles.

You can label section views automatically when you create them, using specified label styles. After creating section views, you can also add Offset Elevation and Grade labels.

If a section view contains projected AutoCAD objects, label styles for these objects are managed as feature settings for the section view object.

Projection labels show the location of an object projected into the section view, such as a block or a point.

Use the Add Section View Labels option to access the Add Labels dialog box (page 1970) if you need to create or modify a style before labeling a section view.

| This type of section view label style... | Labels... |
| --- | --- |
| Offset Elevation | The elevation and offset value at a specified point in the section view, not necessarily on a section. |
| Grade | The elevation difference between two specified points, as well as other selected data, such as slope and distance between the points. |

**To add a section view grade label**

1  Zoom to, and select, the section view that you want to label.

2  Click Section View tab ➤ Labels panel ➤ 🏷 Add View Labels drop-down ➤ 🏷 Grade.

3  Click the section view grid that you want to label.

4  Click any two points. A label is displayed, showing the grade label (default) or other data about the relationship between the two points (depending on the label style).

5  Repeat Step 4 for each point or pair of points that you want labeled.

6  To end the procedure, press Esc. Close the Add Labels dialog box.

**To add a section view offset elevation label**

1  Zoom to, and select, the section view that you want to label.

2  Click Section View tab ➤ Labels panel ➤ 🏷 Add View Labels drop-down ➤ 🏷 Offset Elevation.

3  Click the section view grid that you want to label.

4  Click the location where you want a label. It is immediately displayed, showing the offset and elevation values (default).

5  Repeat Step 4 for each point or pair of points that you want labeled.

6  To end the procedure, press Esc. Close the Add Labels dialog box.

## Quick Reference

# Section View Bands

You can use section view bands to control the location and content of bands in section views.

A data band is an optional graphic frame that is associated with a section view. The data band contains annotations for the section view and the section objects displayed in that section view. Some common annotations include elevation data, offsets, and cut/fill depths.

Bands can be created automatically when you create section views and also added manually to a section view you already created. Use the Section View Properties dialog box.

**Section View Band Styles**

Use the Toolspace Settings tree to create and edit section view band styles. Specify which styles to use when you create section views. Add labels using the Add Labels dialog box (page 1970).

Data band labels are label objects that can be manipulated like other AutoCAD Civil label objects. For more information, see Editing Data Band Labels (page 1529).

Group a set of commonly used bands into a band set that can be applied to a section view as a single selection.

| This type of band style... | Labels... |
| --- | --- |
| Band Sets | Specifies the default set of bands to use (or import) when creating a section view. Also, specifies various properties, such as the gap between bands. |
| Section Data | Specifies the offsets from centerline, elevations of any section, and the cut/fill depths at major/minor increments and other points of interest along the sample line. |
| Section Segment | Specifies section segment band style for each segment (line) of a section object. |

# Adding Section View Bands

Add data bands that display data such as elevations and horizontal geometry.

Place data bands along the top or bottom of a section view grid to annotate the various section lines with elevation data, vertical or horizontal geometry points, superelevation, or pipe network data. You can also group a set of commonly used data bands into a band set that can be applied to a section view as a single selection.

**See also:**

- Section View Band Styles (page 1141)
- Section View Band Set Dialog Box (page 2275)
- Staggering Data Band Labels (page 1528)

**To add bands to a section view**

1  In the section view, click the section view grid.

2  Right-click the section view. Click Section View Properties.

3  In the Section View Properties dialog box, click the Bands tab (page 2283).

4  In the List Of Bands area, select either Bottom or Top as the location for the new band in the section view.

5  Select a band type and style. Click Add.

6  To add more bands to the section view, repeat Steps 4 and 5.

7  Optionally, on the right side of the List Of Bands, move selected bands up ⇧ or down ⇩ in the stack. To delete any unwanted bands, click ✖ .

8  To save this arrangement of bands as a set for reuse, click Save As Band Set.

9  Click OK to close the Section View Properties dialog box. The bands are displayed in the section view.

**NOTE** To label corridor lane widths, create a corridor, build a corridor surface using ETW (edge-of-traveled-way) feature lines, and label that surface with an appropriate section segment band. For more information, see Creating and Editing Section Views (page 1152) and Understanding Corridor Modeling (page 1327).

# Creating and Editing Sample Lines and Sections

AutoCAD Civil enables you can to easily create, manage, and edit sample lines and sections.

# Creating Sample Lines

Create sample lines along an existing horizontal alignment.

Sections are cut along each of the samples lines for a specified set of surfaces. Corridor sections are created when you sample a corridor.

You can create one or more sample lines that are associated with an alignment. In Toolspace, in the Prospector tree, the sample lines are children of an alignment and appear in the hierarchy in the Sample Line Groups collection.

**NOTE** When you create sample lines for the first time for an alignment, you are prompted to create a sample line group in which to place the sample lines. This group also contains the list of surfaces, corridors, corridor surfaces, and pipe networks (if any), based on the alignment so that you can select the data source(s) to be sampled.

In the drawing, sample lines can be labeled with annotations, including stations and other information.

The section can be displayed using the section view. For more information, see Creating and Editing Section Views (page 1152).

**To create a perpendicular sample line, of a specified swath width, across an alignment at a specified station**

1   Click Home tab ➤ Profile & Section Views panel ➤ Sample Lines ⬚ .
    The cursor changes to pick mode. You are prompted to select an alignment.

2   Do one of the following:
    ■ Press Enter to select from a list of alignments.

    ■ In the drawing, click the desired horizontal alignment.

    For information about creating an alignment, see Creating Alignments (page 887).

3   Specify a sample line group. A sample line must belong to a sample line group. Do one of the following:
    ■ If this is the first sample line group you are creating in the drawing, the Create/Edit Sample Line Group dialog box (page 2231) is automatically displayed. Review the default styles. Change them if necessary. Click OK.

    ■ If a sample line group already exists in the drawing, the Sample Line Tools toolbar (page 2265) is displayed. To assign a sample line group to the sample line, select the sample line group in the list.

The cursor changes to station pick mode (default). You are prompted to select a station.

**4** Do one of the following:

- At the command line, specify a station by entering the desired station value.

- In the drawing, use the cursor tooltip to find the station along the alignment. Click the station.

**5** Do one of the following:

- At the command line, enter the left swath width. Press Enter.

- In the drawing, at the desired distance, click the first point, which defines the start of the left swath width. Click the second point, which defines the end of the left swath width (that is, the length).

**6** Do one of the following:

- At the command line, enter the right swath width. Press Enter.

- In the drawing, at the desired distance, click the first point, which defines the start of the right swath width. Click the second point, which defines the end of the right swath width (that is, the length).

**7** Right-click to end the By Stations mode.

Depending on the sample line style, a line is drawn perpendicular across the alignment at the specified location and length. This sample line represents the section.

---

**NOTE** For left and right swath widths, you can attach an alignment, such as a right-of-way alignment. This enables you to define variable sample line widths. If you later use the Edit Swath Widths for Group tool on the Sample Line Tools toolbar (page 2265), all sample line widths will be extended or trimmed to the group's widths.

---

**To create a sample line or multi-segment sample line by picking points on-screen**

**1** Click Home tab ➤ Profile & Section Views panel ➤ Sample Lines ⌐⁂ .

The cursor changes to pick mode. You are prompted to select an alignment.

**2** Do one of the following:

- Press Enter to select from a list of alignments.

- In the drawing, click the desired horizontal alignment.

For more information about creating an alignment, see Creating Alignments (page 887).

**3** Specify a sample line group. A sample line must belong to a sample line group. Do one of the following:
- If this is the first sample line group you are creating in the drawing, the Create/Edit Sample Line Group dialog box (page 2231) is automatically displayed. Review the default styles. Change them if necessary. Click OK.

- If a sample line group already exists in the drawing, the Sample Line Tools toolbar (page 2265) is displayed. To assign a sample line group to the sample line, select the sample line group in the list.

The cursor changes to station pick mode (default). You are prompted to select a station.

**4** On the Sample Line Tools toolbar, in the sample line create method list, click ⌐ , which selects Pick Points On Screen. You are prompted to select a start point.

**5** In the drawing, use the cursor tooltip to find the start point. Click the start point.

**6** Do one of the following:

- In the drawing, click an end point on the opposite side of the alignment. Finish the pick point session by right-clicking. Press Enter.

■ In the drawing, click one or more points to define the sample line (section) with the final end point on the opposite side of the alignment from the start point. Note that if the final end point is not on the opposite side of the alignment from the start point, the sample line is interpolated to attach to the centerline of the alignment.

7 Do one of the following:

■ Continue picking points on screen to draw more sample lines.

■ Right-click to end the Pick Points On Screen mode.

---

**NOTE** When you create a sample line that is located between corridor stations, the data shown in the section is interpolated between the preceding and succeeding stations.

---

Depending on the sample line style, a line or multi-segment line is drawn across the alignment that represents the section.

**To create perpendicular sample lines, by a range of stations, across an alignment at specified station intervals**

1 Click Home tab ➤ Profile & Section Views panel ➤ Sample Lines ⬚ .
The cursor changes to pick mode. You are prompted to select an alignment.

2 Do one of the following:

■ Press Enter to select from a list of alignments.

■ In the drawing, click the desired horizontal alignment.

For information about creating an alignment, see Creating Alignments (page 887).

3 Specify a sample line group. A sample line must belong to a sample line group. Do one of the following:

■ If this is the first sample line group you are creating in the drawing, the Create/Edit Sample Line Group dialog box (page 2231) is automatically displayed. Review the default styles. Change them if necessary. Click OK.

■ If a sample line group already exists in the drawing, the Sample Line Tools toolbar (page 2265) is displayed. To assign a sample line group to the sample line, select the desired sample line group in the list.

The cursor changes to station pick mode (default). You are prompted to select a station.

4 On the Sample Line Tools toolbar, in the sample line create method list, click 🖈 , which selects By Station Range.
The Create Sample Lines - By Station Range dialog box (page 2236)is displayed.

5 Review the default settings. Change them if necessary. Click OK. Note that the station range defaults to the entire length of the alignment.
Depending on the sample line style, sample lines are drawn along the alignment, cutting across the alignment at the specified intervals. These sample lines represent the sections.

**To create perpendicular sample lines across an alignment at specified corridor stations**

1 Click Home tab ➤ Profile & Section Views panel ➤ Sample Lines ⬚ .
The cursor changes to pick mode. you are prompted to select an alignment.

2 Do one of the following:

■ Press Enter to select from a list of alignments.

■ In the drawing, click the desired horizontal alignment.

For more information about creating an alignment, see Creating Alignments (page 887).

3 Specify a sample line group. A sample line must belong to a sample line group. Do one of the following:

■ If this is the first sample line group you are creating in the drawing, the Create/Edit Sample Line Group dialog box (page 2231) is displayed. Review the default styles. Change them if necessary. Click OK.

■ If a sample line group already exists in the drawing, the Sample Line Tools toolbar (page 2265) is displayed. To assign a sample line group to the sample line, select the desired sample line group in the list.

The cursor changes to station pick mode (default). You are prompted to select a station.

4 On the Sample Line Tools toolbar, in the sample line create method list, click ▦ to select From Corridor Stations.

The Create Sample Lines - From Corridor Stations dialog box (page 2236) is displayed.

**NOTE** If you do not have any corridors defined based on the selected alignment, then this command will be inactive.

5 Review the default settings. Change them if necessary. Click OK. Note that the station range defaults to the entire length of the alignment.

Depending on the sample line style, sample lines are drawn along the alignment, cutting across the alignment at the specified corridor stations. These sample lines represent the corridor sections.

**NOTE** For left and right swath widths, you can attach an alignment, such as a right-of-way alignment. This enables you to define variable sample line widths. If you later use the Edit Swath Widths for Group tool on the Sample Line Tools toolbar (page 2265), all sample line widths will be extended or trimmed to the group's widths.

CreateSampleLines

# Editing Sample Lines

Edit sample lines to change their parameters, move, copy, delete, or replace them, and change their appearance.

Use the editing functionality in the Edit Sample Line dialog box (page 2250) to change the name, length, vertex locations, and station value parameters.

In the drawing, use sample line grips to specify the stretch point, base point, or to copy sample lines. You use the grips to change swath widths or stations.

**To use parameters to edit sample line location and length**

**1** In the drawing, click the sample line you want to edit.

**2** Click Sample Line tab ➤ Modify panel ➤ Edit Sample Line 🖉 .
Note that the Edit Sample Line dialog box and Sample Line Tools toolbar are both displayed.

**3** In the Edit Sample Line dialog box (page 2250), review the parameters for each vertex of the sample line by clicking Previous Vertex and Next Vertex.

**4** At the vertex you want to edit, do one or more of the following:

■ In the Name field, change the name of the sample line.

■ In the Sample Line Vertex Northing and/or Sample Line Vertex Easting field(s), enter new values.

■ In the Sample Line Segment Length field, change the length of the swath width to the desired distance in ground units or click 🔲 to pick a new segment length from the drawing.

■ In the Sample Line Station Value field, change the sample line station value or click 🔳 to pick a new station value from the drawing.

**5** Close the Edit Sample Line dialog box and Sample Line Tools toolbar.
The sample line is redrawn with the new parameters.

**To use grips to edit a sample line**

**1** In the drawing, click the sample line you want to edit.
The sample line displays grip edit locations at each vertex.

**2** Use the diamond-shaped center grip to move the sample line to a new location along the alignment.
The sample line slides to the new location while maintaining its relative geometry. As the sample line moves, it reorients to the underlying entity (for example, spiral, curve, or other tangents). It always remains perpendicular to the alignment.

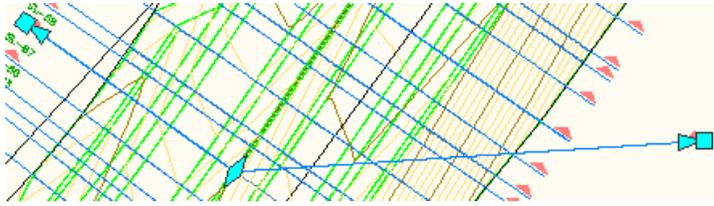
**3** Use the square-shaped end grips to stretch (lengthen or shorten), move, or rotate segments.
The sample line is redrawn.

**4** Use the triangular-shaped grips at the ends of segments to stretch (lengthen or shorten) each segment while keeping its relative direction.
The sample line is redrawn.

**5** Press Esc or enter eXit to complete the procedure.
The sample line segments are moved or edited.

**To restore a rotated sample line to the perpendicular**

**1** In the drawing, click a sample line.
The sample line displays grip edit locations at each vertex.

**2** Use the square-shaped end grips to rotate segments off their perpendicular orientation to the parent alignment.


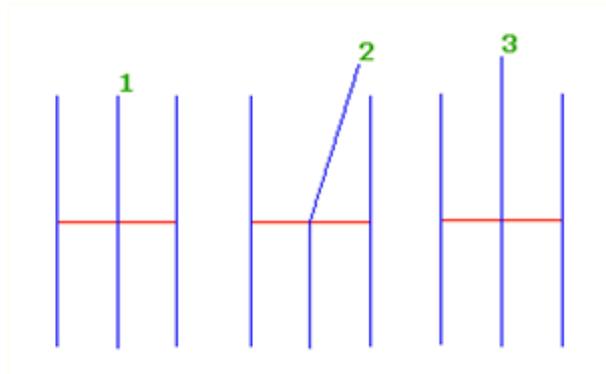
**3** Click the rotated sample line.

**4** Do one of the following:

- Right-click and click Make Orthogonal.

- On the command line, enter MakeSampleLineOrthogonal.

The rotated sample line (1-2) rotates back to a perpendicular orientation (3) to its parent alignment, but retains the length to which it was stretched or contracted.



**To change the display style of a sample line**

**1** In the drawing, click the sample line.

**2** Right-click the sample line. Click Sample Line Properties.

**3** In the Sample Line Properties dialog box, click the Information tab (page 2262).

**4** In the Object Style field, select a different style in the list.

**To resample section sources**

**1** Select a sample line in the drawing.

**2** Click Sample Line tab ➤ Modify panel ➤ Sample More Sources 🔺 .

**3** In the Section Sources dialog box, do one or more of the following:

- Select a source in the Available Sources field and click Add >> to add it to the Sampled Sources field.

- Select a source in the Sampled Sources field and click Remove << to remove it From the Available Sources field.

**4** In the Section Sources dialog box, click OK.

# Editing Sections

Edit a section to change its appearance or move it in the drawing.

Use the section editing functionality within a section view. For example, you can move a section in the vertical plane within a section view.

You can use section grip editing to manipulate static sections (that is, sections that are not dynamic). For example, you can alter the section yet maintain the grade or elevation while stretching a segment or moving grade points.

If the section is dynamic, the data is grayed out and not editable. Change the Update Mode to Static in the Section Properties dialog box if you want to edit a section.

For more information about static and dynamic update modes for sections, see Section Data Tab (Section Properties Dialog Box) (page 2272).

**To edit and move a section**

1   In the drawing, zoom to a section view. Click the static section line you want to edit.

    The section line is displayed with triangular grips at the start and end of each section segment and rectangular grips at grade breaks.

2   Move the section segments. Use rectangular grips for grade points. Use triangular grips for segment stretching (lengthen or shorten).

    As you move the grips, the X and Y values are displayed dynamically.

    ---
    **NOTE** To edit the section segment by editing the dynamic dimensions in place, press Tab to cycle through the offset and elevation values displayed.

    ---

3   Click in the drawing at the desired location.

    The section is redrawn at the new location.

    ---
    **NOTE** The section must be a static type section (that is, a section that is not dynamic). For more information about static and dynamic update modes for sections, see Section Data Tab (Section Properties Dialog Box) (page 2272)

    ---

# Editing Sample Line Group Properties

You can specify sample line group properties, and by extension the sample lines in that group, that control the group's content and format.

For example, for an existing sample line group, you can use the Sample Line Group Properties dialog box (page 2257) tabs to apply major changes to a sample line group by changing general properties:

■ **Information**. Specifies the sample line group's name and description.

■ **Sample Lines**. Specifies the default properties of the sample lines that are included in the sample line group. Also, you can specify the default label style. By changing the default label style here, you instantly change the sample line's displayed appearance.

■ **Sections**. Specifies the properties that draw and manage the section associated with the current sample line group.

■ **Section Views**. Specifies the properties that draw and manage the section view associated with the current sample line group.

■ **Material List**. Specifies the properties of material lists associated with the current sample line group. Each list represents quantity takeoff calculation criteria for the specified materials.

Sample line properties display and specify data only about that sample line. Sample line group properties display and specify rules for creating sample lines by range of stations or from corridor stations.

For more information, see Editing Sample Line Properties (page 1149).

**To edit sample line group properties**

1 In Toolspace, on the Prospector tab, right-click the sample line group name you want to edit. Click Properties.

2 In the Sample Line Group Properties dialog box (page 2257), review or change properties on the following tabs: Information, Sample Lines, Sections, Section Views, and Material List.

## Quick Reference

# Editing Sample Line Properties

When you create a sample line you can specify properties to control the sample line's content and format.

For example, for an existing sample line group, you can use the Sample Line Properties dialog box (page 2261) tabs to apply major changes to a sample line by changing general properties:

■ **Information**. Specifies the sample line's name, text description, and object style. By changing the style here, you instantly change the sample line's displayed appearance.

- **Sample Line Data**. Specifies the sample line's group name, associated alignment, station information, and whether the sample line locks to the station. Also, you can specify the label style. By changing the label style here, you instantly change the sample line's displayed appearance.

- **Sections**. Specifies the properties that draw and manage the section associated with the current sample line. For any sample line, you can also change its style.

- **Section Views**. Specifies the properties that determine which section views are created from the current sample line.

---

**NOTE** Sample line properties display and specify data only about that sample line. Sample line group properties display and specify rules for creating sample lines by range of stations or from corridor stations.

---

**To edit sample line properties**

1 In the drawing, click the sample line you want to edit.

2 Right-click the sample line. Click Sample Line Properties.

3 Review or change properties on the tabs of the Sample Line Properties dialog box.

### Quick Reference

Dialog Box

Sample Line Properties (page 2261)

## Editing Section Properties

When you create a section you can specify properties to set the section's name, type, object style, station details, and labeling.

Open the Section Properties dialog box (page 2272) for an existing section to verify the name of the section and review other information.

Apply changes to a section by changing its general properties.

The **Information** tab specifies the section's name, description, and object style. By changing the style here, you instantly change the section's displayed appearance.

The **Section Data** tab specifies and displays tabular data with a single row listing the properties of the section. Some of these properties, such as layer, mode, and style can be edited. The other properties are only for review.

**To edit section properties**

1 In the drawing, click the section line you want to edit.

**2** Right-click the section line. Click Section Properties.

**3** Review or change properties on the tabs of the Section Properties dialog box (page 2272).

## Quick Reference

# Editing Corridor Section Properties

When you create a corridor section you can specify properties to set the corridor section's name, type, object style, layer, and codes.

Open the Corridor Section Properties dialog box (page 2229) for an existing corridor section to verify the name of the corridor section and review other information. Apply changes to a corridor section by changing its general properties:

■ **Information**. Specifies the corridor section's name, text description, and object style. By changing the style here, you instantly change the corridor section's displayed appearance.

■ **Section Data**. Specifies and displays tabular data with a single row listing the properties of that corridor section. Some of these properties, such as layer, mode, and style can be edited. The other properties are only for review.

■ **Codes**. Displays codes and style information for review. For information about changing the display style of various point, link, and shape codes, see Using Codes and Code Set Styles (page 1405).

**To edit corridor section properties**

**1** On the prospector, click the corridor section collection that contains the corridor section you want to edit.

**2** On the item view, right-click the individual corridor section  . Click Properties.

**3** Review or change properties on the tabs of the Corridor Section Properties dialog box (page 2229).

## Quick Reference

Pipe Network Properties (page 2253)

# Creating and Editing Section Views

AutoCAD Civil enables you can to easily create, manage, and edit section views.

Section views are created from existing sample lines and sections. For more information, see Creating and Editing Sample Lines and Sections (page 1142).

A section view consists of a grid on which one or more sections are displayed as graphed lines. Multiple section views can be plotted on a sheet that is a specified size and configuration.

A section view is very similar to a profile view. It consists of a grid or graph with specific characteristics that are controlled by section view styles. Bands can also be displayed above or below the section view.

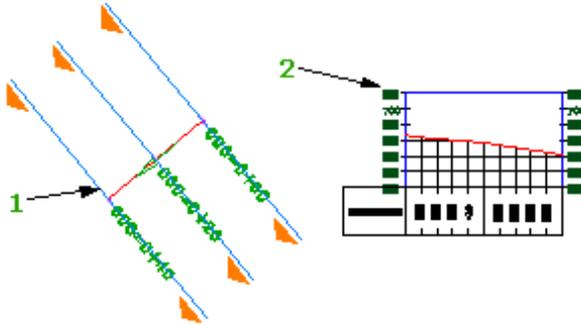
A section view can display one or more of the available sections at the sample line. To plot multiple sections, use a paperspace viewport size to set up the sheet.

Configure bands and section annotations in a section view to make the section view clearer or more informative for the user.

# Creating/Editing Section Views

Create a section view to display an existing ground section, using sample lines cut across a horizontal alignment.

Sample lines (1) must be created prior to creating a section view (2). Section views can display existing ground surface sections, corridor sections, and pipe sections.



Each section view must be linked to an alignment. The section view displays new or existing sections. Sections can also be created without displaying them on a section view. When you create a section view for an alignment, the complete list of sections for the alignment is displayed. Choose which sections to include in the section view.

Create either an EG (existing ground) section view or multiple section views. You can change the display style of a section view, and add labels and bands.

**To create a section view**

1 Click Home tab ➤ Profile & Section Views panel ➤ Section Views drop-down ➤ Create Section View . 

2 In the Create Section View wizard (page 2239), click **Create Section View** to accept location, style, offset, elevation, display, data band, and volume table defaults. You can later change the default settings in the Section View Properties dialog box (page 2281). Alternatively, you can change settings in the following pages of the wizard

- General page (page 2146) – Change the location, name, layer and style of the new section view.

- Offset Range page (page 2146) – Change the width of the offsets of the new section view.

- Elevation Range page (page 2146) – Change the maximum and minimum elevation of the new section view.

- Section Display Options page (page 2148) – Change the visibility and style of the new section view.

- Data Bands page (page 2150) – Change the band set and data band location for the new section view.

- Section View Tables page (page 2152) – Change the type and style of volume tables, and their position relative to, the new section view.

**NOTE** A material list must exist in the drawing, before you can modify **Section View Tables** settings.

3 In the drawing, find a suitable location for the section view, for example, outside the surface boundary for ease of viewing. Click that location to define the origin.

The section view is displayed.

**To create multiple section views**

1   Click Home tab ➤ Profile & Section Views panel ➤ Section Views drop-down ➤ Create Multiple Views
    ![icon] .

2   In the Create Multiple Section Views wizard (page 2232), click **Create Section Views** to accept location, style, offset, elevation, display, data band, and volume table defaults. You can later change the default settings through the Section View Group Properties (page 2279) dialog box. Alternatively, you can change settings in the following pages of the wizard:

    ■ General page (page 2233) – Change the location, name, layer and style of the new section views.

    ■ Offset Range page (page 2233) – Change the width of the offsets of the new section views.

    ■ Elevation Range page (page 2234) – Change the maximum and minimum elevations of, and group options for, the new section views.

    ■ Section Display Options page (page 2234) – Change the visibility and style of the new section views.

    ■ Data Bands page (page 2234) – Change the band set and data band location for the new section views.

    ■ Section View Tables page (page 2235) – Change the type and style of volume tables, and their position relative to, the new section views.

    ---

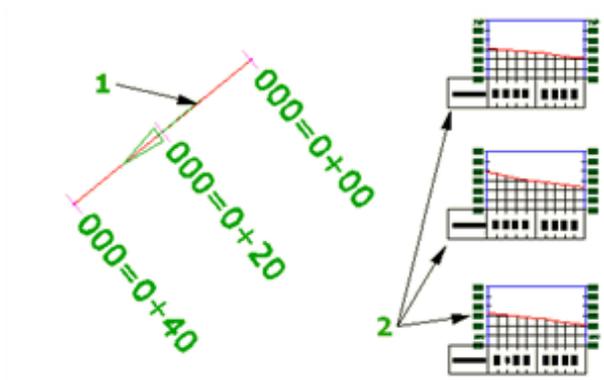
    **NOTE** A material list must exist in the drawing, before you can modify **Section View Tables** settings.

    ---

3   In the drawing, find a suitable location for the multiple section views, for example, well outside the surface boundary for ease of viewing. Click that location to define the origin.

    The multiple section views are displayed.

You can plot an entire sample line group, or you can specify a user-defined station range (1) to control how many section views (2) are created.



**To change the display style of a section**

1   In the section view, click the section line you want to change.

2   Right-click the section line. Click Section Properties.

3   In the Section Properties dialog box, click the Information tab (page 2272).

4   In the Object Style field, select a different style in the list.

**To change the display style of a section view**

1   In the section view, click the section view grid

**2** Right-click the grid. Click Section View Properties.

**3** In the Section View Properties dialog box, click the Information tab (page 2281).

**4** In the Object Style field, select a different style in the list.

**To add a section view label**

**1** Zoom to the section view area to clearly see the section view and its annotations.

**2** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Section View ➤ Add Section View Labels  .

**3** In the Add Labels dialog box (page 1970), for Label Type, select the type of label (either Grade or Offset Elevation) in the list.

**4** Optionally, for style, select the style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

**5** Click Add.
On the command line, you are prompted to select a section view.

**6** In the drawing, click a graph line of the section view you want to label.
On the command line, you are prompted to pick a point.

**7** In the section view, click the point, or points for a grade label, that define the label.
The label is displayed at the desired location in the section view.

**8** Right-click or press Esc to end the session.

**9** In the Add Labels dialog box, click Close.

**To add bands to a section view**

**1** In the section view, click the section view grid.

**2** Right-click the grid. Click Section View Properties.

**3** In the Section View Properties dialog box, click the Bands tab (page 2283).

**4** In the List Of Bands area, select either Bottom or Top as the location for the new data band in the section view.

**5** Select a band type and style. Click Add.

**6** To add more bands to the section view, repeat Steps 4 and 5.

**7** Optionally, on the right side of the List Of Bands, move selected bands up  or down  in the stack.
To delete any unwanted bands, click  .

**8** To save this arrangement of bands as a set for reuse, click Save As Band Set.

**9** Click OK to close the Section View Properties dialog box. The bands are displayed in the section view.

**To add profile grade points to a section view**

**1** In the section view, click the section view grid.

**2** Right-click the grid. Click Section View Properties.

**3** In the Section View Properties dialog box, click the Profile Grade Lines tab (page 2287).

**4** In the Alignment area, click an alignment in the list or click  to pick an alignment from the drawing.

**5** Click Add.

**6** To add more grade point labels to the section view, repeat Steps 4 and 5.

**7** Optionally, to delete any unwanted grade points, select them in the list. Click  .

**8** Click OK to close the Section View Properties dialog box. The profile grade points are displayed in the section view.

# Editing Section View Properties

When you create a section view you can specify properties to control a section view's content and format.

In the Section View Properties dialog box, edit offset range, elevation range, section data, band information, projected object information, volume table information and profile grade line information.

Apply changes to a section view by changing its general properties:

- **Information**. Specifies the section view's name, description, and object style. By changing the style here, you instantly change the section's displayed appearance.

- **Offsets**. Displays the properties of the selected section view and the section view grid on which sections are displayed.

- **Elevation**. Specifies the elevation properties of the selected section view and the section view grid on which sections are displayed.

- **Sections**. Specifies which sections to display in the section view. For any section, you can also override its style and label set to display it differently in the current section view.

- **Bands**. Specifies which bands to include in the section view, and whether to place them along the top or bottom of the grid. Data is displayed for specified section objects.

- **Volume Tables**. Specifies table type and style, and the associated material, material list and layer.

- **Profile Grade Lines**. Specifies a profile and displays its elevation by marking it at the appropriate offset and elevation in the section view.

- **Projection**. Specifies the name, style and elevation of projected objects in a section view.

For more information, see Section View Group Properties Dialog Box (page 2279).

**To edit section view properties**

**1** In the drawing, click any grid or axis line of the section view you want to edit.

**2** Right-click the section view grid. Click Section View Properties.

**3** Review or change properties on the tabs of the Section View Properties dialog box (page 2279).

**To edit section view group properties**

**1** In the drawing, click any grid or axis line of any section view in the group you want to edit.

**2** Right-click the section view grid. Click Section View Group Properties.

**3** Review or change properties on the tabs of the Section View Group Properties (page 2279) dialog box.

### Quick Reference

# Adding Projected Objects to a Section View

Project AutoCAD or AutoCAD Civil objects from plan view into a section view.

You can project AutoCAD points, blocks, 3D solids, and 3D polylines; you can also project COGO points, feature lines, and survey figures.

For more information, see Working with Projected Objects (page 1118).

**To project objects to a section view**

1 Home tab ➤ Profile & Section Views panel ➤ Section Views drop-down ➤ Project Objects To Section View  .

2 Click one or more objects in the drawing that you want to project. Right-click or press Enter after all objects are selected.

3 Click the section view in which you want the objects to appear.

### Quick Reference

Ribbon

Home tab ➤ Profile & Section Views panel ➤ Section Views drop-down ➤ Project Objects To Section View 

Command Line

ProjectObjectsToSect

# Editing Projected Objects in a Section View

Use the shortcut menu for a projected object for quick access to object properties.

When you right-click a projected object in a section view, the shortcut menu is displayed. The only menu selection specific to the projection is Projection Object Properties. It opens the Projections tab (page 2287) of the Section View Properties dialog box.

For more information, see Working with Projected Objects (page 1118).

# Removing a Projected Object from a Section View

Select a projected object and remove it from the section view.

Other projected objects not selected in the section view remain in place.

For more information, see Working with Projected Objects (page 1118).

**To remove a projected object**

1   In the section view, click the object to want to remove.

2   In the Modify Projected Object panel, click Remove From View  .

## Quick Reference

Ribbon

Projected Object tab ➤ Modify Projected Object panel ➤ Remove From View 

Command Line

RemoveFromSectionView

# Sections Command Reference

The AutoCAD Civil commands for section-related functionality and a brief description of their functionality.

| Command | Description |
| --- | --- |
| AddSectionViewLabels | Adds a grade label after you select an existing section view and two points to define grade start and finish (page 1139) |
| AddSectionViewGradeLbl | Adds a grade label after you select an existing section view and two points to define grade start and finish (page 1139) |
| AddSectionViewOffElevLbl | Adds an offset elevation label after you select an existing section view and desired point to define the label location (page 1139) |
| AddSheet | Adds a sheet, on which to draw section views, to the drawing after you select an origin (page 1153) |
| CreateCrossSectionStyle | Creates a new section style (page 1132) |

| Command | Description |
|---|---|
| CreateGroupPlotStyle | Creates a new group plot style (page 1132) |
| CreateMultipleSectionView | Creates multiple section views (page 1153) |
| CreateSampleLines | Creates sample lines based on existing alignments (page 1142) |
| CreateSampleLineStyle | Creates a new sample line style (page 1131) |
| CreateSectionView | Creates a new section view (page 1153) |
| CreateSectionViewStyle | Creates a new section view style (page 1133) |
| EditCrossSection | Edits a selected section (page 1148) |
| EditCrossSectionStyle | Edits the section style after you select a section line in a section view graph (page 1133) |
| EditGroupPlotStyle | Edits a group plot style (page 1132) |
| EditSampleLine | Edits a sample line after you select an alignment and the sample line (page 1145) |
| EditSampleLineLabels | Edits the labels of a selected sample line (page 1137) |
| EditSampleLineGroupProperties | Edits sample line group properties after you select a sample line (page 1149) |
| EditSampleLineProperties | Edits sample line properties after you select a sample line (page 1149) |
| EditSampleLineStyle | Edits an existing sample line style (page 1131) |
| EditSectionLabels | Edits the labels of a selected section (page 1034) |
| EditSectionViewStyle | Edits an existing section view style (page 1133) |
| EditSheetProperties | Edits the sheet properties after you select a sheet (page 2295) |
| EditSheetStyle | Edits the sheet style after you select a sheet. (page 1133) |
| MakeSampleLineOrthogonal | Returns sample line(s) to the perpendicular from their parent alignment (page 1146) |
| SectionProperties | Edits section properties after you select a section line in a section view graph (page 1150) |
| ProjectObjectToSect | Projects an object into a section view (page 1157) |
| RemoveFromSectionView | Removes a projected object from a section view (page 1158) |

# Material and Quantity Analysis

# 26

Use materials and sectional or profile information to extract and report material volumes.

◯ Material and Quantity Analysis Workflow

## Understanding Material and Quantity Analysis

In AutoCAD Civil, you can create, manage, and plot quantities.

You then save or render them using:

- Total volume tables
- Material volume tables
- Volume reports
- Mass haul diagrams

Creating material lists (page 1163) is the essential step in the creation of volume tables and reports. Creation of tables and reports can be performed once the material lists are generated. As part of the production of the material lists, you will need to set quantity takeoff criteria (page 1165).

As with the creation of volume tables and reports, the creation of material lists is also a prerequisite to creating mass haul diagrams (page 1174).

## Quantity Takeoff Settings

Use quantity takeoff settings to specify the default style and name format settings for quantity takeoff and the default behavior for quantity takeoff-related commands.

Settings are handled in a standard way throughout AutoCAD Civil. Access settings using the Toolspace Settings tree. Control settings at three levels: the drawing level, the object collection (feature) level, and the command level. For more information, see Understanding Settings (page 61).

Use the Toolspace Settings tree Quantity Takeoff collection shortcut menu to establish defaults for all of the quantity takeoff-related features and commands. You can change quantity takeoff-specific settings at this level, or you can override the drawing ambient settings.

Use the Commands collection under the ⊞ Quantity Takeoff collection to change quantity takeoff settings for a specific command.

---

**NOTE** Overrides to the drawing ambient settings at the Quantity Takeoff collection level and the quantity takeoff Commands collection level affect only the specified level. The drawing level settings are not changed.

---

The topics in this section describe only those settings that affect quantity takeoff-related features and commands. They do not cover the drawing ambient settings that you can change at the quantity takeoff collection level and the quantity takeoff command level, even though those settings are displayed in the Edit Feature Settings - Quantity Takeoff dialog box. For more information about the drawing ambient settings, see Specifying Ambient Settings (page 68).

## Editing Quantity Takeoff Settings

Change quantity-takeoff-related settings before you create criteria, material lists, tables, or reports.

For example, before creating a quantity takeoff table, you may want to specify the default table format.

If a closed lock appears in the Lock column for a property, the property is locked at a higher level of the Settings tree. It cannot be changed at this level.

If you change a property value, a check mark is placed in the Override column. This override is also noted in the property table for related objects higher up in the Toolspace Settings tree, where an arrow appears in the Child Override column.

**To change quantity takeoff settings**

1 Do one of the following:
   - **To edit the general quantity takeoff settings**: In Toolspace, on the Settings tab, right-click the Quantity Takeoff collection and click Edit Feature Settings.
   - **To edit the settings for a specific command**: In Toolspace, on the Settings tab, expand the Commands collection in the Quantity Takeoff collection. Right-click the command for which you want to change settings.

   The Edit Feature Settings - Quantity Takeoff dialog box (page 2305) is displayed.

2 To specify the default quantity takeoff criteria and material shape style, expand the ⊞ Default Styles property group, and edit the Quantity Takeoff Criteria and Material Shape Style settings.

3 To specify the default naming for quantity takeoff materials and material lists, expand the ⊞ Default Name Format property group, and edit the Material Name Template and Material List Name Template settings.

4 To modify the default material volume table settings, expand the Table Creation property group, and edit the standard table creation options. This property group is available if you accessed the settings from the AddMaterialVolumeTable command in Step 1.

5 To modify the default total volume table settings, expand the Table Creation property group, and edit the standard table creation options. This property group is available when you access the settings from the AddTotalVolumeTable command in Step 1.

6 To modify the default material definition settings, expand the Define Materials Options property group, and edit the curve correction settings. For more information, see Generating Material Lists (page 1163). This property group is available when you access the settings from the ComputeMaterials command in Step 1.

**7** To modify the default quantity takeoff report settings, expand the Quantity Report Options property group, and edit the XML report display setting. This property group is available when you access the settings from the GenerateQuantitiesReport command in Step 1.

**8** Click Apply.

# Analyzing Material Volumes

Use the material volumes functionality to extract and report sectional material volumes, based on sample line groups.

# Material Lists and Material Analysis

Create material lists and quantity takeoff criteria as the first step in analyzing material volumes.

You can create tables and reports for:

■ Volumes along an alignment, comparing various design surfaces and existing ground surfaces.

■ Volumes for shapes, which are closed cross-sectional areas created by a single subassembly. For example, a curb (a closed area within a concrete curb or curb and gutter).

■ Volumes between various (designed/grading/existing) formations.

---

**TIP** To query composite and bounded volume differences between surfaces, use surface volume reporting. For information, see Calculating Surface Volumes (page 690).

---

Material volume reporting uses criteria settings that are portable and extensible. You can create criteria based either on existing data, including surfaces and sample line groups, or on standard surface names.

You prepare to generate material volume information by creating a list of materials and applying the predefined criteria to it, mapping existing surfaces or other objects to the names in the criteria. After the material list is generated, the settings and volume calculations are stored with the sample line group and can be used to generate tables and reports.

You can display material volume information using standard AutoCAD Civil table formats, or view and export the information in an XML format file.

## Generating Material Lists

Use the Compute Materials command to generate a material list for a sample line group.

Material lists are the starting points for creating quantity takeoff tables and reports, and mass haul diagrams. Each time you apply a criteria to a sample line group, a material list is added to the sample line group properties. You can then use the material list to create a volume table or report, or a mass haul diagram.

Before you create a material list, you must first define criteria and create sample lines for the alignment along which you are going to generate quantity takeoff or mass haul information.

The material lists you create are stored as part of the sample line group properties. If you select a sample line group that already has a material list when you are using the Compute Materials command, the existing list is opened for editing.

**Curve Correction**

Use curve correction when a curve correction tolerance value is exceeded. Curve correction may be required to correct volume calculations within a curvilinear section of an alignment (or on two sides of a horizontal intersection point). If the sample lines are within a specified tolerance or if the angle of deflection between the successive stations is small, then curve correction is not used.

**To create a new material list for a sample line group**

1  Click Analyze tab ➤ Volumes And Materials panel ➤ Compute Materials 🖥 .

2  In the Select a Sample Line Group dialog box, click the Select Alignment field. Select an alignment from the list or click 🔲 and select an alignment in the drawing.

3  Click the Select Sample Line Group field. Select a sample line group or click 🔲 to select a group in the drawing.

4  Click OK.

   If there is no material list associated with the sample line group, the Compute Materials dialog box (page 2300) is displayed.

   If one or more material lists are already part of the sample line group properties, the Edit Material List dialog box (page 2307) is displayed. You can add a new materials list or edit an existing list as required.

5  Click the Quantity Takeoff Criteria field. Select the criteria.

6  Optionally, select the Curve Correction Tolerance check box and enter a curve correction value.

7  Optionally, if the criteria uses the same surface and structure names as objects in the drawing, you can quickly map the names by clicking Map Objects With Same Name.

8  Click OK.

   The quantity takeoff calculation is performed and the material list is added to the sample line group properties.

Compute Materials (page 2300)

## Creating Quantity Takeoff Criteria

Create quantity takeoff criteria in preparation for generating quantity takeoff tables or reports.

The criteria are stored in the Toolspace Settings tab under the Quantity Takeoff collection. After you create a criteria, you can apply it to a sample line group to create a material list. You use the material list to generate quantity takeoff tables and reports.

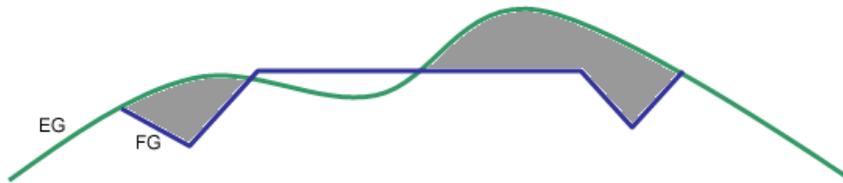
To create a criteria, you create a list of materials and shapes. For example, you can create an entry that calculates the volume of material to remove by creating a material called Ground Removed, and then add to it two surfaces that are compared to generate the volume information.

You can also define materials in a criteria using a sample line group. Select a sample line group, and then create material definitions using the list of surfaces that are used as a data source for the group.

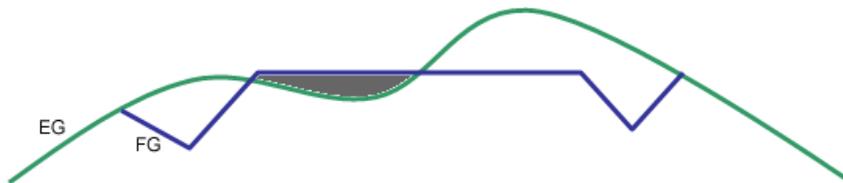
### Quantity Types

Quantity takeoff supports the following quantity types:

- **Cut**. Used to calculate the material to remove. For example, this could be the amount below an existing ground (EG) surface and above a finished ground (FG) surface:

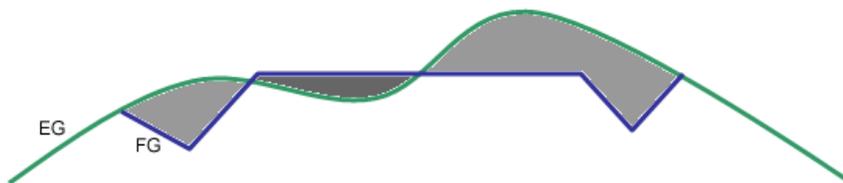


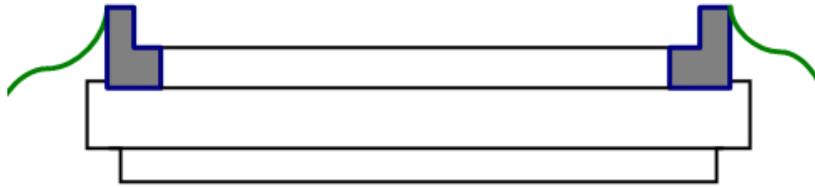
- **Fill**. Used to calculate the material to add. For example, this could be the amount above an existing ground (EG) surface and below a finished ground (FG) surface:



- **Cut and Refill**. Used to calculate the material to remove and add based on a refill factor that is different from the cut factor. For example, an existing subsurface material area for a corridor may have to be removed if it comprises loose soil or marsh land, and refilled with a different type of material to provide structural stability.

- **Earthworks**. Used to calculate the total cut and fill volumes. For example, this could be any differences between the existing ground (EG) surface and the finished ground (FG) surface:



- **Structures**. Used to calculate the volumes of corridor shapes, for example, in the following illustration, which is a cross-section of a corridor, the volume of the sidewalk shape would be calculated:


**Cut, Fill, and Refill Factors**

Use Cut, Fill, and Refill factors to adjust volumes to be hauled. As the hauled volumes are used as a baseline set at an even factor of 1.0. The adjustment factors are:

■ **Cut factor** - As the volume of material generally expands after it is removed, the cut factor is usually set to greater than 1.0, indicating swell or expansion. For example, a 1.2 cut factor would mean that for every 1.0 cubic meter of material removed, 1.2 cubic meters of volume would need to be accounted for transport.

■ **Fill factor** - As the material generally compacts when used as fill, the fill factor is usually set to less than 1.0, which indicates compaction or shrinkage of the material. For example, a 0.8 fill factor would mean that for every 0.8 cubic meter of material required for the fill site, 1.0 cubic meter of that material would need to be transported.

■ **Refill factor** - As this factor depends on the cut material type and other considerations, it can run across a range. A heavy aggregate might have a Refill factor of 1.0, while fill cut from a rock ledge might have a Refill factor of 1.2. Not all cut material may even be reusable, as when it is cut from bog or marsh. The refill factor would then be 0.

**Creating new criteria**

1  In Toolspace, on the Settings Tree, expand the  Quantity Takeoff collection. Right-click the Quantity Takeoff Criteria collection. Click New.

2  In the Quantity Takeoff Criteria dialog box, click the Information tab (page 2321).

3  To edit the name of the criterion, enter a new name in the Name field.

4  To edit the description of the criterion, enter a new description in the Description field.

5  Click Apply to make the changes, or click OK to make the changes and close the Quantity Takeoff Criteria dialog box.

6  To define or edit the criterion, click the Material List tab (page 2321).

7  Click Add New Material.

8  Select the new material. Click the Quantity Type field. Select the quantity type, either Cut, Fill, Cut and Refill, Earthworks, or Structures.

9  Click the Shape Style field. Select the default style used to display the material section in a section view.

10 Optionally, edit the cut, fill, and refill factors by selecting the corresponding fields. Enter new values.

11 If you selected a quantity type of Cut, Fill, Cut and Refill, or Earthworks to add surfaces, select the new material. From the Data Type list, select Surface. In the Select Surface list, enter the surface name or select a surface.

12 If you selected a quantity type of Structures, to add corridor shapes, select the new material. Select Corridor Shapes from the Data Type list. In the Select Shape list, enter the shape name or select a shape. Click the Shape Style field. Select a style for the shapes.

**13** For each data type added to a material, click the Condition field. Select the condition.

**14** Optionally, repeat Steps 7 through 13 to create all required materials and surfaces.

**15** Click Apply.

**Defining criteria from a sample line group**

**1** In Toolspace, on the Settings Tree, expand the  Quantity Takeoff collection. Right-click the Quantity Takeoff Criteria folder and click New.

**2** In the Quantity Takeoff Criteria dialog box, click the Information tab (page 2321).

**3** To edit the name of the criteria, enter a new name in the Name field.

**4** To edit the description of the criteria, enter a new description in the Description field.

**5** Click Apply to make the changes, or click OK to make the changes and close the Quantity Takeoff Criteria dialog box.

**6** To define the criteria, click the Material List tab (page 2321).

**7** Click Define From A Sample Line Group

**8** In the Define Material Criteria dialog box, click the Select Alignment field. Select the alignment or click  to select an alignment in the drawing.

**9** Click the Select Sample Line Group field to select a sample line group.

**10** Select the surfaces to use in the criteria by selecting or clearing the check box in the Select field next to the surface name.

**11** Click OK.

**12** In the Quantity Takeoff Criteria dialog box, click Apply or OK.

Dialog Box

Quantity Takeoff Criteria (page 2321)

# Analyzing Sectional Volumes

Use the quantity takeoff functionality to extract and report sectional material volumes, based on sample line groups.

You can create tables and reports about:

■ Volumes along an alignment, comparing various design surfaces and existing ground surfaces.

■ Volumes for shapes, which are closed cross-sectional areas created by a single subassembly. For example, a curb (a closed area within a concrete curb or curb and gutter).

■ Volumes between various (designed/grading/existing) formations.

**TIP** To query composite and bounded volume differences between surfaces, use surface volume reporting. For information, see Calculating Surface Volumes (page 690).

Quantity takeoff reporting uses criteria settings that are portable and extensible. You can create criteria based either on existing data including surfaces and sample line groups or on standard surface names.

You prepare to generate quantity takeoff information by creating a list of materials and applying the predefined criteria to it, mapping existing surfaces or other objects to the names in the criteria. After the material list is generated, the settings and volume calculations are stored with the sample line group and can be used to generate tables and reports.

You can display quantity takeoff information using standard AutoCAD Civil table formats or view and export it in an XML format file.

## Analyzing Sectional Volumes

Use the table and report creation commands to analyze sectional volumes.

The results of a quantity takeoff calculation are displayed using one of the following three methods:

- Total Volume Table

- Material Volume Table

- Quantities Report

A Total Volume Table contains cut, fill, and cumulative volume information (for example, an earthworks or cut/fill report).

A Material Volume Table contains cut, fill, and cumulative volume information for a specific material in the material list (for example, the cumulative volume of a structure element).

A Quantities Report is an XML format file that contains the criteria definition (comparable surfaces), material types (such as cut type), shrink and swell factors, as well as refill factors. The specific format is determined by the style sheet you select.

Before you create a quantity takeoff report or table, materials must be defined in the Sample Line Group properties or computed using the Compute Materials command.

**Style Sheets**

Three style sheets installed with AutoCAD Civil are used to create external quantity takeoff reports:

- *Earthworks.xsl*. Reports station-by-station values in a tabular format for cut and fill volumes, incremental volumes, and cumulative net volume.

- *Select Material.xsl*. Reports station-by-station values for the selected materials. At each station, all selected materials defined in this criteria and cumulative volumes are reported.

- *Mass Haul - Multiple Materials.xsl*. If you have defined many material types to remove (for example, for embankment creation for road widening along the corridor), you can use this style sheet to aggregate the material types and produce material-by-material reports at each station as well as aggregate volume reports for mass hauls.

**To create a total volume table**

1 Click Analyze tab ➤ Volumes And Materials panel ➤ Total Volume Table 📊 .

2 In the Create Total Volume Table dialog box (page 2303), select a table style and layer.

**3** Click the Select Alignment field. Select an alignment from the list or click  to select an alignment in the drawing.

**4** Click the Select Sample Line Group field. Select a sample line group from the list.

**5** Click the Select Material List field. Select a material list from the list.

**6** Optionally, select Split Table, and then specify the maximum and minimum number of rows in a table, the distance to offset tables from each other, and the method for arranging multiple tables.

**7** Under Behavior, specify whether the table is static or dynamic.

**8** Click OK.

The upper-left corner of the new table is attached to your cursor.

**9** Click in the drawing to set the location of the table.

**To create a material volume table**

**1** Click Analyze tab ➤ Volumes And Materials panel ➤ Material Volume Table  .

**2** In the Create Material Volume Table dialog box (page 2303), select a table style and layer.

**3** Click the Select Alignment field. Select an alignment from the list or click  to select an alignment in the drawing.

**4** Click the Select Sample Line Group field. Select a sample line group from the list.

**5** Click the Select Material List field. Select a material list from the list.

**6** Click the Select a Material field. Select a material from the list.

**7** Optionally, select Split Table, and then specify the maximum and minimum number of rows in a table, the distance to offset tables from each other, and the method for arranging multiple tables.

**8** Under Behavior, specify whether the table is static or dynamic.

**9** Click OK.

The upper-left corner of the new table is attached to your cursor.

**10** Click in the drawing to set the location of the table.

**To generate an external quantity takeoff report**

**1** Click Analyze tab ➤ Volumes And Materials panel ➤ Volume Report 

**2** In the Report Quantities dialog box (page 2323), click the Select Alignment field. Select an alignment from the list or click  to select an alignment in the drawing.

**3** Click the Select Sample Line Group field. Select a sample line group from the list.

**4** Click OK.

**5** Click the Select Material List field. Select a material list from the list.

**6** Enter a style sheet name in the Select A Style Sheet field or click  to browse for one.

**7** To display the quantity takeoff report, select the Display XML Report check box.

**8** Click OK to save the report settings and generate the report.

## Quantity Takeoff Table Styles

Styles control the way quantity takeoff tables are displayed in a drawing.

In AutoCAD Civil, all objects have a standard object style grouping on the Settings tree, called an object style collection. You use this to create, edit, copy, and delete the styles for that object. For more information, see The Object Style Collection (Settings Tree) (page 94).

## Creating and Editing Quantity Takeoff Table Styles

Use the Toolspace Settings tree to copy, edit, or delete a quantity takeoff table style.

Two types of quantity takeoff table styles are listed in the Settings tree under the Quantity Takeoff collection: Total Volume and Material. The two types of table styles have the same properties as other AutoCAD Civil table styles except for the property fields that can be included in the table.

If you generate a quantity takeoff report, the style of the external file is controlled using the specified style sheet. For more information, see the report generation information in Analyzing Sectional Volumes (page 1168).

Create a new quantity takeoff table style by copying an existing style. Then change its properties to suit your requirements. Use the Table Style dialog box (page 2437) tabs to specify the main properties.

---

**NOTE** Before editing an existing quantity takeoff table style to change its properties, remember that any changes you make will apply to tables that use the style. If you want to change the style of some quantity takeoff tables but not all, consider creating a new style.

---

**To create a new quantity takeoff table style**

1   In Toolspace, in the Settings tree, under Quantity Takeoff, expand the Table Styles collection.

**2** For the Total Volume or Material collection, do one of the following:

- Right-click the collection. Click New.

- Right-click the existing style to use as a template. Click Copy.

**3** In the Table Style dialog box (page 2437), enter or change the name of the style and other settings as required.

**4** Click OK.

**To copy an existing quantity takeoff table style**

**1** In Toolspace, in the Settings tree, under Quantity Takeoff, expand the Table Styles collection.

**2** Expand the Total Volume or Material collection.

**3** Right-click an existing style. Click Copy.

**4** In the Table Style dialog box (page 2437), edit the name of the style and other settings as required.

**5** Click OK.

**To edit a quantity takeoff table style**

**1** In Toolspace, in the Settings tree, under Quantity Takeoff, expand the Table Styles collection.

**2** Expand the Total Volume or Material collection.

**3** Right-click the style you want to edit. Click Edit.

**4** In the Table Style dialog box (page 2437), change settings as required.

**5** Click OK.

**To delete a quantity takeoff table style**

**1** In Toolspace, in the Settings tree, under Quantity Takeoff, expand the Table Styles collection.

**2** Expand the Total Volume or Material collection.

**3** Right-click the style to delete. Click Delete.

**4** In the confirmation dialog box, click Yes.

# Using Mass Haul Diagrams

Use mass haul diagrams to display earthwork volumes along an alignment, based on sectional volume computation.

The use of mass haul (page 2477) diagrams helps designers and contractors understand where gross material movements occur and as key indicators used to compare the economies of alternative designs. These diagrams are typically presented along with profile views for design review. They are used to analyze the following aspects of the design:

■ Distance over which the cut and fill will balance

■ Amount of material to be moved and the direction of movement

■ Identification of borrow pit (page 2469)s and dump site (page 2473)s

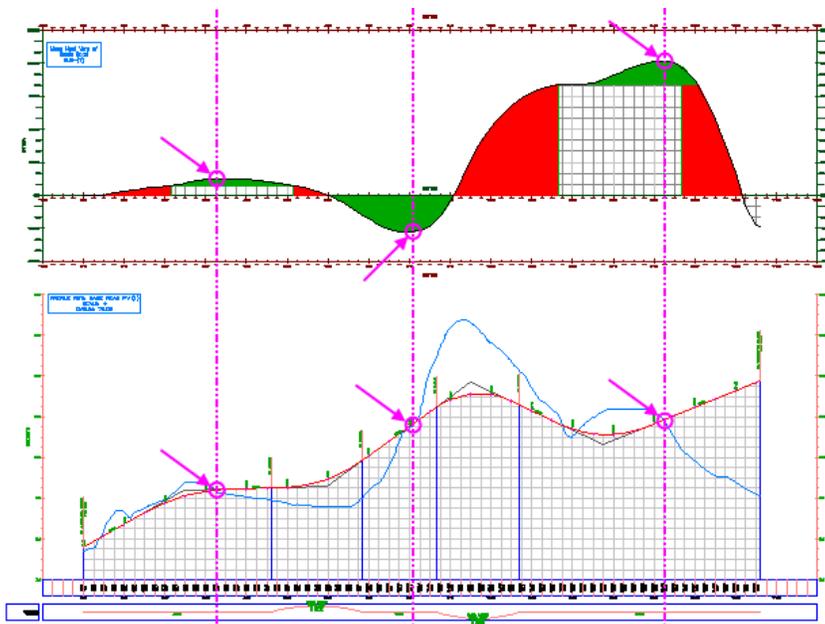
To generate mass haul diagrams, you need an alignment, a sample line group, and a list of materials.

For information about creating a material list, see Generating Material Lists (page 1163).

# Mass Haul

Measure mass haul volumes and mark grade points, balance points, and free haul and overhaul volumes.

A mass haul (page 2477) diagram presents a graphical view of material moved in the proposed design site, displaying balance point (page 2468)s, free haul (page 2474) and overhaul (page 2479) regions, and grade point (page 2475)s. Mass haul diagrams are graphed with stations (sample lines) along the x-axis and cumulative material (typically earthworks) volume on the y-axis. The middle axis (zero cumulative volume) line is called the balance line (page 2468). When the mass haul line (page 2478) rises, it indicates that a project is in a cut region and when it descends, it is in a fill region. A mass haul region is marked with balance points and grade points.



**Grade points (indicated by arrows and circles) in a mass haul diagram (above) and in a profile view connected by lines**

## Free Haul and Overhaul

Represent free haul and overhaul volumes using grade point and balance point methods.

During project development, contractors and design engineers may try to balance the mass haul requirements by considering free haul (page 2474) distances, any overhaul (page 2479), and the use of borrow pit (page 2469)s for embankments and dump site (page 2473)s for extra excavated volumes, based on the economic haul limits and the site conditions.

In AutoCAD Civil, you can specify the free haul distance as required. You can also specify the location of borrow pits and dump sites along the roadway, with assumed capacity of the borrow pits or dump sites.

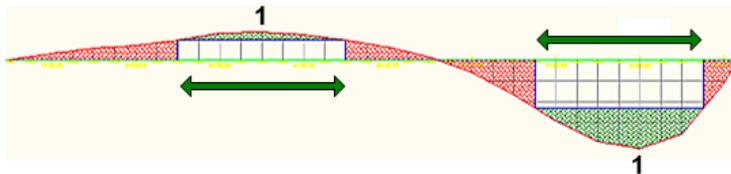
There are two ways of representing free haul (and any overhaul) in mass haul diagrams in AutoCAD Civil:

■  measured from grade point (page 2475)s

■  measured from balance point (page 2468)s

## Measure from Grade Points

Represent free haul and overhaul from grade points along the mass haul line.

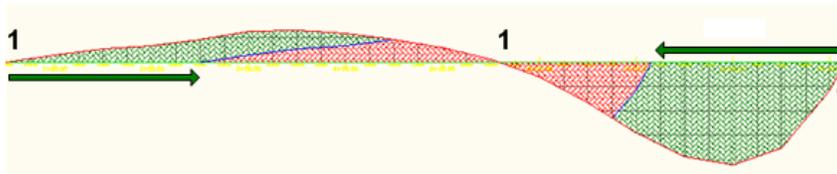


**Grade Point Method: The arrows indicate free haul distance, The number (1) indicates grade points. Freehaul volume is indicated in green (and by the grid between the green areas and the balance line) and overhaul volume is indicated in red.**

From grade point (page 2475)s, a segment the length of the free haul distance, which is parallel to the balance line (page 2468), is dropped so that the ends of the segment just touch the mass haul line (page 2478). The area enclosed within the segment and the mass haul line represents the free haul volume. Further, perpendicular lines from the ends of the segment are dropped so that they touch the balance line. The areas enclosed within these lines, the balance line, and the mass haul line represent the overhaul volume.

## Measure from Balance Points

Represent free haul and overhaul from balance points, where the mass haul line and balance line meet.



**Balance Point Method: The arrows indicate free haul distance. The number (1) indicates balance points. Freehaul volume is indicated in green and overhaul volume is indicated in red.**

In a mass haul diagram, the balance point (page 2468)s are located on the balance line, where the net volume is zero. In the balance points method of measuring free haul, the mass haul line is duplicated and shifted horizontally to the right (where the project transitions from cut to fill) or to the left (where the project transitions from fill to cut) by the free haul distance. The area enclosed by the two mass haul lines on the left if above the balance line, or on the right if below the balance line, represents the free haul volume. The remaining intersecting area represents the overhaul.

# Creating and Editing Mass Haul Diagrams

Create a mass haul diagram using the Create Mass Haul Diagram wizard, and edit the mass haul diagram's properties, styles, and settings.

## Creating Mass Haul Diagrams

Create a mass haul diagram to display a partial or overall view of earthwork volumes.

Using the Create Mass Haul Diagram wizard (page 2301), you can create a mass haul diagram with a single click, accepting the default settings for name, style, display, and balancing options. Later, you can change the default settings in the Mass Haul Properties dialog box (page 2309). Alternatively, you can specify settings in the wizard.

You must have a material list for the drawing before you can create a mass haul diagram. A mass haul diagram (top) can be mapped directly to a profile view (bottom) created from the same alignment.

For information about how to create a material list, see Generating Material Lists (page 1163).

**To create a mass haul diagram**

1   Click Analyze tab ➤ Volumes And Materials panel ➤ Mass Haul.
    The Create Mass Haul Diagram wizard (page 2301) is displayed.

2   On the General page (page 2301), do any of the following:
    ■ Specify the alignment from which the mass haul diagram will be created.

    ■ Specify the sample line group from which the mass haul diagram will be created.

    ■ Specify a mass haul view style.

    ■ To edit the mass haul view style, next to Mass Haul View Style, click . (See Editing Mass Haul View Styles (page 1178).)

3   On the Mass Haul Display Option page (page 2301), do any of the following:
    ■ Select a material list.

    ■ Select a material to display as mass haul line (Total Volume, Total Cut Volume, Total Fill Volume, Total Unusable Volume, and any other material associated with the material list).

    ■ Specify a mass haul line style.

    ■ To edit the mass haul line style, next to Mass Haul Line Style, click . (See Editing Mass Haul Line Styles (page 1177).)

**4** On the Balancing Options page (page 2302), specify a free haul distance, and the type, location, and capacity of borrow pits and dump sites.

**5** Click Create Diagram.

**6** In the drawing, find a suitable location for the mass haul diagram. For ease of viewing, place the diagram outside the surface boundary, and above or below any section or profile views. Click that location to set the origin of the balance line at the left side of the mass haul diagram.

The mass haul diagram is displayed.

## Editing Mass Haul Properties

Edit mass haul properties to specify naming, description and other parameters for the mass haul lines and views.

## Editing Mass Haul Line Properties

Balance mass haul volumes by editing mass haul line properties.

Edit mass haul line properties to specify a new name or description for the mass haul line, to change the free haul distance, and to add or remove borrow pits or dump sites.

**To edit mass haul line properties**

**1** To select a mass haul line and open the Mass Haul Line Properties (page 2309) dialog box, do either of the following:

■ In Toolspace, on the Prospector tab, expand the Sites collection ➤ <site name> ➤ Alignments collection ➤ <alignment name> ➤ Sample Line Groups collection ➤ <sample line group name> ➤ Mass Haul Lines collection. Right-click the mass haul line whose properties you want to edit. Click Properties.

■ In the active viewport, select the mass haul line whose properties you want to edit. Right-click and click Mass Haul Line Properties.

**2** On the Information tab of the Mass Haul Line Properties dialog box, do any of the following:

■ Change the name of the current mass haul line.

■ Enter a description of the current mass haul line.

■ Specify the mass haul line style.

- To edit the current mass haul line style, under Object Style, click  . For more information, see Editing Mass Haul Line Styles (page 1177).

**3** On the Balancing Options tab, you can do any of the following:

- Specify a new free haul distance.

- Add or remove borrow pits and dump sites, specifying their type, location and capacity.

**4** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Dialog Box

Mass Haul Line Properties (page 2309)

## Editing Mass Haul View Properties

Edit mass haul view properties to specify a new name or description.

**To edit mass haul view properties**

**1** To select a mass haul view and open the Mass Haul View Properties dialog box (page 2312), do either of the following:

- In Toolspace, on the Prospector tab, expand the Sites collection ➤ <site name> ➤ Alignments collection ➤ <alignment name> ➤ Sample Line Groups collection ➤ <sample line group name> ➤ Mass Haul Views collection. Right-click the mass haul view whose properties you want to edit. Click Properties.

- In the active viewport, select the mass haul view whose properties you want to edit. Right-click and click Mass Haul View Properties.

**2** On the Information tab of the Mass Haul View Properties dialog box, you can do any of the following:

- Change the name of the current mass haul view.

- Enter a description of the current mass haul view.

- To edit the current mass haul view style, under Object Style, click  . (For more information, see Editing Mass Haul View Styles (page 1178).)

**3** Click OK.

### Quick Reference

## Editing Mass Haul Styles

Edit mass haul style to improve the display of the mass haul line and the mass haul view.

## Editing Mass Haul Line Styles

Edit the mass haul line styles to improve the display of the mass haul and balance lines, and free haul and overhaul volumes.

**To edit mass haul line styles**

1  In the active viewport, select the mass haul line whose styles you want to edit. Right-click and click Edit Mass Haul Line Style.

2  On the Free Haul tab (page 2311) of the Mass Haul Line Style dialog box, specify how you want to show free haul in the mass haul diagram: measured from grade points (page 1173) or measured from balance point (page 1173).

3  On the Display tab (page 2311), do any of the following:
   ■  In Component Display, set visibility and color for the Mass Haul Line, Free Haul Line, Free Haul Area Hatch, and Overhaul Area Hatch.

   ■  In Component Hatch Display, set the pattern, angle and scale of the hatching for Free Haul Area Hatch, and Overhaul Area Hatch.

4  On the Information and Summary tabs, set administrative information.

5  Click OK to save the edits to the mass haul line styles.

### Quick Reference

### Editing Mass Haul View Styles

Edit the mass haul view styles to improve the display of the mass haul graph and its annotation.

**To edit mass haul view styles**

1 In the active viewport, select the mass haul view whose styles you want to edit. Right-click and click Edit Mass Haul View Style.

2 On the Information tab of the Mass Haul View Style dialog box, specify administrative information, such as the name of the style, and a description of the style.

3 On the Graph tab, specify the vertical and horizontal scale, and the view direction.

4 On the Grid tab (page 2314), specify how you want to show the grid.

5 On the Title Annotation tab, specify attributes of the text used to annotate the graph.

6 On the Horizontal Axes and Vertical Axes tabs, specify attributes of the major and minor ticks in the graph.

7 On the Display tab (page 2321), in Component Display, set the visibility and color for the graph.

8 In the Summary tab, modify information specified on other tabs.

9 Click OK to save the edits to the mass haul view styles.

Dialog Box

Mass Haul View Style (page 2313)

# Editing Mass Haul Settings

Use mass haul settings to specify the default style and name format settings for mass haul lines and views and the default behavior for mass haul-related commands.

Settings are handled in a standard way throughout AutoCAD Civil. Access settings using the Toolspace Settings tree. Control settings at three levels: the drawing level, the object collection (feature) level, and the command level. For more information, see Understanding Settings (page 61).

On the Toolspace Settings trees, use the Mass Haul Line and Mass Haul View collection shortcut menus to establish defaults for all of the mass haul-related features and commands. You can change mass haul line- and mass haul view-specific settings at this level, or you can override the drawing ambient settings.

## Editing Mass Haul Line Settings

Edit mass haul line style settings to specify defaults for new mass haul diagrams.

**To create a new mass haul line style**

**1** In Toolspace, in the Settings tree, under Mass Haul Line, expand the Mass Haul Line Style collection.

**2** For the Mass Haul Line Style collection, do one of the following:
- Right-click the collection. Click New.

- Right-click the existing style to use as a template. Click Copy.

**3** In the Mass Haul Line Style dialog box (page 2310), enter or change the name of the style and other settings as required.

**4** Click OK.

**To edit a mass haul line style**

**1** In Toolspace, in the Settings tree, under Mass Haul Line, expand the Mass Haul Line Style collection.

**2** Right-click the style you want to edit. Click Edit.

**3** In the Mass Haul Line Style dialog box (page 2310), change the Free Haul or Display settings as required.

**4** Click OK.

### Quick Reference

## Editing Mass Haul View Settings

Edit mass haul view settings to specify default graph style and command settings for new mass haul diagrams.

**To create a new mass haul view style**

**1** In Toolspace, in the Settings tree, under Mass Haul View, expand the Mass Haul View Style collection.

**2** For the Mass Haul View Style collection, do one of the following:
- Right-click the collection. Click New.

- Right-click the existing style to use as a template. Click Copy.

**3** In the Mass Haul View Style dialog box (page 2313), enter or change the name of the style and other settings as required.

**4** Click OK.

**To edit a mass haul view style**

**1** In Toolspace, in the Settings tree, under Mass Haul View, expand the Mass Haul View Style collection.

**2** Right-click the style you want to edit. Click Edit.

**3** In the Mass Haul View Style dialog box (page 2313), change the Graph, Grid, Title Annotation, Horizontal Axes, Vertical Axes, or Display settings as required.

**4** Click OK.

**To edit mass haul view command settings**

**1** In Toolspace, in the Settings tree, under Mass Haul View, expand the Commands collection.

**2** Right-click CreateMassHaulDiagram. Click Edit Command Settings.

**3** In the Edit Command Settings - CreateMassHaulDiagram dialog box (page 2304), expand the Mass Haul Creation tree.

**4** Specify the Analyze Free Haul value as True.

**5** Specify the Free Haul Distance value or leave the default setting.

**6** Specify the Borrow Pit Capacity value or leave the default setting.

**7** Specify the Dump Site Capacity value or leave the default setting.

**8** Click OK.

| GenerateQuantitiesReport | Generates an external quantity takeoff report (page 1168) |

# Pipe Networks

# Pipe Networks

# 27

Use AutoCAD Civil pipe network features to draw 2D and 3D models of utility systems, such as storm sewers, sanitary sewers, and more.

You can create, edit, and delete pipe networks in plan view. You can also display pipe network parts in profiles and section views. Changes made to pipe networks in plan view are dynamically updated in any profile and section views.

Style-based rendering and labeling capabilities let you quickly create pipe networks with meaningful visual effects and data. For example, you can use many different styles to represent two-dimensional pipe networks in construction documents. You can also use visual rendering features to add realistic looking effects to three-dimensional pipe networks. Labeling features let you automatically add labels to identify specific types of pipes and structures within a pipe network.

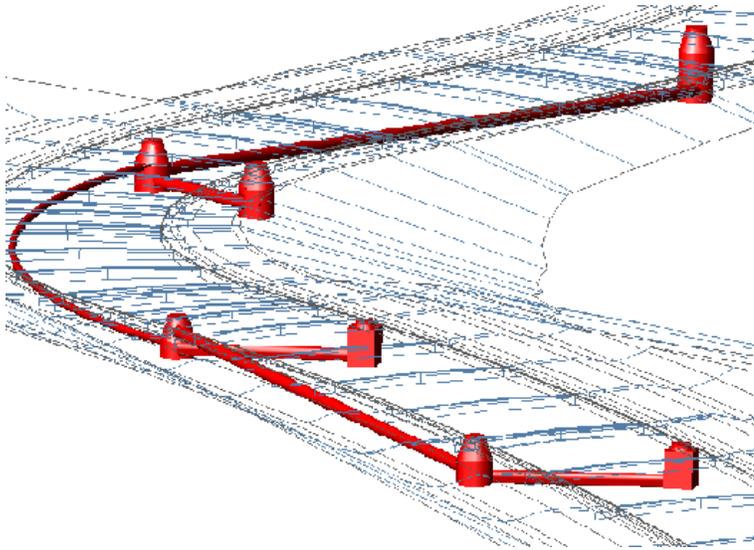
AutoCAD Civil also has interference checking features let you quickly identify areas where pipes or structures physically collide, or are too close to one another.

You can also import or export pipe network data using Autodesk LandXML format, or analyze pipe network data through an API interface or with support from external, third-party analysis programs.

Pipe Networks Workflow

Pipe Networks Best Practices

## Understanding Pipe Networks

In AutoCAD Civil, a pipe network object serves as a container for managing pipe objects and structure objects that form a pipe network.


A pipe network can contain pipes only, structures only, or, more commonly, both pipes and structures. A part catalog provides access to pipe network items, such as circular, elliptical, or rectangular pipes, manholes, catch basins, and headwalls, and more.

After you have added a pipe network to your drawing, you can edit it in the following ways:

- Add, delete, change, swap, or move pipes or structures

- Resize pipes and structures

- Move a pipe network

- Create a parts list comprised of only the part catalog items needed for a particular project or network

- Edit elevations and sizes numerically or graphically

- Add, change, or delete labels on pipes, a span of connected pipes, structures, or on the entire pipe network

- Change the style of any pipe or structure in the pipe network

- Use styles to display pipes and structures according to their true shapes, or choose a symbolic representation, such as a block, for a structure

After the pipe network is created, you can extract a variety of data using LandXML export. For information, see LandXML Import and Export (page 1673).

Like other AutoCAD Civil objects, display styles for pipe network objects are based on styles assigned to the objects: specifically, the pipe objects and structure objects. Before creating pipe networks, you should be familiar with both creating and managing styles (page 53) and command settings (page 97).

## The Pipe Network Object

A pipe network object manages a collection of pipe objects and structure objects that are associated with each other to represent a pipe system.

Typically, the pipes and structures are connected to each other, forming a single pipe run or pipe network. The pipe and structure objects in a pipe network can be associated with a referenced alignment and or a surface, which provide them with station offset and elevation data. Each part in a pipe network can reference any given surface or alignment in the drawing.

The following sections describe the components that can comprise a pipe network:

**Pipe Network**

The pipe network object is used as the container object to associate pipes and structures that are part of the same pipe run or pipe network. A pipe network typically contains pipe objects and structure objects. Pipe network object names are displayed in the Prospector tree and in the Prospector list view.

**Pipe**

A pipe object is a drawing shape that represents straight or curved pipes used in utility networks, such as sewer and irrigation systems. In a drawing, the three-dimensional pipe shape is defined by: 1) the two-dimensional Part Shape (circular, elliptical, egg-shaped, or rectangular) of the pipe part that is selected from the part catalog; and 2) by specifying a linear path (for straight piped) or a curved path (for curved piped). Object names for pipes are not displayed in the Prospector tree. They are, however, displayed in the Prospector list view when you click Pipes under a pipe network in the Prospector tree.

**Structure**

A structure object is a drawing shape that is used to represent items, such as manholes, catch basins, and headwalls, used in utility networks. Structure shapes are inherently more complex than pipe shapes. In a drawing, the three-dimensional structure shape is defined by the definition of the structure part that is selected from the part catalog. Like pipes, object names for structures are not displayed in the Prospector tree. They are, however, displayed in the Prospector list view when you click Structures under a pipe network in the Prospector tree.

**Null Structure**

A null structure object is a special type of structure object that is inserted automatically when you connect a pipe directly to another pipe, with no structure shape between the two pipes. Just like other types of structure objects, object names for null structures are not displayed in the Prospector tree, but are displayed in the Prospector list view. You can assign a style to null structures so that they are not visible in the drawing.

**Part Catalog and Parts List**

AutoCAD Civil comes with a pipe network part catalog that contains a variety of pipe and structure shapes organized into part families and part sizes. Since the part catalog contains many items, you can create a parts list containing only the parts (pipes and structures) that you will use for a particular pipe network. Using a parts list saves you from having to navigate through the entire part catalog to find a desired part. For more information, see Part Catalog and Parts Lists (page 1237).

For overview information about AutoCAD Civil objects, see Understanding Objects (page 51).

# Pipe Network Styles and Display

Specify a variety of style and display characteristics for displaying pipes and structures in plan view, profile views, and section views.

When you first create a pipe network, the pipe and structure objects get their default style, render material, and rules from definitions in their referenced parts list.

After the pipe and structures are inserted into the drawing, the styles and rule settings for the pipe or structure object can be changed using either the Pipe Properties or the Structure Properties dialog box. You can also use the Pipe Network Vistas (page 2064) view to edit style or property values.

If you choose to run interference checks on pipe networks, you can set styles for displaying interferences.

The following table describes the ways you can specify styles for pipes and structures in a pipe network:

| To specify this style... | use the... |
| --- | --- |
| Default object style, rules, and render material for pipe and structure objects | Parts List definition. Specifically, you use the Pipes tab (page 2035) or the Structures tab (page 2036) of the Network Parts List dialog box. |
| Label style for pipe network object during creation | Create Pipe Network By Layout Dialog Box (page 2023) |
| Object style, rules, or render material for pipe and structure objects already in a drawing | Pipe Properties Dialog Box (page 2039) or Structure Properties Dialog Box (page 2051) |
| Display style for pipes or structures displayed in plan, profile, and section views already in a drawing | Pipe Style Dialog Box (page 2045) or Structure Style Dialog Box (page 2058). You can also override styles in Profile View Properties dialog box. |
| Display style for pipe network interferences | Interference Style Dialog Box (page 2074) |

In addition to specifying and editing object styles, display styles, rules, and render material, you can also add labels to pipe and structure objects either during creation or after the objects have been added to a drawing. For more information about pipe and structure labels, see Labeling Pipe Networks (page 1261).

For more information about styles, see Object Styles (page 53).

## Pipe Networks Collection (Prospector Tab)

Use the Pipe Networks collection in the Prospector tree to access the pipe networks and interference checks in a drawing or a project.

As pipe network objects are created, they are displayed in the Networks collection under the Pipe Networks collection. Expand the Networks collection to view the names of the pipe networks. Click Pipes or Structures to display a tabular list of the pipe network object informations in the Prospector list view. For more information, see The Toolspace Item View (page 82).

You can also view interference check results by expanding the Interference Checks collection. For more information, see Checking for Interferences (page 1226).

## Pipe Network Collection (Settings Tab)

Use the Pipe Networks collection in the Settings tree to manage pipe network settings, parts lists, interference styles, and command settings.

The Pipe Network object does not have any display styles. However, elements within the Pipe Network object, such as pipe objects and structure objects, have their own display styles. When you insert a pipe or structure object into a drawing, its default style comes from the part's style definition in the parts list. After the part is inserted into the drawing, you can change its style settings.

Right-click the Pipe Networks collection to do the following:

- Edit the pipe network feature settings. (page 1201)

- Refresh the display of the settings tree.

Expand the Pipe Networks collection to display and edit the command settings that are available for pipe networks.

## Pipe Collection (Settings Tab)

Use the Pipe collection in the Settings tree to manage pipe styles, pipe rule sets, pipe label styles, and pipe table styles.

| For information about ... | See... |
| --- | --- |
| pipe styles | Pipe Network Styles and Display (page 1187) |
| pipe rule sets | Part Rules (page 1247) |
| pipe label styles | Labeling Pipe Networks (page 1261) |
| pipe table styles | Adding Pipe Tables (page 1271) |

## Structure Collection (Settings Tab)

Use the Structure collection in the Settings tree to manage structure styles, structure rule set styles, structure label styles, and structure table styles.

| For information about ... | See... |
| --- | --- |
| structure styles | Pipe Network Styles and Display (page 1187) |
| structure rule sets | Part Rules (page 1247) |
| structure label styles | Labeling Pipe Networks (page 1261) |
| structure table styles | Adding Structure Tables (page 1272) |

## Common Part Terms

This section provides descriptions for some terms that are commonly used when referring to pipe network parts.

**Structure Terms**

■ Rim. The top elevation of a manhole or catch basin (junction) structure.

■ Frame. The support for the cover on a manhole or grate for a catch basin. The top elevation of the frame, cover, and grate typically coincides with the insert (rim) elevation.

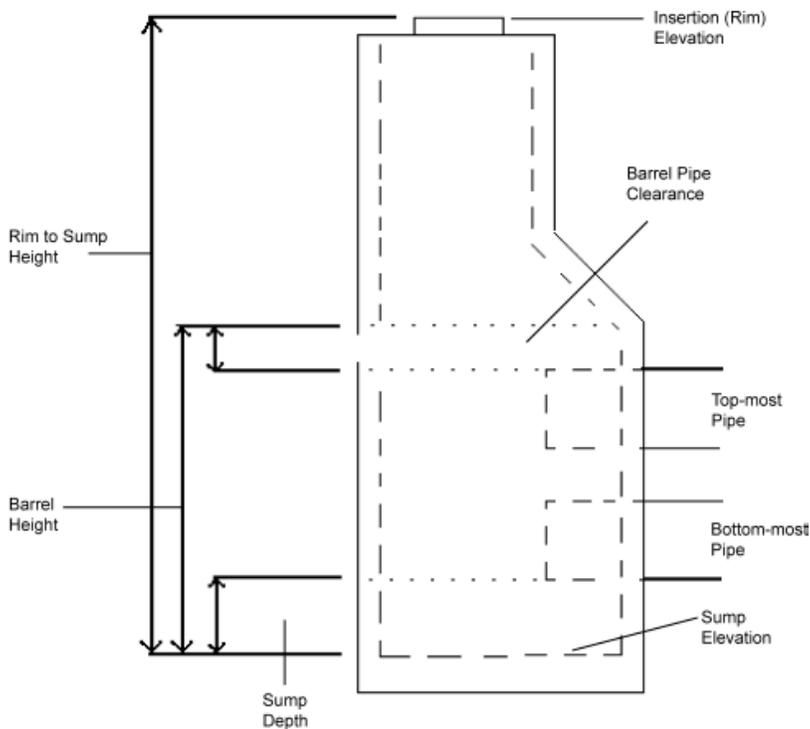
■ Cover. The top access cover of a manhole, used for servicing or inspecting the manhole. Covers are typically circular in shape, but they can also be triangular, so that they do not fall into the manhole when removed. The cover sits in the frame and is usually constructed of cast iron.

■ Grate. The top opening of a catch basin that typically contains numerous openings to allow surface water entry into the structure. The grate sits in the frame and is usually constructed of cast iron. Grates can be various shapes but are typically circular or square.

■ Sump and sump depth. Sump refers to the bottom area or chamber on the inside of a junction structure, such as a catch basin. The sump area is sometimes used as a reservoir to catch debris. Sump depth refers to the distance from the bottom of the inside of the structure to the lowest invert of all pipes connected

to it. The sump depth for a particular type of structure can vary according to design requirements. Manholes typically have no sump depth.

The following illustration shows the locations of components on a typical junction structure.



**Pipe Terms**

■ Invert. The elevation of the inside bottom of a pipe. Also referred to as flowline.

■ Crown. The elevation of the inside top of a pipe.

■ Pipe centerline elevation. The elevation of the centerline of a pipe.

■ Cover or Depth. Refers to the depth of the material above the topmost outer part of a pipe.

■ Slope. When slope is used to refer to the slope of a pipe, it is a measure of steepness. For pipes, the slope is defined by rise (or fall) over run, where rise is the difference in elevation along a run of pipe length, measured horizontally. Slope is typically represented in percent. For example, a slope of pipe at 2% means that for every 100 feet of horizontal length of pipe, the pipe rises 2 feet. In AutoCAD Civil, the slope can be represented in a variety of ways in dialog boxes and in labels in the drawing.

## Hydraulics and Hydrology Feature Overview

You can display hydraulics and hydrology properties in AutoCAD Civil pipe networks.

External applications can be used to add hydraulics and hydrology property information to AutoCAD Civil pipe networks. It is also possible to add hydraulics and hydrology property information directly to AutoCAD Civil pipe networks using the Pipe Network Vista (Panorama window). For more information, see Adding Hydraulic Property Data to AutoCAD Civil Pipe Networks (page 1280).

For more information about how to use these extensions, click Help on the menu bar of the application. The Help menu provides access to the online Help and PDF user's guide provided with each extension.

For information about using AutoCAD Civil to perform hydraulics and hydrology tasks, see Using Hydraulics and Hydrology Features (page 1274).

# Creating Pipe Networks

There are several ways you can create pipe networks.

For example, you can create a pipe network using the Network Layout Tools toolbar, or you can select an existing polyline or feature line in a drawing and create a pipe network from it. You can also use import features to import existing pipe networks into your drawing.

**Importing Pipe Data**

The following table describes the import features available for pipe networks.

| Command | Description |
| --- | --- |
| Import Data From Land Desktop | You can use the Import Data From Land Desktop command (ImportLDTData) to import pipe run data from AutoCAD Land Desktop into AutoCAD Civil. When you import pipe data, each continuous pipe run in AutoCAD Land Desktop is imported as a new, single pipe network object in AutoCAD Civil. For more information, see Importing LandXML Drawing Data (page 1681). |
| LandXML Import | You can export pipe run data from AutoCAD Land Desktop using the LandXML Export command (LandXMLOut) and then import it into AutoCAD Civil using the LandXML Import command (LandXMLIn). For more information about these commands, see LandXML Import and Export (page 1673). |
| ImportStormSewerData | Using this command, you can create AutoCAD Civil pipe networks by importing pipe networks that were created in the Storm Sewers Extension from an *.stm* file. For more information, see Importing Pipe Network Data from an .stm File (page 1278). |

Before importing Land Desktop pipe run data, make sure the Parts List you associate with the pipe network has part sizes that make sense for the pipe run you will be importing. See Part Catalog and Parts Lists (page 1237) for more information.

**Managing, Displaying, and Customizing Pipe Networks**

All pipe networks, once created, are managed in the same way, regardless of the method used to create them. All pipe networks are listed in the Pipe Networks ➤ Networks collection in the Prospector tree.

Before creating a pipe network, it can be useful to first create the underlying data used by the pipe network, such as surfaces, alignments, profiles, section views, and your own custom parts lists. However, you do not have to have these components in place to create a pipe network.

| For information about creating... | See... |
| --- | --- |
| Surfaces | Creating Surfaces (page 601) |

| For information about creating... | See... |
|---|---|
| Alignments | Creating Alignments (page 887) |
| Profiles | Creating Layout Profiles (page 1048) |
| Section Views | Creating/Editing Section Views (page 1153) |
| Parts Lists | Part Catalog and Parts Lists (page 1237) |

When you create a pipe network, the default settings come from the selections you make in the Create Pipe Network dialog box, and from the part definitions specified in the part catalog. After the pipe and structure objects are in your drawing, you can change many of the settings for any new parts created in the network. For information about how to change pipe network default settings, see Changing Pipe Network Default Style Settings (page 1202).

## Creating a Pipe Network Using the Layout Tools

You can create a pipe network using the Network Layout Tools.

To create a new pipe network using the layout command, you must first enter a unique name for the pipe network on the create dialog box.

To automatically reference station and elevation data for the pipe network, you can associate the pipe network with an alignment and a surface.

You can also set label styles and specify automatic labeling as new parts are created. After making these choices or accepting the defaults, you can use the Network Layout Tools to draw the pipe network.

**To create a pipe network using the layout tools**

1   Click Home tab ➤ Create Design panel ➤ Pipe Network drop-down ➤ Pipe Network Creation Tools 🔧 , or in the Prospector tree, expand the Pipe Networks collection, then right-click the Networks collection, and click Create Pipe Network By Layout.

2   In the Create Network (page 2023) dialog box, in the Network Name field, enter a name for the pipe network.

   To name the pipe network, select a default name from the naming template, or enter a new name. For more information, see Name Template Dialog Box (page 1806).

3   In the Network Description field, enter an optional text description for this pipe network.

4   In the Network Parts List field, select a parts list or accept the default parts list for this pipe network. For more information, see Part Catalog and Parts Lists (page 1237).

5   To view or change the default layers that will be assigned to various pipe network parts as they are created, click Layers to open the Network Layers (page 2063) dialog box.

6   To reference a surface and/or an alignment, select the item from the list, or click to select a surface and/or alignment in the drawing.

7   Optionally, you may select label styles for pipes and structures added to the pipe network. When <none> is specified, no labels are added to the items, but you can add labels later if desired. See Labeling Pipe Networks (page 1261) for more information.

8   Click OK in the Create Pipe Network dialog box. The Network Layout Tools toolbar is displayed, and the pipe network name is displayed in the Pipe Networks collection on the Prospector tab.

**9** On the Network Layout Tools toolbar, select the desired parts (pipes and structures) in the Pipe List and Structure List. For example, select 48-inch Concentric Catch Basin for a structure, and 12-inch Concrete Pipe 1 US Imperial for a pipe. For more information, see Part Catalog and Parts Lists (page 1237).

**10** Select the types of pipe network objects you want to insert by clicking the Down Arrow button next to Draw Pipes And Structures and selecting one of the following:

- Pipes and Structures. Inserts pipes and structures during the same command operation. This is the default command when creating a new pipe network.

- Pipes Only. Inserts just one or more pipes (without inserting structures) into the pipe network.

- Structures Only. Inserts just one or more structures into the pipe network, without inserting any pipes.

Pipes and Structures is the default active layout command. The initial prompt (by default) upon entering the layout command is `Specify the structure insertion point:`

Upon reopening the layout toolbar, the default command is the last command that was used.

**11** Click the Toggle Upslope/Downslope button to set the direction of the pipe networks part(s) to either a positive slope value or direction (upslope) or a negative slope value or direction (downslope). This button acts as a toggle. Downslope is the default. When the downslope icon is displayed, each new pipe that is inserted will slope downstream from the previous part. When the upslope icon is displayed, each new pipe inserted will slope upstream from the previous part.

**12** Begin drawing the pipe network by specifying the insertion point for the first part (pipe or structure) of the pipe network.

**NOTE** If you are in Draw Pipes And Structures mode, the first click defines the first structure insertion point, as well as the starting point of the first pipe object. The second click specifies the end of the first pipe object, and inserts a new structure object connected to that pipe. Subsequent clicks specify insertion points for subsequent pipes and structures until you end the command by pressing Enter. If you are in Draw Pipes Only mode, each click specifies the insertion point for a pipe end (a pipe start point or end point). If you are in Draw Structures Only mode, each click specifies the insertion point for a structure.

**13** Specify the next insertion point in the drawing.

**14** When you finish drawing the pipe network, press Enter to end the command.

After you create a pipe network, you may want to refine parts of it. For example, you may want to add a new pipe or structure, remove parts, move parts, or add labels. For information, see Editing Pipe Networks (page 1203).

Command Line

CreateNetwork

Dialog Box

## Creating Pipe Networks from Objects

Create pipe networks from existing objects in your drawing.

Using this method, you can automatically create a pipe network from entities such as lines, arcs, 2D and 3D polylines, feature lines, or alignments.

The following table lists the types of entities you can use to create pipe networks:

| Entity | Description |
| --- | --- |
| Line | Creates a pipe network from a line that you selected. The pipe network is inserted as a straight pipe with structures at each end. |
| 2D polyline | Creates a pipe network from lightweight or heavyweight 2D polylines. |
| 2D spline polyline | Creates a series of straight line segments using fit points to define pipe endpoints and structure locations. For more information about fit points, see the AutoCAD Help. |
| 3D polyline | Creates a pipe network using vertices in 3D to define pipe endpoints and structure locations. |
| Arc | Creates a pipe network from an arc that you selected. The pipe network is inserted as a curved pipe with structures at each end. |
| Feature line | Creates a pipe network from a feature line. |
| Alignment | Creates a pipe network from an alignment. |

You can select objects in the current drawing or from an Xref. You can create a pipe network that includes the types of pipes and structures you specify.

This method of creating a pipe network uses the Pipes and Structures insertion method. You cannot use the Pipes Only or Structures Only insertion mode with this command. If you want to create a single pipe, or a single structure using this command, create the pipe network with pipes and structures, and then delete the desired parts.

For 3D entity types, you can select the Use Vertex Elevations option on the Create Pipe Network From Object dialog box. When this option is selected, the elevations of any vertices along the selected entity are used to set the elevations of the pipes created in the network. For 3D entity types, this option determines if the 3D vertex elevations are honored by the pipes created. When checking this option, rules are not applied as they would likely be in conflict with the vertex elevations

**To create a pipe network from an object**

1  Click Home tab ➤ Create Design panel ➤ Pipe Network drop-down ➤ Create Pipe Network From Object ![icon] .

2  In the drawing, select the object.

**NOTE** You can enter Xref to select an object from an Xref.

You may be prompted to reverse flow direction. Press Enter or click OK to keep the current flow direction. Click Reverse to change the current flow direction. Flow direction arrows indicate the direction of the flow.

**3** In the Create Pipe Network From Object (page 2024) dialog box, specify a name for the pipe network.

**4** In the Description field, enter an optional description for the pipe network.

**5** In the Network Parts List field, select a parts list or accept the default parts list for this pipe network. For more information, see Part Catalog and Parts Lists (page 1237).

**6** In both the Pipe To Create and Structure To Create fields, select the types of pipes and structures to be used.

**NOTE** You must select both a pipe and a structure type. After creating the pipe network, if desired, you can delete parts you want removed.

**7** To view or change the default layers that will be assigned to various pipe network parts, click Layers to open the Pipe Network Layers (page 2063) dialog box.

**8** To reference a surface and/or an alignment, select the item in the list, or click to select a surface and/or alignment in the drawing.

**9** If you want the originally selected object to be removed from the drawing automatically, clear the Erase Existing Entity check box.

**10** Select the Use Vertex Elevations check box if you want to use the elevations of any vertices along the selected entity to set the elevations of the pipes created in the network.

**NOTE** For 3D entity types, this option determines if the 3D vertex elevations are honored by the pipes created. When checking this option, rules are not applied as they would likely be in conflict with the vertex elevations.

**11** Click OK in the Create Pipe Network From Object dialog box.

The new pipe network is displayed in the drawing, and the pipe network name is displayed in the Pipe Networks collection on the Prospector tab.

# Creating Alignments from Pipe Network Parts

Use the Create Alignment From Network Parts command to create an alignment from existing pipe network parts.

Using this method, you can automatically create alignment objects from existing pipe network parts (pipes and or structures) in your drawing.

You can also automatically create a profile and/or profile view showing the parts when you create the alignment.

When you use this command, the new alignment is displayed in the drawing and in the top-level Alignments collection or specified Site on the Prospector tab. The pipe network parts you selected to create the alignment are unaffected by the creation of the alignment.

**To create an alignment from pipe network parts**

1  Click Home tab ➤ Create Design panel ➤ Alignment drop-down ➤ Create Alignment From Network Parts 

2  Select the first pipe network part (pipe or structure) to be used as the starting point for the alignment.

3  Select the next pipe network part to create a path for the alignment, or press Ctrl+Z to undo the previous path specified.

4  In the Create Alignment From Network (page 2025) dialog box, specify a Site or accept the default <None>. See Alignment and Site Interaction (page 721) for more information.

5  Enter a unique name for the alignment.

6  Enter an optional description for the alignment.

7  Specify an alignment style or accept the default style.

8  Specify the object layer settings.

9  Specify an alignment label set or accept the default label set.

10  Optionally, click Create Profile And Profile View to create a profile and a profile view from this alignment.

11  Click OK.

12  If you selected Create Profile And Profile View, the Create Profile View dialog box is displayed. Create the profile view and click OK.

The alignment name is displayed in the top-level Alignments collection or specified Site on the Prospector tab. The pipe network parts you selected to create the alignment are unaffected by the creation of the alignment.

## Drawing Straight Pipes

Draw straight pipes in a pipe network using the Network Layout Tools.

You can draw straight pipes when you are using the Draw Pipes And Structures insertion mode or when you are using the Pipes Only insertion mode.

After they are inserted, you can edit straight pipes using grips.

---

**TIP** You can use transparent commands for pipe network objects when you are prompted to specify radius, length, or station offset. For more information, see Using Transparent Commands Within a Running Command (page 1582).

---

**To draw a straight pipe in a pipe network**

1 Click Home tab ➤ Create Design panel ➤ Pipe Network drop-down ➤ Pipe Network Creation Tools 🗝️ to create a new pipe network, or Pipe Networks tab ➤ Modify panel ➤ Edit Pipe Network 📝 to select an existing pipe network.

2 On the Network Layout Tools toolbar, click or 🔩 .

3 Specify the start point for the pipe.

4 Specify the end point.

Network Layout Tools (page 2031)

## Drawing Curved Pipes

Draw curved pipes in a pipe network using the Network Layout Tools.

You can draw curved pipes when you are using 🔩 Draw Pipes And Structures insertion mode or when you are using the Pipes Only insertion mode.

No matter which insertion mode you are using, the resulting curved geometry is equivalent to the AutoCAD arc object, where the insertion point (or start point) of the pipe, the midpoint, and the endpoint of the curved pipe can be gripped to edit the arc.

Curved pipe objects do not have persistent tangency once the curved pipe is created. Therefore, once a curved pipe is grip edited, any tangency to adjacent pipes may be lost.

There are three ways that you can create curved pipes. Each of these methods are similar to methods used for creating alignment curves, or AutoCAD arc objects.

**Curve Creation Modes**

You can use the default curve creation mode when you are using the Pipes and Structures insertion mode, or when you are using the Pipes Only insertion mode. If you already have a structure inserted, and you are adding a pipe to it, clicking on the structure specifies the initial direction and start point for the curved pipe. You are then prompted for an end point.

This method is used when the curved pipe is starting from a structure (or a null structure) with only one pipe already connected to it. With this method, the initial start point for the curved pipe comes from the structure. The start direction comes from the one pipe that is already connected to that structure. This ensures that the curved pipe will be tangent to the last pipe drawn, or to a pipe that already exists at the structure (or null structure) from where the curved pipe is starting.

If no pipe is found to get a direction from, you are prompted to specify a direction at the first point.

**Specifying Two Points and a Radius**

Using this curved pipe creation mode, you specify the two endpoints of the curve and a radius. This method also lets you choose the curve direction (clockwise or counter-clockwise).

**Specifying Three Points**

Using this curved pipe creation mode, the first point is selected, then a point along the curve, then the curve endpoint.

---

**TIP** You can use transparent commands for pipe network objects when you are prompted to specify radius, length, or station offset. For more information, see Using Transparent Commands Within a Running Command (page 1582).

---

**To draw a curved pipe using the default curve creation mode**

1 On the Network Layout Tools toolbar, click ⬭ Pipes Only or ⬭ Pipes and Structures.

2 If you clicked Pipes and Structures mode, specify the insertion point for the structure.
  If you clicked Pipes Only mode, specify the first pipe point.

3 Enter c (curve), and press Enter to begin specifying the curve.

4 Specify the second point of the curve.

5 Specify the end point for the curve.

6 Press Enter to end the command.

**To draw a curved pipe by specifying two points and a radius**

1 On the Network Layout Tools toolbar, click ⬭ Pipes Only or ⬭ Pipes and Structures.

2 If you clicke ⬭ Pipes and Structures mode, specify the insertion point for the structure.
  If you clicked Pipes Only mode, specify the first pipe point.

3 Enter c (curve), and press Enter.

4 Enter r (radius) and specify a radius.

**5** Specify a curve direction, either clockwise or counter clockwise.

**6** Specify the end point for the curved pipe.

**7** Press Enter to end the command.

**To draw a curved pipe by specifying three points**

**1** On the Network Layout Tools toolbar, click �celⁿ Pipes Only or 🗃 Pipes and Structures.

**2** If you clicked 🗃 Pipes and Structures mode, specify the insertion point for the structure. If you clicked Pipes Only mode, specify the first pipe point.

**3** Enter c (curve), and press Enter.

**4** Specify the second point of the curve.

**5** Specify the end point for the curved pipe.

**6** Press Enter to end the command.

# Creating a Pipe Network Reference

You can create a reference to an existing pipe network in a data shortcut (page 2472) or a Vault project.

The pipe network reference is a lightweight read-only copy of the original, but it gives you access to the network design data. Before you create the pipe network reference, it must exist in the current project collection on the Toolspace Prospector tab.

**See also:**

■ Creating Data Shortcuts (page 131)

■ Vault: Checking a Drawing in to a Project (page 158)

**To create a reference to a data shortcut pipe network**

**1** In Toolspace, on the Prospector tab, in Master View, ensure that the correct working folder is identified on the Data Shortcuts node.

**2** Expand the Data Shortcuts ➤ Pipe Networks collection, right-click the desired network, and then click Create Reference.

The Create Pipe Network Reference dialog box is displayed, in which you can optionally change properties of the reference network, as described in the following steps.

**3** In the Create Pipe Network Reference dialog box, to change the source of the reference, select the source in the Source Pipe Network drop-down list.

**4** Enter a unique name for the pipe network and optionally, a description.

**5** Specify a parts list and object layer.

**6** Specify whether to override reference surface or alignment or select the defaults.

**7** Select to include, or not include, source drawing labels or select other label styles.

**8** Click OK to create the pipe network.

The pipe network name is displayed under the Pipe Networks collection in the Prospector tree with a ▣ next to it.

**To create a reference to a pipe network in a Vault project**

**1** In Toolspace, on the Prospector tab, in Master View, expand the Projects ➤ <project name> ➤ Pipe Networks collection, right-click the desired network, and then click Create Reference.

The Create Pipe Network Reference dialog box is displayed, in which you can optionally change properties of the reference network, as described in the following steps.

**2** In the Create Pipe Network Reference dialog box, to change the source of the reference, select the source in the Source Pipe Network drop-down list.

**3** Enter a unique name for the pipe network and optionally, a description.

**4** Specify a parts list and object layer.

**5** Specify whether to override reference surface or alignment or select the defaults.

**6** Select to include, or not include, source drawing labels or select other label styles.

**7** Click OK to create the pipe network.

The pipe network name is displayed under the Pipe Networks collection in the Prospector tree with a ⤴ next to it.

## Resetting Pipe Network Reference Labels

Use the Reset Network Labels command to reset a referenced network's labels to match the source drawing's labels.

You can make changes to reference network labels after referencing a pipe network into the current drawing.

Use this command when you have created a referenced pipe, and you want the labels in the referenced pipe to match the source drawing's labels, rather than the current drawing's labels.

For information about creating a pipe network reference, see Creating a Pipe Network Reference (page 1199).

**To reset a pipe network reference's labels**

1 Select the pipe network. Click Pipe Networks tab ➤ Labels & Tables panel ➤ Reset Labels .

2 Select a referenced pipe network part. The pipe network's labels are deleted and replaced with labels from the source drawing. If you select parts from multiple referenced pipe networks, changes apply to all of the referenced pipe networks.

**NOTE** After selecting this command, if there are no referenced pipe networks in the current drawing, an error message is displayed. If a source drawing is not found, an error message is displayed. If you select a part that is not from a referenced pipe network, you are prompted to select a referenced pipe network part.

## Editing Pipe Network Settings

Use pipe network settings to specify the default styles and behavior for pipe network commands.

Settings are handled in a standard way throughout AutoCAD Civil. You access settings using the Toolspace Settings tab. You can control settings at three levels: the drawing level, the object collection (feature) level, and the command level. For more information, see Understanding Settings (page 61).

In the Settings tree, you can use the Pipe Network collection, the Pipe collection, or the Structure collection to establish defaults. Use the Pipe Network collection to specify defaults for all pipe network commands. You can change object-specific settings at this level, or override the drawing ambient settings.

**NOTE** Overrides to the drawing ambient settings at the Pipe Network collection level, the Pipe collection level, the Structure collection level, and the Pipe Network Commands collection level affect only the specified level. The drawing level settings are not changed.

The topics in this section describe only those settings that affect pipe networks and pipe network commands. For more information about the drawing ambient settings for the Pipe Network, Pipe, and Structure collections, see Specifying Ambient Settings (page 68).

# Changing Pipe Network Creation Settings

Use the pipe network creation and naming settings in the Pipe Network Settings (page 2026) dialog box to change pipe network settings before you create a pipe network.

For example, before creating a pipe network, you may want to specify the default rules used for pipes or structures in the parts list when new parts are added to it.

Note that if a closed lock appears in the Lock column for a property, the property is locked at a higher level of the Settings tree. It cannot be changed at this level.

If you change a property value, a check mark is placed in the My Override column. This override is also noted in the property table for related objects higher up the Settings tree, where a green arrow appears in the Child Override column.

**To change pipe network creation settings**

1 Do one of the following:

■ **To edit settings for all pipe network commands**: In Toolspace, on the Settings tab, right-click the Pipe Network collection. Click Edit Feature Settings.

■ **To edit settings for a specific command**: In Toolspace, on the Settings tab, expand the Commands collection in the Pipe Network collection. Right-click the name of the command for which you want to change settings. Click Edit Command Settings. For example, right-click the CreateNetwork command and click Edit Command Settings.

The Edit Feature Settings (page 2026) dialog box is displayed.

2 To edit the default naming format for pipe networks and data that can be extracted from the pipe network, expand the Default Name Format property group. Edit the Name Template settings.

3 Click Apply.

## Quick Reference

Dialog Box

Edit Feature Settings (page 2026)

# Changing Pipe Network Default Style Settings

Use the pipe network settings to specify default object styles and labels for pipe network creation and for data that you create or extract from a pipe network.

The default styles specified in these settings are used to establish the default setting for the style in the Create Pipe Network and Pipe Network Properties dialog boxes.

**To change the pipe network style and label default settings**

1 In Toolspace, on the Settings tab, right-click the Pipe Network collection. Click Edit Feature Settings to open the Pipe Network Settings (page 2026) dialog box.

2 Expand the ▒ Default Styles property group.

**3** To specify a default style for pipe network objects, such as pipes and structures, or for render material, click the corresponding field. Click ⊡ to display the default style dialog box, where you can select a style.

**4** To specify a default label style for pipe network components in plan and profile views, click the corresponding field. Click ⊡ to display the label style dialog box, where you can select a label style.

**5** Click Apply.

# Editing Pipe Networks

You can edit pipe networks using the Network Layout Tools toolbar, pipe network vistas, or grips.

## Editing Pipe Network Using the Network Layout Tools

You can use the network layout tools toolbar to edit a pipe network.

Editing commands are the same commands you use for creating a pipe network.

**To edit a pipe network using the layout tools**

**1** In the drawing, right-click a part in a pipe network. Click Edit Network.

**2** Click a button in the Network Layout Tools (page 2031) dialog box to add, change, or delete pipe network parts, or change the surface, alignment or parts list that are referenced.

### Quick Reference

Object Shorcut Menu

Edit Network

Command Line

EditNetwork

Dialog Box

Network Layout Tools (page 2031)

## Editing Pipe Networks Using the Pipe Network Vistas

Use the Pipe Network Vistas to display all the components that are part of the pipe network.

The Pipe Network Vistas display pipe network data in a form that is similar to a spread sheet. Each row represents a pipe network part. Each column represents an attribute for a pipe network part. There is a tab to view pipe objects and a tab to view structure objects. The purpose of this view is to let you quickly see all the parts that make up the pipe network, along with their associated properties. Right-click a column heading to display options for customizing the display of detail in the column views.

**See also:**

■ The Toolspace Item View (page 82)

■ The Panorama Window (page 102)

**To edit a pipe network using the Pipe Network Vistas**

1 Select a pipe network part in the drawing. Right-click the part and click Edit Network.

2 On the Network Layout Tools toolbar, click 🖳 .

> **NOTE** You can edit only values that are available, you cannot edit data in disabled (shaded) cells.

### Quick Reference

Dialog Box

Pipe Network Vistas (page 2064)

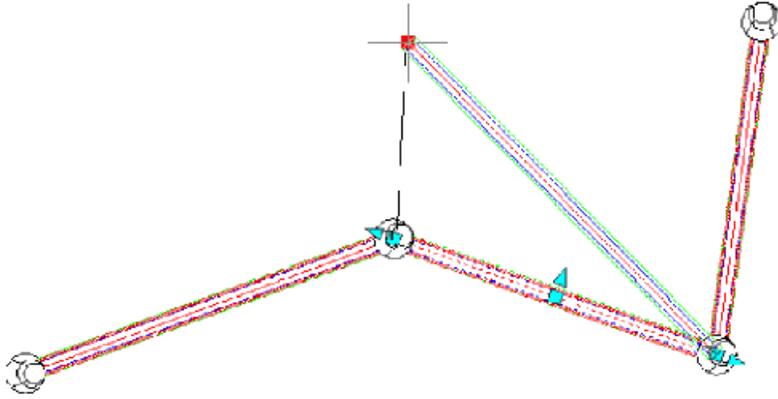
## Editing Pipe Networks Using Grips

Use grips to move, shorten, or stretch pipe or structure objects, or to change the size of a pipe.

Some of the grip editing behavior for pipes and structures is similar to the grip editing behavior for alignments. For more information about basic grip editing behavior for alignments, see Editing Alignments Using Grips (page 996).

**Grip Editing Pipes**

When moving a pipe in a pipe network using grips, structures connected to the pipe are no longer connected to the pipe, unless the pipe end being gripped is moved to another location within the network.

You disconnect the pipe from a structure if the end is attached to a structure. If you grip the end of the pipe to another structure, you can connect to it when a glyph appears next to the grip.


Grip editing a pipe that is connected to a structure does not move the structure along with it. Depending on the rim and sump behaviors of the structure, it may be necessary to adjust the structure vertically to accommodate a new sump elevation, or top of barrel, when the pipe is disconnected from the structure.

### Grip Editing Structures

When the location of a structure is edited, all the pipe ends connected to it move, along with the structure. The elevations of the original pipe ends connected to the structure are maintained.

### Pipes and Elevation Data

When grip editing a pipe, if no three-dimensional object snap is used (any value other than zero), the elevation of the end of the pipe is maintained when the pipe is connected to a new structure.

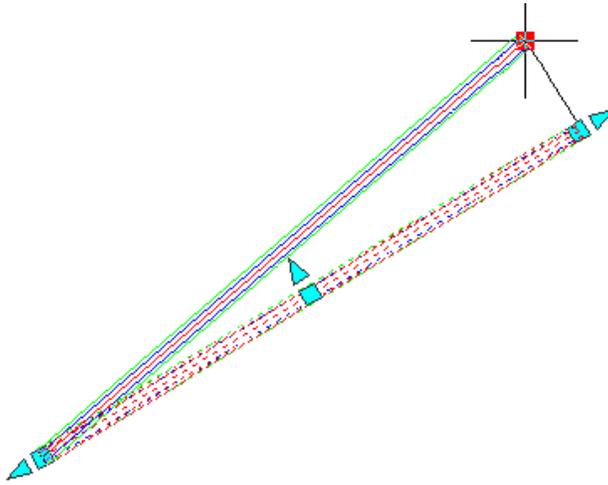
When a pipe is grip edited and moved over an existing pipe that it will "break," the end of the pipe that is being grip edited moves to the elevation of the pipe that is being broken.

The lengthening grips at the ends of the pipes extend the pipe end in a 2D plan view while maintaining the slope of the pipe. A 3D snap does not affect the elevations of the pipe when using the lengthening grip or the resize grips.

### Snapping to 3D

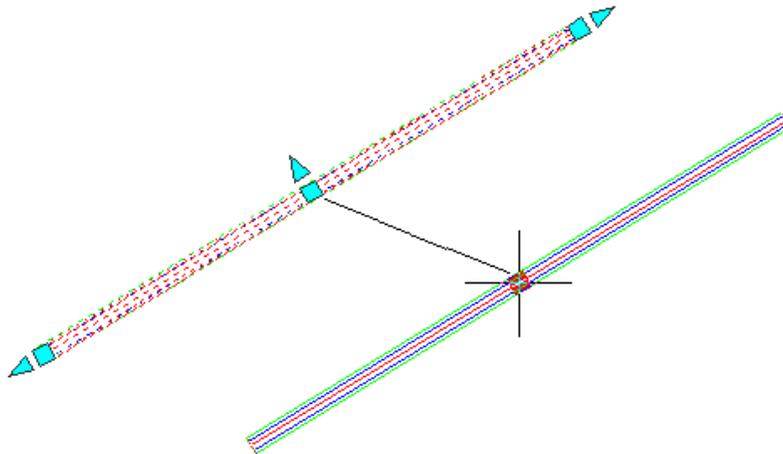
When viewing and editing pipe networks in plan view, you can quickly edit not only the two-dimensional geometry of the pipe, but you can also snap the pipe to three-dimensional locations to affect the elevation of either end of a pipe, or both ends simultaneously.

### Endpoint Free Grip

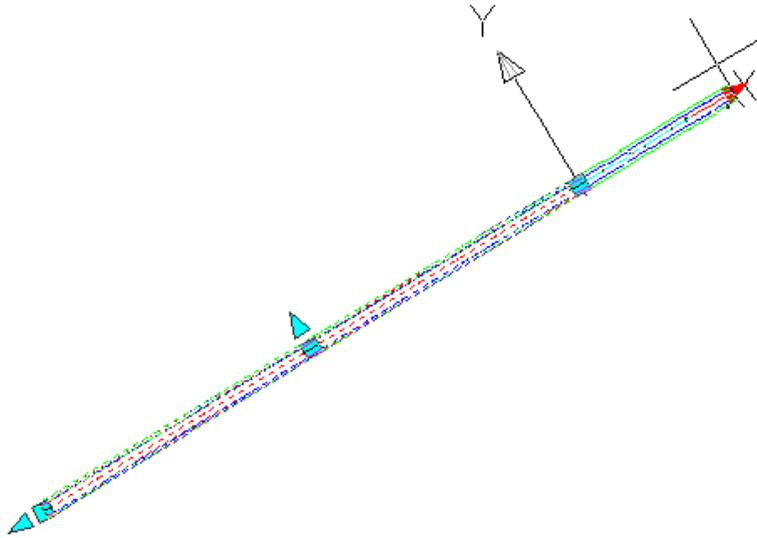
In plan view, clicking the endpoint free grip moves the selected endpoint of the pipe to a new specified point. The midpoint and opposite endpoint of the pipe are held during this edit. On a curved pipe, the behavior is identical to AutoCAD arc object behavior.


**Midpoint Free Grip**

This moves the entire pipe to a new specified point. On a curved pipe, the midpoint grips behaves just like AutoCAD arc objects: the endpoints are held, and the cursor acts as a pass-through location.



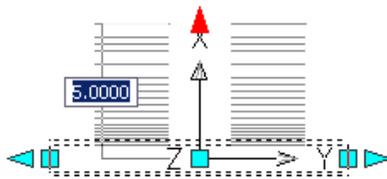
**Length Constraint Grip**

A pipe can be made shorter or longer by gripping the end of the pipe. Only the end that is gripped shortens or lengthens. The direction of the pipe does not change while performing this type of grip edit.


**Midpoint Resize Constraint Grip**

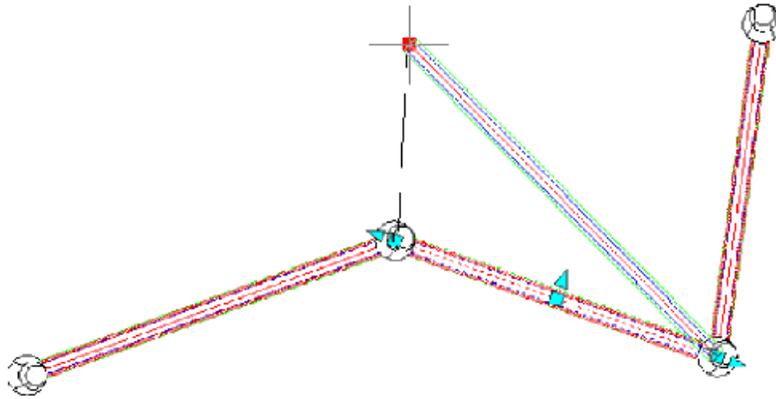
The midpoint resize grip lets you resize the pipe width based on the pipe sizes available in the parts list and the part catalog for the currently selected pipe.

When you use the midpoint resize grip on a pipe, a series of parallel lines display next to the pipe. Each parallel line represents an available pipe width. Tooltip text displays the pipe width. You can snap to any of the parallel lines and select a new pipe width.



**To use grips to edit a pipe**

1  In the drawing, click a pipe in a pipe network.

   The following illustration shows grips for a pipe in a pipe network:


2   Do one of the following:

- Use the end grips to adjust the pipe length.

- Use the center grip to move the location of the pipe.

- Use the midpoint resize grip to change the width of the pipe.

## Editing Pipe Networks Using the Storm Sewers Extension

You can use the Storm Sewers extention to open and edit pipe networks created with AutoCAD Civil.

To open pipe networks in the Storm Sewers Extension, they must first be exported to an *.stm* file.

The *.stm* file can then be opened by the Storm Sewers Extension and edited.

For example, you can create pipe networks in AutoCAD Civil, and then import those pipe networks into Storm Sewers to perform analysis tasks. After performing hydraulic analysis tasks on the pipe network, you can then import that same pipe network back into AutoCAD Civil.

Refer to the following table to find more information about using the Storm Sewers Extension:

| For information about ... | See... |
|---|---|
| exporting AutoCAD Civil pipe networks to an *.stm* file | Exporting Pipe Network Data to an .stm File (page 1279) |
| importing an *.stm* file into the Hydraflow Storm Sewers Extension | the Hydraflow Storm Sewers Extension User's Guide Help |
| editing pipe networks in the Hydraflow Storm Sewers Extension | the Hydraflow Storm Sewers Extension User's Guide Help |
| importing an *.stm* file into AutoCAD Civil | Importing Pipe Network Data from an .stm File (page 1278) |
| adding or editing hydraulic data (HGL, EGL, and so on) | Adding Hydraulic Property Data to AutoCAD Civil Pipe Networks (page 1280) |

You can also use the EditInStorm Sewers command to browse to an .stm file, and automatically open it in the Storm Sewers Extension.

For more information about using the Storm Sewers Extension to edit pipe networks, see the Storm Sewers Extension Help.

When you are finished making changes to the pipe network in the Storm Sewers Extension, save the project to save the changes to the .stm file.

You can import that .stm file back in to AutoCAD Civil, and overwrite (update) the previous version of that pipe network data, if desired. You also have the option of importing it with a new pipe network name.

**To use the EditInStormSewers command**

1  Do one of the following:

  ■ On the Modify tab, click Pipe Networks to display the Pipe Networks contextual tab. On the Pipe Networks contextual tab, click Analyze panel ➤ Storm Sewers drop-down ➤ Edit In Storm Sewers .

  ■ Click a pipe network in the drawing to display the Pipe Networks contextual tab. On the Pipe Networks contextual tab, click Analyze panel ➤ Storm Sewers drop-down ➤ Edit In Storm Sewers .

  ■ At the command line, enter EditInStormSewers and then press Enter.

2  On the Export To Storm Sewers dialog box, select the pipe networks to export, and click OK.

   **NOTE** You must select one or more entire pipe networks. You cannot select individual parts, or a series of connected parts within a pipe network.

3  Enter a name and select a location for the .stm file, and click Save.

The .stm file is created, and the Storm Sewers Extension launches. The exported pipe network data is displayed in Storm Sewers Extension. For more specific information about using the Storm Sewers Extension to edit pipe networks, see the Storm Sewers Extension Help.

## Quick Reference

Command Line

 EditInStormSewers

Dialog Box

 Export to Storm Sewers Dialog Box (page 2078)

# Grip Editing Structures

When you move a structure, all pipe ends connected to it move along with the structure.

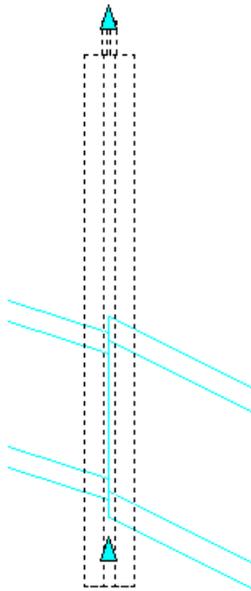
Elevations of the original pipe ends connected to the structure are typically maintained. However, part rules control elevations and slope of connected pipes under certain conditions. See Part Rules (page 1247) for more information.

It is also important to understand the automatic resize behavior that is built into junction structures. This automatic resize behavior is designed to ensure that appropriate aspects of a junction structure's geometry (such as elevations of connected pipes, sump depths, and vertical pipe clearance areas) are maintained even

when the junction structure's elevation changes. For more information, see Junction Structure Resize Behavior (page 1211).

**Rim and Sump Depth Grips**

While viewing a structure in a profile view, use the structure's rim or sump depth grip to adjust the rim or sump depth. In the following illustration, the rim grip is located at the top of the structure. The sump depth grip is located just above the bottom of the structure.



What the structure grips change depends on how the structure's Insertion (Rim) and Sump Behavior properties are set. For example, if you have the structure's Automatic Surface Adjustment property enabled, grip editing the structure modifies the surface adjustment factor. If you have the Automatic Surface Adjustment property disabled, grip editing the structure modifies the rim (insertion) elevation. For sump behavior properties, if you have the Sump Depth property enabled, grip editing the structure modifies the sump depth. If you have the Sump Elevation property enabled, grip editing the structure modifies the sump elevation. See the Part Properties tab (page 2052) of the Structure Properties dialog box for more information.

**NOTE** You cannot grip edit a structure in section view.

**To use grips to edit a structure**

■ To move the location of a structure that has pipes connected to it, in the drawing, click the center grip of the structure and move it to a new location.

■ While viewing structures in a profile view, use the structure's rim or sump depth grips to adjust the elevation of either.

## Editing Pipes Connected to Structures

Use the Connected Pipes tab on the Structure Properties dialog box to quickly edit pipes connected to a single structure.

When you have pipes connected to a structure, you may need to adjust the values of properties such as elevation, and or pipe diameter/width. To do this, you can use the Connected Pipes tab on the Structure Properties dialog box to edit the properties of multiple pipes connected to the same structure.

Using this tab, you can

■ edit inner diameter, inner width, or inner height of pipes connected to a structure

■ quickly edit elevations on multiple pipes to match the elevation of a selected pipe

**To edit pipes connected to a structure**

1　In the drawing, right-click the structure you want to edit, and then select Structure Properties from the shortcut menu.

2　Click the Connected Pipes tab.

3　To edit the following properties, click the value in the cell and enter a new value, or select one from the list: inner diameter (for circular pipes), inner width or inner height (for non-circular pipes).

> **NOTE** On this tab, the read-only slope value refers to the slope of the pipe as it is coming out of the structure (slope out).

4　To edit the elevation for a single pipe, select the pipe and edit the invert, centerline, or crown elevation value.

5　To edit elevations for multiple pipes, see for Matching Elevations on Connected Pipes (page 1219) more information.

6　Click Apply to make the changes, or click OK to make the changes and close the Structure Properties dialog box.

## Junction Structure Resize Behavior

In AutoCAD Civil, junction structures have built in resize behaviors that control how far you can move the rim, connected pipes, and sump up and down.

For example, if you move the top-most pipe invert up, raising its elevation to the point where it reaches the top of the structure (rim), the rim moves up automatically. This is to ensure that the pipe remains connected to the structure *below* the vertical pipe clearance area. The resize behavior allows the junction structure to maintain the frame height, cone height, and honor the vertical pipe clearance area, at the top of the structure, with no pipes connecting in to that part of the structure.

If you try to move a connected pipe into the structure's vertical pipe clearance area, you will notice in your drawing that the top of the structure (rim) automatically moves up.

This is just one example of the resize behavior that is built in to junction structures. Other resize behaviors control how far you can move the junction structure's rim or sump up and down. These resize behaviors are described in more detail in the following sections.

Before editing junction structures, make sure you understand the following about the resize behavior:

■ Elevation changes to the junction structure's rim, connected pipes, or sump, could occur when the structure is grip edited, or when the referenced surface changes, or when pipe elevations are changed.

■ The resize behavior of junction structures is independent of the behavior supplied by part rules. However, part rules can be configured so that they affect the structure resize behavior. For more information, see Part Rules (page 1247).

■ Note that the resize behaviors explained here apply only to junction structures. They do not apply to inlet/outlet structures or null structure types.

■ To verify that a structure is categorized as a junction structure, check that the Part_Type property is set to Struct_Junction. This is displayed on the Part Properties tab of the Structure Properties dialog box, in the Part Data section.

## Junction Structures With Connected Pipes

Moving pipes that are connected to junction structures invokes certain structure resize behaviors.

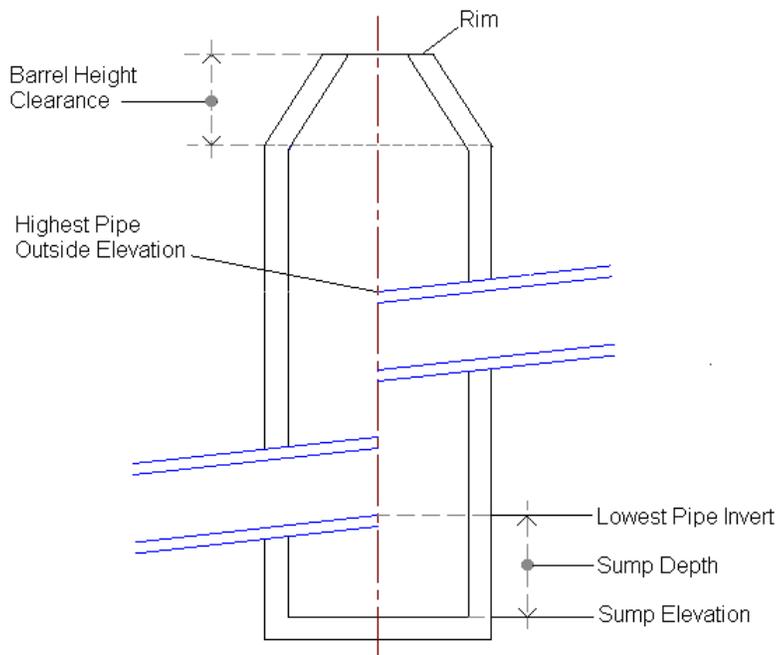
This section describes the structure resize behavior that is invoked in the following situations:

■ moving the top of a junction structure (rim) up or down

■ moving a pipe that is connected to a junction structure up or down

■ moving the bottom of a junction structure (sump) up or down

These changes to elevation in the junction structure's rim, connected pipes, or sump, could occur because the structure is grip edited, or because the referenced surface is edited, or because a connected pipe elevation is moved. Any of these types of edits may result in elevation changes to parts of the structure.



### Moving the Rim

When a junction structure's rim (top of structure) is moved **up**, the rim simply moves to the new elevation. Connected pipes, and sump elevations, remain unchanged.

If you try to move a junction structure's rim **down**, to an elevation where it violates the vertical pipe clearance area, you will not be able do so. The rim must always be located above the vertical pipe clearance area.

### Moving Connected Pipes

The following table describes the resize behavior that occurs when connected pipes are moved **up**.

When a pipe that is connected to a junction structure is moved **up**, to the point where it violates the vertical pipe clearance, the top (rim) of the structure automatically moves up so that the pipe does not touch the vertical pipe clearance area. In this case, the structure's rim elevation changes (moves up).

If you move the pipe **up**, but not to the point where it touches the vertical pipe clearance area, then the pipe is moved up, but the rest of the structure remains where it is. In this case, the structure's rim elevation remains unchanged.

**Understanding the Control Sump By Property**

When you are moving a connected pipe down, there is a part property associated with the junction structure that affects the structure resize behavior in this situation. That property is the Control Sump By property, and it can be set to Depth or Elevation. When this property is set to Depth, the sump depth is controlled by the depth, based on the lowest pipe invert. When this property is set to Elevation, the sump depth is controlled by the elevation value of the sump. The resize behavior is different depending on how this property is set on the structure.

When a connected pipe is moved **down**, to a point where the pipe moves below the connected structure's sump elevation, and the Control Sump By property is set to Depth, since the sump elevation is set to be controlled by the depth, then the sump elevation will be moved down, to a new elevation. This new sump elevation will be the depth of the lowest pipe invert, minus the sump depth value.

If a connected pipe is moved **down**, to a point where the pipe moves below the connected structure's sump elevation, but the Control Sump By property is set to Elevation, then the sump will automatically move down, to an elevation equal to the lowest pipe elevation. This sets the sump depth to zero.

**Moving the Sump**

Using the sump depth grip, you can move a junction structure's sump **up** to the point where it meets the lowest connected pipe. You will be prohibited, however, from moving the sump up past the point where it touches the lowest connected pipe.

When you move a junction structure's sump **down**, the sump will simply move to the new elevation, and not affect any connected pipes, or the structure's rim. This behavior is the same whether the sump is controlled by depth or by elevation.

## Junction Structures With No Connected Pipes

When there are no pipes connected to a junction structure, the rim and vertical pipe clearance take precedence over the sump.

The following sections describe the resize behaviors on junction structures that have no connected pipes.

**Moving the Rim**

When you move the structure's rim **up**, and the Control Sump By property is set to Depth, the sump moves up the same distance as the rim.

When you move the structure's rim **up**, and the Control Sump By property is set to Elevation, the sump moves up the same distance as the rim.

When you move the structure's rim **down**, the sump does not move. You can move the rim down, but only to a location just above the sump. The rim must always be above the sump.

**Moving the Sump**

When you move the structure's sump **up**, and the Control Sump By property is set to Depth, the new sump elevation can be below, at, or above the vertical pipe clearance area. This does not affect the rim elevation, and it sets the sump depth to zero.

When you move the structure's sump **up**, and the Control Sump By property is set to Elevation, the sump can only move up as far as the bottom of the vertical pipe clearance area.

When you move the structure's sump **down**, the sump is moved to its new location (new sump depth), but the rim elevation does not change.

## Adding a Part to a Pipe Network

Add a part (pipe or structure) to an existing pipe network.

To add one or more parts within an existing pipe network, using the Network Layout Tools toolbar, select the type of parts you want to insert (pipes and structures, pipes only, or structures only), and then specify insertion points in the drawing.

You can also add parts to a pipe network by copying and pasting a part within an existing pipe network.

### To add a part to a pipe network

1   In the Prospector tree, click the pipe network object, right-click, and click Edit Network. The Network Layout Tools toolbar is displayed.

2   On tNetwork Layout Tools toolbar, click ![icon] and select one of the following choices: Pipes and Structures, Pipes Only, or Structures Only.

3   In the drawing, specify the insertion point by clicking on the pipe network object you want to connect to.

### Quick Reference

Ribbon

Home tab ➤ Create Design panel ➤ Pipe Network drop-down ➤ Pipe Network Creation Tools ![icon]

Menu

Pipes menu ➤ Create Pipe Network By Layout

Command Line

CreateNetwork

Dialog Box

Create Pipe Network (page 2023)

## Swapping Pipe Network Parts

Select an existing part in a pipe network and replace it with a part that is the same type, but is from a different part family and/or part size.

A part can only be swapped with a part that is the same type.

For example, a pipe can only be swapped with another pipe; a junction structure can only be swapped with another junction structure; an inlet/outlet structure can only be swapped with another inlet/outlet structure.

Note that a null structure can only be swapped with a junction structure, since it connects two pipes together.

If you want to replace a part with a different part type, you must delete the part, and then add the new one.

Note that when swapping parts, connection elevations are maintained. For example, pipe invert elevations remain the same if a pipe is swapped with another pipe, or if a structure with one or more pipes attached to it is swapped with another structure.

You can swap with any part from the pipe network's current parts list.

NOTE Part swapping should not be confused with part sizing. In part sizing, an existing part is resized within the same part family.

**To swap a part in a pipe network**

1 In the drawing, right-click the pipe or structure object to swap and click Swap Part.

2 In the Swap Part Size dialog box, expand a part family. Select the part to swap and click OK.

The new part is displayed in the drawing. View the description of the new part by right-clicking on the part and selecting Pipe Properties.

## Disconnecting Pipe Network Parts

Select a part in a pipe network and disconnect it from the part or parts it is currently connected to.

When you disconnect a part, the disconnected part can then be moved in the drawing without moving parts that were attached to it.

Even though a part may be disconnected from the other parts in the same pipe network, the disconnected part still belongs to the same pipe network.

The following behavior applies to the connectivity of pipes and structures:

■ When grip editing is used to move, lengthen, or shorten a pipe, the connectivity to any structures connected to that pipe will be lost. There is one exception to this rule: if the pipe end being gripped is moved to the location within the structure it was originally attached to, then the connectivity is maintained.

■ When grip editing a pipe that is attached to a structure, moving the pipe does not move the structure. The pipe becomes disconnected from the structure. The only affect this type of edit may have is to possibly resize the structure vertically to accommodate for a new sump elevation or top of barrel when the pipe is disconnected.

■ When grip editing a pipe, if no 3D OSNAP is used (any value other than zero), the elevation of the end of the pipe is maintained when the pipe is grip edited and connected to a new structure.

■ When grip editing a pipe that is moved over an existing pipe that it will "break," the end of the pipe being edited moves to the elevation of the pipe being broken.

**To disconnect a part in a pipe network**

■ In the drawing, right-click the pipe or structure object and click Disconnect From Part. If you selected a structure, you will be prompted to select the pipe to disconnect from.

The part name is displayed in the Pipe Networks collection on the Prospector tab.

## Connecting Pipe Network Parts

Select a disconnected part in a pipe network, or add a new part, and connect it to other pipe network parts.

When you use this command, the disconnected part automatically snaps to connect to the selected part.

**To connect a disconnected part in a pipe network**

1  In the drawing, right-click the disconnected pipe or structure object and click Connect To Part.

2  Click the part you want to connect to.

The second part automatically snaps to connect to the first part.

## Deleting Pipe Network Parts

Delete one or more parts from a pipe network.

When you delete a pipe or structure from a pipe network, the object is erased from the drawing, and also removed from the Prospector list view.

You can delete pipes or structures using the Basic Modify Tools ➤ Erase command, or using the Delete Pipe Network Object button on the Network Layout Tools toolbar, or by selecting the object in the Prospector list view and choosing Delete from the shortcut menu.

**To delete a pipe or structure using the Basic Modify Tools**

■  In the drawing, right-click the pipe or structure you want to delete. Choose Basic Modify Tools ➤ Erase, or select the part and press the Delete key on your keyboard.

The structure or pipe object is erased from the drawing and removed from the Prospector list view.

**To delete a pipe or structure using the Network Layout Tools**

1  In Toolspace, on the Prospector tab, expand the Pipe Networks collection, then expand the Networks collection.

2  Right-click the pipe network and choose Edit Network to display the Network Layout Tools toolbar.

3  On the Network Layout Tools toolbar, click 🗙 Delete Pipe Network object.

4  In the drawing, select the pipe or structure you want to delete.

The structure or pipe object is erased from the drawing and removed from the Prospector list view.

**To delete a pipe or structure in the Prospector List View**

1  In Toolspace, on the Prospector tab, expand the Pipe Networks collection, then expand the desired pipe network to display the Pipes and Structures collections beneath it.

2  If you want to delete one or more pipe objects, click the Pipes collection in the Prospector tree. If you want to delete one or more structures, click the Structures collection. Hold down the Shift key to select multiple objects.

3  Right-click and click Delete from the shortcut menu.

The structure or pipe object is erased from the drawing and removed from the Prospector list view.

## Deleting a Pipe Network

Delete an entire pipe network, erasing it from the drawing and removing it from the Pipe Networks collection in the Prospector tree.

When you delete a pipe network, all parts belonging to the pipe network (pipes, structures, and null structures) are also deleted.

**To delete a pipe network**

1 In Toolspace, on the Prospector tab, expand the Pipe Networks collection, then expand the Networks collection.

2 Right-click the pipe network and click Delete.

The pipe network, and all its associated child objects, are erased from the drawing and removed from the Pipe Networks collection in the Prospector tree.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Pipe Networks ➤ Right-click <network-name> ➤ Delete

## Copying a Pipe Network

Create a copy of an existing pipe network.

You can copy an existing pipe network, copying the parent pipe network object and all of its associated pipes and structures, and paste this to a new location in the drawing.

When a pipe network is copied, a naming convention is used to name the new pipe network object. For example if the original pipe network object is named 'Pipe Network 1', the new pipe network object is named 'Pipe Network 1 (1)' in the Prospector tree. If Pipe Network 1 is copied again, the new pipe network object is named 'Pipe Network 1 (2)'. If 'Pipe Network 1 (1)' is copied, the new pipe network object is named 'Pipe Network 1 (1) (2)'.

**To copy a pipe network**

1 In the drawing, select the entire pipe network.

> **NOTE** Make sure you select all of the pipe network. If you do not copy all of the parts associated with the pipe network, the selected parts will be copied to the existing pipe network.

2 Use any of the following methods to copy the pipe network to the clipboard: CTRL+C, the AutoCAD COPYCLIP command, or Clipboard ➤ Copy from the right-click shortcut menu.

3 Press CTRL+V.

At the command line, you are prompted to specify an insertion point for the pipe network.

4 Click an insertion point in the drawing area.

The pipe network is pasted in the drawing and added as a new pipe network to the Pipe Networks collection in the Prospector tree.

5 To edit the name of the pipe network, right-click the pipe network in the Prospector tree. Click Network Properties.

The Pipe Network Properties dialog box is displayed with the Information tab (page 2033) active. The Name field contains the name of the copied pipe network, which is, by default, " <pipe network-name> (1)."

6 Enter a new name in the Name field.

7 Optionally, enter a new description of the pipe network in the Description field.

8 Click Apply to make the changes, or click OK to make the changes and close the Pipe Network Properties dialog box.

# Renaming Pipe Network Parts

You can easily rename some or all parts in a pipe network.

In order to manage and easily identify pipe runs, you may need to name pipes and structures according to naming conventions that make sense for your projects.

It is easy to rename a single pipe network object, but what is the best way to rename multiple or all parts within a pipe network? If you need to update just one or a few parts within a pipe network, you may want to use the Pipe Network Vistas (page 2064) in the Prospector, or just right-click on the part in the drawing and enter a new name for the object on the Pipe Properties or Structure Properties dialog box.

If you want to rename many parts within a pipe network, use the RenamePipeNetworkParts command. This command lets you rename one, all, or a sequence of connected parts within a pipe network.

Using this command, you can also select a name template to apply the new part names.

**To rename connected parts in a pipe network**

1 Select the pipe network. Click Pipe Networks tab ➤ Modify panel ➤ ▼ ➤ Rename Parts 🖾 .

2 In the drawing, select the first part (pipe or structure) within the pipe network that you want to rename.

   **NOTE** If you select a pipe or structure that is not connected to another pipe or structure, you can only rename that single part.

3 Select the last part in the same pipe network that you want to rename.

4 On the Rename Pipe Network Parts dialog box (page 2077), you may enter or choose a new name (or name template) for the selected pipe network parts. You can choose to rename just the selected structures from the sequence of consecutive parts selected, just the pipes, or both.

5 You can enter a new starting number or leave this field blank.

6 Select one of the following Name Conflict Options. These determine how to handle any conflicts with the naming or numbering, if there are any conflicts.

   ■ Skip Number: When this option is selected, if a name and number combination is already being used by a pipe network part in the drawing, then the number is incremented until that name\number combination is available as a name for the selected part.

   ■ Rename Existing Parts: When this option is selected, if a name and number combination is already being used by a pipe network part in the drawing, then that part will be renamed so that the selected part can use that desired name instead. The original part will be renamed using the next name and number combination that is available.

7 Click OK. The parts are renamed.

To view the updated part names, do one of the following:

■ In the drawing, right-click on a part and select Pipe Properties or Structure Properties. View the updated pipe or structure names on the Information tab of the Pipe Properties or Structure Properties dialog box.

■ In the Prospector tree, expand the Pipe Networks ➤ Networks collection, and then expand the pipe network containing the renamed parts. Click Pipes or Structures and view the updated part names in the Pipe Network Vistas (page 2064).

### Quick Reference

Ribbon

Select the pipe network. Click Pipe Networks tab ➤ Modify panel ➤ ▼ ➤ Rename Parts 🗐

Menu

Rename Pipe Network Parts (page 2077)

## Matching Elevations on Connected Pipes

When multiple pipes enter and exit a structure, you may need to set pipe in and pipe out elevations to consistent, matching values.

This feature lets you quickly set pipe elevations in cases where multiple pipes connect to a single structure. This provides a method for quickly and accurately matching multiple pipe elevations to the invert, crown, or centerline elevation of a selected pipe.

You can also add a drop value that lets you adjust that elevation value between incoming and outgoing pipes.

**To match elevations on pipes connected to a structure**

1  In the drawing, right-click the structure, select Structure Properties, and then click the Connected Pipes tab.

2  Press and hold the CTRL key on your keyboard and select more than one of the pipes displaying on the Connected Pipes tab.

   **NOTE** You must select multiple pipes for the match crown, centerline, and invert options to display on the right-click shortcut menu.

3  While still holding down the CTRL key, right-click and select one of the following options from the shortcut menu.
   - Match crowns
   - Match centerlines
   - Match inverts

4  On the Match Elevation dialog box, click the pipe you want to match crown, centerline, or invert elevations to.

5  Optionally, enter a Drop Amount to adjust the elevation by the specified value.

6  Click OK to make the changes and close the Match Elevation dialog box.

7  On the Connected Pipes tab, verify that the selected elevation value has been edited.

8  Click Apply to make the changes, or click OK to make the changes and close the Structure Properties dialog box.

# Displaying Pipe Networks

You can display pipe networks in plan, profile, and section views.

## Displaying Pipe Networks in Profile Views

You can display selected pipe network parts, or entire pipe networks, in profile views.

To display pipe networks in a profile view, you must have valid station offset data (from the profile view alignment) for the pipe networks.

### Editing Parts in Profile View

If you make changes to the pipe network in plan view, such as moving, swapping, deleting, or resizing parts, those changes are reflected when the parts are displayed in profile view.

**NOTE** You cannot move the X, Y locations of parts in a profile view. However, you can grip edit elevations, edit object properties, or resize parts.

### Editing Display Styles in Profile View

Initially, the object style comes from the part, but it can be overridden in profile view. To edit display characteristics for pipe network parts displayed in a profile view, you right-click the profile view, click Profile View Properties, and then click the Pipe Networks tab. For example, you can select the parts you want to be drawn or not drawn in the profile view, or change layers or object styles. When you edit these display characteristics on the Profile View Properties tab, they would only affect how the object is displayed in profile view. For more information, see the Pipe Networks tab (page 2184) on the Profile View Properties dialog box.

### Pipe Slopes in Profile View

The calculated slope of pipes in a profile view may or may not reflect the apparent slope of the actual linework drawn in the profile view. This is because the slope of the pipe is the slope of the actual model from end to end. If a pipe does not geometrically correspond to the alignment defining the profile view, the pipe shown in that profile view will appear slightly different. Also, the length of the pipe in a profile view may not reflect the true length of the pipe as displayed in plan view. This is because the displayed length of the pipe in the profile may be different than the true length of the pipe, as displayed during layout.

### Curved Pipes in Profile View

Curved pipes represented in a profile view are always represented as a straight line from the start point of the pipe to the end point of the pipe. In reality, when a pipe is projected onto a profile, and depending on the combination of horizontal and vertical geometry, the pipe would have some vertical deflections here and there, even when the pipe is actually straight with no change in grade along its length. This is especially true for curved pipes. Therefore, it is important to understand that AutoCAD Civil represents all pipes in profile views as straight lines drawn end to end.

### Pipe Crossings in Profile View

A pipe crossing in a profile view refers to the location where a pipe crosses an alignment or sample line and is displayed in its profile view. When displaying a cross section of a pipe network in AutoCAD Civil, locations of intersected pipes (pipe crossings) are represented at the correct elevation. However, the projected pipe may not show the same elevation at that location for the reasons described in the previous paragraph. Typically, there is no need to represent pipe networks as both projected and crossings in the same profile. For more information, see Displaying Pipe Crossings (page 1222).

**Structures in Profile View**

Pipe network structures will only display in a profile view if the insertion point of the structure is within the limits of the profile view. Therefore, when the structure's insertion location is outside the profile view, the structure does not display in the profile view.

In the Structure Style dialog box, Display tab you can activate components to display connected pipes in profile and section views.

Pipes can be represented to indicate the size/elevation where they are connected to the structure. Pipes represent the true inside section of the pipe, and are exaggerated to the profile view scale in vertical.

**NOTE** The pipes are represented at the elevation of the pipe where they meet the structure, which is typically the centerline.

**To represent pipe network parts in a profile view**

1  Make sure that the desired profile view is already created. See Profiles (page 1019) for more information.

2  Make sure that the pipe network parts you want to display in the profile view have already been created in plan view, and have valid station offset data from the alignment they reference.

3  Select the profile view. Click Profile tab ➤ Launch Pad panel ➤ Draw Parts In View  .

4  In the drawing, select the pipe network parts you wish to add to the profile view, or enter E to select an entire pipe network.

5  Select a profile view.

The pipe network parts are displayed in the profile view.

## Quick Reference

Ribbon

Click Profile tab ➤ Launch Pad panel ➤ Draw Parts In View 

Menu

Pipes menu ➤ Edit Pipe Network

Command Line

AddNetworkPartsToProf

# Displaying Pipe Networks in Section Views

You can display pipe network parts in section views.

To display pipe networks parts in a section view, the following data must exist:

■  Pipe network parts drawn in plan view

■  A sample line and section view containing pipe or structure crossings

■  Valid station offset data for the pipe network parts

Only the pipe network parts that cross the sample line are displayed in the section view.

**NOTE** Pipe sections are drawn using the FACETDEV (Facet Deviation) system variable. FACETDEV is set to 0.5 by default which will usually cause circular pipe sections to be displayed with eight segments. If you set FACETDEV lower, to 0.05 for example, the appearance of the pipe sections will become more circular. The lower this variable is set, the more segments will be used to draw the pipe, up to a maximum of 500.

Pipes and structures that cross the sample line are displayed in the section view as a crossing version of the part. This is unlike profile views where pipe network parts can be displayed both as projected and crossing versions. See Displaying Pipe Crossings (page 1222) for more information.

Pipe objects that are displayed in a section view are displayed according to the style specified on the Sections tab. Structures are displayed in a section view as a representation of the body of the part, even if only a portion of the shape crosses the sample line.

When you use the Create Sample Line Group dialog box to create a sample line, you can select any and all pipe networks in the drawing. However, only pipe network parts that actually cross the sample line are displayed in the section view.

If you wish to display pipe network parts in a section view, a Pipe Network Section object gets created when you create a sample line with pipe network parts that cross it. The Pipe Network Sections collection is displayed under the Sample Line Groups collection in the Prospector tree. See Sections (page 1123) for more information.

**NOTE** Network parts displaying in a section view are exaggerated vertically to match the vertical scale factor of the view in which they are being represented.

**To represent pipe network parts in a section view**

1  Make sure the pipe network parts you want to display in the section view have already been created in plan view and have valid station offset data associated with them.

2  Create the desired sample line and section view. See Sections for more information. The procedure is similar to the procedure for creating surface sections.

# Displaying Pipe Crossings

Pipes that cross or intersect a profile view or section view are displayed as pipe crossings.

Pipes that cross or intersect a profile view can be displayed as projected, or as pipe crossings. Pipes that cross or intersect a section view are always displayed as pipe crossings.

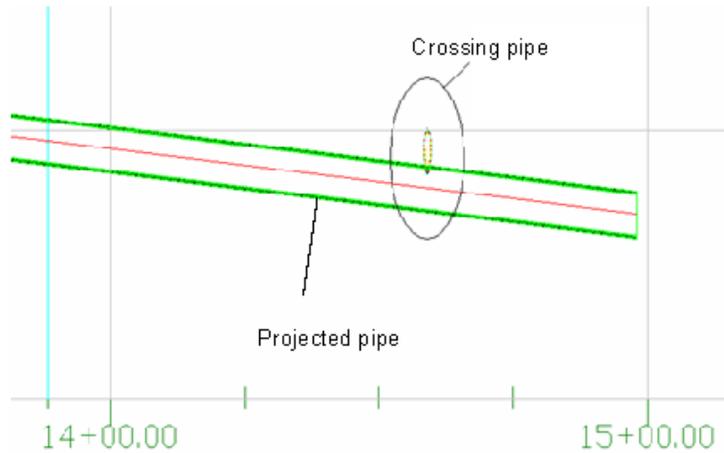
When a pipe is displayed as projected in a profile view, it is drawn as straight linework from pipe beginning to pipe end. It is important to understand, however, that when a pipe is displayed in a profile view, depending on the combination of horizontal and vertical geometry, the pipe will have some vertical deflections, even when the pipe is actually straight with no change in grade along its length. This is especially true for curved pipe. This is how AutoCAD Civil displays pipe in profile views.

When plotting a cross section of a pipe network in AutoCAD Civil, the location of an intersected pipe is displayed at the correct elevation, but the same pipe displayed in a profile view may not show the same elevation at that location due to the behavior described above.

The following illustration shows a pipe crossing and a projected pipe in a section view.

Crossing pipe

Projected pipe

14+00.00          15+00.00


**See also:**

■ [Displaying Pipe Networks in Profile Views](#) (page 1220)

## Pipe End Cleanup Option

You may need to clean up pipe to pipe connections displayed in plan or profile views.

This topic describes how to understand and use the pipe end clean up option that exists on the Plan and Profile tabs of the Pipe Style dialog box.

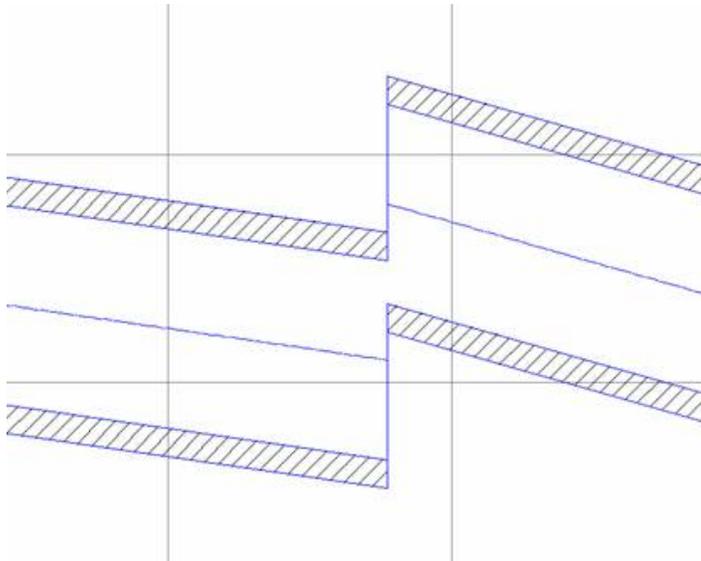
Using this option, you can define a pipe style that either has this option selected (turned on or in use), or not selected (turned off or not in use).

When this option is checked for plan views, the appearance of pipe to pipe connections in plan view is cleaned up so that they more accurately represent the way pipe to pipe connections should look in plan views.

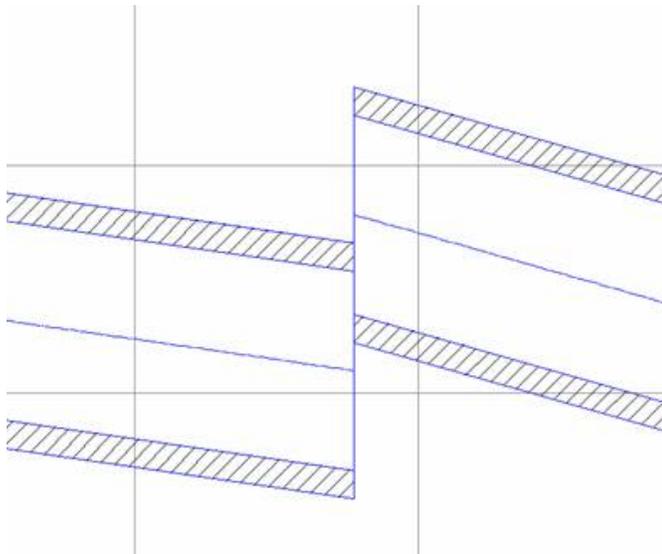
When this option is checked for profile views, the appearance of pipe to pipe connections in profile view is cleaned up as follows:

■ The overlapping pipe ends are trimmed to the inside edges of the pipes when only the inside edges are displayed, or when both the inside and outside edges of the pipes are displayed.

■ The outside edges of the pipes are trimmed only when the outside edges of the pipes are displayed (when the inside edges of the pipes are not displayed).

The following illustration shows a profile of a pipe to pipe connection with the pipe end clean up option turned on.


When this option is not checked, the appearance of pipe to pipe connections displayed in profile view is not cleaned up. The following illustration shows a profile of a pipe to pipe connection with the pipe end clean up option turned off.



By default, this option is not checked (turned off). But you can simply turn it on for existing (legacy) pipes to have the pipe to pipe connections cleaned up.

It is important to understand the following behavior regarding this option:

■ The pipe end clean up option can only be used when there is a null structure between two pipes.

■ This option behaves the same on straight and curved pipes displayed in profile views.

■ This option trims (removes) the overlapping pipe ends to the inside edges when only the inside edges are displayed, or when both the inside and outside edges are displayed.

■ This option trims to the outside edges only when the outside edges are displayed (when the inside edges are not displayed).

**To clean up the appearance of pipe to pipe connections in profile views**

1   Right-click on a pipe in a pipe to pipe connection and click Edit Pipe Style.

2   Click the Profile tab on the Pipe Style dialog box.

3   At the bottom of this dialog box, place a check mark next to the Clean Up Pipe To Pipe Connections option.

4   Click OK.

In profile views, the pipe ends in pipe to pipe connections are trimmed (cleaned up).

**To clean up the appearance of pipe to pipe connections in plan views**

1   Right-click on a pipe in a pipe to pipe connection and click Edit Pipe Style.

2   Click the Plan tab on the Pipe Style dialog box.

3   At the bottom of this dialog box, place a check mark next to the Clean Up Pipe To Pipe Connections option.

4   Click OK.

In plan views, the pipe ends in pipe to pipe connections are trimmed (cleaned up).

# Changing Flow Direction

You can change the flow direction on consecutive parts in a pipe network.

Because some pipe network rules rely on the flow direction assigned to pipes, this command lets you assign direction as needed so that rules can be applied properly.This feature also allows for the display of appropriate flow direction arrows in labels.

The Change Flow Direction command is also useful when other applications using AutoCAD Civil pipe network model data need to be able to determine flow direction within a network.

You may need to change the flow direction of an entire pipe network, or only a portion of a pipe network. Using the Change Flow Direction command, you are prompted to select a path of consecutive parts in a pipe network.

To change the flow in a series of connected parts, select a path by clicking on a starting part, and an ending part within a pipe run.

Changing flow direction can only be performed on a single pipe network at a time. Although you can select structures as well as pipes when using this command, the feature affects pipes only.

**To change pipe network flow direction**

1   Select the pipe network. Click Pipe Networks tab ➤ Modify panel ➤ ▼ ➤ Change Flow Direction ✍ .

    A prompt is displayed indicating that you should select the part (pipe or structure) that you want to be used as the upstream starting point in plan view.

2   In the drawing, click a pipe or structure in the pipe network to define the upstream starting point for the flow direction change.

    A prompt is displayed indicating that you should select the part (pipe or structure) that you want to be used as the downstream ending point in plan view.

**3** Do one of the following:

- Select a path for the flow direction change by clicking a pipe or structure to define the downstream ending point. You can continue clicking consecutive parts in a pipe network to define the path for the change flow direction.

- You can click Undo at any time during this command to undo the previously selected part and path.

**4** When you have finished defining the path for the flow direction change, press Enter to end the command and implement the flow direction change on the parts in the selected path.

A prompt indicating that the flow direction has been successfully applied to the part(s) is displayed.

The Flow Direction property value on the Part Properties tab of the Pipe Properties dialog box is changed (from Start to End to End to Start, or from End to Start from Start to End).

ChangeFlowDirection

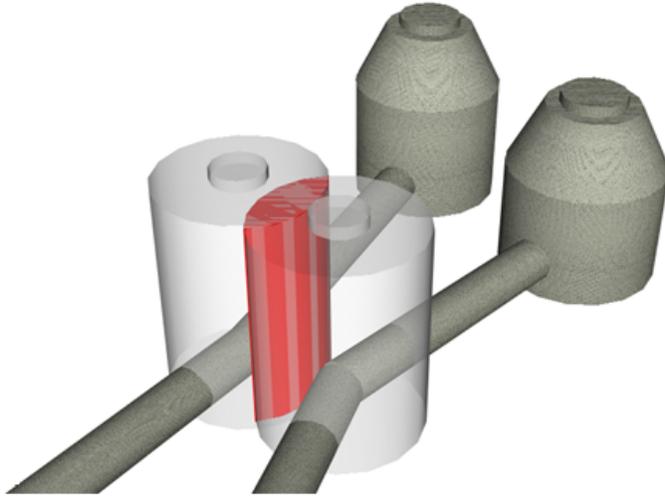
# Checking for Interferences

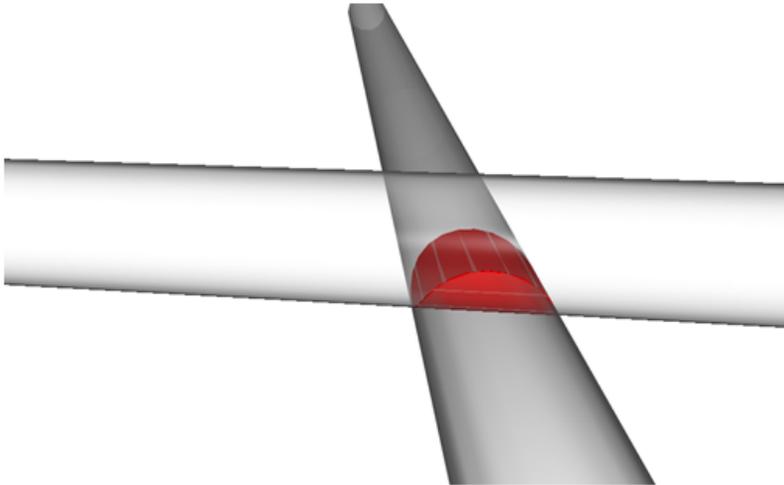
Interference checking lets you quickly identify pipe network parts that may be in conflict with each other.

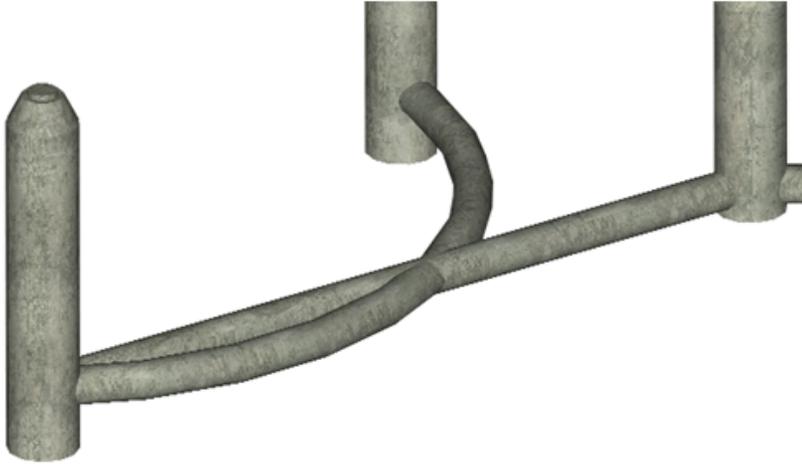
This feature compares the actual 3D model of parts to check for interferences. You can run an interference check to identify pipe network parts that physically overlap, collide, or intersect in an inappropriate way, or that have violated predefined, proximity-based criteria.

For example, you may want to run an interference check on one or more pipe networks to see if any parts physically overlap or are too close to one another. You can select style-based visual markers to identify the interferences, or you can choose to display the interferences as true, three-dimensional representations. You may choose to leave the interference conditions as they are, or you may decide to resolve them by moving parts in the drawing.

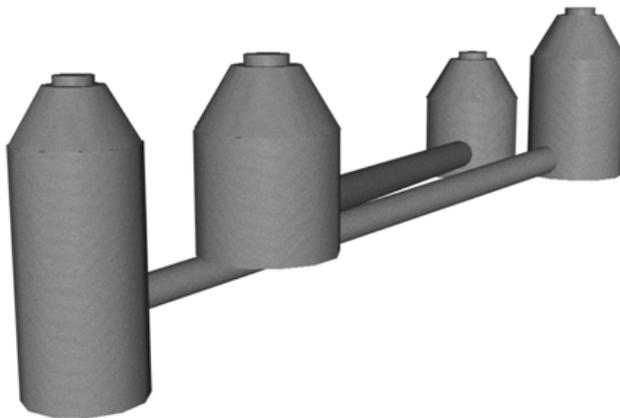
When you run an interference check, you can choose a single pipe network or you can choose two pipe networks. When you run an interference check on a single pipe network, it check for interferences on parts included in that network. When you choose to check two pipe networks, it checks for interferences between the two pipe networks.

The following illustration shows two different pipe networks with structures that physically overlap. Running an interference check would quickly indicate that these parts interference with one another.


Another type of interference that can be detected is when two pipes intersect without a structure joining them, as shown in the following illustrations:




If desired, you can also perform a check for pipe network parts in their 3D representation that are too close to one another, according to predefined distance or scale factor criteria. In the following illustration, the two pipe networks shown are less than ten feet away from each other at the closest point, even though they do not physically collide:



You can run an interference check that identifies parts in their 3D representation that are less than a specified distance away from any part in the other network. The distance is checked in every direction surrounding each part.

When you run an interference check, an Interference Check object gets created and is displayed in the Prospector tree in the Pipe Networks ➤ Interference Checks collection. For more information, see Viewing Interference Check Results (page 1232).

## Proximity Checking Criteria

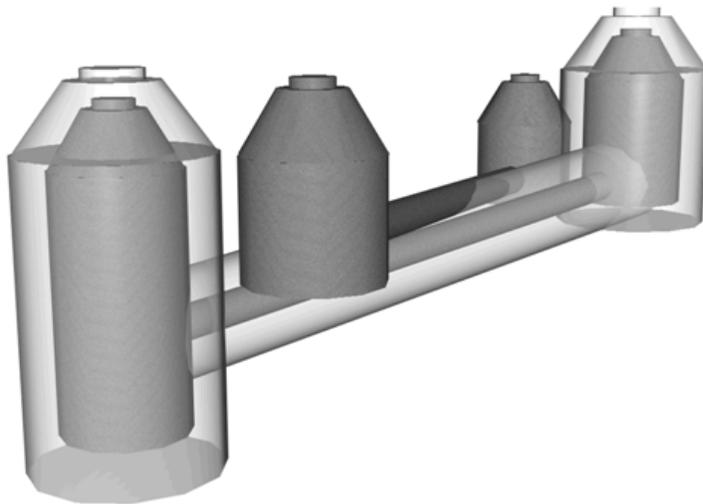
When you run an interference check, you can enable or disable 3D proximity checking criteria.

If you enable the 3D proximity checking option on an interference check, you can identify pipe network parts that are too close to one another in their 3D representation, according to a specified distance or a scale factor. You can check a single pipe network or two pipe networks.

When you use proximity checking on a single pipe network, interferences are created for parts that are less than a specified distance from one another. When you use this feature to check two pipe networks, an interference is created for any parts from one network that are less than a specified distance or scale factor from any parts in the second network.

You can use the 3D proximity check feature to ensure that the distance between two different types of utility networks meets a certain requirement. For example, a sewer and water crossing typically requires that the water line be a minimum of 18 inches above the sewer line. Running an interference check with the Use Distance option set to 18 inches identifies any parts that were less than 18 inches away from the other pipe network.

The following illustration shows how the distance and or the scale factor 3D proximity checking value is used to determine proximity interference violations. The darker shaded outlines represent the actual parts in the selected pipe network. The lighter shaded parts represent the area that is used to identify interferences.



**Specifying a Distance**

When you choose to enter a specified distance to perform the proximity check, you can enter a value that is used to perform the proximity check. When you run the check, interferences are created for any pipe network part that is less than the specified distance away from any other part in the specified network(s), in any direction.

**Specifying a Scale Factor**

When you use the Use Scale Factor option is selected, you can enter a value that is used as a scale factor. When you enter a scale factor value, AutoCAD Civil calculates the limits of the part (the pipe or the structure) multiplied by the scale factor value that is specified. For example, if the pipe diameter is 600mm, and you specify a scale factor value of 2, AutoCAD Civil identifies any interferences within a distance of 1200mm (or the pipe diameter, which is 600, multiplied by the scale factor value, which is two). When the interference check is run, any pipe network parts within that distance away from each other (in any direction) are marked as an interference.

**To define 3D proximity check criteria**

1   In the Create Interference Check dialog box, click 3D Proximity Check Criteria.

**2** In the Criteria (page 2071) dialog box, click Apply 3D Proximity Check to enable this feature.

**3** Do one of the following:

■ Click Use Distance to enter a distance. When the interference check is run, interferences are created for any pipe network part that is less than the specified distance away from any other part in the specified network(s).

■ Click Use Scale Factor to enter a scale factor. When the interference check is run, any pipe network parts within that distance away from each other (on any side) are marked as an interference.

**4** Click OK in the Criteria dialog box.

**5** Click OK in the Create Interference Check dialog box to run the interference check.

The following prompt is displayed:

Interference check created. Number of interferences found: X.

**6** Click OK at this prompt.

To view the results, in Toolspace, on the Prospector tab, expand the Interference Checks collection, and then select the interference check. The Interference Check data is displayed in the Panorama window and Toolspace item view. See Viewing Interference Check Results (page 1232) for more information.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Pipe Networks ➤ Interference Checks ➤ Create Interference Check

Dialog Box

Criteria (page 2071)

## Running an Interference Check

Run an interference check to identify parts in a pipe network that collide or violate proximity criteria.

You can check for interferences on a single pipe network, or you can check two pipe networks to determine if parts collide or violate proximity criteria.

**To run an interference check on a single pipe network**

**1** Click Analyze tab ➤ Design panel ➤ Interference Check ⬚ .

**2** In the drawing, click any part in the pipe network.

**3** Click again on the same part in the pipe network or on any other part in the same pipe network.

**4** In the Create Interference Check dialog box, in the Name field, specify a name for this interference check, or accept the default.

**5** Optionally, enter a description in the Description field.

**6** Specify the pipe network(s) for this interference check using the Network 1 and Network 2 fields.

These should be the same pipe network(s) that you clicked in step 3. If desired, you may change the pipe network(s) here.

To run an interference check on a single pipe network, make sure the same pipe network name is displayed in the Network 1 and Network 2 fields.

**7** Specify the layer the interference check results will be displayed on.

**8** Specify an interference style and a render material.

**9** If you want the interference check to identify pipe network parts that are too close to one another, using a specified distance or scale factor, click the 3D Proximity Check Criteria button.

**10** To use proximity checking options, in the Criteria dialog box, click Apply 3D Proximity Check, and then do one of the following:

- Click Use Distance and enter a distance. When the interference check is run, interferences are created for any pipe network parts that are less than the specified distance away from each other (on any side).

- Click Use Scale Factor and enter a scale factor. When the interference check is run, interferences are created for any pipe network parts that are less than the specified scale factor distance away from each other (on any side).

**11** Click OK in the Criteria dialog box.

**12** Click OK in the Create Interference Check dialog box to run the interference check.

The following prompt is displayed:

Interference check created.

Number of interferences found: X

**13** Click OK at this prompt.

To view the results, in Toolspace, on the Prospector tab, expand the Interference Checks collection, and then select the interference check. The Interference Check data is displayed in the Panorama window and Toolspace item view. See Viewing Interference Check Results (page 1232) for more information.

**To run an interference check between two pipe networks**

**1** Click Analyze tab ➤ Design panel ➤ Interference Check 🐾 .

**2** In the drawing, click any part in the first pipe network.

**3** Click any part in the second pipe network.

**4** In the Create Interference Check dialog box, in the Name field, specify a name for this interference check or accept the default.

**5** Optionally, enter a description in the Description field.

The Network 1 and Network 2 fields display the names of the pipe networks previously selected. If desired, you can use these fields to change the pipe networks for this interference check.

**6** Specify the layer the interference check results will be displayed on.

**7** Specify an interference style and a render material.

**8** If you want the interference check to identify pipe network parts that are too close to one another, using a specified distance or scale factor, click 3D Proximity Check Criteria.

**9** To use proximity checking options, click Apply 3D Proximity Check on the Criteria dialog box, and then do one of the following:

- Click Use Distance to enter a distance. When the interference check is run, interferences are created for any pipe network parts that are less than the specified distance away from each other (on any side).

■ Click Use Scale Factor to enter a scale factor. When the interference check is run, interferences are created for any pipe network parts that are less than the specified scale factor distance away from each other (on any side).

**10** Click OK in the Criteria dialog box.

**11** Click OK in the Create Interference Check dialog box to run the interference check.

The following prompt is displayed:

Interference check created.

Number of interferences found: X

**12** Click OK at this prompt.

To view the results, in Toolspace, on the Prospector tab, expand the Interference Checks collection, and then select the interference check. The Interference Check data is displayed in the Panorama window and Toolspace item view. See Viewing Interference Check Results (page 1232) for more information.

### Quick Reference

Prospector tab: Pipe Networks ➤ Interference Checks ➤ Create Interference Check

Dialog Box

Create Interference Check (page 2070)

## Viewing Interference Check Results

After running an interference check, view the results in the drawing or by looking at the data in the Toolspace list view.

In the drawing, interferences are displayed according to the choices defined in the Interference and Render Material options specified on the Create Interference Check dialog box. These choices are also displayed on the Information tab of the Interference Check Properties dialog box.

To view interference data in the list view, in Toolspace, on the Prospector tab, expand the Pipe Networks ➤ Interference Checks collection. Click on the Interference Check object in the Prospector tree. The interference data is displayed in the list view. You can right-click on the status column and Zoom To an interference in the drawing. If you choose Delete, it deletes only the interference, not the part. In this view, you can also right-click an interference and select Properties to display the Interference Properties dialog box.

## Updating an Interference Check

Update an interference check after pipe network parts have been changed.

An interference check is marked as out of date ▽ when any pipe network part in the interference check is changed. Even changing a description on a pipe network part that is not in interference causes an interference check to become out of date. So does moving, deleting, or adding parts to any network included in the interference check.

**NOTE** Out-of-date icons are displayed only if the Toolspace drawing item modifier icon ▽ display is active. For more information, see Drawing Item Modifier Icons (page 141).

When you update an interference check, you can leave the interference checking conditions as they are currently set, or you can change them before rerunning the check.

Use the Interference Check Properties dialog to change interference check options, criteria, and other properties.

**To update an interference check**

1 In Toolspace, on the Prospector tab, expand the Pipe Networks ➤ Interference Checks collection.

2 Right-click the interference check and click Rerun Interference Check.

The following prompt is displayed:

Interference check created.

Number of interferences found: X

3 Click OK.

The interference check data is updated in the drawing and in the Prospector tree.

**To change interference check conditions or properties**

1 In Toolspace, on the Prospector tab, expand the Pipe Networks ➤ Interference Checks collection.

2 Right-click the interference check and click Interference Check Properties.

3 Change information about the Interference Check Properties (page 2071) dialog box and click Apply to save the changes.

4 Click OK to accept all changes and rerun the interference check.

The following prompt is displayed:

Interference check created.

Number of interferences found: X

5 Click OK.

The interference check data is updated in the drawing and in the Prospector tree.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Pipe Networks ➤ Interference Checks ➤ Create Interference Check

Dialog Box

Criteria (page 2071)

# Setting Interference Styles

You can create styles to display interference conditions in your drawing.

Like other AutoCAD Civil style features, you can set color, size, layer and other styles for interferences.

You can create different interference styles to use for various types of interferences. For example, you can create an interference check and an interference style to specifically identify parts that are too close to one another (but not overlapping), displaying these parts in a certain color.

Use the Pipe Network ➤ Interference Style collection on the Settings tab to create and manage interference styles.

**To create interference styles**

1 In Toolspace, on the Settings tab, expand the Pipe Network collection, then expand the Interference Styles collection, and click New.

The Interference Style (page 2074) dialog box is displayed.

2 Click the Information tab, enter a name for the interference style and, optionally, a description.

3 Click the View Options tab (page 2074) and set interference style options for symbols (markers) and solids that represent interferences.

4 Click the Display tab (page 2075) and set the display style options.

5 Click OK to save changes and close this dialog.

## Quick Reference

Toolspace Shortcut Menu

Settings tab: Pipe Network ➤ Interference Styles ➤ New

Dialog Box

Interference Style (page 2074)

# Deleting Interference Checks

You can easily delete interference checks.

Once you have finalized your drawing or pipe network layout, you may want to delete interference checks from the Prospector tree. When you delete an interference check, it is removed from the Prospector tree. Any visual markers displayed in the drawing to indicate interferences are also removed.

**To delete an interference check**

1 In Toolspace, on the Prospector tab, expand the Pipe Networks ➤ Interference Checks collection.

2 Right-click the interference check and click Delete.

A verification prompt asks if you are sure you want to delete the interference check.

3 Click Yes.

The interference check object is deleted from the Prospector tree. Any visual markers for the interference checking displaying in the drawing are also deleted.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Pipe Networks ➤ Interference Checks ➤ Delete

# Part Properties

Use the Pipe Properties dialog box and the Structure Properties dialog box to view or edit properties associated with any given pipe network part.

Part properties define a variety of characteristics of the part, including the part family the part belongs to, a part type, and properties defining the part's size, shape, elevation, automatic resizing behaviors, and other behaviors. Part properties originate from definitions of the part in the part catalog.

After you insert a part into a drawing, you can edit many of its properties. Those changes apply only to the currently selected part in the drawing. For example, once you add a structure, such as a manhole, to a drawing, you can change the structure's inside diameter by editing the value for the Inner Structure Diameter property, in the Part Data collection, on the Part Properties tab. The default value for the structure's Inner Structure Diameter property that is maintained in the part list (or the part catalog) is not affected.

Part properties are organized into the following categories:

| Category | Description |
| --- | --- |
| General | These properties specify the surface and alignment referenced by the part. For pipes, there are properties that specify flow direction. For structures, the structure elevation at its insertion point is specified. |
| Geometry | For pipes, these properties specify general characteristics of the pipe, such as the flow direction method, flow direction, and the surface and alignment referenced. For structures, these properties specify characteristics such as the structure's rotation angle, offset, station data, and the number of pipes that are currently connected to the structure. |
| Resize Behavior | The resize behavior property is specific to pipes. It specifies the behavior that occurs when the pipe is automatically resized. You can choose to have the pipe hold to its crown, invert, or centerline elevation when it is resized. |
| Hydraulic Properties | For both pipes and structures, these properties specify hydraulic information, such as hydraulic grade lines and energy grade lines, the pipe network may have received from the Storm Sewers Extension. For more information, see Adding Hydraulic Property Data to AutoCAD Civil Pipe Networks (page 1280). |
| Insertion (Rim) and Sump Behavior | These properties are associated with junction structures only. They specify the structure's insertion point (structure rim) and sump elevation and adjustment behavior. |
| Part Data | For both pipes and structures, these properties specify a variety of part characteristics, such as part type, part subtype, and the part size name as defined in the part catalog. Some of these |

| Category | Description |
|---|---|
| | properties define the part's basic primitive shape and behavior, and therefore are read-only. |

The Pipe Properties and the Structure Properties dialog boxes have the following tabs:

■ **Information**. Specifies the name, description, object style, and object render material assigned to the pipe or structure object.

■ **Part Properties**. Displays a list of properties that exist for this part. These properties define the basic size and shape of the part, as well as the part family the part belongs to. This section also specifies hydraulic properties for the pipe network, if they exist. You can edit values for certain properties on this tab.

■ **Rules**. Displays a list of the rules that are associated with the part. These rules originate from the default rule of the part in the part catalog. You can edit the part's rules once you have inserted the part into a drawing. Rules are used to validate certain properties of the part, and also to determine elevation during layout, and during certain editing commands.

The Structure Properties dialog box has the following additional tab for viewing data about pipes connected to the structure:

■ **Connected Pipes**. Displays a list of each pipe connected to the structure, and property values for each pipe. You can edit values for certain properties, such as elevation data, on this tab. It's very useful for quickly editing elevations, slopes, diameters or descriptions for multiple pipes connected to a structure.

**See also:**

■ Part Rules (page 1247)

■ Pipe Properties Dialog Box (page 2039)

■ Structure Properties Dialog Box (page 2051)

**NOTE** Changes made to either the Pipe Properties or the Structure Properties dialog box affect only the selected part in the drawing. It does not affect the part definition in the part catalog or in a parts list.

**To edit pipe or structure properties**

1 Right-click a pipe or structure in the drawing. Click either Pipe Properties or Structure Properties.

2 In either the Pipe Properties or the Structure Properties dialog box, click the Part Properties tab (page 2040).

3 Click a property value, edit it, and click Apply or OK to save changes.

For example, to change the inner diameter of a structure, scroll to the Part Data property group, click the value for the Inner Structure Diameter property, and select a new value.

4 Click Apply or OK to save changes.

For more information, see Part Properties (page 1235).

**NOTE** Changes made to either the Pipe Properties or the Structure Properties dialog box affect only the selected part in the drawing. It does not affect the part definition in the part catalog or in a parts list.

**To edit pipe or structure rules**

1 Right-click a pipe or structure in the drawing. Click either Pipe Properties or Structure Properties.

**2** In either the Pipe Properties or the Structure Properties dialog box, click the Rules tab (page 2043).

**3** Click the desired property value in the Value column, enter a new value, and press Enter.

**4** Click Apply or OK to save changes.

For more information, see Part Rules (page 1247).

# Part Catalog and Parts Lists

The pipe networks feature references a part catalog and a parts list that define the size, shape, and certain behavior of the parts (pipes and structures) you insert into drawings.

### Part Catalog

The AutoCAD Civil part catalog contains definitions for all the pipe network parts that you can insert into a drawing. It is organized at the top level into two basic domains — one for pipe parts, such as cylindrical or rectangular pipes, and another for structure parts, such as headwalls, catch basins, and so on.

Part catalog content is further organized into types, subtypes (also referred to as shapes), and part families. The following table illustrates how the default part catalogs are organized for pipe parts and structure parts.

| Part Domain | Part Type | Part Shape | Part Family |
|---|---|---|---|
| Pipes | Pipe | Circular | Concrete<br>Ductile Iron<br>PVC |
| | | Egg-Shaped | Concrete |
| | | Elliptical | Concrete<br>Concrete Horizontal |
| | | Rectangular | Concrete Box |
| Structures | Inlet-Outlet | Rectangular | Concrete Variable Height<br>Concrete |
| | Junction with Frames | Rectangular | Slab Top Circular Frame<br>Slab Top Rectangular Frame<br>Two-Tier Circular Frame |
| | | Cylindrical | Slab Top Circular Frame<br>Concentric<br>Eccentric<br>Eccentric Two-Tier Circular Frame |

| Part Domain | Part Type | Part Shape | Part Family |
|---|---|---|---|
| | Junction without Frames | Rectangular | Rectangular |
| | | Cylindrical | Concentric Cylindrical |

The files that make up the part catalog content are typically installed to this location: *C:\Documents and Settings\All Users\Application Data\AutoCAD\Civil2010\enu\Pipes Catalog*.

**NOTE** The pipe network part catalog is not related to the corridor (subassembly) catalogs that are available through the Content Browser. Also note that pipe network parts cannot be accessed through a Tool Palette.

### Parts List

A parts list contains a set of pipe network parts – pipes and structures – that you can use in a pipe network. You have parts lists so that you do not have to navigate through the entire part catalog looking for the specific pipe network part that you need.

When you open a new blank drawing by selecting a AutoCAD Civil drawing template, you will typically find default parts lists available, such as Standard. You can create your own parts lists to suit the needs of each project. For example, you may want to create a parts list that contains only the types of parts you will use in a particular project or pipe network. This saves you from having to navigate through the entire part catalog to select a part. While there is only one pipe network part catalog included with AutoCAD Civil, you can create multiple parts lists for your projects.

A parts list also serves as a way to store defaults, such as styles, render materials and design criteria (rules) to any given part upon creation. Parts lists are objects that you can access through the Pipe Network Properties dialog box, the Pipe Network Layout Tools toolbar, and the Toolspace Settings tree.

**NOTE** You can also create a Full Parts list that contains all of the parts that exist in the current metric or imperial part catalog. For more information , see Creating a Full Parts List (page 1239).

## Creating a Parts List

You can create a parts list that contains only the parts (pipes and structures) you will need on a specific pipe network, drawing, or project.

A part list is a subset of available parts in a catalog. It provides quick access to just the parts you need for a specific project.

You can create a parts list by copying an existing parts list and editing it, by creating a new parts list from scratch, or by dragging and dropping a parts list from one drawing into another drawing.

**To create a parts list**

1 In Toolspace, on the Settings tab, expand the Pipe Networks collection, right-click Parts List, and click New. The Network Parts List (page 2035) dialog box is displayed.

2 Click the Information tab, enter a name for the parts list and, optionally, a description.

3 Click the Pipes tab to add pipe parts to this parts list, or the Structures tab to add structure parts.

4 On either the Pipes tab or the Structures tab, right-click the parts list name at the top of the Name field and click Add Part Family. The Part Catalog dialog box (page 2037) dialog box is displayed.

5 In the part catalog, click the check box next to the part families you want to add, and click OK.

6 Click Apply on the Pipes tab or the Structures tabs to save the changes.

**7** On either the Pipes tab or the Structures tab, right-click a part family and click Add Part Size. The Part Size Creator dialog box is displayed.

**8** To add individual sizes of the part, click on and highlight the rows you want to add.

**NOTE** For many part definitions, optional properties are available to the part. For more information, see Assigning Optional Properties to a Part Size (page 1242)

**9** To add all available sizes of the part, place the check mark in the Add All Sizes check box. For more information about adding sizes, see the Part Size Creator (page 2062) dialog box.

**10** Click OK on the Part Size Creator dialog box.

**11** Click Apply to save changes on the Network Parts List dialog box.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: Pipe Networks ➤ Parts List ➤ New

Dialog Box

Network Parts List (page 2035)

## Creating a Full Parts List

You can create a parts list that contains all of the part types and associated sizes that exist in the currently selected metric or imperial part catalog.

It may be useful for you to create this master parts list (full catalog) if you are planning to import pipe networks from LandXML or from the Storm Sewers Extension.

Once the full parts list is created, that is the parts list that you would use when importing pipe network data.

During import, using a full a parts list that contains all of the parts that are available in the catalog can sometimes be the best option for ensuring that appropriate part types and sizes will be found when you import pipe network data.

After creating a full parts list, you may want to configure the Storm Sewers migration settings to always use this full parts list during import. For more information, see Setting the Default Parts List For Migration (page 1277).

**NOTE** It is recommended that you do not use the full parts list while manually laying out (creating by layout) new pipe networks or while editing existing pipe networks. Because the full parts list contains several thousand parts, navigating for parts using this large volume of available part types could be time consuming. The CreateFullPartsList feature is intended primarily to support pipe network data import.

**To create a full parts list**

**1** On the Home tab, click Toolspace ➤ Settings tab, expand the Pipe Network collection, and then expand the Parts Lists collection. Note the names of the existing parts lists displayed in the Settings tree.

**2** Do one of the following:

■ From the ribbon, click the Modify tab ➤ Pipe Network ➤ Network Tools panel ➤ Parts List drop-down menu ➤ Create Full Parts List 

■ At the command line, enter CreateNetworkPartsListFull and then press Enter.

The new full parts list is created. By default, this parts list is named Full Catalog. You may want to rename this to suit your needs.

To configure the Storm Sewers migration settings to always use this full parts list during import, see Setting the Default Parts List For Migration (page 1277).

### Quick Reference

## Copying a Parts List

You can copy an existing parts list in your drawing and give it a new name, or you can copy a parts list from one drawing to another.

**To copy a parts list in a drawing**

1 In Toolspace, on the Settings tab, expand the Pipe Network collection, then expand the Parts Lists collection.

2 Right-click on the parts list you want to copy and click Copy. The Network Parts List (page 2035) dialog box is displayed. A copy of the parts list is created, with Copy of appended to the parts list name.

3 Click the Information tab, change the name for the parts list and, optionally, enter or change the description.

4 Click Apply to save changes.

5 Click the Pipes tab to add or remove pipe parts to this parts list, or the Structures tab to add or remove structure parts.

6 On either the Pipes tab or the Structures tab, right-click the parts list name at the top of the Name field and click Add Part Family. The Part Catalog dialog box (page 2037) dialog box is displayed.

7 In the part catalog, click the check box next to the part families you want to add, and click OK. Note that only part families that are not already included in the current parts list are displayed in the part catalog so that you cannot add the same part family twice in one parts list.

8 Click Apply on the Pipes tab or the Structures tabs to save the changes.

9 On either the Pipes tab or the Structures tab, right-click a part family and click Add Part Size. The Part Size Creator dialog box is displayed.

10 To add individual sizes of the part, click on and highlight the rows you want to add.

---

**NOTE** For many part definitions, optional properties are appended to the part name. For more information, see Assigning Optional Properties to a Part Size (page 1242)

---

**11** To add all available sizes of the part, place the check mark in the Add All Sizes check box. For more information about adding sizes, see the Part Size Creator dialog box (page 2062).

**12** Click OK on the Part Size Creator dialog box.

**13** Click Apply to save changes on the Network Parts List dialog box.

**To copy a parts list from one drawing to another**

**1** With two drawings open, in the first drawing, in Toolspace, on the Setting tab, expand the Pipe Networks collection, and then expand the Parts Lists collection.

**2** Select the desired parts list, drag it (click and hold) to anywhere in the drawing area of the second drawing, and then release the mouse cursor (drop).

**3** In the second drawing, click the Settings tab, expand the Pipe Network collection, and then expand the Parts Lists collection to see the new parts list.

# Adding a Part Family to a Parts List

Add a part family from the pipe network part catalog to a parts list.

After adding a part family, you must select desired part sizes. If you add a part family but do not select the part sizes, part family content is not displayed in the parts list.

**To add a part family to a parts list**

**1** In Toolspace, on the Settings tab, expand the Pipe Network collection, and then expand the Parts Lists collection.

**2** Right-click the desired parts list and click Edit Parts List. The Network Parts List dialog box is displayed.

**3** Click the Pipes tab to add a pipe part family to this parts list, or the Structures tab to add a structure part family.

**4** On either the Pipes or the Structures tab, in the Name column, expand the parts list to view the part families that are currently included.

**5** Right-click the name of the parts list at the top level and click Add Part Family. The Part Catalog (page 2037) dialog box is displayed.

> **NOTE** Part families that are included in the current parts list are not displayed in the part catalog. Only part families that are available to be added to the current parts list are displayed in the part catalog.

**6** In the part catalog, select the part families you want to add, and click OK.

**7** Click OK or Apply on either the Pipes tab or the Structures tab to save the changes.

After you have added one or more part families to the parts list, the next step is to select the part sizes you want. See Adding Part Sizes to a Parts List (page 1242).

## Quick Reference

Toolspace Shortcut Menu

Settings tab: Pipe Network ➤ Parts Lists ➤ <parts list name>➤ Edit Parts List

Dialog Box

Network Parts List (page 2035)

# Adding Part Sizes to a Parts List

After a part family is added to a parts list, select the part sizes you want to be available in that part family.

When creating new parts lists, you first add the part families, and then add the part sizes that you want to be available within that family.

For example, for the Elliptical Concrete Pipe family, you can add only the part size of 8-inch inner pipe width, or you can click Add All Sizes to add all of the size choices that are available in the drop-down list for the inner pipe width value (for example, 8, 12, 18, etc.).

If you do not add part sizes within a part family, no content is displayed for that part family in the parts list.

For existing parts lists, you can add part sizes at any time.

**To add part sizes to a parts list**

1   In Toolspace, on the Settings tab, expand the Pipe Network collection, and then expand the Parts Lists collection.

2   Right-click the desired parts list and click Edit Parts List. The Network Parts List dialog box is displayed.

3   Click the Pipes tab to add sizes for pipe parts, or the Structures tab to add sizes for structures.

4   Expand the parts list so that you can see the part families that are currently included.

5   Right-click a part family and click Add Part Size. The Part Size Creator dialog box is displayed.

6   Use the Part Size Creator (page 2062) dialog box to add part sizes to the current part family.

    You can select existing sizes one at a time, or you can use the Add All Sizes check box. For example, for the Elliptical Concrete Pipe part family, you can add only the part size of "8-inch inner pipe width", or you can check Add All Sizes to add all the size choices that are available in the drop-down list simultaneously: for example, 8, 12, 18, and 24.

7   For each part size that is added, you may also add optional properties which are not defined in the part family.

    For example, to specify a material for a pipe, add the optional Material property and enter the desired text to set the property. For more information, see Assigning Optional Properties to a Part Size (page 1242).

8   Click OK on the Part Size Creator dialog box.

9   Click OK or Apply on either the Pipes tab or the Structures tab to save the changes.

# Assigning Optional Properties to a Part Size

To add further definition to a part, such as a name for a material, you can assign optional properties to a part size definition in a parts list.

After an optional property is assigned to the part, the property may be viewed or edited in the Part Properties tab (page 2040) of either the Pipe Properties or the Structure Properties dialog box, viewed or edited in the Pipe Network Vistas (page 2064), or it can be displayed as labeling text for the part in the drawing.

An example of an optional property is the Material property available for the Concrete Pipe part family. You can assign this optional property to part sizes within the Concrete Pipe part family.

**To add an optional property to a part size**

1   In Toolspace, on the Settings tab, expand the Pipe Network collection, and then expand the Parts Lists collection.

**2** Right-click the desired parts list and click Edit Parts List. The Network Parts List dialog box is displayed.

**3** Click the Pipes tab to assign an optional property to a pipe part size, or the Structures tab to assign an optional property to a structure part size.

**4** On either the Pipes tab or the Structures tab, in the Name column, expand the parts list so that you can see the part families that are currently included.

**5** Right-click the desired part family and select Add Part Size.

**6** The Part Size Creator Dialog Box (page 2062) is displayed. The optional properties are identified in the Source field.

**7** If the optional property can be assigned, you can click in the Value field and set the property from a list of choices. If the optional property has a static value, no choices are available.

**8** Click in the Value field to select and assign the property.

**9** Click OK on the Part Size Creator dialog box.

**10** Type in the value or string.

**11** Click OK or Apply on the Pipes or Structures tabs to save the changes.

---

**NOTE** All optional properties available for a part family can be set, even after the part has been created, by displaying the Pipe Properties or Structure Properties dialog box.

---

**To add a user-defined property to a network part**

**1** Navigate to the Part Parameter Configuration xml file (AeccPartParamCfg.xml). The default location is *C:\Documents and Settings\All Users\Application Data\Autodesk\AutoCAD <version>\enu\Pipes Catalog\Aecc Shared Content*.

**2** Open the file and select View ➤ Source in order to modify the file.

**3** Navigate to the <AeccParamDeclaration> section. A sample optional property is the Hazen Williams Coefficient flow analysis. The entry for this is: <AeccDfParameter name="ACHW" desc="Hazen Williams Coefficient" context="FlowAnalysis_HazenWilliams" index="0" datatype="Float" usage="Double_General" unit="" visible="True" internal="True"/>.

**4** Copy an existing optional property and make changes as appropriate to create a new property.

**5** In the <AeccParamUsage> section, the corresponding entry for the sample in step 3 is <AeccOptParam context="FlowAnalysis_HazenWilliams"/>. Copy and modify an entry as appropriate to create an new entry for your property.

**6** Save and close the xml file.

# Setting the Pipe Network Part Catalog

You can configure AutoCAD Civil to access the imperial or the metric pipe network part catalog, or to access specific folders for pipe and structure parts content.

The part catalog contains the definitions for all the pipe network parts that you can insert into a drawing.

The default part catalog location is *C:\Documents and Settings\All Users\Application Data\AutoCAD\Civil2010\enu\Pipes Catalogs*.

**To set the pipe network part catalog**

**1** Click Home tab ➤ Create Design panel ➤ ▼ ➤ Set Pipe Network Catalog 🔧 .

**2** On the Pipe Network Catalog Settings dialog box, click the folder icon to browse to the location of the pipe network catalog folder. This is the top-level folder containing all the pipe network part catalogs. For example, this folder contains subfolders for imperial and metric pipes and structures.

The default part catalog location is *C:\Documents and Settings\All Users\Application Data\AutoCAD\Civil2010\enu\Pipes Catalogs*.

**3** Select the desired folder and click Open.

**4** You may want to specify different pipe and structure catalogs, if they are available.

**5** Click OK to save changes to this dialog box.

## Editing Part Family Sizes

Use the Part Builder feature to change the part sizes that are available in a part family.

If a part family does not have the sizes you need, you can modify the part family sizes using the Part Builder feature.

**To edit part sizes in a part family**

**1** Enter PartBuilder at the command line and press Enter.

**2** Select Pipe or Structure from the Part Catalog drop-down list.

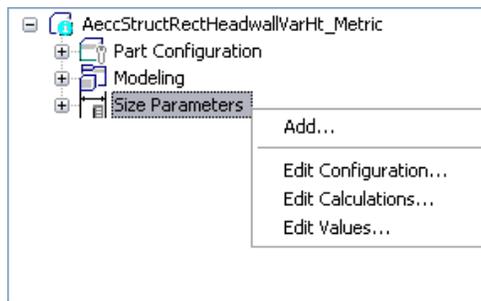
**3** Using the catalog tree, locate and select the Part Family you want to edit.

**NOTE** Pipe and structure families are organized by type. For example, pipe families are organized into types such as circular pipes, egg-shaped pipes, and so on. Structure families are organized into inlet-outlet structures, junction structures with frames, and so on.

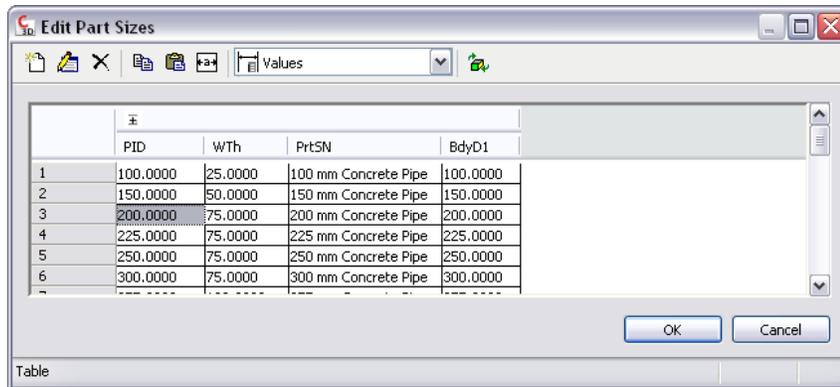
**4** Click the Modify Part Sizes button , or double-click the Part Family, to display the Part Family browser window.

**5** If this is a Part Family that shipped with AutoCAD Civil, click the Save Part Family As button in the Part Family browser window toolbar

**6** In the Save Part Family As dialog box, enter a new Part Name and Part Description and then click OK. This creates your own version of the selected Part Family you can edit.

**7** In the Part Family browser window, right-click the Size Parameters node, and click Edit Values.


**8** In the Edit Part Sizes dialog box, find the parameter (property) value(s) you want to edit.



**9** Edit the values as described below:

**Pipe values**

■ To change values for pipe sizes, select the row and size cell. Double-click to edit.

■ To delete a size row, select the row and click the Delete button ✖ on the Edit Part Sizes dialog box.

■ To add a size row, select the closest size and click the New button on the Edit Part Sizes dialog box, and then edit the values in the new row.

**Structure values**

■ To edit list values for structure sizes, select the cell and click the New button on the Edit Part Sizes dialog box.

**10** After you have completed editing sizes, click OK on the Edit Part Sizes dialog box.

**11** In the Part Family browser window toolbar, click the Save Part Family button .

**12** When finished editing part sizes, close the Part Builder by clicking the close button in the upper right corner of the Part Family browser window.

**13** You will be prompted to save the part family with the following dialog box. Click Yes at this prompt.

**14** Next, you may be prompted to save the part family drawing file with the following dialog box. Click No at this prompt.

The new part family and the new part sizes you create will be available through the Network Layout Tools toolbar.

# Sample Part Family Size Editing

This sample exercise walks you through how to edit the part sizes that are available in a part family.

In this example, you will edit the Pipe Inner Diameter (PID) and Wall Thickness (Wth) values in the Concrete Pipe part family.

**To edit part sizes in the Concrete Pipe part family**

1   Enter PartBuilder at the command line and press Enter.

2   Click the Part Catalog drop-down list and select Pipe.

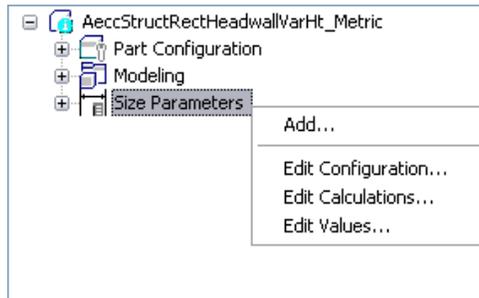
3   In the catalog tree, expand the Circular Pipes node, then select the Concrete Pipe part family.

4   Double-click the Concrete Pipe part family or click the Modify Part Sizes button ▣ .

5   Click the Save Part Family As button ▣ .

6   In the Save Part Family As dialog box, enter a new Part Name and Part Description for this new part family and then click OK. This creates your own version of the selected Part Family you can edit.

7   In the Part Family browser, right-click the Size Parameters node, and click Edit Values.



8   In the Edit Part Sizes dialog box, click the Autosize Column Text button then find the Pipe Inner Diameter (PID) value and the Wall Thickness (WTh) values.

9   Select any row in the table and click the New button ▣ on the Edit Part Sizes dialog box. The selected row is copied to the table.

10   In the new table row, edit the PID and WTh values by double-clicking on them and typing in the new values.

11   After you have completed editing sizes, click OK on the Edit Part Sizes dialog box.

12   In the Part Family browser window toolbar, click the Save Part Family button ▣ .

13   When finished editing part sizes, close the Part Builder by clicking the close ▣ button in the upper right corner of the Part Family browser window.

14   You will be prompted to save the part family. Click Yes at this prompt.

15   Next, you may be prompted to save the part family drawing file. Click No at this prompt.

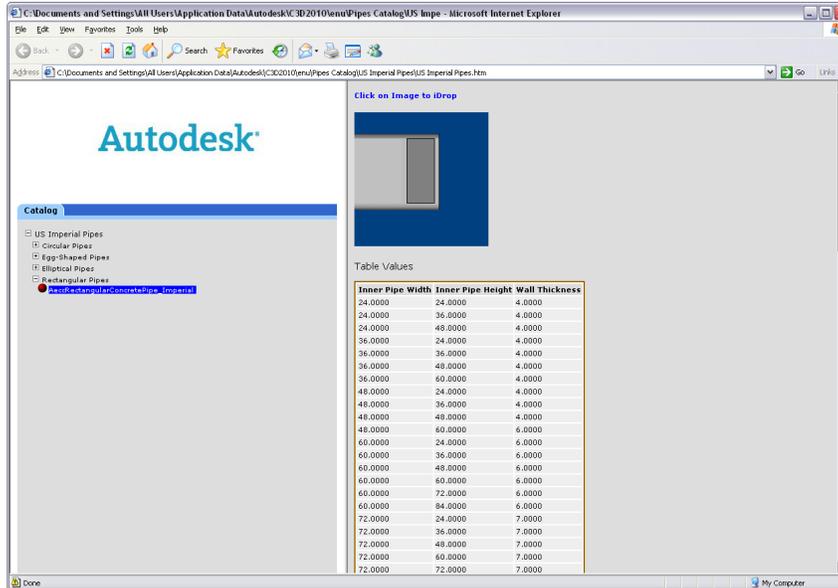
   The new part family will not be available when creating or editing a pipe network until you edit the parts list and add this new part family to your parts list. For more information, see Adding a Part Family to a Parts List (page 1241)

Once you have added the new part family to your parts list, the new part family and the new part sizes you created will be available through the Network Layout Tools toolbar.

# Viewing Part Catalog Content

Use an Internet Explorer window to view content from a published part catalog.

The Internet Explorer view shows an image of the 2D or 3D shape and lists all the defined values associated with the part family. For example, all size parameters, whether defined as table, list, range, and or calculated values (formulas), can be viewed in a read-only mode. Constant values, such as the part domain, type, subtype, part name, description, and the ID associated with the part, are all displayed.



**To view published part catalog content using Internet Explorer**

1  Using Internet Explorer, navigate to the location of the part catalog, for example, *C:\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\Pipes Catalog\US Imperial Structures*.

2  Double-click the name of the desired part catalog, for example, US Imperial Structures.htm.

3  In the left pane catalog tree, expand a node and then select a part family.

   For example, expand the Junction Structures With Frames node, and then select the AeccStructEccentricCylinder_Imperial part family.

Content for the selected part family is displayed in the right pane.

# Part Rules

Part rules are properties that affect how pipe network parts behave on creation and when you move or edit them.

AutoCAD Civil pipe network objects use part rules in the following ways:

■  To determine elevations for pipes and structures when they are created.

■  To determine how pipes connect to junction structures.

■  To warn that certain criteria is not met while creating or editing pipe networks.

Primarily, part rules automatically determine reasonable elevations for parts as they are created. The specific elevation behavior you see is based on choices you make, such as how you define the minimum slope, minimum cover, and desired drop across a structure. Rules also provide automatic validation of your pipe

network design, such as checking to see if a structure is too small to accommodate a pipe size, if the length of a pipe is greater than desired, or the maximum cover above a pipe is exceeded.

Rules provide an excellent way to give a good starting point for design. They also provide a way to quickly determine if the location of a series of pipes and structures is actually constructible.

Rules are applied to parts automatically as they are created. However, you can reapply rules to existing parts in your drawing as needed. Reapplying rules ensures that unintended changes are not made. For example, if you move a structure that has pipes connected to it, you may want to reapply rules after moving the structure to ensure that the pipes connected to it still have the desired elevations, minimum cover, and do not exceed a maximum length.

The pipe network rules features provides a high level of design automation, while still allowing you to specify the design according to your judgment and site-specific requirements. When rule parameter values are violated on pipe network parts in the drawing, you can quickly review the violations and determine if you need to edit the drawing or simply allow the rule violations.

**NOTE** It is important to note that rules are not applied to pipes or structures when importing pipe networks from either LandXML or from the Storm Sewers Extension. For more information about rules, see Part Rules (page 1247).

### Default Rule Behavior

The default rule behavior for pipe network parts is designed to meet the needs of some typical design scenarios. You can lay out a pipe network without editing, removing, or adding part rules, and this behavior may suit your needs. If you want to change the default rule behavior, you can do so by edit part rule values, or by adding or removing rules from a part using Rule Sets. See Editing Part Rules (page 1258) for more information.

The default pipe network rule behavior in AutoCAD Civil is controlled by the following files:

- C3DPipeRules. This Visual Basic script file is similar in design and architecture to the script file that controls AutoCAD Civil subassembly behavior for corridor modeling.

- C3DPipeRules.xml. This file defines the pipe network part rule parameters and rule names.

These files are located in located in the *\data* folder. The *\data* folder installed to *\\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\data* by default.

### Rules and Parts Lists

Each part in a pipe network parts list references a set of pre-defined rules. When a pipe or structure is inserted into a drawing, the rule set is referenced by the part itself. Therefore, changes made to the part in the part catalog, or removing a part from the parts list, will have no effect on a part that has already been inserted into a drawing.

### Rule Sets

A default "rule set" exists for both pipes and structures that are inserted into your drawing. The rule set behaves like a style, except that you can also override values if desired. Rule sets simply provide a way for you to create a set customized set of rules. You can add or exclude certain rules, edit certain rule values, or change the order in which the rules are processed on a part, and you can save all these changes in a named rule set. This gives you the ability to control and customize the rule behavior for a specific pipe network or pipe network part.

**See also:**

- Creating a Rule Set (page 1259)
- Pipe Rule Set dialog box (page 2037)

■ Structure Rule Set dialog box (page 2050)

## Rule Violations

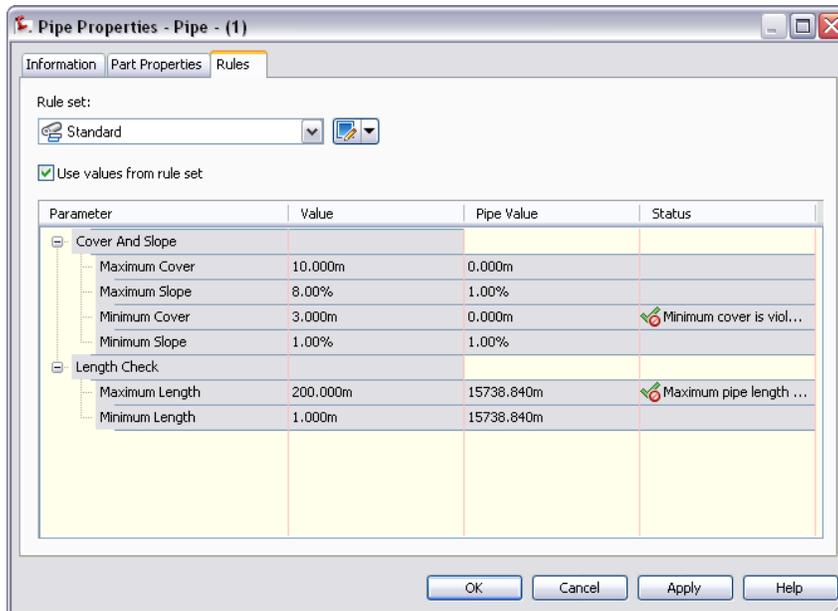
Rule violations inform you when pipe network part parameter values have not been met or exceed certain limits.

Whenever rules are applied to a part, validation checks occur to inform you, for example, if minimum or maximum cover limits have been violated, or if some other condition needs attention.

When warnings occur due to rule violations, they are displayed as warning icons ![icon] in the Pipe Network Vistas (page 2064) (Panorama window or Toolspace item view). Rule violation information is also displayed on the Rules tab (page 2043) of the Pipe or Structure Properties dialog box, in the Status column. Placing the mouse cursor over the warning icon in the Prospector List View displays tooltip text describing the warning (rule violation) condition. This tooltip displays the same rule violation text that is displayed in the Status column on the Rules tab of the Pipe or Structure Properties dialog box.

The following illustration is an example of the Rules tab on a pipe in a drawing. In this example, the Minimum

Cover and Maximum Length properties for this pipe display with descriptive rule violation text ![icon] in the Pipe Value column because they violate the design criteria specified in the Value column. Note the rule violation descriptive text that is displayed in the Status column; for example, "Minimum pipe cover exceeded" and "Exceeds the maximum pipe length by".



**Fixing Broken Rules**

The pipe network rule feature is a mechanism for visually identifying conditions that violate the design criteria rules that are in place for pipes and structures. You can choose to leave broken rule conditions as they are, or you may desire to resolve the broken rule conditions, depending on the circumstances.

If you wish to resolve a broken rule condition, there are a few different ways you can do this. You can edit the value in the Value column (editing the rule). You can also edit the pipe or structure object itself in the drawing so that it no longer violates the rule. For example, you could move a pipe to a different elevation so that it no longer violates a Minimum Cover rule. In some situations, you may want to reapply rules to a pipe network, or to pipe network parts, when you have a rule violation.

**NOTE** It is important to note that reapplying rules does not automatically resolve rule violations. In some situations, reapplying rules may result in more rule violations, some of which you may decide to simply leave as violations. For example, there may be some situations where you have certain site-specific cover constraints that you want to intentionally violate.

Note that if you edit the Rule Value on a pipe network part in a drawing, it does not affect the rule for other parts in the drawing, for parts in the parts list, or for parts in the parts catalog. It also does not alter any physical characteristics of the part in the drawing. It simply alters the rule limit on that particular part in your drawing.

## Applying Rules to Parts in a Drawing

You can apply rules to pipe network parts to ensure that certain conditions are flagged, and to ensure that parts are placed in correct locations.

For example, you may need to reapply rules to ensure that pipes that have not met the maximum cover value are flagged as rule violations. This enables you to quickly identify parts that may need to be adjusted in your drawing. You may also want to reapply rules after you moved a structure that has pipes connected to it to ensure that the connected pipes still exist in the correct elevation and connection locations.

When you apply rules to a pipe network part, rule values as defined in the Pipe Rule Set or Structure Rule Set for the part are copied to the part.

You may need to reapply rules when:

■ The elevation of a pipe network part has changed due to pipe network parts being moved.

■ A part's rule value has changed.

■ You add or delete a rule from a part.

■ You change the order in which rules are processed on the part.

If you look at the rule set assigned to a part, you can view the rule set, and the rules currently associated with the part. You cannot change the processing order of the rules on the Structure or Pipe Properties Rules tab. However, you can change the order of the rules by displaying the Rules tab on the Rule Set.

Applying rules does not automatically resolve rule violations. You can view rule violations leave them as is, or resolve them.

In some situations, reapplying rules may result in more rule violations, some of which you may decide to simply leave as violations. For example, there may be some situations where you have site-specific cover constraints that you want to intentionally violate.

**To apply rules to a pipe network part**

➤ In the drawing, right-click either a pipe or structure in a pipe network, and then click Apply Rules.

At the command line, a prompt is displayed indicating that rules have been successfully applied to the network part(s).

For more information, see Part Rules (page 1247).

**To apply rules to parts in a pipe network**

1 Click Pipe Networks tab ➤ Modify panel ➤ ▼ ➤ Apply Rules 🖳 .

2 In the drawing, select pipe network parts in an up-slope direction.

3 When finished selecting parts, press Enter to end the command.

At the command line, the following prompt is displayed:

Rules successfully applied to X network parts.

For more information, see Part Rules (page 1247).

# Pipe Rules

These rules primarily govern how the elevations of a pipe object are determined when the object is created. There are also rules to flag pipes that exceed certain values, such as maximum length, for example.

When a pipe rule is violated, you can complete the action, but a warning icon ![icon] is displayed for the pipe object in the Pipe Network Vistas (page 2064) (Panorama window or Toolspace item view), and on the Rules tab (page 2043) of the Pipe Properties dialog box. This indicates that a rule violation exists.

After a pipe object is created, you may make changes to the pipe that result in the pipe rules being violated. For example, you might move a pipe so that the Minimum Cover distance is not met.

The following sections describe the standard rules available for pipe objects.

## Cover And Slope Rule

This rule ensures that a pipe slopes appropriately and warns when a pipe is placed too close to a ground surface.

For gravity-based systems, this is perhaps the most useful rule. It ensures that a pipe slopes in the desired direction under various conditions, while ensuring that minimum cover is not exceeded. In addition, it manages conditions when a pipe drop across structure rule conflicts with the pipe's slope and cover rules.

When drawing a pipe, the pipe attempts to stay within minimum and maximum cover values, unless the minimum or maximum slope is reached. At that point, maximum cover distance is exceeded to satisfy the minimum slope requirement, if it is violated.

This rule ensure the following, with the first pipe having the highest precedence or priority:

■ The connections to structures are at a location as specified by the structure rules, if any are specified.

■ The pipe always slopes in the proper direction, with the minimum slope being honored, unless this is in conflict with a connected structure.

■ The minimum cover is maintained unless this is in conflict with a connected structure.

### Parameters

The following parameters govern the behavior of the pipe Cover And Slope rule.

■ Maximum Cover. Specifies the maximum cover of soil over the length of the pipe, based on the surface being referenced by that pipe. If the maximum cover is exceeded, a rule violation occurs. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

■ Maximum Slope. Specifies the maximum slope of the pipe, expressed in percent. If the pipe slope is greater than the maximum, a rule violation occurs for that object.

■ Minimum Cover. Specifies the minimum cover of soil over the pipe, based on the surface being referenced by that pipe. During layout, a pipe will be created that attempts to maintain the minimum cover. This is also used to determine the initial elevations of the pipe. If the pipe is edited so that its cover is less than the minimum cover value, a rule violation occurs for that object.

- Minimum Slope. Specifies the minimum slope of the pipe, expressed in percent. During layout, a pipe will be created according to its minimum slope rule value. If the pipe is edited so that its slope is less than the minimum, you can still edit the pipe as desired, breaking the minimum slope rule, but a rule violation occurs for that object.

## Cover Only Rule

This rule is intended for laying out pipes in a pressure-based pipe network where pipe elevations are determined according to a specified depth below a terrain.

This rule ensures that the minimum cover is met along the length of the pipe, and also validates that both the minimum and maximum cover values are not violated along any length of the pipe.

### Parameters

The following parameters govern the behavior of this rule:

- Maximum Pipe Cover. Specifies the maximum cover of soil over the pipe, based on the surface being referenced by that pipe. If the pipe cover exceeds the maximum cover value, a rule violation occurs for that object. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

- Minimum Pipe Cover. Specifies the minimum cover of soil over the pipe, based on the surface being referenced by that pipe. During layout, a pipe will be created that attempts to maintain the minimum cover. If the pipe is edited so that its cover is less than the minimum cover value, a rule violation occurs for that object.

- Start Cover. Specifies the cover at the start of the pipe.

- End Cover. Specifies the cover at the end of the pipe.

---

**NOTE** For spanning pipe labels **Start Cover** will display the cover at the beginning of the span of pipes that comprise the spanning pipe label. **End Cover** will display the cover for the very end of the span. The start and end of the spanning pipe label depends on the order in which pipes where selected when creating the pipe span.

---

## Length Check Rule

This rule governs the behavior that produces a warning condition on a pipe if the pipe length exceeds the value specified for the maximum pipe length, or is less than the value specified for the minimum pipe length.

This rule determines whether the 2D length of the pipe meets the values specified for the minimum and maximum pipe lengths. For this rule, the pipe is measured from pipe end to pipe end, not from the inside edge of the structure.

This rule is useful for design situations that require or recommend a maximum, continuous pipe length. This rule also includes a minimum pipe length warning option. Keep in mind that this rule does not prevent you from exceeding the minimum/maximum lengths. It notifies you that the specified length is being exceeded.

### Parameters

The following parameters govern the behavior of the Length Check rule.

- Maximum Pipe Length. This parameter lets you define a maximum length for pipes. When this parameter (rule) is in use, you can still draw pipes that exceed the defined maximum pipe length. However, the object will be displayed with a warning icon in the Prospector list view. Note that this parameter provides

validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

■ Minimum Pipe Length. This parameter lets you define a minimum length for pipes. When this parameter (rule) is in use, you can still draw pipes that are shorter than the defined minimum pipe length. However, the object will be displayed with a warning icon in the Prospector list view. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is not met.

## Pipe To Pipe Match Rule

This rule governs how a pipe elevation is determined in a pipe network that contains only pipes (no structures), and or when a pipe is inserted onto an existing pipe to break the pipe.

This rule applies only during the following conditions:

■ Creating a pipe network that has pipes only (no structures)

■ Breaking into an existing pipe with another pipe

■ Connecting a pipe to a null structure (pipe to pipe connection with no structure)

■ Connecting a pipe to an existing pipe end

This rule manages conditions so that only continuous runs of pipe are created as typically expected. In pipe networks where the pipe size is constant, pipes connected to other pipes must to match end to end. In pipe networks where pipe sizes change, the point where pipes match may change, depending on the type of system. For example, in pressure systems, it may be typical to match the pipe centerline. In gravity systems, it may be typical to match the crowns of the pipes.

This rule also incorporates a drop value for cases where a pipe-to-pipe connection requires a drop amount.

### Parameters

The following parameters govern the behavior of this rule:

■ Match Location. This parameter controls whether the inserted pipe holds to the pipe's invert, crown, or centerline elevation (location).

■ Drop Value. The drop value allows you to specify an additional drop amount at pipe to pipe connections.

## Structure Rules

These rules govern primarily how a structure object is placed and sized during object creation. They also can determine the elevations of connected pipes. There is also a rule to flag pipes that are too wide to connect to a structure.

Just like pipe rules, when structure rules are violated, a warning icon is displayed for the object in the Pipe Network Vistas (page 2064) (Panorama window or Toolspace item view), and on the Rules tab (page 2057) of the Structure Properties dialog box.

The following sections describe the standard rules associated with structure objects.

## Pipe Drop Across Structure Rule

This rule compares all pipes connected to a single structure and ensures that pipes enter and exit the structure according to the specified drop value.

This rule applies to junction structures only and is intended specifically for gravity-based systems. It is important to note that this rule does not alter the structure in any way, nor does it alter any of the pipes that are connected to the structure. Instead, this rule actually inserts data onto the structure that is read by the pipes when they are using rules. It ensures that the following conditions are achieved when connecting a new pipe to a structure that already has one or more pipes connected to it:

■ A pipe exiting a structure is no higher than the lowest pipe entering the structure.

■ A pipe entering a structure is no lower than the highest pipe exiting a structure.

■ There is always a specified minimum drop distance between the lowest incoming pipe and the highest outgoing pipe.

The drop can be based on a comparison between the crowns, inverts, or centerlines of pipes. A validation check is performed for drops exceeding a certain distance. This determines whether a maximum drop value is violated or whether a drop is required.

**Parameters**

The following parameters govern the behavior of this rule:

■ Drop Reference Location. Specifies the drop location by referencing the pipe's invert, crown, or centerline elevation.

■ Drop Value. Specifies the drop value between the lowest incoming pipe and the highest outgoing pipe connected to the structure.

■ Maximum Drop Value. Specifies what the maximum drop value is between the lowest incoming pipe and any outgoing pipe connected to the structure. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded. This is intended to raise awareness when a drop structure might be needed.

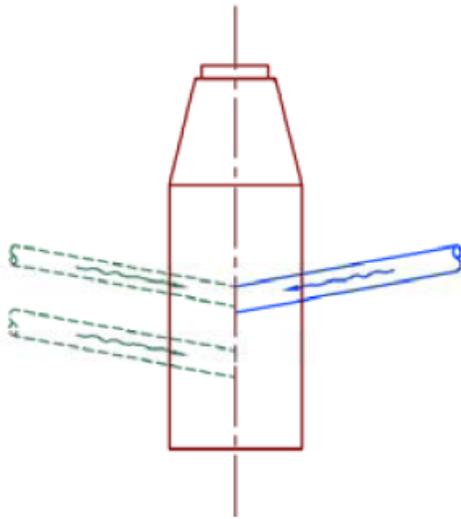
## Pipe Drop Across Structure Rule Examples

The Pipe Drop Across Structure rule applies in a variety of scenarios.

The following examples show how the Pipe Drop Across Structure rule is applied when a new incoming or outgoing pipe is added to a structure that already has pipes connected to it.

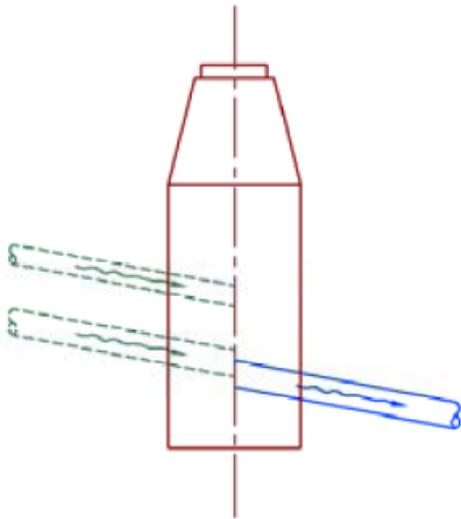
The following illustration shows a junction structure that has two incoming pipes already connected to it on the left side of the structure. When a new incoming pipe is added to the right side of the structure, the pipe cover and slope rule determines the optimal connection elevation for the new incoming pipe.

**Example 1: Existing Incoming Pipes with New Incoming Pipe**



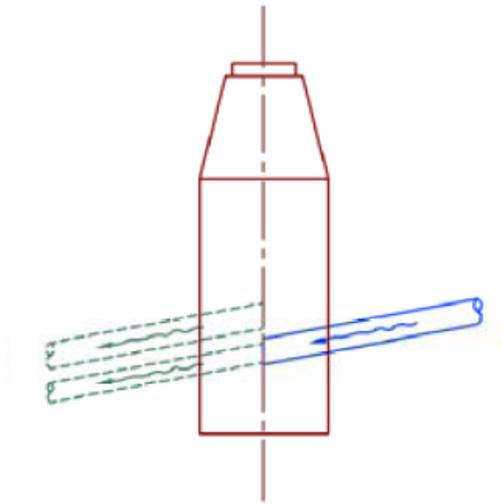
In the following illustration, the junction structure has two incoming pipes already connected to it on the left side of the structure. A new outgoing pipe is added to the right side of the structure. The pipe cover and slope rule determines the optimal connection elevation for the new outgoing pipe.

**Example 2: Existing Incoming Pipes with New Outgoing Pipe**



The following illustration shows a junction structure that has two outgoing pipes already connected to it on the left side of the structure. A new incoming pipe is added to the right side of the structure. The pipe cover and slope rule determines the optimal connection elevation for the new incoming pipe.

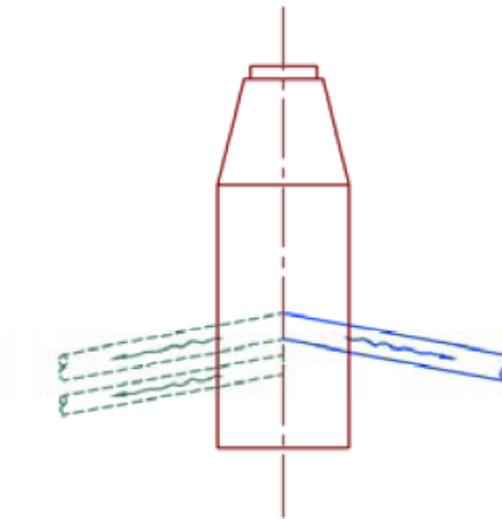
**Example 3: Existing Outgoing Pipes with New Incoming Pipe**



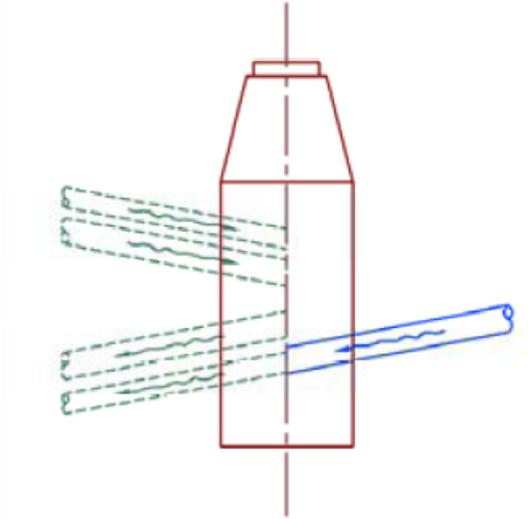
.

The following illustration shows a junction structure that has two outgoing pipes already connected to it on the left side of the structure. A new outgoing pipe is added to the right side of the structure. The pipe cover and slope rule determines the optimal connection elevation for the new outgoing pipe.

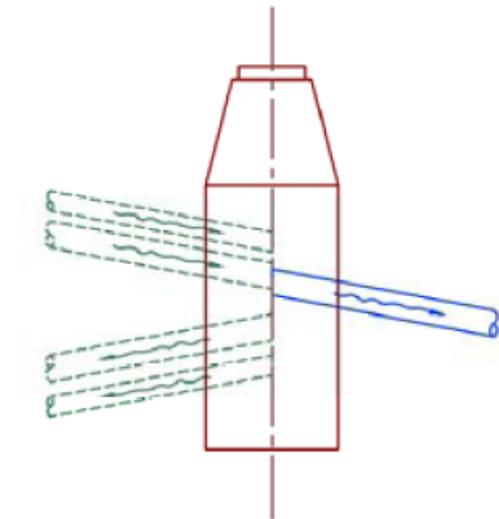
**Example 4: Existing Outgoing Pipes with New Outgoing Pipe**



The following illustration shows a junction structure that has four pipes already connected to it on the left side of the structure. Two of those pipes are incoming pipes, and the other two are outgoing pipes. A new *incoming* pipe is added to the right side of the structure. The pipe cover and slope rule determines the optimal connection elevation for the new incoming pipe.

**Example 5: Existing Incoming and Outgoing Pipes with New Incoming Pipe**


The following illustration shows a similar situation with both incoming and outgoing pipes already connected. In this case, a new *outgoing* pipe is added to the structure. The pipe cover and slope rule determines the optimal connection elevation for the new outgoing pipe.

**Example 6: Existing Incoming and Outgoing Pipes with New Outgoing Pipe**


## Maximum Pipe Size Check Rule

This rule checks to see if pipes entering a structure have a diameter or width that exceeds a specified maximum value.

This rule analyzes all pipes attached to a structure and checks to see whether the pipe diameter or width is within the specified maximum value. For example, a manhole that is three feet wide in diameter may not be able to accommodate a pipe that is three feet wide in diameter.

### Parameters

The following parameters govern the behavior of this rule:

■ **Maximum Pipe Diameter or Width.** For circular pipes, this parameter measures the pipe diameter. For rectangular pipes, it measures width. If a pipe diameter or width exceeds the maximum value, a warning is issued on the structure. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

## Set Sump Depth Rule

This rule sets the sump elevation of junction structures based on the user-specified parameters and the invert elevations of pipes attached to the structure.

When this rule is applied, the elevation of the inside bottom (sump) of the structure is calculated by subtracting the user-specified sump depth from the elevation of the lowest invert in the structure.

### Parameter

The following parameter governs the behavior of this rule:

■ **Sump Depth.** Specifies the sump depth, or the vertical distance from the invert of the lowest pipe attached to the structure to the inside bottom of the structure.

# Editing Part Rules

Use the Rules tab of either the Pipe Properties or the Structure Properties dialog box to edit the values for rules associated with a part in a pipe network.

Editing the rule values for a part in a drawing affects only the currently selected part in your *drawing*. It does not affect the definition of the part as it exists in the pipe network *part catalog*.

You can also edit rules as they are defined for a rule set in the Settings tree. For example, in the Toolspace Settings tree ➤ Pipe ➤ Pipe Rule Set collection, you can add rules, remove rules, or edit rule values for a particular rule set. This provides a convenient method for creating rule sets intended for a specific pipe network or project.

For example, you could create a rule set that has the Length Check rule value set to a certain value. You could do the same for the Cover and Slope rule.

**To edit rule values for a part in a pipe network**

1 In the drawing, right-click either a pipe or structure in a pipe network, and then click either Pipe Properties or Structure Properties.

2 Click the Rules tab.

3 Select the value of the rule you want to edit and enter a new value.

4 Click Apply or OK to save the changes.

**To add, remove, or edit rules in a rule set**

1 In Toolspace, on the Settings tab, expand either the Pipe or Structure collection.

**2** Expand either the Pipe Rule Set or Structure Rule Set collection

**3** Double-click a rule set. The Pipe or Structure Rule Set dialog box is displayed.

**4** Click the Rules tab.

Add or delete rules by clicking Add Rule or Delete Rule. Edit a rule value by clicking on the value and entering a new value.

**5** Click Apply or OK to save the changes.

## Overriding Part Rules

Override part rules if you do not want certain conditions flagged with warnings in the Prospector list view and in the Event Viewer.

You can select a part in a pipe network and override the rule value that governs it.

**To override rules from a rule set**

**1** In the drawing, right-click a pipe network part (either a pipe or structure), and then select either Pipe Properties or Structure Properties.

**2** Click the Rules tab.

**3** Clear the Use Values From Rule Set check box.

**4** Click Apply or OK to save the changes.

## Creating a Rule Set

Use rule sets to create customized rule behavior for pipe network parts.

A default "rule set" exists for both pipes and structures. The rule set simply provides a way for you to create a set of customized rules. You can add or exclude certain rules, or edit certain rule values, and save them in a named rule set designed to control the behavior for a specific pipe network or project.

For more information, see Part Rules (page 1247), the Pipe Rule Set dialog box (page 2037), or the Structure Rule Set dialog box (page 2050)

**To create a rule set**

**1** In Toolspace, on the Settings tab, expand either the Pipe or Structure collection.

**2** Right-click either Pipe Rule Set or Structure Rule Set. Click New.

**3** On the Rule Set Information tab, enter a name for the new rule set. Optionally, enter a description.

**4** Click the Rules tab.

**5** Click Add Rule to add a rule.

**6** In the Add Rule dialog box, in the Rule Name drop-down list, select a rule to add.

When you select a rule, its parameters are displayed in the Rule Parameters table.

**7** Click OK in the Add Rule dialog box.

**8** Edit a rule value by clicking a value on the Rules tab and entering a new value, or select one from a list.

**9** Click Apply or OK to save the changes.

## Converting VBA Rules to .NET

In drawings, you can convert AutoCAD Civil pipe and structure rules that are VBA-based to .NET.

In Civil 3D 2008, and in earlier versions of Civil 3D, the pipe and structure rules that were included in the product were created using VBA, and maintained in a .dvb file (*C3DPipeNetworkRules.dvb*).

In Civil 3D 2009, new pipe network rule sets that are created now point to the .NET dll version of rules, and therefore point to a .NET .dll file (*C3DPipeNetworkRules.dll*).

The .NET-based rules typically provide optimal performance over VBA-based rules. Civil 3D 2009, and later versions, still support VBA-based rules.

If you have not made any modification to your VBA pipe networks rules file (*C3DPipeNetworkRules.dvb*), it is recommended that you convert the pipe and structure rules in drawings to .NET using this command. If you have made edits to the C3DPipeNetworkRules.dvb rules file, it is not recommended that you convert rules to .NET because you will lose any VBA changes you made to *C3DPipeNetworkRules.dvb*.

If you create a new rule set in AutoCAD Civil 2009 or later, the rules will point to the .NET dll version of rules. If you open a drawing that has a rule set that was created in Civil 3D 2008, or earlier versions of Civil 3D, the rule set will still point to and execute the VBA version of rules, unless you run the convert to .NET command.

Please note the following:

■ This command only converts the VBA-based AutoCAD Civil pipe and structure rules that were included with the product. It does not convert any VBA custom rules you may have created behind the scenes.

■ By default, the rules files are installed to the following location:

■ Internally, this command just changes a pipe rule reference to the .NET version of that rule, instead of the VBA version of that rule.

■ In drawings, you can have a mix of pipe networks that point to VBA-based and .NET-based part rules. For example, when you open a drawing that was created in Civil 3D 2008 or earlier in Civil 3D 2009, that contains pipe networks, and then create a new rule set, that drawing will contain references to both VBA and .NET rules.

■ In a single pipe network, you can have a mix of parts that point to VBA-based and .NET-based part rules.

**To convert pipe and structure rules in a drawing from VBA to .NET**

1  Click Modify tab ➤ Design panel ➤ ▼ ➤ Convert VBA Pipe And Structure Rules To .NET.

    You are prompted to make sure that you really want to convert all pipe and structure rules in the drawing to .NET.

2  Click Yes.

    All VBA pipe and structure rules in the drawing are converted to VB.NET. Prompts indicate that the command has completed, and that the Event Viewer displays more details about the conversion.

### Quick Reference

Command Line

ConvertVBARulesToDot.Net

# Labeling Pipe Networks

You can add labels to pipe network parts either when you create the objects or after you create them.

Use the Create Pipe Network dialog box (page 2023) to specify label styles for pipes and structures in plan view. Use the Pipe Network Properties dialog box (page 2033) to change plan view label styles, or to specify label styles for profile and section views. If you select a label style of <none>, labels are not added.

Use the Add Pipe Network Labels option to access the Add Labels Dialog Box (page 1970) if you need to create or modify a style before labeling a pipe network.

Pipe network label types you can add after creation include entire network, single part, and spanning labels.

If desired, you can add a Material type to a pipe or structure label, as long as the Material property has been added to the part family that the pipe or structure part belongs to. See Adding a Material Property to a Part (page 1322) for more information. You can also label hydraulic properties in pipe networks. See Labeling Hydraulic Properties in Pipe Networks (page 1270) for more information.

You can use the following commands to add labels to pipe network parts.

| Command | Description |
| --- | --- |
| AddNetworkPartPlanLabel | Adds labels to pipes and structures in plan view. |
| AddNetworkPartProfLabel | Adds labels to pipes and structures in profile view. |
| AddNetworkPartSectLabel | Adds labels to pipes and structures in section view. |
| AddNetworkPlanLabels | Adds labels to a pipe network in plan view. |
| AddNetworkProfLabels | Adds labels to a pipe network in profile view. |
| AddNetworkSectLabels | Adds labels to a pipe network in section view. |
| AddSpanningPipeLabel | Adds label to a span of connected pipes. |

For more information, see Understanding Labels in AutoCAD Civil (page 1466).

# Labeling Multiple Pipes and Structures in Plan Views

You can label pipe and structures in plan views with Pipe label styles.

**To label all pipes and structures within an entire network in plan views**

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Pipe Network ➤ Entire Network Plan .

2 Select the part contained in the network to be labeled. All pipes or structures will be labeled in the network.

OR

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Pipe Network ➤ Add Pipe Network Labels .

**2** In the Add Labels dialog box (page 1970), under Feature, ensure that Pipe Network is selected.

**3** Under Label Type, select Entire Network Plan.

**4** Specify the other options as required.

**5** Click Add and then select the part to label.

# Labeling a Span of Connected Pipes

In plan or profile views, you can label a series of consecutively connected pipes with a single pipe label.

A spanning label helps minimize the number of labels displayed in a pipe network.

When you place the cursor over the spanning pipe label, the pipes that are in the span are highlighted. You can also use the AutoCAD list command to list the connected pipes. After adding a spanning label, you can highlight the connected pipes that comprise the span by selecting the label.

**See also:**

■   Resetting the Anchor Pipe on Spanning Labels (page 1270)

**To label a span of pipes in a plan view**

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Pipe Network ➤ Spanning Pipes Plan ✎ .

**2** At the command line, you are prompted to select the first pipe network part (pipe or structure).

**3** In the drawing, click a pipe or structure in the pipe network to define the starting point for the connected pipe span.

**4** At the command line, you are prompted to select the next pipe network part (pipe or structure).

**5** Click a part (pipe or structure) to define the ending point for the span.

**6** Press Enter.

The following prompt is displayed:

Specify label location on pipe:

**7** Specify the location for the label by clicking one of the pipes in the span. You must click a pipe, not a structure.

If you select a pipe that is not included in the span, a prompt is displayed indicating that the label location must be on a spanned pipe.

Note that the label can be slid along the span with the slider grip ◥ .

OR

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Pipe Network ➤ Add Pipe Network Labels ✎ .

**2** In the Add Labels dialog box (page 1970), under Feature, ensure that Pipe Network is selected.

**3** Under Label Type, select Spanning Pipes Plan.

**4** Specify the other options as required.

**5** Click Add.

You are prompted to select the first part (pipe or structure) in the span.

**6** Define the span by clicking the first and last parts (pipes or structures) in the span. The parts must belong to the same pipe network.

**7** Press Enter.

The following prompt is displayed:

Specify label location on pipe:

**8** Specify the location for the label by clicking one of the pipes in the span. You must click a pipe, not a structure.

If you select a pipe that is not included in the span, a prompt is displayed indicating that the label location must be on a spanned pipe.

Note that the label can be slid along the span with the slider grip ◥ .

**To label a span of pipes in a profile view**

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Pipe Network ➤ Spanning Pipes Profile ✎ .

**2** At the command line, you are prompted to select the first pipe network part (pipe or structure).

**3** In the drawing, click a pipe or structure in the pipe network to define the starting point for the connected pipe span.

**4** At the command line, you are prompted to select the next pipe network part (pipe or structure).

**5** Click a part (pipe or structure) to define the ending point for the span.

**6** Press Enter.

The following prompt is displayed:

Specify label location on pipe:

**7** Specify the location for the label by clicking one of the pipes in the span. You must click a pipe, not a structure.

If you select a pipe that is not included in the span, a prompt is displayed indicating that the label location must be on a spanned pipe.

Note that the label can be slid along the span with the slider grip ◣ .

OR

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Pipe Network ➤ Add Pipe Network Labels ◈ .

**2** In the Add Labels dialog box (page 1970), under Feature, ensure that Pipe Network is selected.

**3** Under Label Type, select Spanning Pipes Profile.

**4** Specify the other options as required.

**5** Click Add.

You are prompted to select the first part (pipe or structure) in the span.

**6** Define the span by clicking the first and last parts (pipes or structures) in the span. The parts must belong to the same pipe network.

**7** Press Enter.

The following prompt is displayed:

Specify label location on pipe:

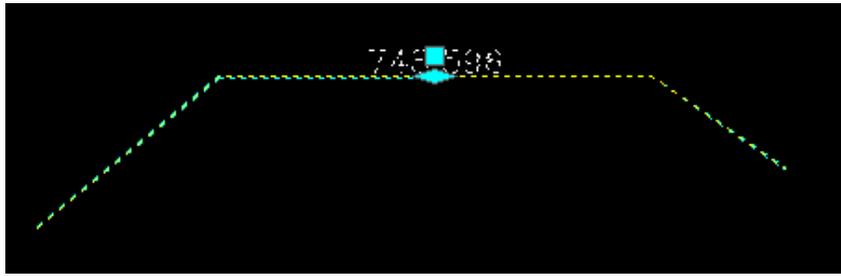
**8** Specify the location for the label by clicking one of the pipes in the span. You must click a pipe, not a structure.

If you select a pipe that is not included in the span, a prompt is displayed indicating that the label location must be on a spanned pipe.

Note that the label can be slid along the span with the slider grip ◣ .

**To highlight a connected pipe span, do one of the following**

■ Hover the cursor over the spanning label. This highlights all of the parts that are in the span.

■ Right-click the pipe span label and select Show Spanning Pipes. A dotted line will appear from the starting point to the end point of the connected pipe span, as shown in the following illustration. The diamond-shaped slider grip can be used to slide the label along the span. To remove the highlight, deselect Show Spanning Pipes from the right-click menu.


### Quick Reference

Menu

Pipes menu ➤ Add Pipe Network Labels ➤ Spanning Pipes Plan

Command Line

AddNetworkLabels

## Editing Spanning Labels with Grips

Spanning labels are not anchored to any particular pipe or structure. You can move them freely to any connected pipe or structure in the span.

It is also possible to reset the anchor point of a spanning label. For more information, see Resetting the Anchor Pipe on Spanning Labels (page 1270).

**To move a spanning pipe label**

■ Click the label to be moved and select the slider grip  .

Move the label to the desired location.

---

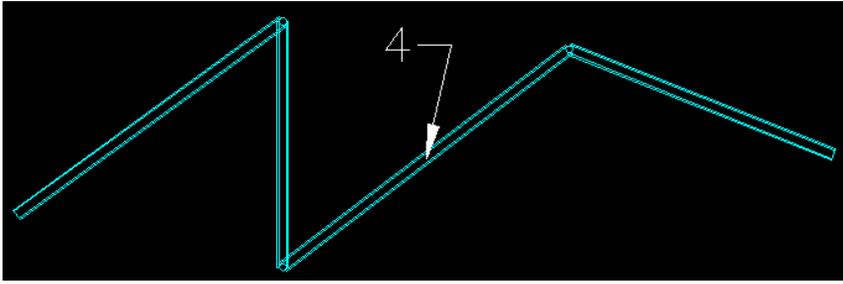
**NOTE** Spanning pipe labels have the same dragged state behavior as regular pipe labels. Click the round grip  to restore a dragged label to its default state.

---

## Deleting Pipes Labeled with Spanning Labels

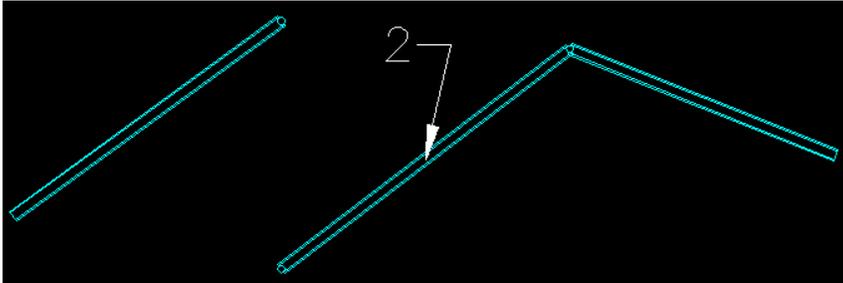
Deleting an individual pipe from a span labeled with a spanning label has various affects depending on where the label is located in relation to the deleted pipe.

To delete a pipe, select it and press delete.

In the following example, the pipe span is comprised of four connected pipes. Note where the spanning label is located. In this example, the Text Component Editor was used to create a label that dynamically indicates the number of pipes in the span by inserting the Number of Pipes in Span property. For more information see, Text Component Editor Dialog Box (page 1961).


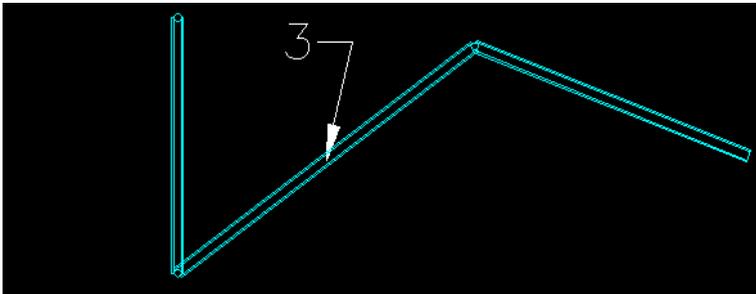
**Example 1**

In the following example, the vertical pipe has been deleted, or detached from the other pipes. The result is that only the connected pipes to the right are now included in the span label. The label stays at the same location.



**Example 2**

In the following example, the pipe to the left has been deleted, or detached from the vertical pipe. The result is that only the remaining pipes are included in the span. The label indicates the span is now comprised of three pipes.



**Example 3**

In the following illustration, the pipe with the span label has been deleted. The result is that the span label is also deleted.

## Resetting the Anchor Pipe on Spanning Labels

You can reset the anchor position of label that spans multiple parts in a pipe network.

**To reset the anchor position of a label that spans multiple pipe network parts**

1   At the command line, enter ResetAnchorPipe.

2   In the drawing, select a label that spans multiple pipe parts (spanning pipe label).

3   Select the new anchor point by clicking on a pipe in the same network. You must select a pipe, not a structure.

    The new anchor position is set, and the spanning label will display at the midpoint of the selected pipe.

## Adding a Material Type to a Pipe or Structure Label

You can add a material type, such as ductile iron or corrugated steel, to display in a pipe or structure label.

If the part family the pipe or structure belongs to includes the Material property, you can configure that property to display text identifying the type of material used for that part. Using the Label Style Composer, you can add that Material property to labels for pipe network parts.

**To add a material type to an existing pipe or structure label**

1   In the drawing, select a pipe or structure and then click Pipe Properties or Structure Properties.

2   On the Pipe Properties dialog box, or the Structure Properties dialog box, click the Part Properties tab.

3   Scroll down to the Part Data section and the Material property should be displayed.

    If the Material property is not displayed, this means that this part family does not contain the Material property. See Adding a Material Property to a Part (page 1322) for instructions on how to add this property to a part family.

4   Click in the Value cell to select an existing or enter a new value for the Material property.

5   Click OK on the Pipe Properties dialog box or the Structure Properties dialog box.

**To add a material type to a pipe or structure label style**

1   In the Label Style Composer, click the Layout tab.

2   In the Text section, click in the Contents cell, and then ⊡ click to display the Text Component Editor.

3   In the Text Component Editor, select Material in the Properties list and add it to your label.

4   Click OK on the Text Component Editor dialog box.

5   Click OK on the Label Style Composer dialog box.

## Labeling Hydraulic Properties in Pipe Networks

You can create a label style for labeling hydraulic properties, such as HGL and EGL, in pipe networks.

Use the Label Style Composer to create a label style that lets you add labels that display values for hydraulic properties, such as hydraulic grade line and energy grade line in pipe networks.

Once the label style is created, you can select that label style on the following tabs of the Pipe Network Properties dialog box: Layout Settings tab, Profile tab, Section tab.

**To create a label style for pipe network hydraulic properties**

**1** In Toolspace, on the Settings tab, expand the Pipe collection, then expand the Label Styles collection.

**2** In the Label Styles collection, expand a collection. For example, expand the Plan Profile collection , and then right-click on an existing label style. For example, right-click on Standard, and then click New or Edit.

**3** On the Label Style Composer, click the Layout tab.

**4** Under the Text collection, click the Browse button [icon] in the Value cell next to the Add Contents property.

**5** Use the Text Component Editor to add the desired hydraulic properties to the label style. For example, on this dialog box, under Properties, click the drop-down arrow to display the list of properties you can add to the label. Select the desired hydraulic properties from this list. For example, click Hydraulic Grade Line Up, and then click the right-arrow button to add the property to the label style.

**6** When finished composing label text using this dialog box, click OK to save changes.

**7** Click OK on the Label Style Composer dialog box to save changes to the label style.

For more information, see Text Component Editor Dialog Box (page 1961)or Adding Content to Labels (page 1502).

Dialog Box

Text Component Editor (page 1961)

# Adding Pipe Tables

You can create tables that display information about pipes inone or more a pipe networks.

When you insert a pipe table into a drawing, specified pipe information is automatically displayed in the table.

Pipe tables can include data such as pipe shape, size, length, slope, start and end stations, or any pipe property.

You create and edit tables for most objects using the same common procedures and standard dialog boxes. The procedure in this topic explains how to access the pipe table creation command. It provides a link to information about the Pipe Table Creation dialog box. For information about modifying tables, see Modifying Tables (page 1567).

**To create a pipe table**

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Pipe Network ➤ Add Pipe [icon] .

**2** In the Pipe Table Creation (page 2075) dialog box, change the generic table settings as needed.

**3** Select a network to be included in the table.

**4** Click OK.

**5** Select the location for the upper-left corner of the table in the drawing.

### Quick Reference

Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Pipe Network ➤ Add Pipe ⊞

Menu

Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Pipe Network ➤ Add Pipe ⊞

# Adding Structure Tables

You can create tables that display information about structures in one or more pipe networks.

When you insert a structure table into a drawing, specified structure information is automatically displayed in the table.

Structure tables can include data such as structure type, elevation, sump depth, station, or any structure property.

You create and edit tables for most objects using the same common procedures and standard dialog boxes. The procedure in this topic explains how to access the structure table creation command. It provides a link to information about the Structure Table Creation dialog box. For information about modifying tables, see Modifying Tables (page 1567).

**To create a structure table**

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Pipe Network ➤ Add Structure ⊞ .

**2** In the Structure Table Creation (page 2076) dialog box, change the generic table settings as needed.

**3** Select a structure to be included in the table.

**4** Click OK.

**5** Select the location for the upper-left corner of the table in the drawing.

# Editing Structure Table Styles

Edit structure table styles in the Table Styles collection in Toolspace, on the Settings tab.

Structure table styles govern how structure tables are displayed in a drawing. You can create, edit, or delete structure table styles. Create an entirely new table style, or create a table style based on an existing style.

You can compose a table cell with more than one text component in order to show connected pipe data for a given structure. The text components display data for each object associated with a parent object (the

object you are storing data for). For example, you can use a component in a structure table style to include cell components for pipes associated with that structure.

**To edit a structure table style**

1  In Toolspace, on the Settings tab, expand Structure ➤ Table Styles.

2  Right-click the table style that you want to edit and click Edit.

3  In the Table Style dialog box, modify style settings.

**To add table cell components**

1  Double-click a Structure Table cell in the Data Properties tab of the Table Style dialog box to access the Table Cell Components dialog box.

2  Click the down arrow in $A_+$ , and then click $\oplus$ to create a new text component.

   You can add any number of components, and there can be more than one of any given component type. The possible components are: Structure, Structure All Pipes, Structure In Flow Pipes, and Structure Out Flow Pipes.

3  Click Text $\boxed{\cdots}$ to access the Text Component Editor Dialog Box (page 1961). When this option is selected, the component is added to the list of available components. You can edit the name of the component and/or enter the content for the table cell.

4  Set the cell justification.

5  Click OK.

# Rendering Pipe Network Parts

Render pipe network parts using the AutoCAD Render command.

The render material that is assigned to a pipe network part by default, upon creation, is defined in the parts list. After the part is added to the drawing, you can edit the render material for the part using the Render Material option on the Information tab of either the Pipe Properties or the Structure Properties dialog box.

For more information about rendering AutoCAD Civil objects and data, see Rendering Objects (page 1579).

**To render pipe network parts**

1  Create a pipe network.

2  Do one of the following:
   ■  In Toolspace, on the Prospector tree, expand the Pipe Networks collection, then expand the desired pipe network, and click either Pipes or Structures. In the Prospector list view, choose a render material for the desired parts.

- In the drawing, right-click the pipe network part and click Properties. On either the Pipe Properties or the Structure Properties Information tab, select a render material.

- Use the AutoCAD Render command to render the pipe network. For more information, see Render a Model in the AutoCAD Help.

# Using Hydraulics and Hydrology Features

The Hydraflow extensions allow you to peform a variety of hydraulics and hydrology analysis tasks on pipe networks created with AutoCAD Civil or with the Hydraflow Storm Sewers Extension.

You can migrate pipe network data between AutoCAD Civil and the Hydraflow Storm Sewers Extension.

**NOTE** The Hydraflow extensions (Storm Sewers, Hydrographs, and Express) are included with AutoCAD Civil 3D; however, they are not included with AutoCAD Civil.

## Moving Pipe Network Data Between AutoCAD Civil and Storm Sewers

You can migrate pipe network data between AutoCAD Civil and the Storm Sewers Extension.

For example, with AutoCAD Civil, you can:

- export one or more AutoCAD Civil pipe networks to an *.stm* file that can then be opened by the Hydraflow Storm Sewers Extension for analysis and or editing

- import one or more pipe runs from an *.stm* file that has been exported from the Hydraflow Storm Sewers Extension into AutoCAD Civil

When importing Storm Sewer data into AutoCAD Civil, you can import a single pipe network, or multiple pipe networks. However, you must import entire pipe networks; you cannot import individual parts, or a series of connected parts within a pipe network.

Before migrating pipe network data between AutoCAD Civil and the Storm Sewers Extension, there are a few preparation tasks you must perform. For more information, see Preparing for Migrating Storm Sewers Data (page 1275).

**Importing STM Files From Previous Versions**

In AutoCAD Civil, you can import *.stm* files that were created or saved from older versions of the Storm Sewers Extension; for example, the Storm Sewers Extension for AutoCAD Civil 3D 2009 or earlier. You can also successfully open *.stm* files that were created or saved from 2009, or earlier, versions of the Storm Sewers Extension in the Storm Sewers Extension version 2010. However, in the Storm Sewers Extension for Civil 3D 2009, or earlier versions of the Storm Sewers Extension, you cannot open *.stm* files that were saved in the Storm Sewers Extension for Civil 3D 2010, or that were exported from AutoCAD Civil.

It is also important to note that when importing *.stm* files that were saved prior to version 2010, they may contain hydraulic grade line (HGL) values, however, they will not contain some of the other hydraulic properties, as listed below. The following values are calculated in the Storm Sewers Extension version 2010, but are not found in older versions of *.stm* files (prior to 2010):

- Pipes

  - Energy Grade Line Up

  - Energy Grade Line Down

- ■ Flowrate

- ■ Structures

  - ■ Energy Grade Line
  - ■ Known Capacity

**Storm Sewers Pipe Size Calculations**

In the Storm Sewers Extension, the list of pipe sizes is hard coded and cannot be customized. This list does not distinguish between inner and outer pipe diameter, pipe material, or pipe class, as does AutoCAD Civil. When you perform calculations that resize pipes in the Storm Sewers Extension, the results include only the sizes that are available in the hard coded list. This may result in a pipe size or sizes that are not typical of the pipe material they are working with. However, you can always manually edit the pipe size. For more information, see the Storm Sewers Extension Help.

# Preparing for Migrating Storm Sewers Data

There are a few preparatory tasks to perform before migrating data between AutoCAD Civil and the Storm Sewers Extension.

The table below summarizes these tasks.

| Task | Description |
|------|-------------|
| Verify that your pipe network data meets the necessary criteria for migration | Review the criteria for migrating pipe network data. For more information, see Criteria for Migrating Pipe Networks (page 1276). |
| Create the parts list that will be used during migration | When you import or export pipe networks between AutoCAD Civil and the Storm Sewers Extension, a parts list that contains appropriate parts for the import or export is required. You will need to create this parts list first, before you begin importing or exporting the data. You may need to create a full parts list, containing all of the available parts in the entire catalog, or you may need to create a smaller, customized parts list that contains only the parts included in the migrated data. For more information, see Creating a Full Parts List (page 1239) or Creating a Parts List (page 1238). |
| Set the part matchup settings that will be used during migration | In Toolspace, on the Settings tab, you need to configure defaults that will be used for matching up part types between AutoCAD Civil and the Storm Sewers. For more information, see Setting Part Matching Defaults for Migration (page 1276) . |
| Choose the default parts list that will be used during migration | In Prospector, on the Settings tab, you also need to choose the default parts list that will be when you migrate data between AutoCAD Civil and the Storm Sewers. For more information, see Setting the Default Parts List For Migration (page 1277). |

Optionally, you may want to create a label style for displaying labels for hydraulic properties, such as hydraulic grade lines and energy grade lines in pipe networks. For more information, see Labeling Hydraulic Properties in Pipe Networks (page 1270).

## Criteria for Migrating Pipe Networks

To successfully migrate pipe network data between the Storm Sewers Extension and the AutoCAD Civil, the pipe network data must meet certain conditions.

Verify that your pipe network data meets these criteria before migrating:

■ Note that in the Storm Sewers Extension, a pipe and its corresponding upstream inlet structure make up a Hydraflow Storm Sewers line.

■ The Storm Sewers Extension can accept a maximum of 250 pipes (lines) with structures in one project. If a single AutoCAD Civil pipe network contains more than 250 pipes (lines), then the pipe network must be divided into smaller pipe networks (and therefore, multiple .stm files) before the pipe network data can be opened in the Hydraflow Storm Sewers Extension.

■ All catch basin and junction structures must have an outlet pipe. To verify this, in AutoCAD Civil display the Connected Pipes tab of the Structure Properties dialog box. Look at the In/Out column.

It is also important to be aware of the following before exporting pipe networks to an .stm file (or any type of export of pipe data):

■ If a pipe does not have an upstream structure in AutoCAD Civil, it is given a null structure in the exported file.

■ If a structure is not attached to a pipe, the structure will not be exported.

## Setting Part Matching Defaults for Migration

You must set part matching defaults before migrating pipe network data between AutoCAD Civil and Storm Sewers.

Setting the part matching defaults enables you to choose the specific AutoCAD Civil part types that will be matched up with Storm Sewers part types when you import and export pipe network data between AutoCAD Civil and Storm Sewers.

Performing this task helps avoid error messages during migration, and ensures that AutoCAD Civil part types are recoginized as appropriate part types in the Storm Sewers Extension. and vice versa.

You may only have to perform this procedure once. However, if you are adding, deleting, or changing part types after import or export, then you would need to perform this procedure again to ensure that parts are appropriately matched between the two applications.

**To set part matching defaults for migrating pipe network data**

1 In Toolspace, on the Settings tab, right-click the Pipe Network collection and select Edit Feature Settings.

2 In the Edit Feature Settings - Pipe Network dialog box, expand Storm Sewers Migration Defaults.

3 For the Part Matching Defaults, click the Browse button in the V ⬚ alue cell to display the Part Matchup Settings - Storm Sewers Settings dialog box (page 2079).

4 To set the defaults that will be used when you are **importing** data from the Storm Sewers Extension into AutoCAD Civil, click the Import tab.

5   On the Import tab, expand each part type category in the first column, and click on an item in the column on the right to display the Browse button $\boxed{\cdots}$. For example, click in the Concentric Cylindrical Structure cell.

6   Click $\boxed{\cdots}$ to display the Part Catalog dialog box.

7   On the Part Catalog dialog box, select the desired AutoCAD Civil part type and then click OK.

8   On the Import tab, scroll down to ensure that all part types in the first column are matched up with appropriately part types in the second column.

9   To set the part type defaults that will be used when you are **exporting** data from AutoCAD Civil into the Storm Sewers Extension, click the Export tab.

10  On the Export tab, click in the column on the right to select appropriate parts from the drop-down list.

11  On the Export tab, scroll down to ensure that all part types in the first column are matched up with appropriately part types in the second column.

12  When you are finished matching part type defaults, click OK.

Once you have finished matching up part types, the next step is to select the parts list that will be used for migration by default. See Setting the Default Parts List For Migration (page 1277) for more information.

## Setting the Default Parts List For Migration

You must set the default parts list that will be used during migration before migrating pipe network data between AutoCAD Civil and Storm Sewers.

Typically, you will want to create a parts list that contains all of the needed prts for the import or export. You may need to create a full parts list, containing all of the available parts in the entire catalog, or you may need to create a customized, smaller, more manageable parts list that contains only the parts included in the migrated data. For more information, see Creating a Full Parts List (page 1239) or Creating a Parts List (page 1238)

**To set the default parts list for migration**

1   In Toolspace, on the Settings tab, right-click the Pipe Network collection and select Edit Feature Settings.

2   In the Edit Feature Settings - Pipe Network dialog box, expand Storm Sewers Migration Defaults.

3   For Parts List Used For Migration, click the Browse button in the Value cell to select a parts list.

4   Click OK to select the parts list.

When pipe network data is imported into or exported from AutoCAD Civil, this is the parts list that will be used to search for part families and part sizes.

Dialog Box

Part Matchup Settings Dialog Box (page 2079)

# Importing Pipe Network Data from an .stm File

You can import pipe network data from a Storm Sewers Extension *.stm* file into AutoCAD Civil.

Pipe networks imported from the Storm Sewers Extension can contain hydraulic property information (page 1280), such as hydraulic grade lines (HGL) and energy grade lines (EGL) and more.

When you import the .stm file, if any of the pipe network names in the *.stm* file match pipe network names in the AutoCAD Civil drawing, you must choose to either create new pipe networks, or update existing pipe networks.

If there are no name conflicts, the new pipe networks are added to the AutoCAD Civil drawing with their existing names.

Before importing an *.stm* file, it is important to understand issues associated with importing *.stm* files that were saved prior to version 2010. For more information, see Moving Pipe Network Data Between AutoCAD Civil and Storm Sewers (page 1274).

**NOTE** It is important to note that rules are not applied to pipes or structures when importing pipe networks from either LandXML or from the Storm Sewers Extension. For more information about rules, see Part Rules (page 1247).

**Matching Pipe Network Names**

In cases where the *.stm* file contains one or more pipe network names that match pipe network names in the currently open AutoCAD Civil drawing, you will be prompted to choose one of the following options:

**Create new pipe network:** When you choose this option, the pipe network will be imported into the drawing as a new pipe network. The name of the newly imported pipe network is appended with a numeric counter (1). For example, StormSewerNetwork1(1).

**Update the existing pipe network:** When you choose this option, the pipe network will be imported into the drawing and it will update the existing pipe network that has the same pipe network name. For example, if you have a pipe network named StormSewerNetwork1 in the drawing, and you import an *.stm* file that contains a pipe network named StormSewerNetwork1, then the StormSewerNetwork1 imported from the *.stm* file updates (overwrites) the pipe network named StormSewerNetwork1 in the drawing.

**No Matching Pipe Network Names**

As previously mentioned, if the pipe network names contained in the *.stm* file do not match any pipe network names that exist in the currently open drawing, then the new pipe networks will be added to the drawing with their existing names. These new pipe networks will be displayed in the drawing and in the Prospector tree.

**To import an *.stm* file into AutoCAD Civil**

1 From the Home tab, click the Insert tab, and then click Import Storm Sewers .

2 On the Import Storm Sewers File dialog box, navigate to the desired *.stm* file, select it, and then click Open.

   You are prompted to either update the existing pipe network, or to create a new pipe network.

3 Choose to either update the existing pipe network, or to create a new pipe network.

**NOTE** It is important to note that rules are not applied to pipes or structures when importing pipe networks from either LandXML or from the Storm Sewers Extension. For more information about rules, see Part Rules (page 1247).

**Quick Reference**

File menu ➤ Import ➤ Import Data From Storm Sewers

Command Line

ImportStormSewers

# Exporting Pipe Network Data to an .stm File

You can export pipe network data from AutoCAD Civil to an *.stm* file.

The *.stm* file can then be opened bythe Hydraflow Storm Sewers exstension for analysis and editing. After editing the file in Storm Sewers, you can import it back into AutoCAD Civil. Changes made to the file while in the Storm Sewers extention are recognized in AutoCAD Civil.

You can export one or more pipe networks into an *.stm* file. You must choose entire pipe networks. You cannot export individual parts, or a set of connected parts within a pipe network.

It is important to note the following before exporting pipe networks to an *.stm* file (or any type of export of pipe data):

- If a pipe does not have an upstream structure in AutoCAD Civil, it is given a null structure in the exported file.

- If a structure is not attached to a pipe, the structure will not be exported.

---

**NOTE** You cannot open *.stm* files that were exported from AutoCAD Civil, or that were saved in the Storm Sewers Extension for Civil 3D 2010, in the Storm Sewers Extension for Civil 3D 2009, or earlier versions of the Storm Sewers Extension.

---

**To export an *.stm* file from AutoCAD Civil**

1 Do one of the following:
   - In the drawing, select a pipe network. On the Pipe Networks tab, click the Analyze tab ➤ Storm Sewers drop-down ➤ Export To File.

   - Click the Output tab ➤ Export panel ➤ Export To File.

   - In Toolspace, on the Prospector tab, right-click the Pipe Networks collection, or right-click the pipe network you want to export, and then select Export to Storm Sewers  .

   - At the command line, enter ExportStormSewerData.

2 On the Export to Storm Sewers dialog box, specify the pipe networks to be exported, and then click OK.

3 On the Export Storm Sewers to File dialog box, specify the location and the name for the *.stm* file, and then click Save.

**To export an *.stm* file from AutoCAD Civil and open it in Storm Sewers for editing**

1   Do one of the following:

■ In the drawing, select a pipe network. From the Pipe Networks tab ➤ Analyze panel ➤ Storm Sewers drop-down ➤ Edit In Storm Sewers ⊘ .

■ At the command line, enter EditInStormSewers.

2   On the Export to Storm Sewers dialog box, specify the pipe networks to be exported, and then click OK.

3   On the Export Storm Sewers to File dialog box, specify the location and the name for the *.stm* file, and then click Save.

## Adding Hydraulic Property Data to AutoCAD Civil Pipe Networks

You can add hydraulic property data to AutoCAD Civil pipe networks in a few different ways.

Pipe networks created in AutoCAD Civil do not contain values for hydraulic property information, such as hydraulic grade lines (HGL) and energy grade lines (EGL), by default. While the pipe networks contain the properties for this type of information, the hydraulic properties are set to zero or are "not set" by default.

You can add hydraulic property data to a AutoCAD Civil pipe network using the following methods:

■ by exporting the pipe network to an *.stm* file, importing that file into the Storm Sewers Extension, and using the Storm Sewers Extension to add hydraulic properties to the pipe network
You can use the Storm Sewers Extension to perform the hydraulic analysis on the pipe run. Once you have done this, you can then import the *.stm* file back into AutoCAD Civil. At this point, the AutoCAD Civil pipe network will containing the valid hydraulic property data (HGL, EGL, and so on) that it got from the Storm Sewers Extension.

■ You can also obtain hydraulic property data by importing an .xml file that contains valid hydraulic property information.

■ You can also enter your own values for hydraulic properties using the Panorama. This may be useful if you intend to later import the pipe network data into some other application, such as the Storm Sewers Extension, to perform hydraulic analysis.

Once you have the hydraulic property data in a AutoCAD Civil pipe network, you can display, edit, and label the hydraulic grade lines and energy grade lines in profile views. You can also view and edit the specific hydraulic property data values on the pipe and structure Properties dialog boxes and vistas.

When you add hydraulic analysis data to AutoCAD Civil pipe networks, the following hydraulic properties are populated with valid values for pipes and structures:

| Hydraulic Property | Available for... |
| --- | --- |
| hydraulic grade line (page 2475) | pipes and structures |
| energy grade line (page 2473) | pipes and structures |
| flow rate (page 2474) | pipes |
| junction loss (page 2476) | pipes |
| return period (page 2481) | pipes |
| known capacity (page 2476) | structures |
| bypass target (page 2470) | structures |

In AutoCAD Civil, hydraulic grade lines and energy grade lines are displayed as a straight line through structures, connected between the HGL Up or EGL Up property from one pipe to the HGL Down or EGL Down property of the next pipe. See Viewing Hydraulic Data in Profile Views (page 1282) for an illustration of a hydraulic grade line and an energy grade line displayed in a profile view.

You can also create label styles that display labels for hydraulic properties, such as HGL and EGL. For more information, see Labeling Hydraulic Properties in Pipe Networks (page 1270).

**To add hydraulic property data to an AutoCAD Civil pipe network**

1 In AutoCAD Civil, export the pipe network to an *.stm* file. For more information, see Exporting Pipe Network Data to an .stm File (page 1279).

2 In the Storm Sewers extension, perform the hydraulic analysis tasks on the pipe network. This adds valid hydraulic property data (HGL, EGL) to the pipe network. For more information, see the Storm Sewers extension Help.

> **NOTE** The Hydraflow extensions (Storm Sewers, Hydrographs, and Express) are included with AutoCAD Civil 3D; however, they are not included with AutoCAD Civil.

3 Export the pipe network from Storm Sewers to an *.stm* file. For more information, see the Storm Sewers extension Help.

In AutoCAD Civil, import the *.stm* file that now contains valid hydraulic property data. For more information, see Importing Pipe Network Data from an .stm File (page 1278)

Verify that the AutoCAD Civil pipe network contains valid HGL and EGL data. See verifying hydraulic property data (page 1282).

**To verify hydraulic property data**

1 In AutoCAD Civil, right-click a part in the pipe network and select Pipe Properties or Structure Properties.

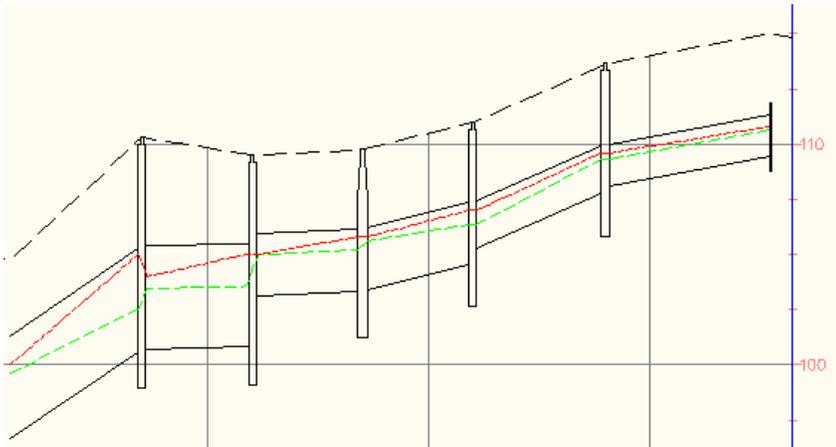
2 On the Pipe Properties or Structure Properties dialog box, click the Part Properties tab.

Note the items listed in the Hydraulic Properties section. The values listed here are set when the pipe network is imported from the *.stm* file. For more information on these properties, see the Pipe Properties dialog box (page 2039) or the Structure Properties dialog box (page 2051).

## Viewing Hydraulic Data in Profile Views

You can view hydraulic property data (hydraulic grade lines and energy grade lines) from pipe networks in profile views.

For example, the following illustration shows a hydraulic grade line and an energy grade line displayed in a profile view.



The energy grade line is displayed as a red dashed lined (on the top). The hydraulic grade line is displayed as a green dashed line (below the energy grade line).

In order to view hydraulic and energy grade lines in profile views, you must ensure that the following tasks have been performed:

| Task | Description |
|------|-------------|
| Add hydraulic property information to the pipe network by performing hydraulic analysis on the pipe network using the Storm Sewers Extension | For more information, see Adding Hydraulic Property Data to AutoCAD Civil Pipe Networks (page 1280). |
| Edit the pipe style to configure display styles for the HGL and EGL components | Edit the HGL and EGL components listed on the Display tab of the Pipe Style dialog box. You only need to do this for pipe styles, not for structure styles. See Editing Pipe Display Styles for HGL and EGL Components (page 1283)for step-by-step instructions. |
| Create profile view and profile | For more information, see Displaying Pipe Networks in Profile Views (page 1220). |

You can also create label styles that display labels for hydraulic properties, such as HGL and EGL. For more information, see Labeling Hydraulic Properties in Pipe Networks (page 1270).

In addition to viewing the hydraulic and energy grade lines in profile views, you can also view and edit the hydraulic property data values in the following ways:

| Editing Method | Description |
|---|---|
| Pipe or Structure Properties dialog box | Click the Part Properties tab of the Pipe or Structure Properties dialog boxes, and scroll down to view the values for hydraulic properties. |
| Pipe Network Vista | Display the pipe network in the Pipe Network Vista, and scroll to view or edit the hydraulic property data values. |

For more information, see Displaying Pipe Networks in Profile Views (page 1220).

**To edit the pipe display style for HGL and EGL**

1   In Toolspace, on the Settings tab, expand the Pipe collection, then expand the Pipe Styles collection.

2   Double-click the desired pipe style to edit it.

3   Click the Display tab on the Pipe Style dialog box.

4   Select Profile in the View Direction drop-down.

5   For the Hydraulic Grade Line and Energy Grade Line components, turn on visibility, and set other display characteristics, such as color and layer, as desired.

# Editing Hydraulic Property Data

Editing a pipe network may cause the hydraulic property data to become invalid.

It is important to note that if you choose to edit a pipe network's physical properties after if has been imported from an *.stm* file, the hydraulic information can become invalid. To notify you of this possibility, a warning message similar to the following is displayed whenever you edit pipe network parts from a pipe network that has been imported from the Storm Sewers Extension:

**A pipe network containing hydraulic properties has been altered and the properties may be invalid.**

This message is displayed only the first time you try to edit the pipe network. If you try to edit the pipe network again, the message is not displayed.

If you do see this message, you may want to use the Edit in Storm Sewers command to export pipe network data and update hydraulic properties. As a minimum, it is recommended that you verify that the hydraulic information for the pipe network is still valid, and has not changed in such as way as to cause undesireable or unexpected results in your design.

If you are editing a pipe network that does not contain values for hydraulic properties, this message is not displayed.

# Understanding Event Viewer Messages

Event Viewer messages alert you to certain conditions when importing and exporting Storm Sewer data.

The following table provides information on some of the messages that can be displayed in the Event Viewer when importing or exporting Storm Sewer data.

| Event Viewer Message | Description |
|---|---|
| Multiple barrels were found in the *.stm* file. | The import is successful, however, one or more pipe networks in the *.stm* file con- |

| Event Viewer Message | Description |
|---|---|
| | tained a No. of Barrels property that is set to more than 1. In Storm Sewers a No. of Barrels property that is set to more than 1 creates two lines (pipes) with the same size, invert, slope, and so on, in parallel. AutoCAD Civil cannot represent pipes in this way. Therefore, when you attempt to import a Storm Sewers file that contains No. of Barrels set to more than 1, AutoCAD Civil ignores this value, and displays this message in the Event Viewer. |
| Error importing pipe network <pipe network name>: The current layer is locked. | You attempted to import pipe network data from an *.stm* file when the current layer in the drawing is locked, or the object layers for pipes or structures is locked. In this case, no new pipe networks are created, and no existing pipe networks are overwritten. The import is aborted. Unlock appropriate layers and try importing again. |
| Error overwriting pipe network <pipe network name>: Objects reside on a locked layer. | You attempted to update an existing pipe network with a pipe network from an *.stm* file when the current layer in the drawing is locked, or the object layers for pipes or structures is locked. In this case, no new pipe networks are created, and no existing pipe networks are overwritten. The import is aborted. Unlock appropriate layers and try importing again. |
| Pipe or structure <pipe or structure name> was not matched exactly. The closest larger matching part size was used. | The import was successful; however, one or more Storm Sewers parts could not find part sizes that matched exactly with Auto-CAD Civil part sizes. In cases like this, AutoCAD Civil uses the closest larger part size for the imported Storm Sewer part. |

# Pipe Network Command Reference

You can use commands to quickly access pipe network functionality.

The following table lists the pipe network AutoCAD Civil commands and briefly describes their functionality.

| Command | Description |
|---|---|
| AddNetworkLabels | Invokes a labeling tool to annotate pipes and structures (page 1261) |
| AddNetworkPartPlanLabel | Adds labels to selected pipes and structures in plan view (page 1261) |
| AddNetworkPartProfLabel | Adds labels to selected pipes and structures in profile view (page 1261) |

| Command | Description |
|---------|-------------|
| AddNetworkPartSectLabel | Adds labels to selected pipes and structures in section view (page 1265) |
| AddNetworkPartsToProf | Updates a profile view to show newly added pipe network parts (page 1220) |
| AddNetworkPipeTable | Creates a pipe network table (page 1271) |
| AddNetworkPlanLabels | Adds labels to a pipe network in plan view (page 1261) |
| AddNetworkProfLabels | Adds labels to a pipe network in profile view (page 1261) |
| AddNetworkSectLabels | Adds labels to a pipe network in section view (page 1261) |
| AddNetworkStructTable | Creates a pipe structure table (page 1272) |
| AddSpanningPipePlanLabel | Adds labels to connected pipe spans in plan view (page 1265) |
| AddSpanningPipeProfLabel | Adds labels to connected pipe spans in profile views (page 1265) |
| ApplyRules | Invokes a labeling tool to annotate pipes and structures (page 1250) |
| ChangeFlowDirection | Changes flow direction for selected pipes (page 1225) |
| CreateAlignFromNetwork | Creates an alignment from existing pipe network parts (page 1196) |
| CreateInterferenceCheck | Runs an interference check (page 1226) |
| CreateNetwork | Creates a pipe network by layout (page 1191) |
| CreateNetworkFromObject | Creates a pipe network from a polyline, line, arc, or feature line (page 1194) |
| CreateNetworkPartsList | Creates a pipe network parts list (page 1238) |
| CreateNetworkPartsListFull | Creates a parts list that contains all of the parts in the current pipe network catalog (page 1239) |
| CreateNetworkReference | Creates a pipe network reference (page 1199) |
| EditNetwork | Edits a pipe network (page 1203) |
| EditNetworkPartList | Edits a network part list (page 1241) |

| Command | Description |
| --- | --- |
| ExportStormSewerData | Exports pipe network data to an .stm file for future import into the Storm Sewers Extension (page 1279) |
| ImportStormSewerData | Imports pipe network data from the Storm Sewers Extension (.stm file) into AutoCAD Civil (page 1278) |
| PartBuilder | Invokes the part builder interface (page 1287) |
| ResetAnchorPipe | Resets the anchor position of a label that spans multiple pipe network parts (page 1270) |
| ResetNetworkLabels | Resets pipe network reference labels (page 1201) |
| SetNetworkCatalog | Sets a default path for pipe and structure catalogs (page 1243) |
| ShowSpanningPipes | Displays the span of pipes that are specified as a span for labeling a span of pipes with a single label (page 1265) |

# Understanding Part Builder

# 28

Part Builder lets you create and modify pipe network parts that are available in AutoCAD Civil part catalogs.

This section describes the fundamental concepts involved with using Part Builder and explores the user interface.

## Before You Begin

Part Builder is intended primarily for users who are experienced with parametric modeling design and with pipe network features.

Individuals who have experience with parametric modeling design, concepts, and techniques should be comfortable making use of the full spectrum of features available through Part Builder. Individuals with little or no experience with parametric modeling should be comfortable using the more basic Part Builder features, such as adding or changing part sizes in existing part families. For more information on these features, see Editing Part Family Sizes (page 1244).

Before using Part Builder, make sure you understand the following:

**WARNING** Before using Part Builder to create or modify pipe network parts, it is important that you create and save a backup copy of the AutoCAD Civil pipe network part catalogs and support files. These files are installed by default in: C:\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\Pipes Catalog. Create and save a backup copy of this folder and its contents, including all subfolders and their corresponding content.

- Pipe parts created with Part Builder must have a width, a height, and a centerline. Therefore, any pipe shapes that do not meet this criteria are not supported in AutoCAD Civil pipe networks. This includes open channel pipes.

- The section profiles of a pipe must have an enclosed loop. Therefore, it is not possible to create pipe types such as horseshoe shape or U-shape (open channel).

- Pipe part definitions must include a uniform wall thickness. Therefore, you cannot create pipe parts with varying wall thicknesses.

- Part Builder cannot create a rectangular box culvert shape that has chamfers on the inner diameter corners.

- When a pipe connects to a structure, there is a single point of connection between the pipe and the structure. Therefore, you cannot customize a pipe part to have two connection points at one end of the pipe, where it connects to the structure.

For more information, see the Pipe Networks chapter in the AutoCAD Civil Best Practices Guide.

# Part Builder Overview

With Part Builder, you can design and edit shapes for drawing content that represent real-world pipe network parts, such as pipes, manholes, catch basins, and headwalls.

Part Builder is intended primarily for advanced users who are experienced with parametric modeling design and with pipe network features.

Each piece of content represents a part family, such as concrete pipe, ductile iron pipe, and concrete elliptical culvert. Each part family contains a collection of part sizes within that part family. For example, within the concrete pipe part family, there are a variety of pre-defined part sizes available for that part. Part Builder enables you to create and modify part families as well as individual part sizes.

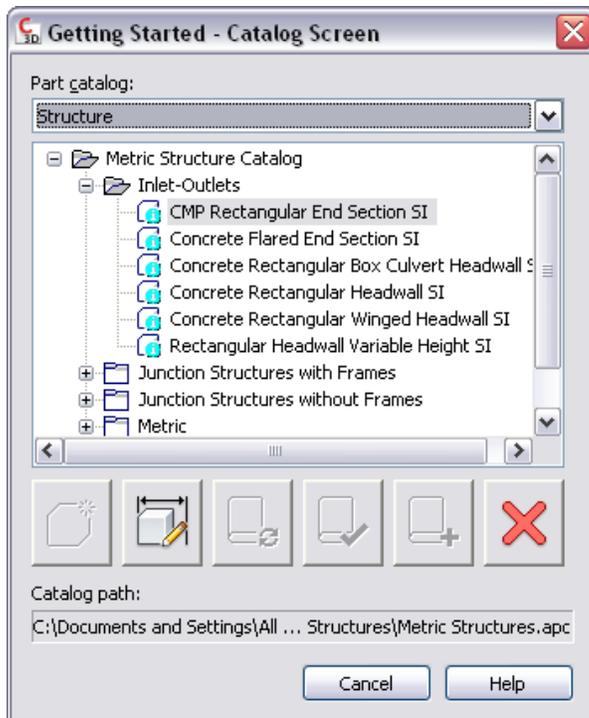
When you use Part Builder, you can build 2D models of pipe parts, and/or 3D models of structure parts, and generate 2D drawing views of those parts to use in design layouts. The model you create is defined according to the size, shape, and position of the features that make up the part. Parts are stored in a part catalog, such as the US Imperial Pipe Catalog, and you can navigate to and select the part from within a catalog when you want to add it to your layout.

**Accessing Part Builder**

To access Part Builder, click Home tab ➤ Create Design panel ➤ 🔲 Part Builder.

When you do this, the Getting Started - Catalog Screen dialog box is displayed.

**Getting Started - Catalog Screen**

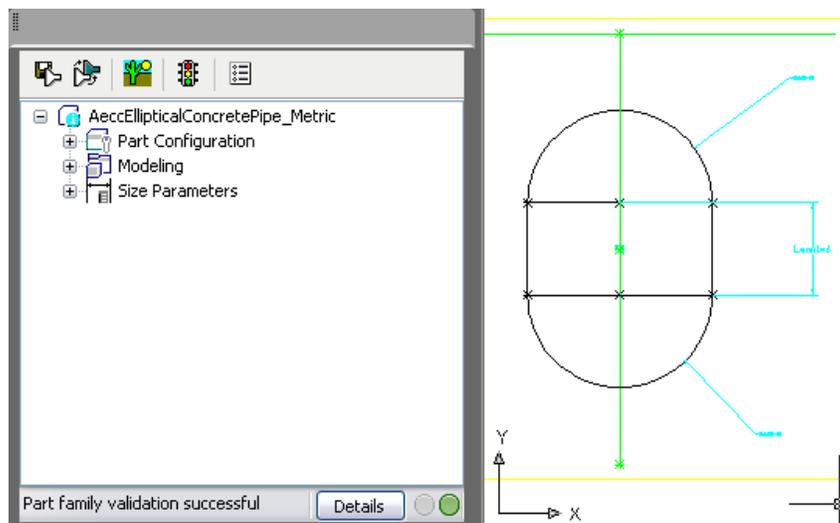
From the Getting Started - Catalog Screen dialog box, you can choose to work with the pipe catalog or structure catalog and navigate through the categories within that catalog.


The icons on this dialog box let you perform several tasks. If you position your mouse over an icon, a tooltip provides an explanation of the icon. Icons are activated based on what is selected in the catalog tree.

| If you want to… | then do this … |
|---|---|
| create a new part | select a chapter folder then click New Parametric Part. Enter a name and description for the new part on the New Part dialog box, and click OK. After doing this, the building environment is opened for part creation. |
| modify an existing part size | select the part in the catalog tree, and click Modify Part Sizes. The building environment is opened for modifying the part. |
| regenerate the catalog | after making changes to parts or to a catalog, click Catalog Regen to regenerate the entire pipe or structure part catalog. |
| test (validate) the catalog | after making changes to a catalog, click Catalog Test to verify that the validation is successful. |
| add a new chapter for a part | click New Chapter and enter a name. You can add chapters to the catalog or to another chapter. |
| delete a part | select the part and click Delete. The part is deleted from the catalog and is removed from the catalog tree. |

**Parametric Building Environment**

When you choose to create or modify a part, Part Builder opens a parametric building environment that includes a variety of features:



■ Part browser. The part browser is displayed on the left side of the screen. It provides an organized view into the features of the currently selected part. As you define your part, additional features are nested in a hierarchy under the appropriate folder. In the browser, you can show more or less detail by expanding or collapsing the folders.

- Modeling area (viewport). The modeling area (viewport) is displayed on the right side drawing space and is designed to give you full view control over your part model. You can use the standard AutoCAD view commands to change the direction in which you view your part model.

- Toolbar. The toolbar provides quick access to select Part Builder commands. Icons are available for saving your part, saving an existing part as a new part, generating a preview image, validating your part, and specifying part options.

- Status bar. The status bar, located at the bottom of the part browser, provides updated information about part validation when you click the Validate icon on the toolbar. A description of the validation status is provided. A details button provides a list of warnings and/or errors found in your model.

- Feature-specific menus. Feature-specific menus are available by right-clicking a part feature in the browser window. Options not available are shaded.

The part browser and the modeling area are resizable windows.

# Understanding Parametric Parts

Parametric parts give you the flexibility to create pipe network parts that are dynamically sized according to size parameters.

You define a parametric part by creating a 3D model of the part and assigning variables, or parameters, to control its shape and size. Parameters are defined by individual values, lists of values, or calculated values based on equations. When the pipe network part is placed in your drawing, you select specific part sizes and the part is dynamically built to reflect the specified shape and size. Parametric parts enable you to create a single 3D model for a part family that can be updated to represent multiple part sizes. You can define millions of parts through a single model, depending on the number and type of parameters defined.

It is beneficial to create pipe network shapes as parametric parts for many reasons. Many of the shapes used to represent pipe network components share the same geometric features; however, the features change in size according to the design. For example, an 8-inch circular PVC pipe looks just like 10-inch PVC pipe except for the pipe diameter. Similarly, you may have two headwall structures that are the same basic shape but have different heights, widths, or both.

- Pipes: An 8-inch circular pipe looks the same as a 10-inch circular pipe, except for the size of the diameter. By creating a parametric part, you can create a 2D cross section of a circular pipe and assign a parameter for the pipe diameter that can change in size. When the pipe is placed in your drawing, the 3D pipe uses this cross-sectional shape parametrically sized to match your part size selection. You specify which size pipe you want and the appropriate diameter is dynamically built to match.

- Structures: A 38-inch concentric catch basin looks the same as a 48-inch catch basin, except for the height and diameter. By creating a parametric part, you can create a 3D model of a catch basin structure and assign parameters for the height and diameter that can change in size. When the catch basin is placed in your drawing, you can specify the height and diameter, and the appropriate size catch basin structure is dynamically built to match.

# Key Terms

Understanding the following key terms will help as you begin using Part Builder.

**constraint** Controls the shape of a feature by establishing relationships between features in the model.

**degree of freedom** In part modeling, determines how a geometric object, such as a line, arc, or circle, can change shape or size. For example, a circle has two degrees of freedom: center and radius. When these values are fixed, degrees of freedom are said to be eliminated.

**dimension** Controls the size of a feature. When changed, the feature is resized. May be expressed as a constant value, a value as part of a table, a calculated value, or a list of values.

**domain** Refers to the part category. There are only two domain types by default: pipes and structures. Each domain type has a unique behavior in AutoCAD Civil.

**feature** A building block of a pipe network part model. You combine features to create pipe network part models.

**model** The part shape representing all possible sizes, and defined by parameters, geometry, dimensions, and geometric constraints.

**parametric** A solution method that uses the values of part parameters to dynamically size the part.

**part size** A specific set of values applied to the parametric model to define a single size.

**work plane** An infinite plane related to one or more features of the model. Work planes provide a defined place in space from which to build the model.

# Overview of Creating a Part

This section provides an overview of the steps involved with creating a part.

When you create a pipe network part, you define the features of the part and how they are associated with one another. Each pipe network part represents a unique part family. You should analyze the pipe or structure catalog hierarchy to determine the best place to add part families. It is also important to notice the relationships between the different part sizes you want to create. The features you define in the model determine the flexibility you have to create multiple part sizes. You should look at the entire part you want to create, decide how to break it down into simple shapes, and determine the relationships to establish between the different shapes.

Creating a part with Part Builder involves performing the following tasks in the order they are presented below:

**1** Specify the part configuration.

You work in the parametric building environment to create single pipe network parts. While you are working in this environment, only one part can exist in a drawing. The individual drawings are associated with a part catalog to build a library of parts. You specify the type and subtype of the part to establish basic part behavior. For more information, see Part Configuration (page 1292).

**2** Create a 2D or 3D model of the part.

During this phase of the process, you create models of 2D pipe parts, or 3D structure parts, and use them to dynamically generate 2D views of the part. You build your part from features that are combined to define the part. The model is defined according to the size, shape, and position of its features. You can restrict how the features of the parts fit together. To better conceptualize the size and shape of the part model, you define dimensions, constraints, and modifiers that determine how your part is built. For more information, see Part Modeling (page 1293), Dimensions (page 1296), Constraints (page 1297), and Modifiers (page 1299).

**3** Generate a preview image and define the insertion position of the part.

Once you have finalized the model, you generate a preview image for the part by taking a snapshot of the model. You also specify the placement position that you use to place the part in your drawing. For more information, see Generating a Preview Image of a Part (page 1317) and Defining Part Insertion Position (page 1317).

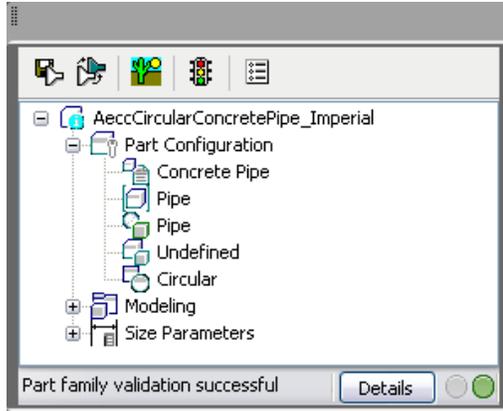
**4** Validate and save the part.

Once you have finalized the model, you must validate and save the part. Validation checks the model and detects any errors that make the part invalid. You must correct all errors in order to successfully save the part and add it to a drawing. For more information, see Validating and Saving a Part (page 1318).

# Part Configuration

Defining the part configuration is the first step in creating a part.

When the parametric building environment opens, the top folder in the part browser is the Part Configuration folder. The part configuration defines the characteristics and behavior of the part according to the domain (pipe or structure), type, and subtype, and it is required to save the part. To ensure that the part can be validated and saved correctly, you should define the part configuration before starting to model the part.



The part configuration is defined once for a part family and remains constant for all part sizes. The following components are required to define the part configuration:

**Part Name** You cannot change the part name of existing (default) parts. This is because part names for existing parts are used in the filenames for the parts. You can, however, create a new name for a new part using Save as.

**Part Description** Describes the part family. When you create and name a new part, you enter the description in the New Part dialog box. By default, the description is the same as the part name unless a different description is entered. For existing parts, the part description is predefined.

**Part Domain** Defines the family of parts. The two basic domains are pipes and structures. You cannot edit the part domain in the part browser. The part domain is predefined based on the part catalog you selected in the Getting Started - Catalog Screen dialog box of Part Builder. The part domain is selected from a list of predefined domains for pipe networks (pipes and structures). In the illustration above, the part domain is Structure.

**Part Type** The part type defines certain behavior properties that are assigned to the part.

For pipes, the predefined part type is always "pipe". A variety of pipe *shapes* may be available; for example, circular, egg-shaped, elliptical, and rectangular. However, they are all defined with same part type (*pipe*).

For structures, the predefined part types include general, inlet-outlet structures, and junction structures. As previously mentioned, the part type defines certain application behavior properties that are associated with the part. A general structure, for example, has a different set of application behavior properties than an inlet-outlet structure, and so on. In the illustration above, the part type is Inlet-Outlet Structure.

From the part browser, you can specify the part type by right-clicking on an item under Part Configuration and choosing Edit. The list of predefined part types is displayed.

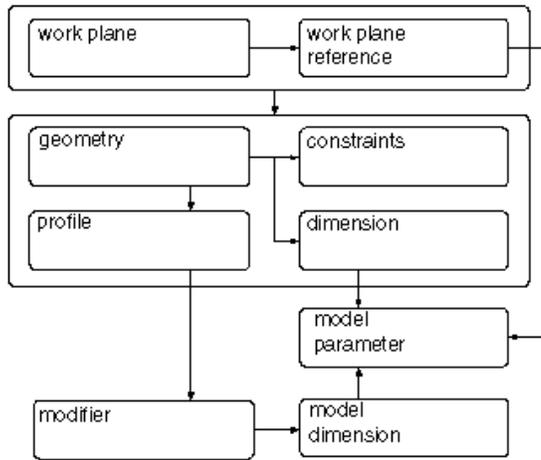
**Part Subtype** Lets you organize parts into more detailed, logical groupings. This grouping does not affect the part behavior. In the part browser, you specify the part subtype from the list of predefined subtypes. You can also enter a custom part subtype if you wish. The part subtype is helpful during part selection to filter a large group of parts that are of a similar type. In the illustration above, the part subtype is Undefined.

# Part Modeling

Modeling a part involves configuring a variety of part features.

In Part Builder, the term model refers to the graphical representation of a part. A model consists of various features that have specific relationships to each other and that define the behavior of the part. Some features require that you create simple shapes or points, while others require an extrusion or path. Some features represent visible geometry, and some help you to position geometry precisely on a part. You can modify features to refine and improve your parts over time. You change features by modifying their size and shape or by flipping or moving them. To effectively model a part, it is important to understand how each feature relates to the other features of modeling.

The following illustration shows the features that make up the model. Arrows indicate the direction of the relationship between features. For example, modifying geometry affects a profile, which affects a modifier, and so on.



The following sections introduce the features of modeling. Refer to this illustration as you learn more about each feature to help you understand the relationships between features.

# Work Planes Overview

Use work planes to define a part, position geometry, and define relationships between part features.

In Part Builder, a work plane is a modeling feature that defines the location of a plane in three-dimensional (3D) space. It is an infinite construction plane that can be placed at any orientation in space. It can be offset from an existing work plane, or it can reference 3D geometry. Using a work plane, you define the geometry, dimensions, constraints, and profiles that make up the part model. Work planes help you to place geometry that would otherwise be difficult to position. By constraining geometry to work planes, you can control their location. Work planes help you to define relationships between features and provide control when placing features.

A work plane is displayed as a rectangular two-dimensional (2D) object. The work plane display is only a visual representation of the infinite plane and cannot be moved or resized. However, you can control its visibility for ease of viewing the model. Offset and reference work planes are user-defined and provide the flexibility to be moved and redefined.

**NOTE** To ensure a manageable model size, it is recommended to use a minimum number of work planes.

When you right-click on a work plane in the part browser, it is highlighted in the modeling area. You can change the view direction to match that of the selected work plane when adding geometry or dimensions by using the Set View option on the Work Plane shortcut menu.

**IMPORTANT** Any features attached to a work plane are restricted to the original plane. If you move a work plane, any features attached to the plane also move. If you delete a work plane, any features attached to the plane are also deleted. Each feature attached to a work plane appears under the Work Plane folder in the part browser.

Part Builder provides three default work planes that intersect at the origin of the *X*, *Y*, and *Z* axes. The default work planes help you to get started with modeling a part. Generally, it is best to start your modeling in the top work plane, and add others as needed. You can add work planes at any time during the modeling process. Each work plane has its own internal coordinate system. Work planes can be created on any plane in the current user coordinate system (UCS) or in the World Coordinate System (WCS).

The following preset work planes can be added to a model from the Create Work Plane dialog box:

**Default** Creates the standard *ZX*, *YZ*, and *XY* work planes of the WCS.

**Custom** Creates a work plane that is not available by the preset work planes. The work plane has user-defined values for the *X* and *Y* direction and the origin of the plane in the current UCS.

**Offset** Creates a work plane that is offset by a specified distance from a selected source work plane. For more information, see Offset and Reference Work Planes (page 1294).

**Reference** Creates a work plane that is attached to the extents of a modifier feature. For more information, see Offset and Reference Work Planes (page 1294).

**Top** Creates a work plane that matches the standard Top 3D view.

**Bottom** Creates a work plane that matches the standard Bottom 3D view.

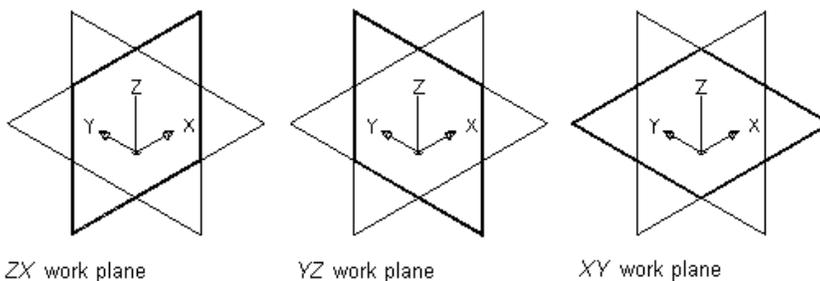
**Front** Creates a work plane that matches the standard Front 3D view.

**Back** Creates a work plane that matches the standard Back 3D view.

**Left** Creates a work plane that matches the standard Left 3D view.

**Right** Creates a work plane that matches the standard Right 3D view.

**Viewing default work planes**

ZX work plane          YZ work plane          XY work plane


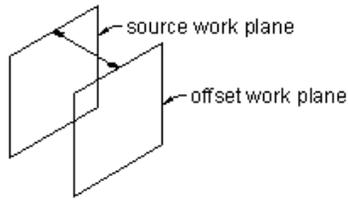
# Offset and Reference Work Planes

Offset and reference work planes are relational and are based on one or more defined features in the model, such as other work planes or modifiers.

**Offset Work Planes**

An offset work plane is a specified distance away from another work plane. This work plane can be offset from any existing work plane, including another offset or reference work plane. You define an offset work plane by selecting a source work plane and specifying a distance between the work planes. You can use offset work planes to maintain specified or calculated distances between features, such as profiles, geometry, or modifiers. You can also use offset work planes as construction guides for locating features that would otherwise be difficult to locate. For example, use an offset work plane to define the length of a transition.

**Creating an offset work plane**

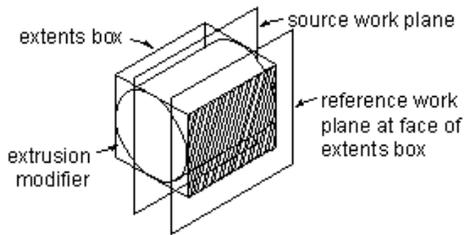


specify offset
distance

### Reference Work Planes

A reference work plane is defined as a plane on the face of the extents of a modifier. Every modifier has an invisible extent, or boundary box, that defines the extents of the feature. You can create a work plane that references one of the planes of the extent. To define a reference work plane, you select a modifier and a source work plane that represents the plane direction you want to create. The extents, or boundary box, of the feature is detected, and two valid reference work planes are available for selection. If the modifier is moved or resized, the reference work plane is moved with it.

**Creating a reference work plane**



## Geometry

Geometry features are the basic building blocks for defining the size and shape of the model.

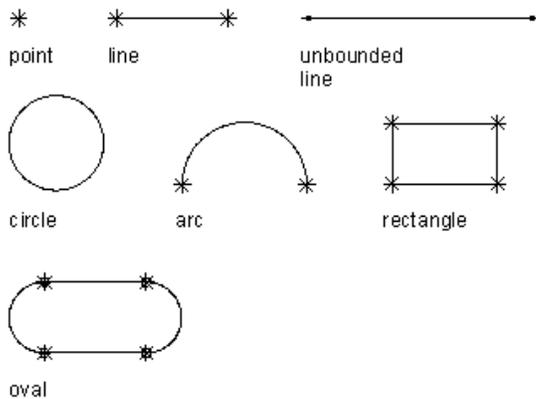
In Part Builder, geometry that you define is constraint based, two-dimensional (2D), and must be attached to a work plane. You can switch between work planes to define different geometry. As you add geometry to a work plane, the geometry features appear under the Geometry folder of the associated work plane.

---

**WARNING** Avoid using basic AutoCAD geometry commands. AutoCAD geometry is not valid for work planes and cannot be used to create features for part models.

---

**Viewing geometry types**



Part Builder provides nine types of geometry you can use to build the model:

**Point** Defined by an *X* and *Y* coordinate.

**Line** Defined by a position and a direction; constrained by a start point and endpoint.

**Unbounded Line** Defined by a position and a direction; infinite in length because it has no constraining start point or endpoint.

**Circle** Defined by a center point and a radius.

**Arc** Defined by a center point and a radius; constrained by a start point and endpoint.

**Rectangle** Defined by lines and points that are constrained to maintain start points and endpoints for each side and perpendicular angle.

**Oval** Defined by lines, arc, and points that are constrained to create two arcs tangent to two lines, with defined start points and endpoints.

**Point Reference** Defined by a point in the work plane that is based on a source point selected from a different work plane. A point reference is moved or deleted with the source point.

**Project Geometry** Defined by a projection of a modifier on a specified work plane. The project geometry is fixed and cannot be moved in the work plane. It is linked to the modifier and adjusts as the modifier changes.

# Dimensions

Add dimension information to specify the length, diameter, or rotation angle of geometric elements in the model.

Models require dimension information to define the size and position for the design. Dimensions are typically added after you have finalized the geometric features of the model; however, you can add dimensions at any time during the creation process. When you add dimensions, you apply rules that control the size and position of features in the model. Dimensions work in conjunction with constraints. The model is updated when changes are made to the dimensions.

Dimensions specify the length, diameter, or rotation angle of geometric elements in the model. When a dimension is added, a corresponding size parameter is also added. This parameter creates a placeholder value for the dimension that provides flexibility for defining the values of dimensions. Dimensions can be defined as default numeric constants or as equations. Although you can use them interchangeably, they each have specific uses.

- Numeric constants are useful when a geometric element has a static or fixed size that is populated as a value in a basic table, list, or constant storage type.

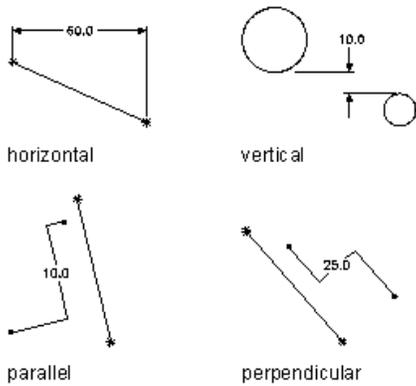
- Equations are useful when the size of a feature icon must be mathematically defined relative to the size of another feature.

Part Builder assigns a variable name to each dimension parameter. Letters and numbers are used to signify the type of dimension (such as length or diameter) and the sequence in which the dimension was added to the model (1 for first, 2 for second, and so on). To keep the model shape from becoming distorted as the dimensions resize it, define the large dimensions first. Dimension type depends on the feature you choose and where you place the dimensions.

**NOTE** When adding dimensions it is recommended to select points to specify the start and end locations. It is also helpful to turn off geometry that you not dimensioning for ease of selection.

**Viewing dimension types**

horizontal      vertical

parallel      perpendicular


Part Builder provides seven types of dimensions you can add to the model:

**Distance** Can be defined for pairs of geometry of all types. Defines a value between two features. The value of a distance dimension cannot be negative. When adding distance dimensions between two lines, it is implied that the lines are parallel with a given separation.

**Horizontal Distance** Can be defined for pairs of geometry of all types. Defines a value between two features in a horizontal direction. The value of a distance dimension cannot be negative.

**Vertical Distance** Can be defined for pairs of geometry of all types. Defines a value between two features in a vertical direction. The value of a distance dimension cannot be negative.

**Parallel Distance** Can be defined for pairs of geometry of all types. Defines a value between two features in a parallel direction. The value of a distance dimension cannot be negative.

**Perpendicular Distance** Can be defined for pairs of geometry of all types. Defines a value between two features in a perpendicular direction. The value of a distance dimension cannot be negative.

**Diameter** Can be defined for circular and arc geometry. Defines a value for the diameter of a circular feature.

**Angle** Can be defined for pairs of linear geometry. Defines a value for the degrees between two linear features.

# Constraints

Add constraints to create rules that control how a part can change in shape or size.

Depending on the geometry of the model, you may need to add one or more constraints to define the shape or size of the model. Constraints enforce rules that you want the model to obey. Constraining a model controls how a model can change in shape or size, called "degrees of freedom." For example, a circle has two degrees of freedom: the location of its center and its diameter. If the center and diameter are defined, the circle is fully constrained and those values can be maintained. Constraints specify the relationships of geometric features; for example, whether two features are perpendicular, parallel, tangent, concentric, or have the same midpoint or radius.

**NOTE** After you add geometry, dimensions, or constraints to the model, the degrees of freedom are listed on the command line.

Constraints work in conjunction with dimensions to control the shape and size of the model. Any time you modify the model, the geometry retains the relationships among features in accordance with the applied constraints. You add constraints to indicate your design intent. For example, a parallel constraint could be defined between two lines based on the geometry of the model. You could also add a constraint to force both lines to have the same length.

As you apply geometric constraints, continue to analyze the model, reviewing and replacing constraints as necessary. As you gain experience, you will be able to determine which constraints control the model to

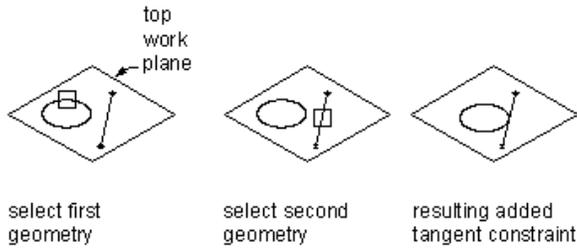
meet your design requirements. Some constraints work only with lines, while others work only with arcs, circles, or points.

See Adding a Constraint (page 1315) for step by step instructions on how to add a constraint.

**Applying a tangent constraint**

select first geometry

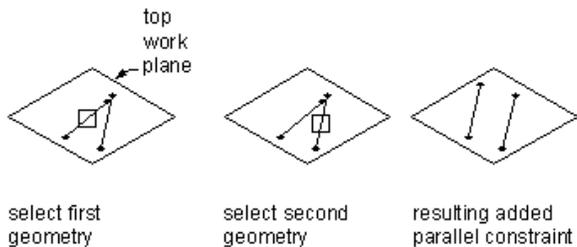
select second geometry

resulting added tangent constraint


**Applying a parallel constraint**

select first geometry

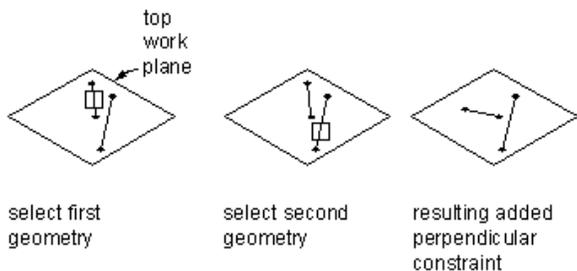
select second geometry

resulting added parallel constraint


**Applying a perpendicular constraint**

select first geometry

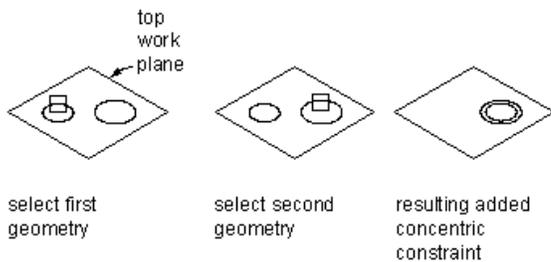
select second geometry

resulting added perpendicular constraint


**Applying a concentric constraint**

select first geometry

select second geometry

resulting added concentric constraint


Part Builder provides ten geometric constraints. The following list describes these constraints and the features with which they can be used.

**Tangent** Can be defined between curved geometry (such as a circle or arc) and either another curved geometry or a line. Makes two curves tangential to one another, even if they do not physically share a point. Tangency is commonly used to constrain a line to an arc or circle.

**Parallel** Can be defined between pairs of geometry with a direction, such as lines. Causes two or more lines to be parallel to one another.

**Perpendicular** Can be defined between pairs of geometry with a direction, such as lines. Causes selected lines to lie at right angles to one another.

**Concentric** Can be defined for any combination of circles and points. Fixes the centers of the geometry to the same location. Common uses include circle to circle, where the center of both circles is the same; circle to point, where the point lies at the center of the circle; and point to point, where the points are the same.

**Coincident** Can be defined between a point and any geometry. Fixes two points (including center points) together; essentially, the point lies on the geometry.

**Equal Distance** Can be defined between two pairs of geometry. The distance between the first pair of geometries is fixed to the distance between the second pair. Equal distance constraints do not control the actual distance. Each pair of geometries must be one of the following: any combination of points and lines, two circles or arcs concentrically constrained, or a point and circle or arc concentrically constrained.

**Equal Radius** Can be defined between two circles or two arcs. Fixes the radius of both circles or arcs to be of the same value. Equal radius constraints do not control the value of the radii.

**Midpoint** Can be defined between a point and either two other points or two lines. The point is equal distance from the other two geometries. Midpoint constraints do not control the distance. A common use is constraining a point to the middle of a line.

**Symmetric** Can be defined between two geometries of the same type and a line. The two geometries are symmetrically arranged on opposite sides of the line. The symmetric constraint does not force constrained geometry to maintain an exact mirror image.

**Normal** Can be defined between a line or curve and a curve. (Two lines cannot be made normal; a perpendicular constraint must be used instead.) The curves intersect and the directions of curve tangents are perpendicular at the point of intersection. A common use is constraining a line to the normal of an ellipse.

# Profiles

Create profiles to define a two-dimensional (2D) outline of a part's geometric shape.

Using Part Builder, creating a profile is as easy as drawing a closed shape. Profiles are similar to geometry in that they are a visual representation of the 2D shapes that make up the model. Because profiles automatically associate constraints to the geometry, you can use profiles as a source of information from which to create features. You create profiles on a work plane and apply modifiers, such as extrusions, to them.

> **NOTE** Profiles can be used to create solids using modifiers. Non-profile geometry cannot be used to create solids directly. However, you can group a set of non-profile geometries together to create a custom profile.

Part Builder provides four types of profiles to use for creating features in the model:

**Circular** Creates a profile based on a circle defined by a center point and diameter to maintain its shape.

**Rectangular** Creates a profile based on a rectangle defined by four lines, four points, and four perpendicular constraints to maintain its shape.

**Oval** Creates a profile based on an oval defined by two lines, two arcs, four points, and four tangent constraints to maintain its shape.

**Custom** Creates a profile from existing geometry in the model. The geometry must be attached to a single work plane. Constraints are assigned as needed to maintain the shape of the geometry as it was selected.

# Modifiers

Use modifiers to create three-dimensional features of the model.

A modifier is a general term for any operation that affects features of the model. After creating profiles, you can use modifiers to extrude, add, or subtract features and to sweep a profile along a path. You can also use modifiers to create cut planes and transition features.

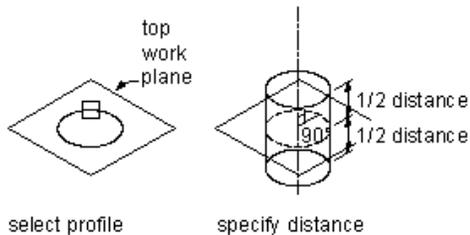
Part Builder provides six types of modifiers: extrusion, path, transition, cut plane, Boolean add, and Boolean subtract. The extrusion modifier is the most common type used in part modeling and is generally the base feature for a model. When you extrude a profile to create a feature, you specify how the feature will modify the shape by choosing one of four operations: midplane, plane, from-to, or blind.

See for step by step instructions on how to apply a modifer.

**Midplane Extrusion Modifier**

A midplane extrusion uses a profile as the center of the extrusion and sweeps the profile an equal distance away from each side of the center.

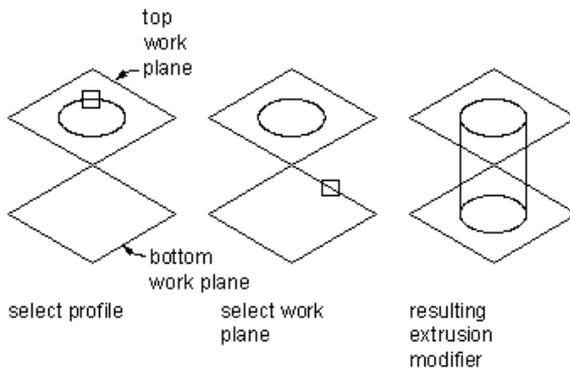
**Applying a midplane extrusion modifier**



**Plane Extrusion Modifier**

A plane extrusion sweeps a profile between the profile itself and a specified work plane. If the work plane is a reference work plane, the extrusion is updated when the work plane is moved.

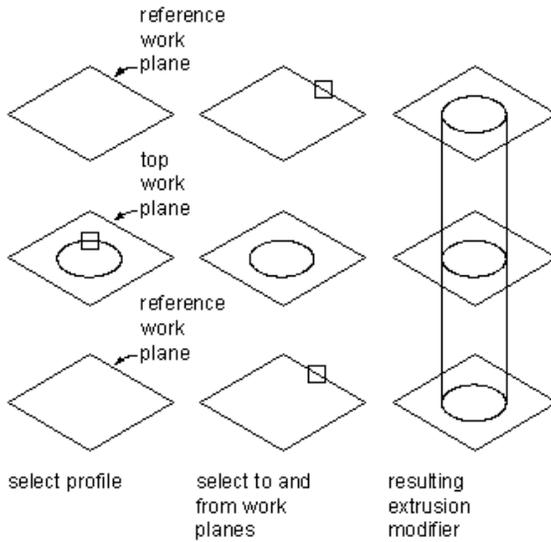
**Applying a plane extrusion modifier**



**From-To Extrusion Modifier**

A from-to extrusion sweeps a profile between two work planes.

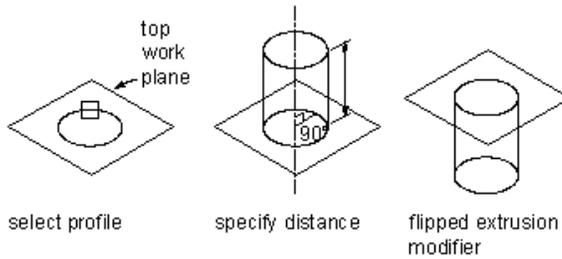
**Applying a from-to extrusion modifier**

select profile     select to and from work planes     resulting extrusion modifier


### Blind Extrusion Modifier

A blind extrusion sweeps a profile a specified distance along its normal, or perpendicular axis. You can flip the extrusion to sweep the profile in the opposite direction as the default normal.

**Applying a blind extrusion modifier**

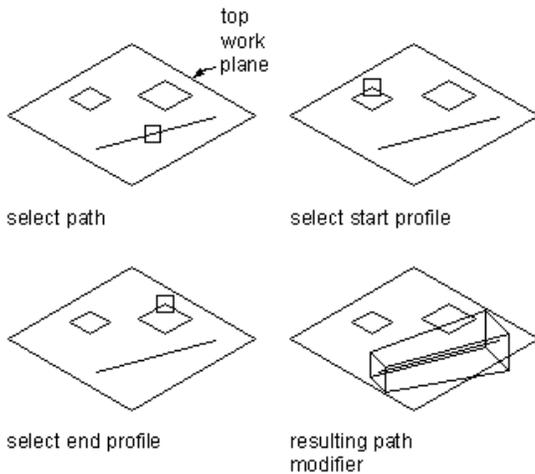
select profile     specify distance     flipped extrusion modifier


### Path Modifier

A path modifier sweeps a profile along path geometry. It creates a 3D feature based on the start and end profile of a piece of geometry, such as a line or an arc. The start and end profiles can be different.

**Applying a path modifier**

select path     select start profile

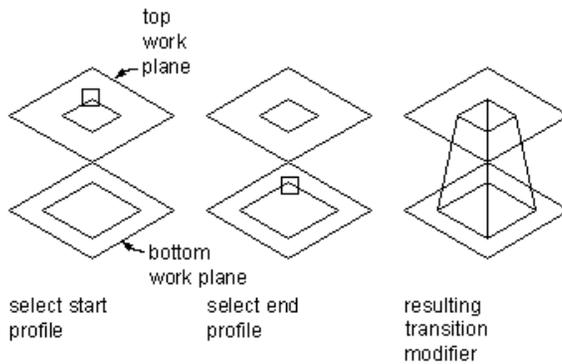
select end profile     resulting path modifier


You can also specify the number of segments to use to create a 3D feature.

**Transition Modifier**

A transition modifier creates a transition body between two profiles. A transition includes both a start and end profile, which cannot be in the same work plane. Point references are useful to ensure that the profiles align between work planes; however, the centers do not need to align.

**Applying a transition modifier**



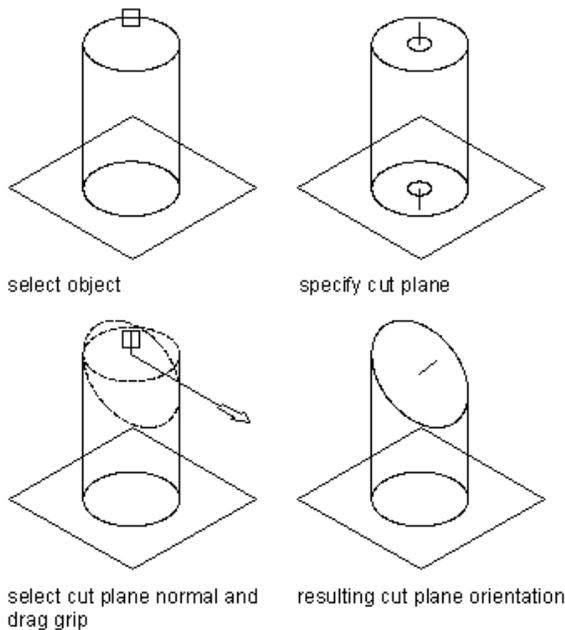
**Cut Plane Modifier**

A cut plane modifier cuts a feature into two parts, only one of which is kept. A cut plane modifier enables you to change the end of a feature to a slope, providing for the creation of more advanced features, such as an exhaust vent. You can modify the cut plane by dragging the normal, or perpendicular axis, of the modifier to create custom slopes. Cut planes are updated when the length of the modifier changes.

---

**NOTE** Cut planes cannot be defined parametrically. How they are defined in the model is how they will be displayed when placed in your drawing.

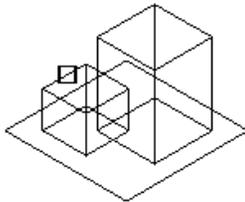
---

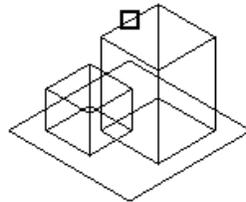
**Applying a cut plane modifier**


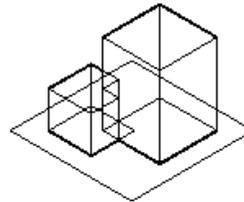
**Boolean Add Modifier**

A Boolean add modifier combines two features to create a single feature. This modifier assumes a basic concept of addition: that geometry inside other geometry, when added together, is removed. This modifier is helpful when creating models of parts that are placed in your drawing exactly as they were created in the model.

**Applying a Boolean add modifier**



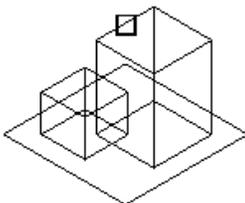
select first object        select second object        resulting Boolean addition modifier


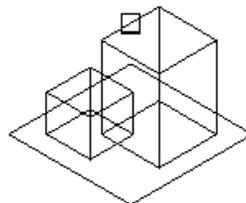


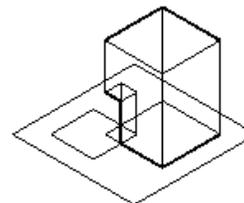
**Boolean Subtract Modifier**

A Boolean subtract modifier subtracts one or more features from another to create a new feature. The Boolean subtract modifier uses a basic formula when creating the resulting feature: that the subtractor objects are removed from the base object. To see results in the model, the subtractor features must intersect with the base feature. When no intersection of features exists, the subtractor features are removed from the base feature with no visible change in the model.

**Applying a Boolean subtract modifier**



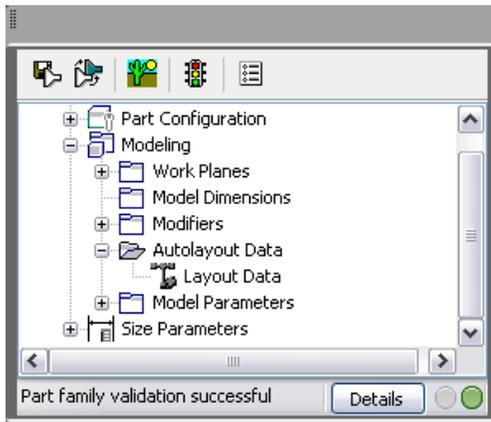


select base object        select subtractor object        resulting Boolean subtraction modifier


# Placement Points

Use the Autolayout Data option to define the part placement point in the drawing.

After finalizing the part model, you need to define the placement point for the part to ensure that it can be placed correctly in a drawing. The Autolayout Data option in the part browser controls how placement points can be defined. When you enable this option, an Autolayout Data folder is available in the part browser that includes commands for adding placement points.

This is done by selecting a fixed point in the model. This point must be in the z = 0 plane. By choosing a fixed point, the parametric model will retain this position as it is dynamically sized.


The placement point is the insertion point used to place the part in a drawing. You simply specify a point in your model for the placement point.

# Model Parameters

Configuring model parameters enables you to control the model's shape and size by establishing relationships between defined parameters.

As you add dimensions and constraints to the model, parameters appear under the Model Parameters folder in the part browser. The Model Parameters dialog box provides a central location where you can view, create, and edit the dimensional parameters of the model. You can define parameters to create additional model relationships later.

It is often more efficient to assign numeric values to dimensions and other feature parameters as you build the model. When you finalize the geometry, you can edit the model parameters to add calculated values. An equation assistant is available in the Model Parameters dialog box to ensure that the equation you create is valid and can produce a result. Each parameter in the Model Parameters dialog box includes the following:

**Name** A unique identifier for the model parameter. Model parameters are assigned default names, such as LenB1, (Length Body 1), WTh (Wall Thickness), PID (Pipe Inner Diameter), and BdyD1 (Body DImension 1), that can be changed. Model Parameter names are typically short acronyms because they can be used in equations. User-defined parameters must have unique names.

**Value** The result of evaluating the equation.

**Equation** The mathematical expression that defines the value of the parameter. Constants, other model and user-defined parameters, and mathematical operators can be used in an equation. You can use the Equation Assistant to define the equation.

**Description** A narrative, user-defined description of the parameter.

**NOTE** When using a constant value in an equation, be sure to define the constant as a model parameter. You should verify that the result of the equation is non-zero to avoid undesirable results in your model.

# Size Parameters

Part sizes are controlled by size parameters that set the dimensions of the part size.

Model parameters define the default part size of the model, and act as placeholders for new values that can be specified later. There is a direct connection between the model parameters and size parameters in that each model parameter is added to the size parameters in the part browser. Size parameters enable you to create different sizes for the model to represent multiple part sizes and to add non-graphical parameters to the part family.

You work with size parameters in the Edit Part Sizes dialog box. This dialog box lets you view and edit parameter values and configuration attributes in a table. Each parameter is viewed or modified independently of the others, so you can modify a single parameter at a time without scrolling through a large table.

The Edit Part Sizes dialog box has three working modes: Calculations, Parameter Configuration, and Values.

■ The Calculations mode provides access to the calculation formula of the parameter.

■ The Parameter Configuration mode provides access to attributes of the parameters, and includes description, data storage, data type, units, visibility, context, and index.

**NOTE** When parameters are added to the model, the name, data storage, context, and type attributes are assigned, and they cannot be changed.

■ The Values mode provides access to defined values of the parameter when they are stored as constants, lists, and tables.

**NOTE** Any calculations set in the model are fixed and can be changed only in the model.

The parameter configuration allows you to configure data storage. The type of data storage lets you define the parameter as a list or table of values, in addition to a constant or calculated value. You can also revise the parameter description and control parameter visibility. For more information, see Adding Individual Part Sizes (page 1312). You can define constant values, and copy and paste lists of values from other parts to define multiple part sizes. Calculated values can only be viewed. Use the Model Parameters dialog box to modify formulas for calculated values.

By creating a new parameter, you can define values that store additional information about the part. You can add custom parameters in which you define all parameter attributes, such as data storage type. You can also add parameters by selecting from a list of optional parameters that have been defined for you. The list of predefined parameters is determined by the part type and existing parameters found in the part family. These parameters provide additional part information that can help to identify parts in your drawing during the design process or when you produce a set of construction documents.

# Creating Parts with Part Builder

# 29

This section provides step-by-step procedures, illustrations, and tips for creating pipe network content using Part Builder.

In AutoCAD Civil, content is used to represent real-world pipe network parts such as pipes, manholes, catch basins, and headwalls. Pipe shapes are organized into the following part family categories based on the shape of the pipe: circular, egg-shaped, elliptical, or rectangular pipes. Structure shapes, such as manholes, catch basins, and headwalls, are organized into the following categories, or part families, based on shape characteristics: general structures, inlet-outlet structures (headwalls), junction structures (catch basins). Part Builder enables you to create and modify part families as well as individual parts.

## Tips for Creating Parts

Make sure you understand these tips before modeling parts with Part Builder.

### Tips for Using Part Builder

Keep the following tips in mind as you use Part Builder:

■ Save a backup copy of the part catalogs before using Part Builder, in case you need to revert to the original catalogs provided with AutoCAD Civil. You can use a browser application, such as Windows® Explorer, to copy and paste the catalogs and their sub-folders to a new location.

■ Determine model dependencies. Analyze the model design to determine how features interrelate; then decide how to create the model.

■ Work in a three-dimensional (3D) view. Creating the model in a two-dimensional (2D) view may lead to confusion.

■ Start any new model in the top work plane and pick your fixed insertion position before modeling.

■ Use the order of the folders in the part browser as a guide to the steps involved in the creation process.

■ Do not use the EXPLODE command. Exploding a part deletes the part definition from the catalog.

■ Part Builder generates drawing views of your pipe network part. The AutoCAD MVIEW command does not create associative views of your parts.

■ AutoCAD object snaps can be used to assist in object selection.

**Tips for Modeling the Part**

Keep the following tips in mind as you model the part:

- Use work planes to control the UCS orientation. Using the AutoCAD UCS command does not associate the current plane with your part.

- Use the AutoCAD Point Style command to increase point sizes. It is recommended to use an absolute point size.

- Use a minimum number of points. Reusing points is less confusing and helps in constraining the model.

- Use both constraints and dimensions. Some constraint combinations may distort unconstrained features of the model. If so, delete the last constraint and consider using a dimension or a different constraint combination.

- Use Part Builder dimensions. AutoCAD dimensions are not parametric and therefore cannot control the size, shape, or position of part content.

- Dimension large features before small features. To minimize distortion, define larger features that have an overall bearing on the model. Dimensioning small features first may restrict overall size. Delete or undo a dimension if the model shape is distorted.

- Define shape before size. If you apply constraints before dimensions, your model shape is less likely to become distorted.

- Determine model dependencies before applying constraints. A single constraint can often be used to define more than one feature's shape. Therefore, analyze the model design to help identify necessary constraints.

- Add constraints as needed to define the model shape. Because constraints often restrict more than one feature, use fewer constraints to avoid distorted models.

- When using calculated values for model parameters, be aware that calculated values are not available in the part Add Size dialog box.

# Creating a Part

This section contains step-by-step instructions for creating a simple part using Part Builder.

Each section describes a separate phase in the creation process. You should perform the steps in the order in which they are presented to avoid creating unusable parts.

# Creating a New Part

Use this procedure to start Part Builder and to begin creating a new part.

1 Click Home tab ➤ Create Design panel ➤ ▼ ➤ Part Builder 🔲 .
   The Getting Started - Catalog Screen dialog box is displayed.

2 Select the Structure part catalog by selecting Structure from the Part Catalog list at the top of this dialog box.

3 Select the Simple Shapes folder, then click New Parametric Part 🗋 .
   The New Part dialog box is displayed.

4 Enter a name for this new part family. For example, enter Simple Cylinder 2.

5 Click in the Description field.

By default, when you click in the Description field, the description is the same as the part name until you change it. You can type over this text to change it or add to it.

**6** Click OK to create the new, undefined part family.

The new part family is displayed in the part browser window.

**7** Proceed to Specifying the Part Configuration (page 1309).

## Specifying the Part Configuration

Use this procedure to specify the part configuration, defining certain behavior of the new part family you just created (Simple Cylinder 2).

**1** In the part browser, expand Part Configuration.

**2** To specify the part type, right-click Undefined Part Type, click Edit, and select a part type, such as General Structure.

The predefined part types are dependent on the selected part domain. For example, for a pipe part, the only available part type choice is "Pipe". For structure shapes, which are more complex than pipe shapes, there are multiple part type choices, such as general, inlet-outlet structures, junctions structures, and so on.

**3** To specify the part subtype, right-click Undefined Bounded Shape, click Edit, and select Cylinder.

The list of predefined subtypes depends on the selected type. For example for pipes, choices are arched, circular, egg-shaped, elliptical, rectangular, and undefined shape. For structures, you can specify the following subtypes for undefined bounded shapes: box, cylinder, sphere, and undefined.

**4** If desired, you can also enter a new subtype.

**5** Proceed to Modeling a Part (page 1309).

## Modeling a Part

To model a part, you must first define work planes on which to create the geometry of your model.

You can then create profiles and apply modifiers to define the shape and default size of the part. To avoid distortion in the model, start with the larger features, which have more impact on the overall size of the part, and then add the smaller features.

## Establishing Work Planes

Use this procedure to add work planes on which to create the geometry of the model.

To avoid confusion, work with only one work plane visible, unless you are using offset or reference work planes.

**1** In the part browser, expand Modeling.

**2** Right-click Work Planes and click Add Work Plane.

The Create Work Plane dialog box is displayed.

**3** Click Top and then click OK.

The top work plane is created.

You can add other types of work planes as needed. For more information, see Work Planes Overview (page 1293).

**4** To view the work planes in the modeling area, on the View menu, click 3D Views ➤ SW Isometric.

You can select any view direction or use the Views toolbar to zoom extents of your work planes.

**5** In the part browser, expand the Work Planes folder.

When you select a work plane in the part browser, the work plane is highlighted in the modeling area.

**6** Add more work planes as necessary to model the shape.

To avoid confusion, work with only one work plane visible at a time. To make only one work plane visible at a time, in the part browser, right-click a work plane and remove the check from the Visible check box (uncheck it).

When a workplane is marked as unvisible, the workplane icon in the part browser is grayed out, and the work plane itself is not displayed in the modeling area.

## Modeling a New Part

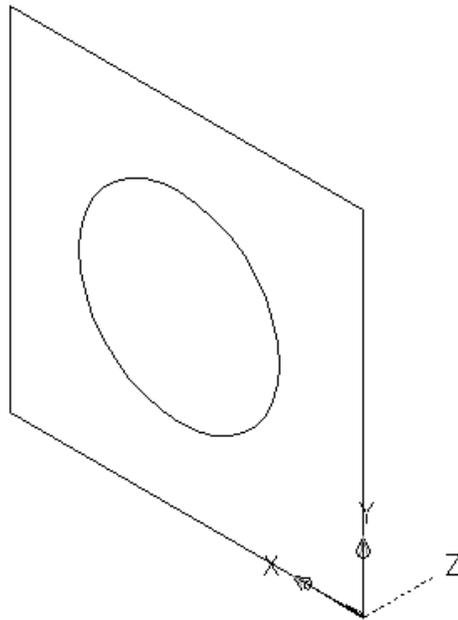
Use this procedure to model the new part you are adding.

Modeling any part typically involves adding a profile, geometry, dimensions, and constraints. You may need to add extrusions, but these are typically used for more complex structure shapes.

For a simple cylindrical structure part, the profile is circular, the geometry is typically fixed center, and an example of a constraint is concentric. Dimension parameters define various diameters for the shape. For example, a dimension parameter named BdyD1 is used to define the diameter for the body of a simple cylindrical structure.

**1** To create the new cylindrical structure, in the part browser, right-click XY Plane and click Add Profile ➤ Circular.

For more information about profiles, see Profiles (page 1299).

**2** Select a center point in the modeling area and specify a second point, or enter a value such as 12, to define the cylindrical shape radius.


A circular profile is created and is added to XY Plane in the part browser.

**3** The next step is to add model dimensions to the part. Proceed to Adding Model Dimensions (page 1311).

For some shapes, you may want to add constraints or extrusion modifiers. For more information, see Constraints and Modifiers in Understanding Part Builder.

## Adding Model Dimensions

Use this procedure to add dimensions to specify the overall default size of the model.

Dimensions are used to define the default size of a part family (or part within a part family). You can add other sizes, such as a list of values, to create individual part sizes within a part family.

**TIP** You may find it easier to add model dimensions in the top view, rather than in a model view direction. To change the view, on the View menu, click 3D Views ➤ Top.

**1** To define the overall length of the part, in the part browser, right-click Model Dimensions, and then click Add Distance.

**NOTE** For constant parameter values, you can define a constant dimension, or choose not to add a dimension and use the default value based on the actual size of the geometry. When no dimensions are added, the parameter and its value are not displayed during part size selection.

**2** Select the model modifier feature in the modeling area, and specify a location to place the dimension.

A length dimension (for example, LenB1 or LenB2) is placed in the model and is added to Model Parameters and Size Parameters in the part browser.

**3** To modify the default, or to specify a calculated value for the length of the component, in the part browser, expand Model Parameters, right-click a length dimension, and click Edit.

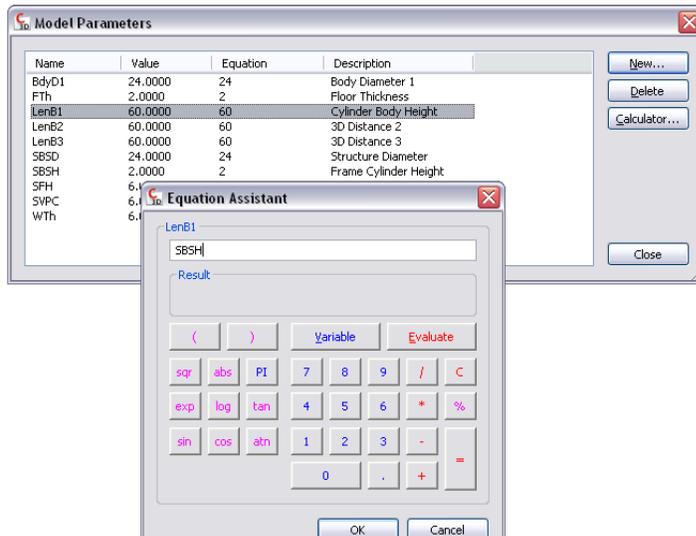
The Model Parameters dialog box is displayed.

**4** Double-click the Equation column value for a model parameter (such as LenB1), and you can enter a value or an equation to specify the length of the part.

---

**TIP** Click Calculator to access the Equation Assistant.

---



**5** The next step is to add individual part sizes to the model. Proceed to Adding Individual Part Sizes (page 1312)

## Adding Individual Part Sizes

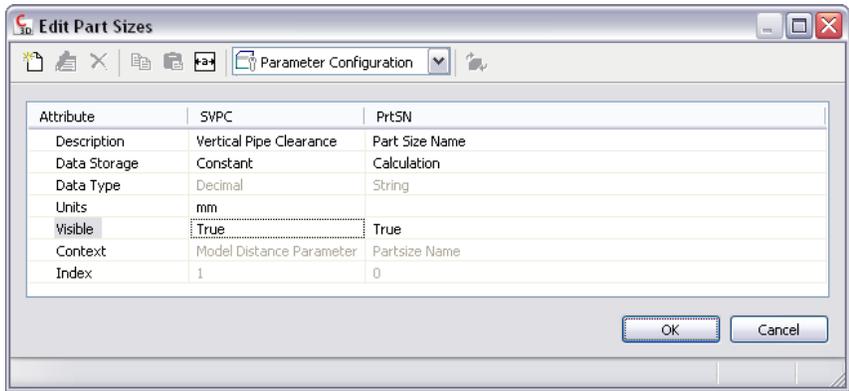
Use this procedure to add individual part sizes to the model.

You create individual part sizes by adding parameter values. Values can be a list or table of values, a constant value, or a calculation.

You can also create unique part size names. Each part size name is generated using a calculation – a formatted string of parameter values and text.

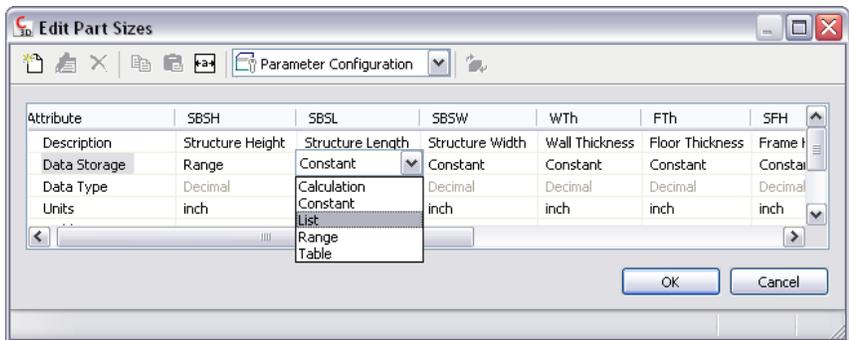
The set of default size parameters that are available for each part differs depending on the part type. For example, a structure part defined as a junction structure (part type = junction structure) has a certain set of default size parameters that are appropriate for junction structures. Inlet-outlet structures (part type = inlet-outlet structure) have a different set of default size parameters available. Pipe parts have yet another set of available size parameters.

**1** To add part sizes, in the part browser, right-click Size Parameters and click Edit Configuration.

The Edit Part Sizes dialog box is displayed, showing all of the currently available size parameters for the selected part. For the Simple Cylindrical Structure part example, some default size parameters are Part Size Name (PrtSN) and Structure Vertical Pipe Clearance (SVPC).


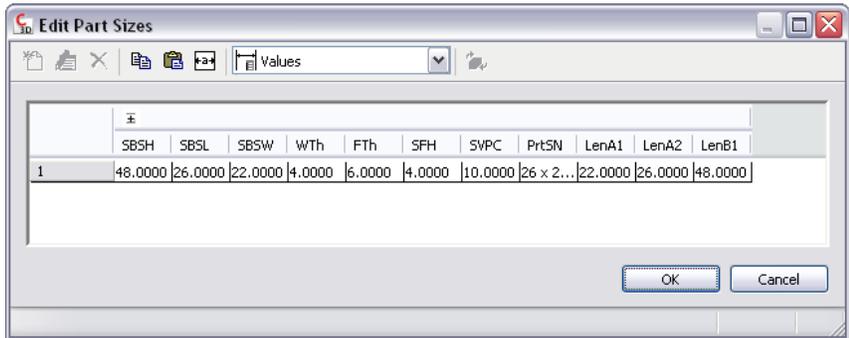
**NOTE** Calculated values set in the model cannot be edited in the Edit Part Sizes dialog box. To change these values you must edit the model.

**2** To add a list of available sizes for the part, change the data storage type of a size parameter to List.

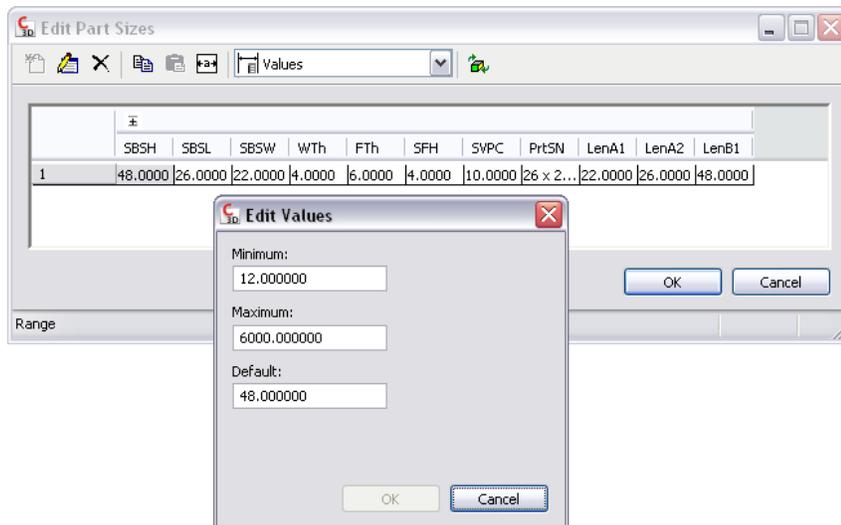


**3** In the toolbar, select Values from the list.

The parameter values are displayed.



**4** To add new sizes for the part, click a parameter value such as the LenB1 parameter, and click Edit on the toolbar.

The Edit Values dialog box is displayed.


**5** Click Add and enter a new size. When you are finished adding sizes, click OK.

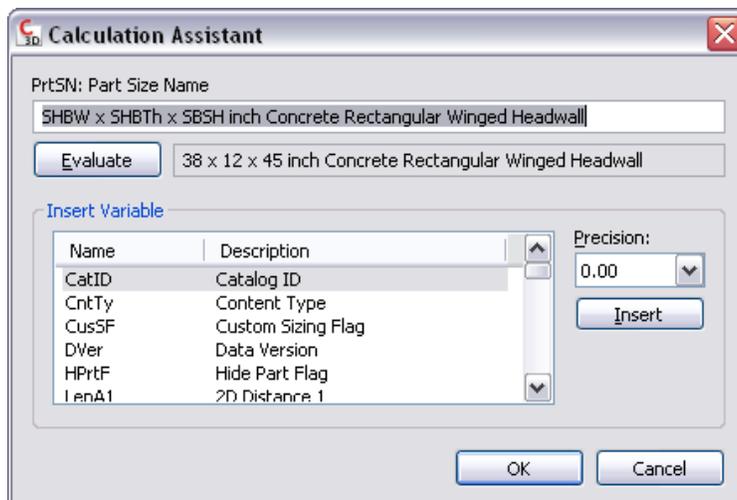
> **TIP** You can cut and paste values from other part families using standard Microsoft® Windows cut and paste functionality (CTRL+C and CTRL+V). Open another part in Part Builder, select the size parameter you want to copy, and then paste the selected values in the desired parameter of your part. You can also create a list of values in Microsoft® Excel, select the list of values you want to add, and then paste the values in the desired parameter of your part.

Now when you click in the size parameter value you edited (for example, LenB1) on the Edit Part Sizes dialog box, the list of sizes you just added is displayed.

**6** To specify a unique, calculated part size name, select Calculations from the toolbar list box.

The calculation strings associated with parameter values are displayed. For example, the calculation formula for a Part Size Name (PrtSN) for a structure could be "SHBW x SHBTh x SBSH inch Concrete Rectangular Headwall". Or for a pipe, it could be FormatNumber($PID,0) + " inch Concrete Pipe".

**7** Double-click the value cell of PrtSN.

The Calculation Assistant is displayed.


**8** Define the part size name with a calculated value:

- Highlight the value in the PrtSN: Part Size Name text box and press DELETE to remove the text.

- Select 0 for Precision.

- Under Insert Variable, select a variable and click Insert.

- Click the value of PrtSN:Part Size Name and enter the text you want to display in the Part Size Name string. For example, enter inch Dia. Concrete Pipe to add that text to the part size name.

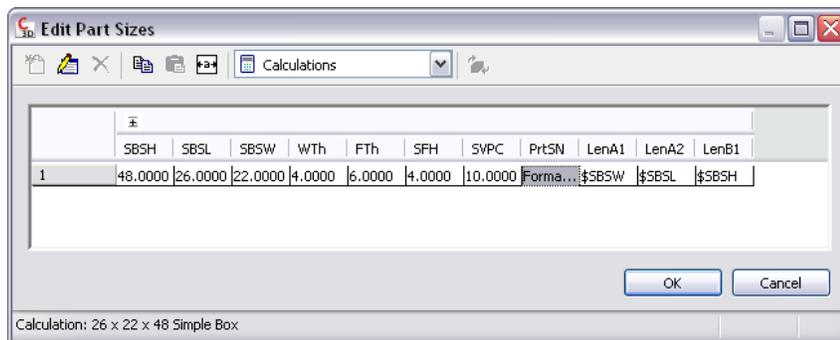
- Under Insert Variable, select Ptype and click Insert.

- Select PTyp and click Insert.

**9** Click Evaluate; the calculation result is displayed.

**10** Click OK.

The calculation value of PrtSN is updated with the valid string and, when selected, the result is displayed in the status bar.



**IMPORTANT** The part size name is generated using VB (Visual Basic) Script's FormatNumber function and simple string substitutions. Correct syntax is crucial. Use the Calculator to ensure that the string is valid.

**11** Click OK.

## Adding a Constraint

Use this procedure to add constraints to the model.

The procedure below uses the example of aligning the top and bottom faces of a rectangular shaped part. For more information on constraints, see Constraints in Understanding Part Builder.

**1** In the part browser, right-click XY Plane and click Add Geometry ➤ Point.

**2** In the modeling area, specify a point near the center of the top face rectangular profile and press Enter.

**3** In the part browser, right-click XY Plane and click Add Constraints ➤ Equal Distance.

**4** In the modeling area, specify the pairs of geometric constraints.

**5** For the first pair, select the point in the center of the top face, and then the lower-left edge of the top face rectangular profile.

**6** For the second pair, select the point in the center of the top face, and then the upper-right edge of the top face rectangular profile.

The model of the top face is updated to the specified constraint.

**7** Repeat steps 3 and 4 to constrain the upper-left and lower-right edges of the top face.

The model of the top face is updated to the specified constraint.

---

**NOTE** When adding constraints, you may be prompted that the geometry is unconstrained by a specific number of dimensions. These prompts are for informational purposes only to assist you during the modeling process. It is recommended that you add a minimum number of constraints to define the shape of the part to avoid undesirable results.

---

**8** To ensure the alignment of the top and bottom faces, in the part browser, right-click Bottom Face and click Add Geometry ➤ Point Reference.

**9** Select the existing point in the center of the top face rectangular profile.

A reference point is added to the bottom face work plane.

**10** Repeat steps 3 through 5 to constrain all four edges of the bottom face using the reference point in the center of the bottom face.

The model of the bottom face is updated to the specified constraints.

## Applying a Modifier

Use this procedure to apply modifiers to the model.

The procedure below uses the example of applying a transition modifier to the two rectangular shaped parts described in Adding a Constraint. For more information on modifiers, see Modifiers in Understanding Part Builder.

**1** In the part browser, right-click Modifiers and click Add Transition.

**2** In the modeling area, select the top face rectangular profile for the start profile; then select the bottom face rectangular profile for the end profile.

A transitional box is created to represent the diffuser, and a transition modifier is added to Modifiers in the part browser.

**3** To add the lip of the diffuser, in the part browser, right-click Work Planes and click Add Work Plane.

The Create Work Plane dialog box is displayed.

**4** Click Offset, enter Lip Offset for Name, and click OK.

**5** In the modeling area, select the XY plane as the reference work plane, drag the cursor above the XY plane, and enter 1 for the offset distance.

The Lip Offset work plane is created.

**6** In the part browser, expand Modifiers, right-click Transition, and click Visible.

The transition modifier display is turned off in the modeling area.

**7** In the part browser, right-click Modifiers, click Add Extrusion, and select the top face rectangular profile.

The Extrusion Modifier dialog box is displayed.

**8** Under Termination, select Plane for Type, select Lip Offset for To, and then click OK.

A box is created to represent the top lip of the diffuser, and an extrusion modifier is added to Modifiers in the part browser.

**9** To see the entire model of the part, in the part browser, right-click Transition and click Visible.

## Generating a Preview Image of a Part

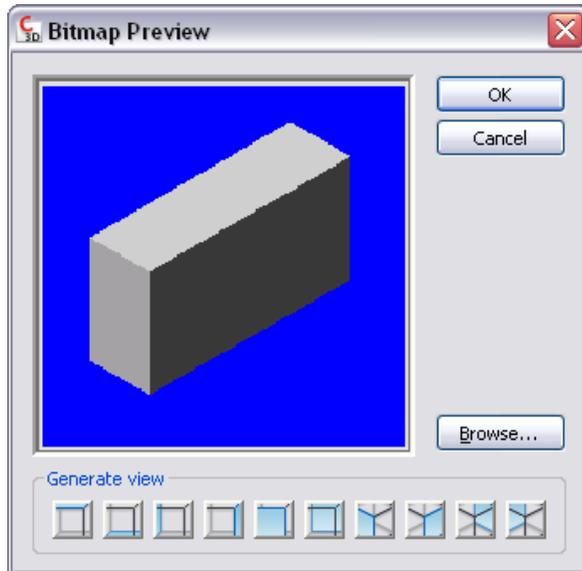
Use this procedure to generate a preview image of the part to help during part selection.

Part Builder generates the preview image based on a specified view direction. You can select from the ten standard AutoCAD view directions to view the model (top, bottom, left, right, front, back, SW isometric, SE isometric, NE isometric, and NW isometric).

1 To create a preview image, on the toolbar, click Generate Bitmap.

The Bitmap Preview dialog box is displayed.

2 Under Generate View, click a view direction for the preview image of the part.



**TIP** As you select a view, the preview image window in the dialog box is updated. This enables you to view all the available preview images for the part before selection.

You can also click Browse to navigate to and select a bitmap image. Predefined images must be 200 x 200 pixels saved with 256 colors.

3 Click OK.

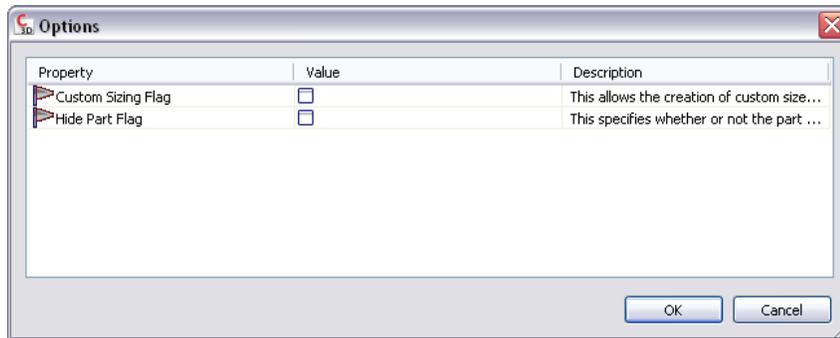
## Defining Part Insertion Position

Use the Part Builder Autolayout commands to define the placement point where a part is inserted into a drawing.

**NOTE** It is helpful to clean up the appearance of the model before defining the placement point. To turn off all work planes and the associated geometry, profiles, and dimensions on those work planes, in the part browser, right-click each feature and click Visible.

1 On the Part Builder toolbar, click Options.

The Options dialog box is displayed.

2 Make sure the check box in the Value column for the Custom Sizing Flag property is unchecked, and that the Hide Part Flag property is checked, then click OK.


In the part browser, Autolayout Data is added to Modeling, and trim length points are displayed on the model in the modeling area.

**3** Change the model view to plan view. On the View menu, click 3D Views ➤ Plan View ➤ World UCS.

**4** In the part browser, expand Autolayout Data, right-click Layout Data and click Add Trim Length.

---

**NOTE** To ensure components are trimmed correctly when placing a part into a drawing, you must define trim lengths for the part in a specific order—left to right, then bottom to top.

---

You are prompted to select the start and end of the trim length. Repeat this for the three trim lengths required for auto layout of the part.

- Define the first trim length.
  For the start of trim length 1, select the point at the center of the part. For the end of trim length 2, select the point at the left end of the part.

- Define the second trim length.
  For the start of trim length 2, select the point at the center of the part. For the end of trim length 2, select the point at the right end of the part.

- Define the third trim length.
  For the start of trim length 3, select the point at the top of the branch (the center of the part). For the end of trim length 3, select the point at the bottom of the branch.

Trim length lines are displayed between the selected points.

**5** In the part browser, right-click Layout Data and click Select Placement Point.

You are prompted to select a point on your model. This point is the location at which connecting segments would intersect if they were extended along their logical paths. The placement point is used as the insertion point for the part when it is added to a drawing during autolayout.

**6** Select the trim length point at the center of the part.

A placement point is displayed at the selected location.

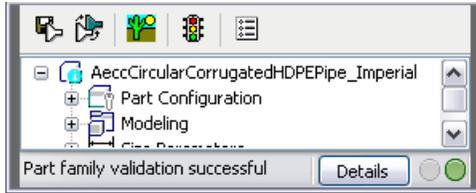
## Validating and Saving a Part

Use this procedure to validate and save the part.

**1** On the Part Builder toolbar, click Validate.

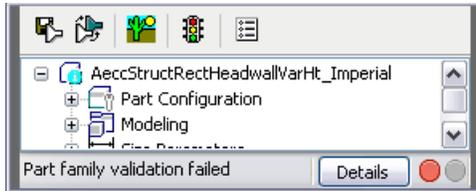
Upon successful completion of these procedures, the part is validated and the status bar is updated with a message indicating if the part validation is successful.

**Part is valid**

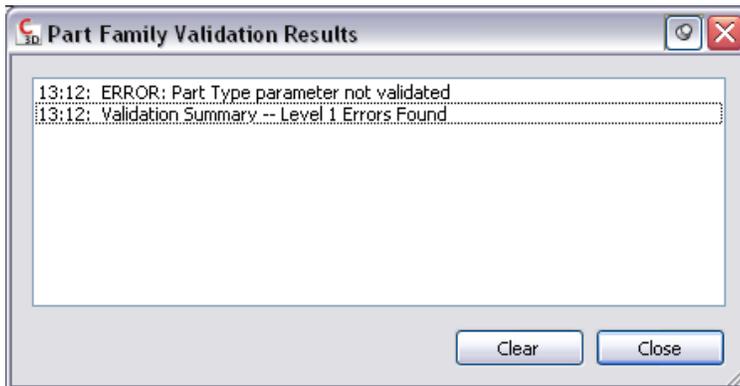


If you have errors in your model, the status bar message displays that the part validation failed, and a dialog box is displayed listing the errors. Review the errors, make necessary modifications, and repeat this step until validation is successful.

**Part is invalid**



**resulting error dialog box when part is invalid**



**NOTE** You may have warnings in the Part Family Validation Results dialog box even when the part is valid.

**2** Once validation is successful, on the toolbar, click Save Part Family or Save Part Family As.

**3** Specify whether to make the part available in the catalog.

■ Click Yes to make the part available to users.

■ Click No to keep the part hidden.

**NOTE** This prompt toggles the Hide Part option in the Options dialog box in Part Builder.

The part is saved in the specified catalog location.

**4** Click Close on the File menu.

**NOTE** At this point, you are prompted to save changes to the drawing file <new part family name>.dwg. If you saved the part family, you should also save this drawing file, so click Yes at this prompt. If you did not save the part family, then you should click No at this prompt and not save this drawing file.

# Testing Parts

The guidelines presented here will verify that your part sizes work correctly for your AutoCAD Civil drawings.

It is important to test each part size before using it in your drawings. You should verify the insertion point, and all view representations. If testing produces undesirable results, you should modify and retest the appropriate part sizes.

## Testing the Display Representations

This section summarizes how to test the display representations of parts.

Depending on whether you test part sizes in a drawing started from scratch or from a template, you verify accurate view representations in one of two ways: by scrolling through the various display configurations in a viewport, or by scrolling through the various layout tabs in a template. You should see representations on the Model tab similar to the following as you change display configurations for the viewport.

**TIP** To quickly change display configurations for a viewport, select a display configuration from the list in the bottom-right corner below the drawing area.

## Using Catalog Regen

Catalog Regen is a necessary step that runs through an entire part catalog and validates all parts.

You can run Catalog Regen by clicking the Catalog Regen button on the Getting Started - Catalog Screen dialog box. Use this procedure to regenerate a part catalog that you have modified. Regenerating a part catalog updates the APC file. A part catalog can be used inAutoCAD Civil only if regeneration has been completed.

**To regenerate a part catalog**

1   Verify that the part catalog you modified is the current catalog that is selected in the Part Catalog field of the Getting Started - Catalog Screen dialog box.

    For example, if you modified the pipe catalog, make sure Pipe is selected in the Part Catalog field. If you modified the structure catalog, make sure Structure is selected in the Part Catalog field.

2   On the Getting Started - Catalog Screen dialog box, select the top-level catalog folder in the tree view, and then click the Catalog Regen button. This regenerates the selected part catalog and updates the catalog to reflect new or deleted part sizes.

    The Catalog Regen dialog box is displayed, showing the status of the regeneration process.

3   To verify that the part catalog has been regenerated and updated, open Windows Explorer.

4   Navigate to the part catalog location \Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\Pipes Catalog\US Imperial Structures\Validate, and double-click the Validate folder located in the same directory as the appropriate Autodesk part catalog (APC) file.

5   In the Validate folder, open Catalog_Regen_Summary.txt, and scroll through the file to verify that the selected part sizes have been copied to, or deleted from, the part catalog.

## Validating Parts in a Catalog

Use this procedure to validate parts you have changed or added to a part catalog.

Validating a part catalog steps through the catalog structure and verifies its parts. Remember that only valid parts are available during part selection.

**To validate parts in a part catalog**

1   Verify that the appropriate part catalog is the current catalog that is selected in the Part Catalog field of the Getting Started - Catalog Screen dialog box.

    For example, if you want to validate the pipe catalog, make sure Pipe is selected in the Part Catalog field. If you want to validate the structure catalog, make sure Structure is selected in the Part Catalog field.

2   On the Part Builder Getting Started - Catalog Screen dialog box, click the Catalog Test button.

    The Test Catalog feature steps through the catalog structure and validates part sizes by verifying that necessary part size information exists for each part size. The Catalog Test dialog box is displayed, showing the status of the testing process. When the catalog test is complete, an AutoCAD alert dialog box is displayed, reporting the results of the test.

3   To verify that the part sizes in the part catalog have been validated, open Windows Explorer.

4   Navigate to the part catalog location \Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\Pipes Catalog\US Imperial Structures\Validate, and double-click the Validate folder located in the same directory as the appropriate Autodesk part catalog (APC) file.

5   In the Validate folder, open Catalog_Validation_Summary.txt, and scroll through the file to verify that all the part sizes have been validated. If a part was not validated, an error notice in the file states which information is missing for the part size.

# Modifying Parts

This section summarizes how to modify existing parts using Part Builder.

For parts in the pipe network catalogs provided by AutoCAD Civil, you can change the part behavior and part size parameters. For parts you create using Part Builder, you can change the part behaviors, part size parameters, and part model including geometry, profiles, modifiers, constraints, and dimensions. You can also delete parts that you no longer need. Deleting parts can be helpful when creating custom catalogs to ensure that all associated definition files are managed correctly.

# Starting Part Builder for Modifying a Part

Use this procedure to start Part Builder and modify a part.

1   Home tab ➤ Create Design panel ➤ ▼ ➤ Part Builder 🔲 .

    The Getting Started - Catalog Screen dialog box is displayed.

2   In the part browser, navigate to and select a part.

3   To modify the part, click 🗗 .

    The existing part is opened in the parametric building environment.

4   To delete a part, click ✖ .

    The selected part family is deleted from the part catalog, including all associated definition files (XML, DWG, and BMP files).

# Making Changes to a Part

As your design develops and parts change, you can modify parts using Part Builder. You can change the part behavior and part size parameters. For parts you created using Part Builder, you can also change the part model, including geometry, profiles, modifiers, constraints, and dimensions. You can use the same procedures that guide you through creating a part to modify it. This section outlines how you can modify a part and provides references to the related procedures that you can use to make changes.

---

**IMPORTANT** When making changes to a part, refer to the illustration in Part Modeling (page 1293). This illustration shows the relationship dependencies between features that must be maintained to ensure you are creating a usable part.

---

### Modifying the Part Configuration

You can change the part configuration that controls the behavior of and defines the characteristics of the part. In the part browser, expand Part Configuration and change the part type or subtype. For more information, see Specifying the Part Configuration (page 1309).

### Modifying the Part Model

For parts that you created using Part Builder, you can change the model parameters that define the overall size of the model. You can change the geometry, dimensions, and constraints of the model.

You can add, modify, or remove geometry in the model; however, you must append the changed geometry to the profile in order for Part Builder to update the model and assign new geometric constraints.

You can also change the parametric relationships of model elements by modifying the geometric and dimension constraints. Because constraints control the overall shape of the model, you cannot safely make changes until you know the current constraints applied to the model. You can delete an unwanted constraint or add new constraints to reshape the sketch.

Part Builder's parametric commands ensure that relationships among geometric elements remain intact; however, after changes are made to the model you should re-examine the geometric constraints and dimensions to verify that nothing else in the model needs to be updated.

### Modifying Part Sizes

You can change the model dimensions of the part that determine the overall size of the model, such as length and width. You can also change individual size parameters for a specific part size. For example, you can change a constant size parameter value to a list of values. For more information, see Adding Model Dimensions (page 1311) and Adding Individual Part Sizes (page 1312).

### Modifying the Preview Image or Part Insertion Behaviors

You can change the preview image by selecting a different view direction that Part Builder uses to generate the preview image. For more information, see Generating a Preview Image of a Part (page 1317).

You can change the insertion configuration of the part that defines the placement point of a part in a drawing. For more information, see Defining Part Insertion Position (page 1317).

# Adding a Material Property to a Part

Use this procedure to add the Material property to a part family in the part catalog.

Having the Material property available for parts enables you to use Civl 3D labeling features to add text to identify the type of material used for the pipe. For example, you can configure the Material property to display text such as PVC, ductile iron, or corrugated steel.

Some part families may already have the Material property included by default. However if a part family does not have the Material property included, you can add this property to a part family using the following procedure.

**To add the Material property to a part family**

1 Open Part Builder by selecting Home tab ➤ Create Design panel ➤ ▼ ➤ Part Builder 🔲 .

The Getting Started - Catalog Screen dialog box is displayed.

2 In the Getting Started - Catalog Screen dialog box, open the desired pipe or structure part catalog.

For example, under Pipe ➤ US Imperial Pipe Catalog ➤ Circular Pipes, open the Concrete Pipe catalog by double-clicking it, or by clicking Getting Started - Catalog Screen Modify Part Sizes.

3 In the Part Builder left pane, right-click Size Parameters, and then click Add.

4 On the New Parameter dialog box, click Material, and then click OK.

Notice that when you do this, the Mat (material) property is added to the Edit Part Sizes dialog box. You may need to scroll to the right on this dialog box to see this property added.

5 Now that the Material property is added to this dialog box, you can configure the attributes for this property by clicking in the cell for each attribute.

For example, you may want this Material property to show or not show in AutoCAD Civil drawings. Do this by setting the Visible attribute to True or False.

6 Make sure you set the Visible attribute to True so that the value for the Material property displays in the drawing.

7 Click OK on the Edit Part Sizes dialog box.

8 Click Save Part Family.

Now the Material property is available for parts in this part family. Using AutoCAD Civil labeling features, you can add text to this property to identify the type of material used for the pipe. For more information, see Adding a Material Type to a Pipe or Structure Label (page 1270).

# Corridor Modeling

# Corridors

# 30

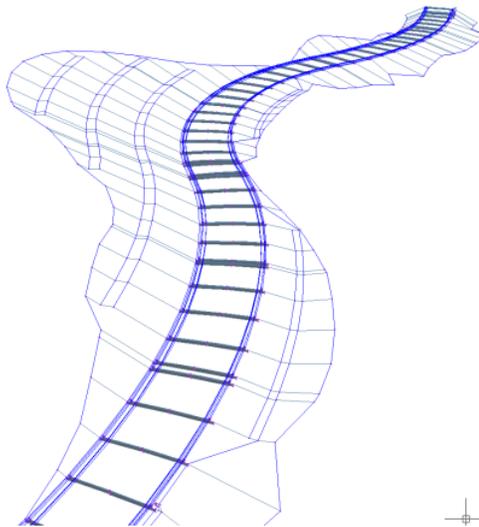
You can use AutoCAD Civil corridor modeling to create flexible and configurable 3D models of corridors, such as highways and railways.

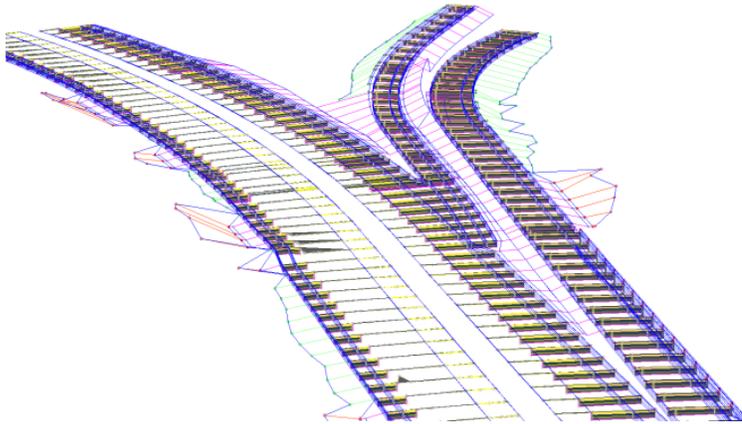
Corridor Modeling Workflow

## Understanding Corridor Modeling

A corridor model builds on and uses various AutoCAD Civil objects and data, including subassemblies, assemblies, alignments, surfaces, profiles, and intersections.

A corridor object is created from a baseline (alignment) by placing 2D sections (assemblies) at incremental locations, and by creating matching slopes that reach a surface model at each incremental location:



You can also create corridors with multiple baselines, which enables you to create more complex designs, such as intersections (page 1428).


Corridors are created from and based on existing AutoCAD Civil objects, which include:

- **Alignments** (horizontal). Used by a corridor as its centerline. For information, see Alignments (page 855).

- **Profiles** (vertical alignments). Used to define surface elevations along a horizontal alignment. For information, see Creating Profiles (page 1046).

- **Surfaces**. Used to derive alignments and profiles, and for corridor grading. For information, see Surfaces (page 599).

- **Subassemblies**. A fundamental component of a corridor model. Subassemblies define the geometry of a corridor section (assembly). For example, a typical roadway may be composed of paved lanes (on either side of the centerline), a paved shoulder, a gutter and curb, and a roadside grading. These parts are defined independently as subassemblies. You can stack any type of subassembly to make up a typical assembly and apply the same assembly for a station range along an alignment. For more information, see Understanding Subassemblies (page 1394).

- **Assemblies**. Represent a typical section of a corridor. Assemblies comprise one or more subassemblies connected together. For more information, see Understanding Assemblies (page 1377).

After you have created a corridor, you can extract data from it, including surfaces, feature lines (as polylines, alignments, profiles, and grading feature lines), and volume (quantity takeoff) data. For information, see Exporting Corridor Data (page 1369) and Analyzing Sectional Volumes (page 1167).

Corridors have their own display style and also inherit styles from their components. Before creating corridors, you should be familiar with creating and managing styles (page 53) and command settings (page 97).

## The Corridor Object

Corridors persist in an AutoCAD drawing as objects with the name AeccCorridor.

Corridor objects are defined by associating a baseline (alignment) with sectional design elements, and other structural data. The corridor object manages the data, tying various assemblies (applied for different ranges of stations) to the baselines (alignments) and their finished grade profiles. It manages the connection of project-specific surface and alignment data to the subassembly and assembly content. The object includes corridor body geometry, longitudinal feature lines, embedded surfaces, rendering support, and slope hatching support.

A corridor can define and display components, such as:

■ Feature lines connecting points along the point codes, which are defined in the subassemblies (used to create the assemblies).

■ Surfaces, using link codes and feature lines.

For overview information about AutoCAD Civil objects, see Understanding Objects and Styles (page 51).

## Corridor Styles and Display

How corridor elements are displayed is controlled both by a specific corridor style and the styles and labels associated with the objects used to create the corridor.

Use corridor styles to control the appearance of corridor region boundaries, assembly insertion stations, and stations where the default properties of the subassemblies are overridden.

For more information, see Corridor Style Dialog Box (page 1824).

In addition, various components within the corridor are controlled by their own display styles and labels:

■ Display styles for corridor components include alignments, code sets, slope patterns, surfaces, and feature line styles.

■ Components of the corridor object have their own labels. Corridor surface objects support all annotation capabilities that a regular surface supports.

The following table lists the styles of the corridor components and where they are derived from.

| Corridor Component | Display Style | Notes |
| --- | --- | --- |
| Links | Link style | Set through associated Code Set style. |
| Points | Marker style | Set through associated Code Set style. |
| Shapes | Shape style | Set through associated Code Set style. |
| Feature Line | Feature Line style | Defined in the corridor properties. |
| Surfaces | Surface style | Defined in the corridor properties and in the surface properties, if a dynamic surface is generated. |
| Material Rendering | Render Material | Defined in the corridor properties. |
| Corridor Section | Code Set style; assigned from corridor. | View of an assembly, so all elements, such as links, points, and shapes, are displayed through respective styles in the set. |
| Surface Section | Section style | |

For more information about styles, see Object Styles (page 53).

## Corridors Collection (Prospector Tab)

Use the Corridors collection in the Prospector tree to access the corridors in a drawing or a project. As corridor objects are created, they are displayed in the Corridors collection.

Expand the Corridors collection to view the names of the corridors and display a tabular list of the corridors in the Prospector list view. For more information, see The Toolspace Item View (page 82).

## Corridor Collection (Settings Tab)

Use the Corridor collection in the Settings tree to manage corridor settings, styles, and command settings.

Right-click the Corridor collection to do the following:

■ Edit the corridor feature settings

■ Refresh the display of the settings tree.

For more information about the contents of this shortcut menu, see "The Object Collection (Settings Tree)".

Expand the Corridor collection to display and edit the styles and command settings that are available for corridors.

| For information about... | See... |
| --- | --- |
| Corridor settings | Editing Corridor Settings (page 1333) |
| Corridor styles | Corridor Styles and Display (page 1329) |

# Creating Corridors

You can use two methods to create a corridor: using the Create Corridor command or the Create Simple Corridor command.

All corridors are managed in the same way, regardless of how you create them. Also, all corridors are listed in the Corridors collection in the prospector tree.

Before you can create a corridor, you must create the underlying data, such as surfaces, alignments, profiles, subassemblies, and assemblies.

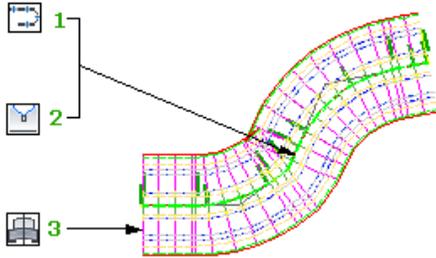
| For information about creating... | See... |
| --- | --- |
| Surfaces | Creating Surfaces (page 601) |
| Alignments | Creating Alignments (page 887) |
| Profiles | Creating Layout Profiles (page 1048) |
| Subassemblies | Creating Subassemblies (page 1396) |
| Assemblies | Creating Assemblies (page 1380) |

For information about how a corridor is displayed after it is created, see Changing Corridor-Related Default Style Settings (page 1335).

# Creating a Simple Corridor

Use the Create Simple Corridor command to quickly create a basic corridor.

This method is ideal for creating basic corridors based on a single alignment (1), a profile (2) along the alignment, and an assembly (3) across it. You can subsequently add more complexity to the corridor by editing it.



For information about adding more complexity, see Managing and Editing Corridors (page 1333).

**NOTE** Before you create a corridor, you must create the underlying data, such as surfaces, alignments, profiles, and assemblies.

**To create a simple corridor**

1 Click Home tab ➤ Create Design panel ➤ Corridor drop-down ➤ Create Simple Corridor 🔧 .

2 In the Create Simple Corridor Dialog Box (page 1830), in the Name field, enter a name for the corridor.

  To name the corridor, select its default name and enter a new name, or use the name template. For more information, see Name Template Dialog Box (page 1806).

3 In the Description field, enter a description for the corridor.

4 To change the style used by the corridor, click the Corridor Style list or use the standard style creation tools to edit or create a style. For more information about the style creation tools, see the Select Style Dialog Box (page 1805).

  The corridor style controls the appearance of corridor region boundaries and assembly insertion stations. For more information, see Corridor Styles and Display (page 1329).

5 Click 📚 to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

  **NOTE** If you do not select a layer, the corridor is placed on the default layer.

6 Click OK.

7 Select an alignment in the drawing or press Enter to select an alignment in the Select An Alignment dialog box (page 1810).

8 Select a profile in the drawing or press Enter to select a profile in the Select A Profile dialog box (page 1838).

9 Select an assembly in the drawing or press Enter to select an assembly in the Select An Object dialog box (page 1810).

10 The corridor name is displayed in the Corridors collection on the Prospector tab. For information about editing and managing the corridor, see Managing and Editing Corridors (page 1333).

Menu

Corridors menu ➤ Create Simple Corridor

Command Line

CreateSimpleCorridor

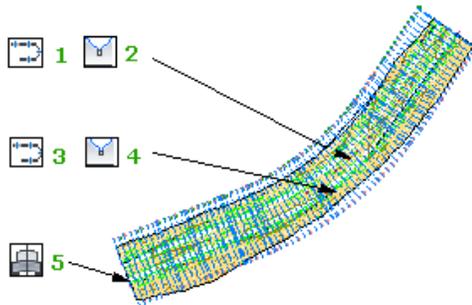
Dialog Box

Create Simple Corridor (page 1830)

## Creating a Corridor

Use the Create Corridor command to specify complex parameters at creation time.

You specify the station range, profile, assembly, and any necessary targets.



Other parameters could include station frequency and controlling offsets, as well as information about multiple baselines and regions.

**To create a corridor**

1 Click Home tab ➤ Create Design panel ➤ Corridor drop-down ➤ Create Corridor  .

2 Select an alignment in the drawing or press Enter to select an alignment in the Select An Alignment dialog box (page 1810).

3 Select a profile in the drawing or press Enter to select a profile in the Select A Profile dialog box (page 1838).

4 Select an assembly in the drawing or press Enter to select an assembly in the Select An Assembly dialog box (page 1810).

5 In the Create Corridor dialog box (page 1826), in the Name field, enter a name for the corridor.

To name the corridor, select its default name and enter a new name, or use the name template. For more information, see Name Template Dialog Box (page 1806).

6 In the Description field, enter a description for the corridor.

7 Click  to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

NOTE If you do not select a layer, the corridor is placed on the default layer.

**8** To change the style used by the corridor, click the Corridor Style list or use the standard style creation tools to edit or create a style. For more information about the style creation tools, see the Select Style Dialog Box (page 1805).

The corridor style controls the appearance of corridor region boundaries and assembly insertion stations. For more information, see Corridor Styles and Display (page 1329).

**9** Edit the parameters in the properties table. You can add additional controlling baselines, regions, or offsets, modify alignments, profiles, assemblies, or station ranges and frequency, or edit targets. For more information, see Editing Corridor Parameters (page 1336).

**NOTE** If targets are required for the corridor and not set, messages are displayed in the Event Viewer. To display the Event Viewer, click General ➤ Utilities ➤ Event Viewer. For more information about the event viewer, see The Event Viewer Vista (page 1626).

**10** Click OK to create the corridor.

The corridor name is displayed in the Corridors collection on the Prospector tab.

### Quick Reference

Ribbon

Menu

Corridors menu ➤ Create Corridor

Command Line

CreateCorridor

Dialog Box

Create Corridor (page 1826)

# Managing and Editing Corridors

You can control the default settings and styles for creating corridors and also edit or add data to individual corridors after you create them.

Use the Corridor Properties dialog box to set:

■ a corridor's administrative information

■ parameters such as baselines, frequencies, and targets

■ code sets

■ corridor feature lines, surfaces, boundaries, and slope patterns

# Editing Corridor Settings

Use corridor settings to specify the default behavior for corridor-related commands.

Settings are handled in a standard way throughout AutoCAD Civil. You access settings using the Toolspace Settings tree. You can control settings at three levels: the drawing level, the object collection (feature) level, and the command level. For more information, see Understanding Settings (page 61).

In the Settings tree, use the Corridor collection's shortcut menu to establish defaults for all corridor-related commands. You can change corridor-specific settings at this level, or override the drawing ambient settings.

Use the Commands collection in the Corridor collection to change corridor settings for a specific command.

**NOTE** Overrides to the drawing ambient settings at the Corridor collection level and the Commands collection level affect only the specified (and subordinate) levels. The drawing level settings are not changed.

The topics in this section describe only those settings that affect corridor-related commands. They do not apply to the drawing ambient settings that you can change at the Corridor collection level. For more information about the drawing ambient settings, see Specifying Ambient Settings (page 68).

## Changing Corridor Creation Settings

Use the corridor creation and naming settings in the Edit Feature Settings - Corridor dialog box to change corridor-related settings before you create corridors.

For example, before creating a corridor, you may want to specify the default assembly frequency along tangents, curves, or spirals.

If a closed lock appears in the Lock column for a property, the property is locked at a higher level of the Settings tree. It cannot be changed at this level.

If you change a property value, a check mark is placed in the Override column. This override is also noted in the property table for related objects higher up the Settings tree, where an arrow is displayed in the Child Override column.

**To change corridor creation settings**

1  Do one of the following:
   ■  **To edit settings for all corridor-related commands**: In Toolspace, on the Settings tab, right-click the Corridor collection. Click Edit Feature Settings.

   ■  **To edit settings for a specific command**: In Toolspace, on the Settings tab, expand the Corridor collection. Expand the Commands collection. Right-click the name of the command and click Edit Command Settings. For example, right-click the CreateCorridor command and click Edit Command Settings.

   An Edit Feature Settings - Corridor dialog box (page 1830) is displayed.

2  To specify the default highlight settings for corridor region baselines, boundaries, targets and internal assemblies; right-click the Corridor collection and click Edit Feature Settings. Edit the Region Highlight Graphics settings.

3  To specify the default assembly frequency along tangents, curves, and spirals, right-click the CreateCorridor or CreateSimpleCorridor commands and click Edit Command Settings. Edit the Assembly Insertion Defaults settings.

4  To specify whether assemblies are to be inserted at specific points, such as horizontal geometry or superelevation critical points, right-click the CreateCorridor or CreateSimpleCorridor commands and click Edit Command Settings. Edit the Assembly Insertion Defaults settings.

5  To edit the default scale to view corridor sections, right-click the ViewEditCorridorSection command and click Edit Command Settings. Expand the View/Edit Options property group. Edit the Default View Scale setting.

6  To specify whether a corridor is automatically rebuilt when you edit a subassembly parameter, right-click the ViewEditCorridorSection command. Click Edit Command Settings. Expand the View/Edit Options property group. Edit the Rebuild On Edit setting.

**7** To specify the front and back clip values for 3D objects displayed in a corridor section view, right-click the ViewEditCorridorSection command and click Edit Command Settings. Expand the View/Edit Options property group. Edit the Front Clip and Back Clip settings.

**8** To specify whether the station tracker is on, right-click the ViewEditCorridorSection command. Click Edit Command Settings. Expand the View/Edit Options property group. Set the Turn Off Unassociated Layers setting to no and the Station Tracker in Multiple Viewports setting to yes.

**9** To specify the grid and grid text display settings for a corridor section view, right-click the ViewEditCorridorSection command and click Edit Command Settings. Expand the Grid Settings and Grid Text Settings property groups. Edit the grid line, grid spacing, color, and text size settings.

**10** To edit the default naming format for corridors and data that can be extracted from the corridor, expand the Default Name Format property group. Edit the Corridor Name Template settings.

**11** Click Apply.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click Corridor collection ➤ Edit Feature Settings
OR
Settings tab: Corridor ➤ Commands ➤ Right-click <command-name> ➤ Edit Command Settings

Dialog Box

Edit Feature Settings - Corridor (page 1830)

## Changing Corridor-Related Default Style Settings

Use the corridor settings to specify default styles and labels for corridor creation and for data that you create or extract from corridors.

You can select the default styles for alignments and profiles exported from corridors and a default corridor style and label set.

The default styles specified in these settings are used to establish the default setting for the style in the Create Corridor and Corridor Properties dialog boxes.

**To change the corridor-related style and label settings**

**1** In Toolspace, on the Settings tab, right-click the Corridor collection. Click Edit Feature Settings to open the Edit Feature Settings - Corridor dialog box (page 1830).

**2** Expand the Default Styles property group.

**3** To specify a default style for corridor output objects, such as alignments and profiles generated from corridors, click the corresponding field. Click ⬚ to open the Select Style dialog box.

**4** To specify a default corridor style, click Corridor Style. Click ⬚ to open the Select Style dialog box.

**5** To specify a default style for a label set, click the corresponding field. Click ⬚ to open the Select Label Set dialog box.

**6** To specify a default style for viewing corridor sections, click Section View Style. Click ⬚ to open the Select Style dialog box.

**7** Click Apply.

### Quick Reference

## Editing Basic Corridor Information

After creating a corridor, use the Prospector tree to edit a corridor's name and description.

**To edit basic corridor information**

**1** In Toolspace, on the Prospector tab, expand the ![icon] Corridors collection. Right-click the corridor. Click Properties.

**2** In the Corridor Properties dialog box, click the Information tab (page 1815).

**3** To change the name of the corridor, enter a new name in the Name field.

**4** To change the description of the corridor, enter a new description in the Description field.

**5** To change the style of the corridor, click the Object Style list. Alternately, or use the standard buttons to create, edit, or select a style.

**6** Click Apply to make the changes, or click OK to make the changes and close the Corridor Properties dialog box.

### Quick Reference

## Editing Corridor Parameters

Edit the parameters of the current corridor, including the selected baselines, regions, and controlling offsets.

A corridor is defined by at least one baseline (alignment) and an assembly that is applied for a range of stations on that baseline. In many cases, corridors will have different assemblies at different stations, depending on the existing ground and other design considerations. Also, it may be necessary to build a corridor model that is controlled by multiple baselines, for example, one that includes intersection objects (page 1424). To add and edit this type of complexity, use the Parameters tab, where you can modify the associated alignments, profiles, and assemblies, change assembly frequency and range, and update targets.

# Adding and Editing Corridor Regions

Add additional regions to a corridor or modify the parameters (such as start, end, and station frequency, assembly association, and targets) of existing regions.

Corridor regions are used to associate assemblies to specific station ranges along the corridor. Therefore, to assign different assemblies to sections of the corridor, you create regions.

To edit corridor regions, use the commands:

### Edit Region

Edit the parameters of the selected region including; alignment, profile, assembly, start and end stations, the frequency to apply assemblies, target mapping, and station overrides.

### Isolate Region

This command turns off the visibility of all corridor regions, except the selected one. This command has the same effect as clearing all region check boxes on the Parameters tab of the Corridor Properties dialog box, except that of the selected region.

### Show All Regions

This command restores the visibility of any regions whose visibility is currently turned off. The command is not available if all regions are visible.

**To add a corridor region**

1   In the drawing, click the corridor object, right-click, and click Corridor Properties.

2   In the Corridor Properties dialog box, click the Parameters tab (page 1815). Do one of the following:
   ■   To add a new region after any existing regions, right-click the baseline for which you want to add a new region. Click Add Region.

   ■   To insert a new region between two existing regions, right-click the first region. Click Insert Region.

3   In the Select An Assembly dialog box, select the assembly to assign to the region.

   The region is added to the corridor.

   ---
   **NOTE** If the assembly has offsets defined, the offsets are displayed as children of the region. For information about creating an assembly offset, seeCreating an Assembly Offset (page 1382). For information about editing a corridor region's offset, see Editing Offsets (page 1341)
   ---

4   Edit the region. For information, see To Edit a Corridor Region (page 1337).

**To edit a corridor region**

1   In the drawing, select the corridor object you want to edit.

2   Click Corridor tab ➤ Modify panel ➤ Edit Region .

3   In the Corridor Properties dialog box, click the Parameters tab (page 1815).

4   To edit a selected region from the drawing, click  Select Region From Drawing and select the region in the drawing.

5   To change the assembly for the region, click the Assembly field. Select the assembly in the Select An Assembly dialog box.

**6** To change either the start or end station for the region, select either the Start Station or End Station field. Enter the station number or click ⌖ and click the station in the drawing.

**7** To change the station frequency, click Set All Frequencies. Specify the frequency in the Frequency To Apply Assemblies dialog box (page 1836).

**8** To change the target to which the region is mapped, click Set All Targets. Specify the targets in the Target Mapping dialog box (page 1840).

If you do not change the target when you change an assembly, the target will remain the same for most common target types.

**9** To delete a region, select the region, right-click, and click Remove Region.

**10** Click Apply to make the changes.

**To isolate a corridor region to edit it**

**1** In the drawing, select the corridor region you want to edit.

**2** Click Corridor tab ➤ Modify panel ➤ Isolate Region ⬚ .

**3** On the Modify panel, click Edit Region ✐ .

**4** In the Corridor Properties dialog box, Parameters tab (page 1815), edit the region. Click OK to make the changes.

**5** Click Corridor tab ➤ Modify panel ➤ Show All Regions ⬚ .

All corridor regions are again visible.

> **NOTE** You may have to rebuild (page 1361) the corridor to restore the visibility of all its regions.

**To add stations to a region**

**1** In the drawing, click the corridor object, right-click, and click Corridor Properties.

**2** In the Corridor Properties dialog box, click the Parameters tab (page 1815).

**3** Click the Frequency field for the region to which you want to add stations.

**4** In the Frequency To Apply Assemblies dialog box (page 1836), click ⊹ . Select the station location in the drawing.

**5** To add a description for the station, click the Description field. Enter the description.

**6** Click OK.

**To split a region**

**1** In the drawing, select the corridor object you want to split.

**2** Click Corridor tab ➤ Modify panel ➤ Corridor Properties drop-down ➤ Corridor Properties ⬚ .

**3** In the Corridor Properties dialog box, click the Parameters tab (page 1815).

**4** In the table, right-click a corridor region. Click Split Region.

**5** In the drawing, click a point or points parallel to the alignment to split the selected region.

**6** Right-click to stop selecting split point(s).

**7** Click OK to split the region.

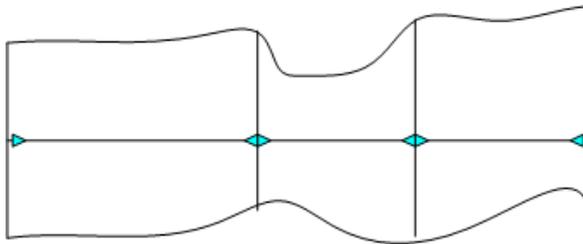
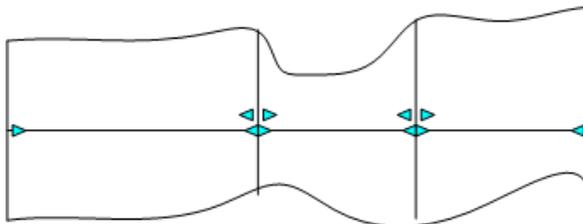
## Editing Corridor Regions Using Grips

When you select a corridor region, triangular grips are displayed at the start and end stations of the region. Use these grips to manually change the start and end station for a region.

If the start station of one region is the end point of another region, the grip at the station is displayed as a diamond shape, which enables you to edit the shared extents of the adjacent regions at the same time.



If you want to edit the start or end point of a region without editing the adjacent region, additional grips enable you to edit the extents of the regions independently.


**To edit a corridor region using editing grips**

**1** In the drawing, select the corridor object.

Grips are displayed at the start and end stations of the region.

**2** Ctrl+click a grip to make it active, and drag it to a new location.

**3** If the grip is diamond-shaped, the start of one region and the end of another are both at this location. You can edit the two regions at the same time, or edit the extents of the regions independently.

## Adding Baselines

Add additional baselines to a corridor to create offset alignments.

Typically, you need to add additional baselines if you require offsets or more complex corridor models, such as ones with intersections.

**To add baselines**

**1** In the drawing, click the corridor object, right-click, and click Corridor Properties.

**2** In the Corridor Properties dialog box, click the Parameters tab (page 1815).

**3** To add a new baseline, click Add Baseline.

**4** In the Pick Horizontal Alignment dialog box, select the alignment from the list or click  to select an alignment in the drawing.

**5** To select the profile for the baseline, click the Profile field. Select the profile from the list or click  to select a profile in the drawing.

**6** To add a region to the baseline, right-click the baseline. Click Add. For information, see Adding and Editing Corridor Regions (page 1337).

**7** Click Apply.

## Hiding and Showing Regions

Hide or show corridor regions or entire baselines.

If a region or baseline is hidden, it is not updated if underlying elements, for example, alignments and profiles, are modified.

---

**NOTE** The check boxes you use to hide a region have a tri-state display. If a baseline has multiple regions and only one of the regions is selected, the check box is dimmed and not available.

---

**To hide corridor regions or baselines**

1 In the drawing, click the corridor object, right-click, and click Corridor Properties.

2 In the Corridor Properties dialog box, click the Parameters tab (page 1815).

3 To hide a region or baseline, clear the check box next to the region or baseline name.

---

**NOTE** The hide/display check boxes have a tri-state display. If there are multiple regions under a baseline and only one of the regions is selected, the check box is dimmed.

---

4 Click Apply.

5 To display a hidden region or baseline, select the check box next to the region or baseline.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Corridors ➤ <corridor name> ➤ Properties ➤ Parameters tab

Object Shortcut Menu

Corridor Properties

Dialog Box

Corridor Properties - Parameters tab (page 1815)

## Editing Offsets

If a region has an assembly offset specified, you can edit the alignment, profile, and station start and end for the offset.

For information, on assembly offsets, seeCreating an Assembly Offset (page 1382).

**To edit an offset alignment for a region**

1 In the drawing, click the corridor object, right-click, and click Corridor Properties.

2 In the Corridor Properties dialog box, click the Parameters tab (page 1815).

3 To change the alignment for the offset, click the Alignment field. Select the alignment in the Pick Horizontal Alignment dialog box.

4 To change either the start or end station for the region, select either the Start Station or End Station field. Enter the station number or click ⬚ and select the station in the drawing.

5 Click Apply.

Object Shortcut Menu

Corridor Properties

Dialog Box

Corridor Properties - Parameters tab (page 1815)

## Changing Station Frequency

Add or modify the frequency of stations in a corridor region.

Stations frequency can be specified by referencing the existing alignment and profile geometry:

- **Along tangents**. Specify the assembly insertion frequency along the tangent portion of an alignment.
- **Along curves**. Specify the assembly insertion frequency along the curve portion of an alignment.
- **Along spirals**. Specify the assembly insertion frequency along the spiral portion of an alignment.
- **Along profile curves**. Specify the assembly insertion frequency along the curve portion of the profile.
- **At specific points**. Specify whether assemblies should be inserted at specific geometry points, including horizontal geometry, superelevation critical, profile geometry, and profile high and low points.

---

**NOTE** If both an assembly frequency setting that references horizontal geometry and a setting that references vertical geometry apply to a portion of a corridor, the setting that results in a smaller interval is used. For example, if a segment is both a horizontal tangent and a vertical curve, and the vertical curve frequency adds assemblies at more frequent intervals, the frequency specified for vertical curves is used.

---

You can also modify station location and frequency by manually adding stations.

**To change the station frequency for a region**

1   In the drawing, click the corridor object, right-click, and click Corridor Properties.

2   In the Corridor Properties dialog box, click the Parameters tab (page 1815).

3   Click the Frequency field for the region to which you want to add stations.

4   In the Frequency To Apply Assemblies dialog box (page 1836), modify the properties as required.

5   To manually add a station, click ⊕ . Select the station location in the drawing.

6   To add a description for the station, click the Description field. Enter the description.

7   Click OK.

## Viewing and Deleting Overridden Stations

View and delete stations that have assembly overrides applied.

Assembly overrides are created and edited using the View/Edit Corridor Section Tools. However, you can view and delete overrides in the Corridor Properties Parameters tab.

For information about creating assembly overrides, see Editing Corridor Sections (page 1365).

**To view or delete assembly overrides for a region**

1   In the drawing, select the corridor object, right-click, and click Corridor Properties.

2   In the Corridor Properties dialog box, click the Parameters tab.

3   For a region that has assembly overrides, click the Overrides column. For information about creating assembly overrides, see Editing Corridor Sections (page 1365).

4   In the Assembly Override Stations dialog box (page 1814), the assembly name, range, stations, and override method are displayed.

5   To remove the assembly overrides from a station (and apply the default assembly parameters) and delete the station from the list, click the station and click ✖ .

6   To remove all the assembly overrides from the region, click Delete All.

The list is cleared and the default assembly parameters are applied to all stations in the corridor region.

7   Click OK to close the dialog box.

  Assemblies Overrides (page 1814)

## Setting and Editing Targets

On a corridor, you can set and edit the values of subassembly target objects, such as surfaces, alignments, and profiles.

Targets are required when the geometry of one or more of an assembly's subassemblies requires corresponding surface, offset, or elevation targets for defining that geometry. A few subassemblies even use pipe networks as target objects. When a corridor contains subassemblies that use targets, the object names of the intended target objects must be mapped from the subassembly definition to the corresponding drawing objects. This task is referred to as setting targets or mapping targets.

**NOTE** If targets required for the corridor are not set, messages are displayed in the Event Viewer, indicating that target objects are not found. To display the Event Viewer, click View tab ➤ Palettes panel ➤ ▼ ➤ Event Viewer ⟁ . For more information about the event viewer, see The Event Viewer Vista (page 1626).

For example, a subassembly 'SideSlope' parameter is used to define roadside grading, starting from the edge of shoulder, and sloping at a specified grade, until it intercepts with an existing ground surface. In the subassembly, references to the target surface are made by calling a surface object named 'TargetDTM.' However, when you create the corridor, and apply the subassembly to a corridor definition, there may not be a surface named 'TargetDTM', and there may be multiple ground surfaces. Therefore, after the assembly is applied to the corridor, you need to map the target name (TargetDTM) to an actual surface object name.

Typically, subassembly parameters that can use a target object to define a width or an offset can use the following types of objects to define that width or offset: alignments, polylines, feature lines, or survey figures.

Similarly, subassembly parameters that can use a target object to define an elevation can use the following types of objects to define that elevation: profiles, 3D polylines, feature lines, or survey figures.

Subassemblies that can use a target object to define a surface can only use a surface object to define that surface.

As previously mentioned, a few subassemblies allow you to use pipe network objects as targets, such as the TrenchPipe subassemblies.

The following table summarizes these capabilities:

| Target Type | Object types that can be used as targets |
| --- | --- |
| widths or offsets | alignments, polylines, feature lines, or survey figures |
| elevations | profiles, 3D polylines, feature lines, or survey figures |
| surfaces | surfaces |
| pipe networks | pipe networks |

The Help topic for each subassembly lists the parameters in the subassembly that can be associated with a target object.

**To set or edit targets**

1 In the drawing, click the corridor object, right-click, and click Corridor Properties.

2 In the Corridor Properties dialog box, click the Parameters tab (page 1815)

3 Do one of the following:
- To view or map all targets required by the corridor, click Set All Targets.
- To view or map the targets for a specific baseline or assembly, click the Target field for that baseline or assembly.

4 In the Target Mapping dialog box (page 1840), set the surface, offset, and elevation targets in the corresponding Object Name fields.

5 Click OK to close the Target Mapping dialog box.

6 Click Apply.

**To select a surface to target**

1 In the Target Mapping dialog box (page 1840), do one of the following:
- To select surfaces individually, click the Object Name field next to the corresponding surface in the Target column.

■ To select all surfaces at once, click <Click Here To Set All> in the Object Name field. This is useful for mapping TargetDTM's that are referenced by multiple subassemblies used in the corridor through multiple assembly regions. For example, all side slope subassemblies typically need to be mapped to the same existing ground surface.

**2** In the Pick a Surface dialog box, select the surface from the list or click  and select the surface in the drawing.

**3** Click OK to close the Pick a Surface dialog box.

**To select a width or offset to target**

**1** In the Target Mapping dialog box (page 1840), click the Object Name field next to the corresponding width or offset target name in the Target column.

**2** To target an alignment:

■ In the Select Object Type To Target list of the Set Width Or Offset Target dialog box (page 1840), select Alignment.

■ Select an alignment from the Alignment list, or click  and select an alignment in the drawing, to add to the list.

■ Click Add >> to add an alignment to the Selected Entities to Target list.

**3** To target a feature line, survey figure or polyline:

■ In the Select Object Type To Target of the Set Width Or Offset Target dialog box select, Feature Lines, Survey Figures and Polylines.

■ Click Select By Layer to import all named targets on any layer selected in the Select By Layer, dialog box or click Select From Drawing to select entities in the drawing.

■ Click  to remove any excess entities from the Selected Entities To Target list.

■ If there are two or more targets in the Selected Entities To Target list, select Target To Nearest Object or Target To Farthest Object for Selection Choice If Multiple Targets Are Found.

**4** Click OK to close the Set Width Or Offset Target dialog box.

**NOTE** If you select more than one target object, **Varies** is displayed in the Object Name field.

**To select a slope or elevation to target**

**1** In the Target Mapping (page 1840) dialog box, click the Object Name field next to the corresponding slope or elevation target name in the Target column.

**2** To target a profile:

■ In the Set Slope Or Elevation Target dialog box (page 1839), in the Select Object Type To Target list, select Profiles.

■ Select from the Select An Alignment list, or click  and select an alignment in the drawing.

■ Select from the Select Profiles list, or click  and in the drawing select a profile to add to the list.

■ Click Add >> to add a profile to the Selected Entities To Target list.

**3** To target a feature line, survey figure or polyline:

- In the Select Object Type To Target of the Set Slope Or Elevation Target dialog box select, Feature Lines, Survey Figures and Polylines.

- Click Select By Layer to import all named targets on any layer selected in the Select By Layer dialog box or click Select From Drawing to select entities in the drawing.

- Click to remove any excess entities from the ✖ Selected Entities to Target list.

- If there are two or more targets in the Selected Entities To Target list, select Target To Nearest Object or Target To Farthest Object for Selection Choice If Multiple Targets Are Found.

**4** Click OK to close the Set Slope or Elevation Target dialog box.

**NOTE** If you select more than one target object, **Varies** is displayed in the Object Name field.

## Editing the Code Set Style

View and modify the code set style for the corridor.

A corridor is defined using a set of subassemblies. These subassemblies can have styles assigned to points, links, and shapes. You may want to display these components in a variety of ways. Code set styles enable you to manage the display these components by using a mapping system that maps code to style.

For information about code set styles and subassemblies, see Using Codes and Code Set Styles (page 1405).

**To edit a corridor's code set style**

**1** In the drawing, click the corridor object, right-click, and click Corridor Properties.

**2** In the Corridor Properties dialog box, click the Codes tab (page 1817). All codes used by the corridor with their corresponding descriptions, style, and label style information are displayed in the properties table.

**3** To change the code set style used by the corridor, click the Code Set Style list or use the standard style creation tools to edit or create a style. For more information about the style creation tools, see the Select Style Dialog Box (page 1805).

These styles control the way the corridor is displayed in section view.

**4** Click ◫ to view information for the selected style.

**5** Click Apply.

### Quick Reference

Toolspace Shortcut Menu

Object Shortcut Menu

Corridor Properties

Dialog Box

Corridor Properties - Codes tab (page 1817)

## Editing Feature Lines

Use the Feature Lines tab to view the feature line codes and display styles or to modify how a corridor's feature lines are connected.

By default, AutoCAD Civil joins all points with the same point code along a baseline and displays them as feature lines. You can modify how points are connected when a point code is used multiple times at consecutive stations.

### Editing Feature Line Connections

Modify feature line connections by specifying which point codes are connected using branching options and the direction for branching, and whether extra point codes are to be connected.

**Branching and Connecting Extra Points**

If an assembly is applied at consecutive stations with a varying number of point codes (of the same type), you can control both whether the feature lines are connected and how they are connected.

The following illustrations show different branching and point connection options and the resultant feature lines.

In all illustrations:

- Assemblies with a varying number point codes of the same type are used at the stations.

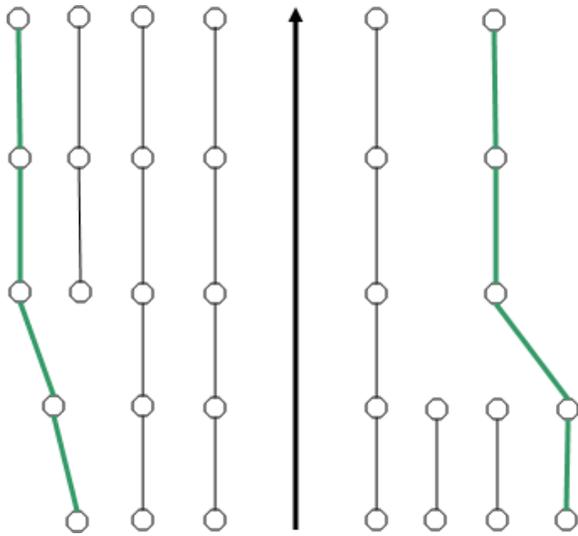
- The centerline (heavy black line) is the corridor baseline (alignment).

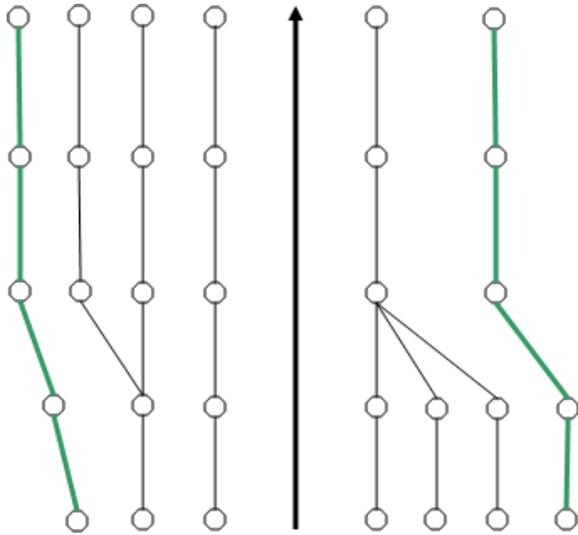
- The circular points on the gray lines are of one type of point code.

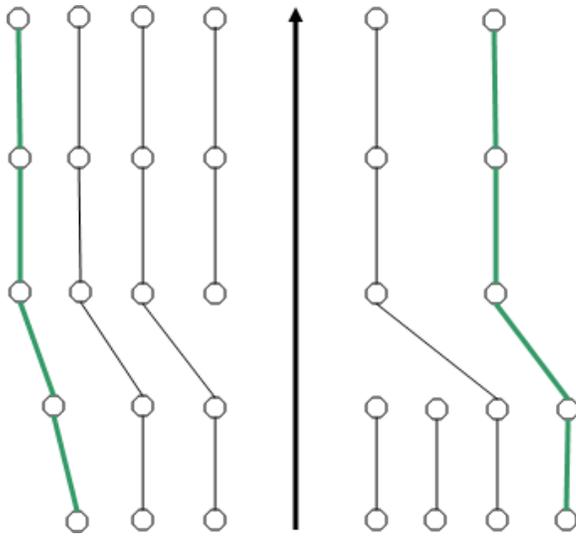
- The circular points on the green lines are of another type point code.

- There are two groups in each assembly: left and right (of the baseline).

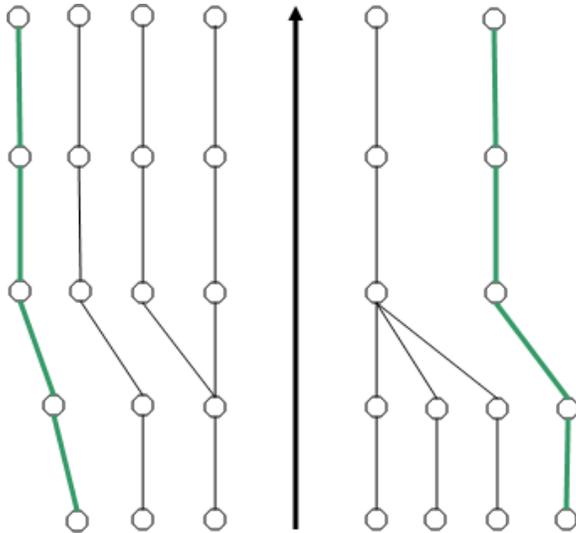
- The Connect option is selected for both types of point codes.

Inward branching and extra points (with the same point code) are not connected:


Inward branching and extra points (with the same point code) are connected:


Outward branching and extra points (with the same point code) are not connected:


Outward branching and extra points (of the same point type) are connected:



**To edit the feature line connection**

1 In the drawing, click the corridor object, right-click, and click Corridor Properties.

2 In the Corridor Properties dialog box, click the Feature Lines tab (page 1818).

3 By default, all identical point codes are connected as longitudinal feature lines. To delete feature lines between one or more types of point codes, clear the check box in the Connect field for the appropriate code.

---

**NOTE** If the Connect check box is disabled, the feature line is being used in a corridor surface definition. It cannot be disconnected.

---

4 To control how to connect point codes that are used a varying number of times at different sections, use the Branching field. Select one of the following:

■ **Inward**: The feature line branches inward, joining the innermost points.

■ **Outward**: The feature line branches outward, joining the outermost points.

**5** To prevent feature lines from being disconnected when there is branching, select Connect Extra Points.

**6** Click Apply.

Dialog Box

Corridor Properties - Feature Lines tab (page 1818)

## Editing Feature Line Styles

View and modify the feature line styles for the corridor.

Use different feature line styles to distinguish the feature lines for easier selection and identification. The feature line style for each code is controlled by the code set style.

**To edit the feature line styles**

**1** In the drawing, click the corridor object, right-click, and click Corridor Properties.

**2** In Corridor Properties dialog box, click the Feature Lines tab (page 1818). All point codes with their corresponding types and feature line style information are displayed in the grid.

**3** To edit feature line styles applied to a point code, click the Code Set Style list, or use the standard controls to create or edit a style.

**4** To change the style for an individual code, for the point code you want to change, click  in the Feature Line Style field. Select a style in the Pick Feature Line Style dialog box. For more information about the style creation tools, see the Select Style Dialog Box (page 1805).

**5** Click Apply.

## Creating and Editing Corridor Surfaces

Use the Surfaces tab of the Corridor Properties dialog box to create corridor surfaces.

Because corridor surfaces are an output of a corridor model, they remain dynamically linked to the corridor object. Any changes to the corridor definition are reflected in the surface definitions. You can also create a detached surface from a corridor surface.

For information about creating a detached surface, see Exporting Corridor Surfaces (page 1373).

When you create a corridor surface, it is added to the Surfaces collection on the Toolspace Prospector tab. You can work with a corridor surface the same way you do with any surface in the Surfaces collection, including changing its style, adding labels to it, and using it for surface analysis. The following features and behaviors are unique to corridor surfaces:

■ When you select a corridor surface, only the surface is selected. The corridor it is based on is not selected.

■ When you change the surface style of a corridor surface using its surface properties, the style is also changed on the corridor properties Surfaces tab.

■ When a corridor is rebuilt, corridor surfaces are updated to reflect any changes in the corridor, and then any edits are applied to the corridor model.

■ The corridor from which the surface was taken is listed in the surface properties definition.

---

**NOTE** Do not use a corridor surface as a target for assemblies.

---

## Creating a Corridor Surface

You can create a corridor surface and then add the required feature line or link codes. Also, you can create a separate corridor surface from each link code in a single operation.

■ **Create a corridor surface**. Use this method if a corridor surface is to be extracted from a set of link codes and corridor feature lines. For example, create a surface using the Links data type and the Top code. After a surface is created, you can add more link codes and feature lines to the surface definition.

■ **Create a corridor surface from each link code**. Use this method to create one surface based on each link code. For example, if Top, Paved, and Side_slope are defined as link codes (in the subassemblies used to build the corridor), this method creates three surfaces: one surface using Top as breaklines, a second surface using Paved, and a third surface using Side_slope.

**To create a corridor surface**

1 In the drawing, click the corridor object, right-click, and click Corridor Properties.

2 In Corridor Properties dialog box, click the Surfaces tab (page 1818).

3 Optionally, click  to open the Name Template dialog box. Set or modify the corridor surface naming convention. For information about the name template, see Name Template Dialog Box (page 1806).

4 Click  to create an empty corridor surface.

5 To add data to the surface, select it in the grid. Select the data type from the Data Type list. Select the code from the Specify Code list. Click  .

6 In the grid, expand the surface to view its data components.

7 Optionally, to add additional data to the corridor surface, repeat Step 5.

8 Optionally, to create another surface and add data to it, repeat Steps 4 and 5.

9 If you do not want to create a dynamic corridor surface, clear the check box next to the surface name.

10 Click Apply to display the corridor surface in the drawing.

If the check box beside the surface name is selected, the surface is added to the Surfaces collection on the Toolspace Prospector tab.

**To create a corridor surface for each link**

1   In the drawing, click the corridor object, right-click, and click Corridor Properties.

2   In Corridor Properties dialog box, click the Surfaces tab (page 1818).

3   Optionally, click to open the Name Template dialog box. Set or modify the corridor surface naming convention. For information about the name template, see Name Template Dialog Box (page 1806).

4   Click to create a corridor surface from each link code. Corridor surfaces are created from all link codes and are listed in the grid. You can view and modify them.

5   If you do not want a corridor surface added to the Surfaces collection on the Toolspace Prospector tab, clear the check box next to that surface name.

6   Click Apply to display the corridor surfaces in the drawing.

   If the check box next to a surface name is selected, the surface is added to Surfaces collection on the Toolspace Prospector tab.

## Quick Reference

Object Shortcut Menu

   Corridor Properties

Dialog Box

   Corridor Properties - Surfaces tab (page 1818)

## Copying Corridor Surfaces

Create a copy of an existing corridor surface

**NOTE** Because a corridor has a large number of dependencies, it cannot be moved, copied, rotated, nor scaled up or down. However, a corridor surface can be copied. You can then edit the copied surface.

When a corridor surface is copied, a naming convention is used. For example if the original corridor surface is named 'Corridor - Datum', the new surface is named 'Corridor - Datum (1)'. If the 'Corridor - Datum' surface is copied again, the new surface is named 'Corridor - Datum (2)'. If the 'Corridor - Datum (1)' surface is copied, the new surface is named 'Corridor - Datum (1) (2)'.

**To copy a corridor surface**

1   In the drawing area, click the corridor surface. Right-click and click Basic Modify Tools  ➤  Copy.

   At the command line, you are prompted to specify a base point for the corridor surface.

2   Click an insertion point in the drawing area.

   The corridor surface is pasted in the drawing and added as a new surface to the Surfaces collection in the Prospector tree.

**3** To edit the name of the corridor surface, right-click the surface in the Prospector tree. Click Properties.

The Surface Properties dialog box is displayed with the Information tab (page 2346) active. The Name field contains the name of the copied corridor, which is, by default, " <surface-name> (1)."

**4** Enter a new name in the Name field.

**5** To specify the description of the corridor surface, enter a new description in the Description field.

**6** Click Apply to make the changes, or click OK to make the changes and close the Surface Properties dialog box.

## Editing a Corridor Surface

Modify corridor surfaces to change how they are displayed and to add or remove data from the surfaces.

When you create a corridor surface as a dynamic surface, you can edit many of the surface properties and perform surface analysis using the surface properties. Access surface properties using the Surfaces collection in the Toolspace Prospector tab. For more information, see Understanding Surfaces (page 599)

**To edit a corridor surface**

**1** In the drawing, click the corridor object, right-click, and click Corridor Properties.

**2** In Corridor Properties dialog box, click the Surfaces tab (page 1818).

**3** In the properties table, select the surface that you want to edit.

**4** To modify the name of the surface, click the name. Modify accordingly.

**5** To change the surface display style used by the corridor surface, click the Surface Style field. Select the style from the Pick Corridor Surface Style dialog box or use the standard style creation tools to edit or create a style. For more information about the style creation tools, see the Select Style Dialog Box (page 1805).

**6** To change the render material used by the corridor surface, click the Render Material field. Select the style from the Select Render Material dialog box or use the standard style creation tools to edit or create a style. For more information about rendering corridor surfaces, see the Rendering Corridor Models (page 1374).

**7** To add data to the surface, select the surface in the properties table. Select the data type in the Data Type list. Select the code in the Specify Code list. Click ⊕ .

**8** To remove data from a surface, in the properties table, expand the surface. Select the data component that you want to delete, and click ✖ .

**9** To remove the corridor surface from the Surfaces collection on the Toolspace Prospector tab, clear the check box next to the surface name.

**10** Click Apply.

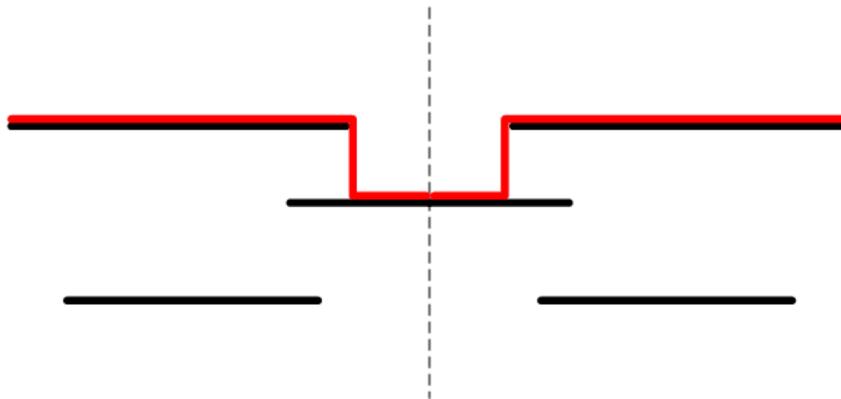
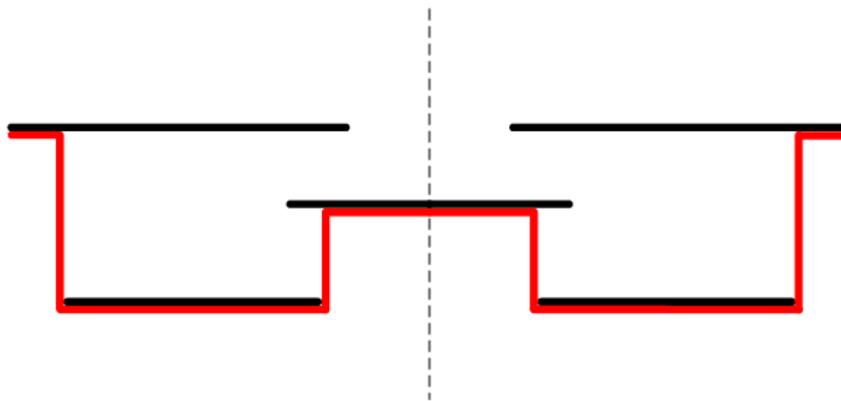
## Resolving an Overhanging Surface

Correct overhanging surfaces in the corridor.

When subassemblies are joined to form an assembly, surfaces of the subassemblies can overhang one another. This presents an incorrect representation of how the surface should be modeled.

Overhanging surfaces are corrected in the Surfaces tab, Corridor Properties dialog box. You can correct the overhang by following the top links or bottom links in the assembly. The overhang correction feature defaults to no links.


**Surface (red) corrected to top links**


**Surface corrected to bottom links**

**To resolve an overhanging surface**

1 In the drawing, click the corridor object, right-click, and click Corridor Properties.

2 In Corridor Properties dialog box, click the Surfaces tab (page 1818).

3 In the Name column, select the corridor surface.

4 Click in the Overhang Correction column, and select Top Links or Bottom Links. The entry defaults to None.

**5** Click OK to correct the overhang.

## Adding and Editing Corridor Boundaries

Use corridor surface boundaries to prevent triangulation outside of the daylight lines of a corridor surface and prevent them from being displayed or to render an area of the corridor surface as a render material.

Corridor surfaces support the following types of boundaries:

■ **Render Only**. Used to represent different parts of corridor surface with different materials (when rendering), for example, asphalt and grass. For more information about rendering, see Rendering Objects (page 1579).

■ **Hide Boundary**. Used to mask to create void areas or punch holes in the corridor surface. For example, if a link code Paved is used on either side of the corridor with another surface (a median), separating them, when you create a corridor surface using Paved as the data, AutoCAD Civil tries to connect the gap in between two link codes. To create voids, you define boundaries to represent the surface appropriately.

■ **Outside Boundary**. Used to define the outer boundary of the corridor surface.

> **NOTE** A corridor surface must exist before you can add a corridor boundary. For information about creating a corridor surface, see Creating and Editing Corridor Surfaces (page 1350).

## Adding Boundaries to a Corridor Surface

Use the Boundaries tab of the Corridor Properties dialog box, or the Create Boundary From Corridor command on the Create Design panel of the Home tab, to create corridor boundaries.

In the Boundaries tab, you can create the boundaries:

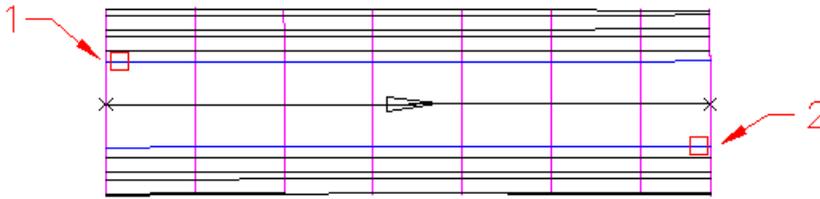
■ Automatically, when there is a single baseline, based on point codes to which feature lines are assigned

■ Corridor Extents As Outer Boundary, when there are multiple baselines, based on feature lines or surface link codes

■ Interactively, by selecting feature lines in the drawing

■ From Polygon, using a closed polygon that forms the boundary

When selecting the feature lines from which to create the boundary, first select the bottom end of one feature line, followed by the top end of its pair.

For example, select the bottom outside edge of a lane followed by the top outside edge of a lane to create a boundary that encompasses both lanes:


If you are creating the corridor boundary using a polygon, you can create the required polygon by exporting corridor feature lines as polylines, and then join them to create the required polygon.

For more information about converting feature lines to polylines, see Exporting Corridor Data (page 1369).

**NOTE** The option to add boundaries Automatically is not available if more than one baseline is used in the corridor. In that case, select Corridor Extents As Outer Boundary, to automatically add a boundary for each corridor surface.

**To automatically create outer boundaries**

1   In the drawing, click the corridor object, right-click, and click Corridor Properties.

2   In the Corridor Properties dialog box, click the Boundaries tab (page 1820).

3   Right-click the corridor surface to which you want to add a mask.

■   To automatically add a boundary to a corridor with a single baseline, click Add Automatically ➤ <code name>.

**NOTE** Only point codes that form a pair of feature lines in the corridor are listed, for example daylight and ETW.

■   To automatically add a boundary to a corridor with multiple baselines, click Corridor Extents As Outer Boundary.

The boundary is added to the corridor surface where you can modify its name, style usage and type. For information, see Editing a Corridor Boundary (page 1357).

**To interactively add a boundary to a corridor surface**

1   In the drawing, click the corridor object, right-click, and click Corridor Properties.

2   In Corridor Properties dialog box, click the Boundaries tab (page 1820).

3   Right-click the corridor surface to which you want to add a boundary. Click Add Interactively.

**NOTE** A corridor surface must exist before you can add a corridor boundary. For information about creating a corridor surface, see Creating and Editing Corridor Surfaces (page 1350).

4   In the drawing, click a corridor feature line that will form one side of the boundary. If you make an ambiguous selection, the Select A Feature Line dialog box is displayed. Select a feature line from the list.

5   In the drawing, click the corridor feature line that will form the other side of the boundary. If you make an ambiguous selection, the Select A Feature Line dialog box is displayed. Select a feature line from the list.

6   When you finish selecting the feature lines, press Enter.

7   In the Boundaries tab grid, expand the corridor surface to display the boundary.

8   Click Use Type. Select the type of boundary, either: Render Only, Hide Boundary, or Outside Boundary.

**9** Click Apply.

**To create outer boundaries using a closed polygon**

**1** In the drawing, click the corridor object, right-click, and click Corridor Properties.

**2** In the Corridor Properties dialog box, click the Boundaries tab (page 1820).

**3** Right-click the corridor surface to which you want to add a mask. Click Add From Polygon.

**4** In the drawing window, click the closed polygon you want to use to define the boundaries of the corridor surface.

**5** The boundary is added to the corridor surface where you can modify its name, render style, and type. For more information, see Editing a Corridor Boundary (page 1357).

---

**NOTE** If you create an invalid boundary, you will be prompted to continue (and correct the error), to save the invalid boundary (which can be corrected later) or to cancel the boundary creation.

---

**To create a polyline boundary from a corridor**

**1** Click Home tab ➤ Create Design panel ➤ 🔻 ➤ Create Boundary From Corridor.

**2** Click a corridor in the drawing, or press Enter to select a corridor in the Select A Corridor dialog box.

A closed polyline is created as the outer boundary of the corridor. This closed polyline can then be used to create a surface boundary, using the Add From Polygon (page 1357) command.

## Editing a Corridor Boundary

Rename, change styles, view, and modify the boundary definition.

Because boundaries are connected based on how the feature lines are selected, you can use the Corridor Boundary Definition dialog box to iteratively modify, preview, and validate the boundaries after you create them. You can:

■ Add or remove feature lines from the boundary definition

■ Specify if the boundary is to be drawn on a feature line in reverse of the station incrementing order.

- Change the draw order of feature lines in the boundary.

- Preview the boundary. The boundary is temporarily drawn as a green polygon.

- Ensure that the boundary is well-formed and has no crossing edges.

**To edit a corridor boundary**

1 In the drawing, click the corridor object, right-click, and click Corridor Properties.

2 In the Corridor Properties dialog box, click the Boundaries tab (page 1820).

3 Expand the corridor surface for which you want to modify a boundary.

4 To modify the boundary name or description, click its Name or Description field. Enter a new name or description.

5 To change the render material, which is used for Render Only boundaries, click the Render Material field for the boundary. Select a render material from the Select Render Material dialog box.

6 To view the boundary definitions and change the extents, click **[...]** in the Definition column.

7 In the Corridor Boundary Definition dialog box (page 1813), to change either the start or end points for the boundary, either select the Start Point or End Point fields and enter the values number, or click and click the point in the drawing.

8 To reverse the boundary draw direction along a feature line, either select or clear the Reverse Direction check box.

9 To add a new feature line to the boundary definition, click . Click the feature line in the drawing.

10 To delete a feature line from the boundary definition, select the feature line. Click .

11 To move a feature line up or down in the boundary definition order, select the feature line. Click to move it up or to move it down.

12 To preview the corridor boundary, click .
The boundary is displayed as a green polyline.

13 To verify that the boundary polygon is well formed (for example, that its edges do not cross each other), click .
A message is displayed next to the button, indicating the state of the boundary.

14 Click OK to close the Corridor Boundary Definition dialog box.

15 To change the boundary type, click Use Type. Select the boundary type.

16 Click Apply.

## Creating and Editing Corridor Slope Patterns

Add slope patterns between a set of feature lines.

Slope patterns are slope indicator lines. They have one or more repeating lines that are aligned with the flow direction. The lines can be the length of the slope or less. They can have a predefined symbol or an AutoCAD block inserted at one end. Slope patterns are applied between any two feature lines (typically, between a grading footprint and daylight line). For more information about slope patterns, see Creating Grading Styles (page 737).

Typical slope pattern usage along a corridor:

## Adding a Corridor Slope Pattern

Add slope patterns to corridor surfaces.

**To add a corridor slope pattern**

1  In Toolspace, on the Prospector tab, expand  Corridors, right-click the corridor, and click Properties.

2  In Corridor Properties dialog box, click the Slope Patterns tab (page 1820).

3  Click Add Slope Pattern >>.

4  In the drawing, select the first corridor feature line that will form one side of the slope. If you make an ambiguous selection, the Select A Feature Line dialog box is displayed. Select a feature line from the list.

5  Select the second corridor feature line that will form the other side of the slope. If you make an ambiguous selection, the Select A Feature Line dialog box is displayed. Select a feature line from the list.

6  Click Apply.

## Editing a Corridor Slope Pattern

Modify the display and extents of a slope pattern.

**To edit a corridor slope pattern**

1   In Toolspace, on the Prospector tab, expand ![icon] Corridors. Right-click the corridor. Click Properties.

2   In the Corridor Properties dialog box, click the Slope Patterns tab (page 1820).

3   To change the slope pattern style, click ![icon] in the Slope Pattern Style field. Select a style from the Pick Style dialog box or use the standard style creation tools to edit or create a style. For more information about the style creation tools, see the Select Style Dialog Box (page 1805).

4   To change either the start or end points for the slope pattern, select either the Station Start or Station End fields. Enter the values, or click ![icon] and click the location in the drawing.

5   Click Apply.

## Rebuilding a Corridor

When you make changes to a corridor, such as editing data or the build parameters, the corridor may become out-of-date. You can rebuild it.

If the corridor definition is out-of-date, a warning is displayed next to the corridor's name in the Prospector tree. The corridor needs to be rebuilt.

In AutoCAD Civil, you can rebuild a corridor either automatically or manually.

**To automatically rebuild a corridor**

1   In Toolspace, on the Prospector tab, expand the Corridors collection.

2   Right-click the corridor with the warning ![icon] .

3   Click Rebuild - Automatic.

> **NOTE** If a check mark is displayed next to the Rebuild - Automatic menu item, it is enabled. Then, when changes are made to the corridor or to one or more of its baselines, profiles, or dependant surfaces, the corridor is automatically rebuilt and updated.

**To manually rebuild a corridor**

**1** In Toolspace, on the Prospector tab, expand the Corridors collection.

**2** Right-click the corridor with the warning ⚠ .

**3** Click Rebuild.

# Deleting a Corridor

You can delete a corridor, erasing it from the drawing and removing it from the Corridors collection in the Prospector tree.

**To delete a corridor**

■ In Toolspace, on the Prospector tab, expand the Corridors collection. Right-click the corridor. Click Delete.
The corridor is erased from the drawing and removed from the Corridors collection in the Prospector tree.

**NOTE** You cannot delete objects that have dependencies (other objects). For example, if you have created a section object from the corridor, you must delete the section before you delete the corridor.

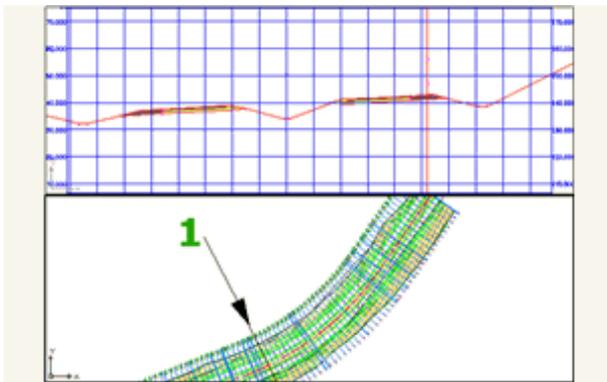
## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Corridors ➤ right-click <corridor name> ➤ Delete

# Viewing and Editing Corridor Sections

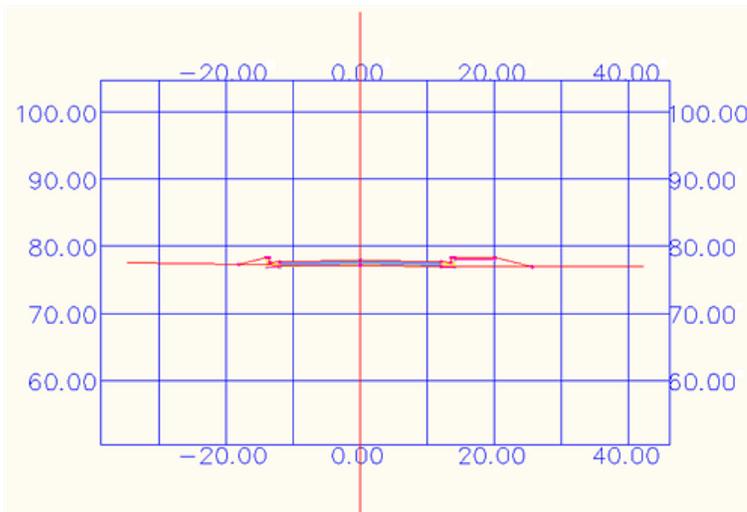
You can use the Corridor Section Editor to view and modify corridor sections.

Use the Corridor Section Editor to apply assembly overrides to a corridor section or a range of sections and then view only those sections. To view both the corridor section view and its location along the corridor (1), open two horizontal viewports.


## Viewing Corridor Sections

Use the Corridor Section Editor to visually inspect how assemblies are applied at various stations.

A simple corridor section as viewed with the Corridor Section Editor.



You can step through corridor stations or jump to any station of interest.

**To view a corridor by sections**

1   Select a corridor in the drawing.

2   Click Corridor tab ➤ Modify panel ➤ Corridor Section Editor .

3   Optionally, you can use the Select A Baseline list to select another baseline for the corridor or click and select an alternate alignment in the drawing.

Alternately, in the prospector or the viewport, you can right click on the corridor you wish to view as sections, right-click and click View/Edit Corridor Section.

**To change your view of corridor sections**

1   To view a section at a different station: On the Station Selection panel, select it from the Select a Station drop-down list.

**2** On the Station Selection panel, click ▯◁ or ▷▯ to view the first or end station.

**3** Click ◁ to view the previous station or click ▷ to view the next station.

**4** To view only the stations that have assembly overrides applied to them, click ▯ Show Overridden Stations. Only stations with assembly overrides are displayed in the list.

**5** To view all stations, click ▯ Show Overridden Stations again.

**6** To set zoom options, on the View Tools tab, either:

■ Click ▯ Zoom to Extents to view the entire corridor section view.

■ Click ▯ Zoom to an Offset and Elevation to lock the zoom to a selected elevation or offset.

■ Click ▯ Zoom to Subassembly to lock the zoom to a selected subassembly.

**7** Optionally, to view detailed information about the assembly and subassemblies used by the region in the Corridor Parameters vista: On the Corridor Edit Tools panel, click ▯ Parameter Editor.

**To edit corridor section viewing and editing options**

**1** To change corridor section viewing and editing options: On the Section Editor tab, View Tools panel, click ▯ View/Edit Options.

**2** In the View/Edit Corridor Section Options (page 1841) dialog box, under View/Edit Options, select a style from the Code Set Style list, to change the display of corridor section elements such as shapes, links, and points.

**3** Under View/Edit Options, enter a new scale in the Default View Scale field.

**4** Under View/Edit Options, select the Rebuild on Edit option, to automatically rebuild the corridor model when you edit a subassembly using the section viewing and editing tools.

> **NOTE** To change the default section viewing scale or automatic corridor rebuild value, on the Toolspace Settings tab, expand Corridor ➤ Commands. Right-click ViewEditCorridorSection, and click Edit Command Settings. In the Edit Command Settings dialog box, expand the View/Edit Options property group. Modify the Default View Scale and Rebuild On Edit settings as required.

**5** Under View/Edit Options, edit the values in the Front Clip and Back Clip fields, to display 3D objects, such as pipe network parts located at the specified station.

You can display any 3D object located at the station, including pipe network parts, blocks, and polylines. The clip values control the start and end of the visible extents of objects in the corridor section, from front to back.

> **NOTE** Unless 3D Objects reside on a visible layer, they are not displayed in the corridor section view. By default, layers for objects that are not referenced by the corridor are not visible.

**6** Under Grid Settings, set the visibility and separation of grid lines, the color of grid lines, and the visibility and color of a center axis for the grid.

**7** Under Grid Text Settings, set the style, color and size of text, along with the visibility of center axis annotation.

## Tracking Corridor Sections at Stations

Use the Station Tracker and Corridor Section Editor to track the location of corridor sections in plan and profile view.

Station Tracker displays (in both plan and profile view) the location of the station from which the current corridor section view is sampled. Station Tracker can be used only with multiple viewports, where one viewport contains the corridor section view and one or two others contain plan and profile views.

**To track corridor section views in plan and profile views**

1   Change the ViewEditCorridorSection command settings:

   ■   In the Corridor settings, expand the Commands folder.

   ■   Right-click ViewEditCorridorSection and click Edit Command Settings.

   ■   In the Edit Command Settings - ViewEditCorridorSection dialog box, expand the View/Edit Options property group.

   ■   Set the Turn Off Unassociated Layers setting to No.

   ■   Set the Station Tracker in Multiple Viewports setting to Yes.

   ■   Click OK.

2   Set the view to multiple viewports:

   ■   Click View tab ➤ Viewports panel ➤ New 📷 .

   ■   In the Viewports dialog box, New Viewports tab, Standard Viewports list, select Three: Above.

   ■   Click OK.

3   Set the corridor plan view in one of the smaller viewports, and the profile view in the other smaller viewport.

4   Select a corridor in the top viewport.

5   Click Corridor tab ➤ Modify panel ➤ Corridor Section Editor 📷 .

6   In the Section Editor tab, Station Selection panel, Select a Station list, select a station.

   That station's corridor section view will be displayed in the top viewport. Station Tracker displays the station location in both plan and profile views.

## Editing Corridor Sections

You can use the Corridor Section Editor to override corridor and assembly parameters and apply the overrides to a station or range of stations.

Edit corridor and assembly parameters as required, using the following methods:

■ Edit the assembly numerically by editing the subassembly parameters.

■ Edit the assembly manually by adding links and points to the subassembly part geometry.

■ Resize assembly parameters by grip editing the subassembly part geometry.

■ Insert or remove subassemblies from a corridor section.

Overriding assemblies may require you to edit the way points, links, and shapes are represented in the corridor as feature codes. Use the Edit User Defined Codes command to change or delete codes as required.

**NOTE** If you have edited a subassembly by either adding or deleting a point, adding or deleting a link, or editing the subassembly geometry using grips, you cannot edit the values of the changed parameters in the Corridor Section Editor.

**To override subassembly parameters by editing their values**

1 Select a corridor in the drawing.

2 Click Corridor tab ➤ Modify panel ➤ Corridor Section Editor  .

3 To view detailed information about the assembly and subassemblies used by the region in the Corridor

Parameters vista: On the Section Editor tab, Corridor Edit Tools panel, click  Parameter Editor.

4 Click the station drop-down list and select the station for which you initially want to override one or more assembly parameters.

5 In the Corridor Parameters vista, click the Value field for the parameter that you want to override. Enter a new value. When an override is applied, the Override column displays True. To remove an individual override, clear the check box next to the subassembly or parameter. To remove all overrides in an assembly, clear the checkbox in the Override column next to the assembly name.

**6** To apply the override to a range of stations: On the Section Editor tab, Corridor Edit Tools panel, click ![icon] Apply to a Station Range.

**7** In the Apply To A Range Of Stations dialog box, enter both the start station and the end station. Click OK.

**8** To view only the stations that have assembly overrides applied to them: On the Station Selection panel, click ![icon] Show Overridden Stations. Only stations with assembly overrides are displayed in the list.

**9** To view all stations, click ![icon] Show Overridden Stations again.

**10** If the corridor is not set to rebuild automatically, click ![icon] Update Corridor to rebuild the corridor.

Corridor surfaces and any other data that is derived from the corridor are updated using the overrides.

**To override subassembly parameters by adding or deleting points**

**1** Select a corridor in the drawing.

**2** Click Corridor tab ➤ Modify panel ➤ Corridor Section Editor ![icon] .

**3** To view detailed information about the assembly and subassemblies used by the region in the Corridor Parameters vista: On the Section Editor tab, Corridor Edit Tools panel, click ![icon] Parameter Editor.

**4** In the Section Editor tab, Station Selection panel, Select a Station list, select the station to which you want to add a point.

**5** To add a point: On the Section Editor tab, Corridor Edit Tools dropdown, click ![icon] Add Point.

**6** In the drawing window, select the link you want to break by adding a point.

**7** Enter a point code value for the new point.

The new vertex is added at the midpoint of the link. The points at the end of the links retain the codes from the original link.

In the Corridor Parameters vista, the Override column displays ![icon] True.

**8** To delete a point: On the Corridor Edit Tools dropdown click ![icon] Delete Point.

**9** In the drawing window, click the point you want to delete.

The point and all links connected to it are deleted.

**10** To view only the stations that have assembly overrides applied to them: On the Station Selection panel, click ![icon] Show Overridden Stations. Only stations with assembly overrides are displayed in the list.

**11** To view all stations, click ![icon] Show Overridden Stations again.

**12** If the corridor is not set to rebuild automatically, on the Corridor Edit Tools panel, click ![icon] Update Corridor to rebuild the corridor. Corridor surfaces and any other data that is derived from the corridor are updated using the overrides.

**To override subassembly parameters by adding or deleting links**

**NOTE** You can add links only to individual subassemblies. You cannot add links that connect two subassemblies.

**1** Select a corridor in the drawing.

**2** Click Corridor tab ➤ Modify panel ➤ Corridor Section Editor .

**3** In the Section Editor tab, Station Selection panel, Select a Station list, select the station to which you want to add a link.

**4** To add a link: On the Corridor Edit Tools dropdown, click  Add Link.

**5** In the drawing window, select the first point of the two points you want to connect.

**6** Select the second point.

The link is added.

**7** To delete a link: On the Corridor Edit Tools dropdown, click  Delete Link.

**8** In the drawing window, click the link you want to delete.

The link is deleted. The points that were connected to create the link are not deleted.

**9** To view only the stations that have assembly overrides applied to them: On the Station Selection panel, click  Show Overridden Stations. Only stations with assembly overrides are displayed in the list.

**10** To view all stations, click  Show Overridden Stations again.

**11** If the corridor is not set to rebuild automatically, on the Corridor Edit Tools panel, click  Update Corridor to rebuild the corridor. Corridor surfaces and any other data that is derived from the corridor are updated using the overrides.

**To override subassembly parameters by inserting or deleting subassemblies**

**1** Select a corridor in the drawing.

**2** Click Corridor tab ➤ Modify panel ➤ Corridor Section Editor .

**3** To view detailed information about the assembly and subassemblies used by the region in the Corridor Parameters vista: On the Section Editor tab, Corridor Edit Tools panel, click  Parameter Editor.

**4** In the Section Editor tab, Station Selection panel, Select a Station list, select the station to which you want to add subassemblies.

**5** Select a subassembly from a tool palette in the Tool Palettes window.

**6** Press Enter to create a detached subassembly.

**7** To add the subassembly to the assembly: On the Corridor Edit Tools dropdown, click  Add Subassembly.

**8** In the drawing window, select the subassembly to which you want to attach the new subassembly.

**9** Optionally, if you are inserting the subassembly between two existing subassemblies, select the second assembly.

**10** To delete a subassembly: On the Corridor Edit Tools dropdown, click  Delete Subassembly.

**11** In the drawing window, click the subassembly you want to delete.

The subassembly is deleted. If the deleted subassembly connected two subassemblies, they are attached to each other at the attachment point of the deleted subassembly.

**12** To view only the stations that have assembly overrides applied to them: On the Station Selection panel, click 🖼 Show Overridden Stations. Only stations with assembly overrides are displayed in the list.

**13** To view all stations, click 🖼 Show Overridden Stations again.

**14** If the corridor is not set to rebuild automatically, on the Corridor Edit Tools panel, click 🔄 Update Corridor to rebuild the corridor. Corridor surfaces and any other data that is derived from the corridor are updated using the overrides.

---

**NOTE** You cannot undo a subassembly deletion. To rebuild the original design, insert a new instance of the subassembly or repeat the assembly selection for the region.

---

**To override subassembly parameters by editing a user-defined code**

**1** Select a corridor in the drawing.

**2** Click Corridor tab ➤ Modify panel ➤ Corridor Section Editor 🖼 .

**3** In the Section Editor tab, Station Selection panel, Select a Station list, select the station for which you want to edit feature codes.

**4** To edit a feature code: On the Corridor Edit Tools dropdown, click 🖼 Edit User Defined Codes.

**5** In the corridor section view, select a point marker, link, or shape.

**6** Do one of the following:

■ Enter a new code for the feature.

■ Enter d (delete), and then click Yes to delete the user-defined codes associated with the feature.

---

**NOTE** You can only delete user-defined point, link, and shape codes. You cannot delete codes added by the subassembly macro using the Edit User Defined Code command.

---

**7** If the corridor is not set to rebuild automatically, on the Corridor Edit Tools panel, click 🔄 Update Corridor to rebuild the corridor. Corridor surfaces and any other data that is derived from the corridor are updated using the overrides.

**To override subassembly parameters by grip editing**

**1** Select a corridor in the drawing.

**2** Click Corridor tab ➤ Modify panel ➤ Corridor Section Editor 🖼 .

**3** In the Section Editor tab, Station Selection panel, Select a Station list, select the station at which you want to edit.

**4** Ctrl+click a subassembly in the corridor section view.
Grip behavior depends on the type of grip:

| Grip Type | Behavior |
| --- | --- |
| Square grip at end of link | Moves the end of one of more links at this point to any point in the grid. When active, the following values are labeled: offset from baseline or controlling offset, elevation, grade, and slope.To maintain the elevation value while editing, keep the point near its original vertical location. |

| Grip Type | Behavior |
|---|---|
| | To maintain the offset value, keep the point near the original horizontal location. |
| Triangular grip at end of link | Moves the endpoint of a link while preserving the grade. When active, the following values are labeled: offset and length of link, elevation difference from original location. |
| Square grip at link mid-point | Moves the link to a parallel position above or below the current position. When active, the following values are labeled: offset from baseline or controlling offset, elevation, elevation difference from original location. |

**5**  Identify the grip you want to move, and then Ctrl+click it once to make it active.

The grip changes color from blue to red, and the link property labels are displayed.

**6**  To edit a value in one of the grip labels, press Ctrl+Tab until the value you want to edit is active. Enter a new value.

**7**  Drag the grip to its new location, and click to place it there. The grip follows your mouse pointer, within the limits imposed by the grip type.

# Exporting Corridor Data

Use the corridor export utilities to export corridor data.

You can export alignments along known point codes/feature lines, feature lines for grading (using the grading feature), corridor surfaces as surface objects, and COGO points at stations on a baseline where assemblies are inserted.

# Exporting Corridor Feature Lines

Export feature lines as polylines, grading feature lines, alignments, and profiles.

**NOTE**  Exported feature lines are not connected to the corridor and are not updated if the corridor changes.

## Exporting Feature Lines as Polylines

Export polylines from corridor feature lines.

Use this option if you want to use the corridor geometry for another purpose, such as for drafting or for surface data.

**To export corridor feature lines as polylines**

1   Click Home tab ➤ Create Design panel ➤ ▼ ➤ Create Polyline From Corridor ⬚ .

2   In the drawing, click the corridor feature line. If you make an ambiguous selection, the Select A Feature Line dialog box is displayed. Select a feature line from the list.

    The feature line is exported as a polyline. The feature line's point code is displayed at the command line.

### Quick Reference

Ribbon

Dialog Box

  Select a Feature Line (page 1838)

## Exporting Feature Lines as Grading Feature Lines

Export corridor feature lines as grading feature lines.

Use this option to create a feature line that grading commands recognize and use as a grading baseline or target.

A grading feature line represents an object in the drawing from which to grade. For more information, see Creating Feature Lines (page 743).

**To export corridor feature lines as a grading feature line**

1   Click Home tab ➤ Create Design panel ➤ Feature Line drop-down ➤ Create Feature Line From Corridor ⬚ .

2   In the drawing, click the corridor feature line you want to export. If you make an ambiguous selection, the Select A Feature Line dialog box is displayed. Select a feature line from the list.

3   In the Create Feature Line From Corridor dialog box:

    ■   Select the Name check box and enter a name for the feature line.

    ■   Click the Create Dynamic Link To The Corridor check box to maintain a link between the feature line and the corridor.

4   If more than one site exists in the drawing, the Pick A Site dialog box is displayed. Select a site.

5   The feature line is exported as a grading feature line. For information about grading feature lines, see Creating Feature Lines (page 743).

> **NOTE** Grading feature line objects are not named components in AutoCAD Civil. The style for the feature line is derived from the corridor object properties for the point code from which the feature line was derived. For information about changing the style for the grading feature line, see Using Grading Styles (page 737).

# Exporting Corridor Feature Lines as Alignments

Export corridor feature lines as alignments.

Use this command if you want to apply an alignment style or label set, or to view a specific feature line in profile view.

**To export feature lines as alignments**

1  Click Home tab ➤ Create Design panel ➤ Alignment drop-down ➤ Create Alignment From Corridor .

2  In the drawing, select a corridor feature line to export. If you make an ambiguous selection, the Select A Feature Line dialog box is displayed. Select a feature line from the list.

3  Enter the required data in the Create Alignment - From Polyline dialog box. For more information, see Creating an Alignment from Graphic Entities (page 891).

4  Select another feature line to export as an alignment or press Enter to end the command.

5  The feature line(s) is exported as an alignment and can be viewed and edited in the Toolspace Prospector tree. For information, see Editing Alignments (page 988).

Dialog Box

Create Alignment - From Polyline (page 1760)

## Exporting Corridor Feature Lines as Profiles

Export corridor feature lines as profiles.

Profiles that are exported from corridor feature lines are listed in Prospector under the baseline alignment from which the original corridor feature line is derived.

**To export feature lines as profiles**

1 Click Home tab ➤ Create Design panel ➤ Profile drop-down ➤ Create Profile From Corridor .

2 In the drawing, select the corridor feature line to export. If you make an ambiguous selection, the Select A Feature Line dialog box is displayed. Select a feature line from the list.

3 In the Create Profile - Draw New dialog box, enter the required data. For more information, see Creating Layout Profiles (page 1048).

The message "<profile name> is created" is displayed at the command line. If you have any profile views in the current drawing for the baseline alignment, the new corridor profile is added to it and displayed with the selected style.

4 Select another feature line to export as a profile or press Enter to end the command.

5 The feature line(s) is exported as a profile and can be viewed and edited in the Toolspace Prospector tree. For information, see Profile Properties (page 1024).

## Exporting Corridor Points as COGO Points

Export corridor points as COGO points.

You can either export all points from a selected corridor or constrain the selection based on station ranges or point code types.

COGO points are basic building blocks in AutoCAD Civil. Use points in land development projects to identify existing ground locations and design elements.

For more information about COGO points, see Understanding Points (page 407).

**To export corridor points as COGO points**

1 Click Corridor tab ➤ Launch Pad panel ➤ ▼ ➤ Points From Corridor ⬚ .

2 In the drawing, click the corridor from which you want to export the points.

3 In the Export COGO Points (page 1825) dialog box, click For Entire Corridor Range to export all points or click For User Specified Range to select a range of points.

4 Optionally, if you selected For User Specified Range, click the Select A Baseline list to select the baseline or click ⬚ and select an alignment in the drawing.

5 If you selected For User Specified Range, enter the start and end range in the Alignment Start and Alignment End fields, or click ⬚ and click the locations in the drawing.

6 In the New Point Group Name field, enter the name for the point group that will contain all the extracted points. For information about point groups, see Point Groups (page 521).

7 Optionally, select the points you want to export, based on their point codes, by selecting or clearing the point code's Select field in the Select Point Codes To Export table. For information about point codes, see Understanding Point, Link, and Shape Codes (page 1406).

8 Click OK.

The point group is created and is displayed in the Point Groups collection in the Toolspace Prospector tree. The points are displayed in the drawing using the default Point Group display settings. They are labeled with their point code names.

# Exporting Corridor Surfaces

You can export corridor surfaces as detached (DTM) surface objects.

You export corridor surfaces, which are components of the corridor object, as AutoCAD Civil surface objects. For more information, see Surfaces (page 599).

The exported surface comprises breaklines based on how the corridor surface was defined (links or feature lines).

For information about corridor surfaces, see Creating and Editing Corridor Surfaces (page 1350).

**NOTE** Exported surfaces are no longer part of the corridor. They will not react to changes to the underlying corridor object.

**To export corridor surfaces as detached (DTM) surfaces**

1   Click Home tab ➤ Create Ground Data panel ➤ Surfaces drop-down ➤ Create Surface From Corridor .

2   In the drawing, click the corridor from which you want to export the surface.

    The Export Corridor Surfaces (page 1828) dialog box is displayed. View all the available corridor surfaces for the selected corridor.

3   Clear the Select field for a surface you do not want to export.

4   Optionally, to set the style for an exported surface, click the Surface Style field. Select a new style in the Pick Corridor Surface Style dialog box.

5   Optionally, to set the render material for an exported surface, click the Render Material field. Select a new render material in the Select Render Material dialog box.

6   Click OK.

    The surface(s) is created and available in the Surfaces collection in the Toolspace Prospector tree. The surfaces are displayed in accordance to the surface style set in the Export Corridor Surfaces dialog box.

## Quick Reference

Ribbon

Dialog Box

   Create Corridor Surfaces (page 1828)

# Rendering Corridor Models

Render corridor data using the AutoCAD Render command.

For more information about rendering AutoCAD Civil objects and data, see Rendering Objects (page 1579).

**To render corridor data**

1   Create a corridor model (page 1331) for an alignment.

2   Optionally, create feature line styles (page 1350) with different colors and apply them to the feature lines in the corridor model. For example, create a blue Edge Of Pavement style to distinguish it from a red Shoulder style.

3   Use the Feature Lines tab (page 1818) of the Corridor Properties dialog box to assign the feature line styles to the feature lines. This step helps distinguish the feature lines for easier selection when you are creating the corridor boundaries. A corridor boundary specifies an area of the corridor to render using a specified render material.

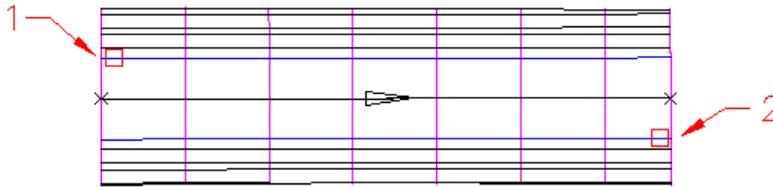
**4** Use the Surfaces tab (page 1818) of the Corridor Properties dialog box to create a corridor surface. For example, create a surface using the Links data type and the Top code. Assign a simple surface style that does not have triangles visible, such as border and contours only.

**NOTE** You can more easily create the corridor boundaries if the triangles are not visible.

**5** Select the Render Material for the corridor surface.

**6** Optionally, use the Boundaries tab (page 1820) of the Corridor Properties dialog box to create corridor boundaries that correspond to the areas on the corridor that you want to render with a specific material. You create the boundaries by selecting corridor feature lines that form the boundaries of the area. You should select the bottom end of one feature line followed by the top end of its pair.

For example, select the bottom outside edge of the lane followed by the top outside edge of the lane to create a boundary that encompasses both lanes:



**7** Use the AutoCAD Render command to render the corridor. For more information, see Rendering Objects (page 1579).

# Corridor Command Reference

You can use these commands to quickly access corridor functionality.

The following table lists the corridor-related AutoCAD Civil commands and briefly describes their functionality.

| Command | Description |
| --- | --- |
| CorridorExtractSurfaces | Exports a (DTM) surface object from a corridor surface (page 1373) |
| CreateAlignFromCorridor | Creates an alignment from a corridor feature line (page 1371) |
| CreateBoundaryFromCorridor | Creates a boundary at the outer edge of corridor (page 1357) |
| CreateCorridor | Creates a corridor (page 1332) |
| CreateProfileFromCorridor | Creates a profile from a corridor feature line (page 1372) |
| CreatePointsFromCorrdor | Exports corridor points as COGO points (page 1372) |
| CreatePolylineFromCorrdor | Exports a corridor feature line as a polyline (page 1370) |

| Command | Description |
| --- | --- |
| CreateSimpleCorridor | Creates a basic corridor (page 1331) |
| DefineCorridorSurfaces | Defines a surface object for the selected corridor (page 1353) |
| FeatureLineFromCorridor | Creates a grading feature line from a corridor feature line (page 1370) |
| IsolateCorridorRegion | Turns off the visibility of all corridor regions except the selected region (page 1338) |
| ShowAllCorridorRegions | Restores the visibility of all corridor region (page 1338) |
| UpdateCorridor | Rebuilds the selected corridor (page 1361) |
| ViewEditCorridorSection | Displays corridor sections (stations) (page 1362) |

# Assemblies and Subassemblies

# 31

Assembly and subassembly objects create the primary structure of an AutoCAD Civil corridor model.

## Understanding Assemblies

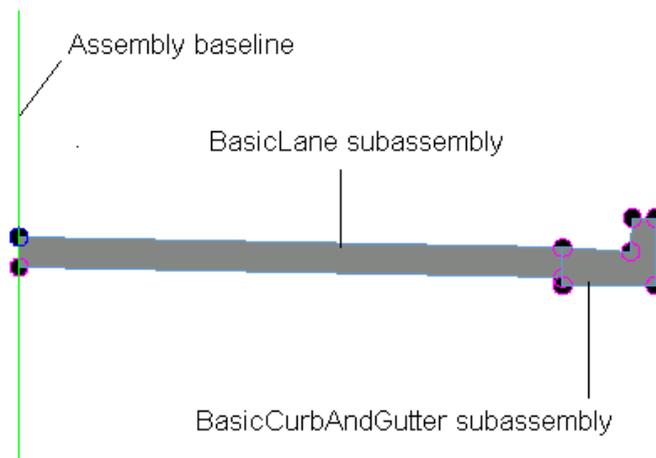
Assembly objects contain and manage a collection of subassemblies that are used to form the basic structure of a 3D corridor model.

Adding one or more subassembly objects, such as travel lanes, curbs, and side slopes, to an assembly baseline creates an assembly object. This forms the design for a corridor section.

The following illustration shows a simple assembly object that represents one side (lane) of a two-lane road. Subassembly objects named BasicLane and BasicCurbAndGutter have been added to a baseline alignment, forming a single travel lane with a curb and gutter.

Assembly baseline

BasicLane subassembly

BasicCurbAndGutter subassembly


It is also possible to create more advanced assemblies referred to as conditional assemblies. A conditional assembly contains one or more conditional subassemblies, which apply subsequent subassemblies when

specified conditions at a given station are met. For more information, see Creating Assemblies with Conditional Subassemblies (page 1384).

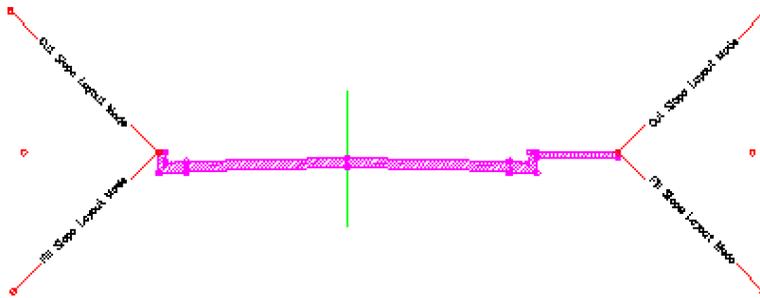
After creating assembly objects, you can proceed with other corridor modeling tasks, such as creating corridor objects, feature lines, and section views. For more information, see Corridors (page 1327).

Review the assemblies and corridors tutorials for step-by-step instructions on how to create a variety of assemblies for corridor model.

## The Assembly Object

Use an assembly object to create the structure for a corridor section.

An assembly is a AutoCAD Civil drawing object (AECCAssembly) that manages a collection of subassembly objects. Together, assemblies and subassemblies function as the basic building blocks of a roadway or other alignment-based design. An assembly object must be applied along an alignment to form a corridor, and it can reference one or more offsets.



An assembly object, like its corridor and subassembly counterparts, can adapt to conditions such as superelevation and cut or fill requirements.

The following components comprise an assembly object:

■ **Insertion Point**. This is the initial point in the drawing that is selected to create the assembly object. It corresponds to the centerline of the eventual corridor object. This is also known as the ground reference point and typically follows an alignment as well as a design profile (vertical alignment).

■ **Baseline**. The baseline of an assembly typically displays as a visual aid (marker) representing a vertical axis at the assembly baseline point. If you want to attach a subassembly to the baseline point, you can do so by selecting the baseline marker. This method of attaching subassemblies to an assembly is sometimes easier than selecting the baseline point, especially when there are already one or more subassemblies attached at that point.

■ **Baseline Point**. This is a point on the assembly typically representing the start point of the first subassembly that is attached to the assembly near the controlling alignment. By default, the baseline point coincides with the insertion point and therefore follows the centerline alignment and profile. If you want to begin sectional elements oriented away (horizontally and vertically) from the centerline, do so by moving this baseline point away from the assembly insertion point.

■ **Offset Line**. The offset line is a typically vertical line visually representing a vertical axis at the offset point. If you want to attach a subassembly at an offset point, you can do so by selecting the offset line marker instead of selecting the offset point. This method of attaching subassemblies to an assembly offset point is sometimes easier than selecting the offset point, especially when there are already one or more subassemblies attached at that point.

■ **Offset Point**. This is a point on the assembly representing the ground reference point along an offset alignment for the eventual corridor object. Subassemblies attached at this point follow an offset alignment

and its designed profile. For example, in the case of a highway with service roads on one or both sides, the service road centerlines are represented by offset points. There is always just one baseline point on an assembly, and there can be zero or many offset points on an assembly. Offset points can be added to or deleted from an assembly at any time.

To complete the definition of an assembly object, you typically add multiple subassembly objects, such as lanes, curbs, or ditches, along an alignment. Each subassembly can connect to the assembly baseline point, any assembly offset point, or to another subassembly already associated with the assembly. A subassembly can also be attached to these points with a relative offset and/or elevation from the point. For more information, see Understanding Subassemblies (page 1394).

## Assembly Settings

Use assembly settings to control the behavior of assembly-related commands.

Work with assembly settings the same way you work with other object settings in AutoCAD Civil, using the Toolspace Settings tree. You can control assembly-related settings at both the object collection (feature) level and at the command level. For information about how the levels of settings work together, see Specifying Drawing Settings (page 63).

Right-click the Settings tree Assemblies collection to establish defaults for all assembly-specific settings and to override the drawing ambient settings for all assembly-related commands. Use the Commands collection in the Settings tree Assembly collection to override assembly-specific settings or drawing ambient settings for a specific command.

**NOTE** Overrides to the drawing ambient settings at the Assemblies collection level and the Assembly Commands collection level affect only the specified level. The drawing level settings are not affected. For more information, see Understanding Settings (page 61).

## Assembly Properties

Specify administrative, and codes structural information using assembly properties.

Assembly properties specify all the information associated with an assembly, including its style, subassemblies, and link, point, and shape codes.

Display the properties of an assembly:

■ Right-click an assemblies collection in the Prospector tree and click Properties.

■ Select an assembly in the drawing, right-click and click Assembly Properties.

For more information, see Assembly Properties Dialog Box (page 1779) and The Toolspace Item View (page 82).

## Assemblies Collection (Prospector Tab)

Use the Assemblies collection in the Prospector tree to access the assemblies in a drawing. As assemblies are created, they are displayed in the Assemblies collection.

Right-click the Assemblies collection to do the following:

■ Turn on or off the assembly preview (page 1391).

■ Refresh the Assemblies collection in the Prospector tree.

If an assembly has been added to the current drawing, you can expand the Assemblies collection to view the names of the assemblies in the Prospector list view. For more information, see The Toolspace Item View (page 82).

Each assembly in a site is displayed as a named object under the Assemblies node of the site. Right-click an assembly name to do the following:

- Display assembly properties (page 1379).

- Delete an assembly (page 1388) in the drawing.

- Zoom or pan to an assembly in the drawing.

- Refresh the Prospector tree.

## Assembly Collection (Settings Tab)

Use the Assembly collection in the Settings tree to manage assembly settings, styles, and command settings.

Right-click the Assembly collection to do the following:

- Edit assembly feature settings (page 1379).

- Refresh the Settings tree.

Expand the Assembly collection to display and edit the styles and command settings available for assemblies.

# Creating Assemblies

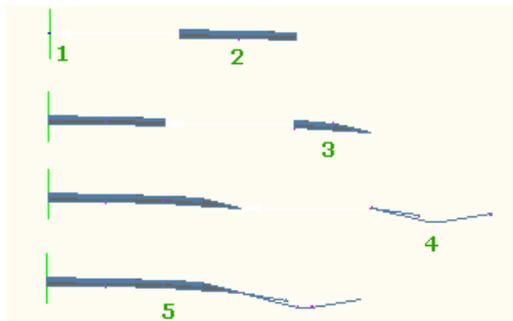
You can create an assembly from the ribbon, from a tool palette, from a catalog, or from an assembly drawing.

You can create a basic assembly, without an offset, or you can create an assembly with an offset. When you create an assembly without an offset, the subassemblies included in the assembly are controlled by a single baseline. When you add an offset to an assembly, the subassemblies included in the assembly are controlled by the baseline and by the offset alignment.

It is also possible to specify different subassemblies to apply depending on the conditions that exist at a given corridor station. This type of assembly is referred to as a conditional assembly. For more information, see Creating Assemblies with Conditional Subassemblies (page 1384).

## Creating an Assembly

Use the Create Assembly command to define the baseline of an assembly, and start adding subassemblies to the assembly.

Define the assembly basepoint (1), then add subassemblies (2,3,4) to the baseline to build the assembly (5).


When designing an assembly that contains a left side and a right side, typically you add the subassemblies to the one side, and then add subassemblies to the other side.

The following options are available from both the Assembly and Subassembly tabs (when you click on an assembly or subassembly in the drawing):

**Copy To Assembly** lets you copy subassemblies from one assembly to another, or to another location (marker point) on the same assembly.

**Move To Assembly** lets you move subassemblies from one assembly to another, or to another location (marker point) on the same assembly.

**Mirror Subassemblies** is available on subassemblies that have a Side parameter. You can use it to quickly copy subassemblies from one side of an assembly to the other.

While creating an assembly, you can first add the right-side (right lane) subassemblies, then use Mirror Subassemblies to copy the right-side subassemblies to the left-side (left lane) of the assembly. Subassembly parameter values are automatically set to appropriate values.

Alternately, you can enter CopySubassemblyTo, MoveSubassemblyTo, or MirrorSubassembly on the Command line, to invoke the commands.

**NOTE** Corridor target settings (page 1343) of a copied, moved or mirrored subassembly are not preserved. You will have to set any targets (page 1344) of the subassembly.

**To create an assembly**

1   Click Home tab ➤ Create Design panel ➤ Assembly drop-down ➤ Create Assembly  .

2   In the Create Assembly dialog box (page 1784), in the Name field, enter a name for the assembly.

   **NOTE** To name the assembly, select its default name and enter a new name, or you can use the Name Template. For more information, see Name Template Dialog Box (page 1806).

3   For Description, enter an optional description of the assembly.

4   For Assembly Style and Code Set Style, either accept the default style, select another style, or create a new style. For more information, see Assembly Styles and Display (page 1389) and Using Code Set Styles (page 1415).

5   Click  to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

   **NOTE** If you do not select a layer, the assembly is placed on the default layer.

6   Click OK.

7   To insert the assembly into the drawing, click a baseline location in the drawing.

   The assembly name is displayed under the Assemblies collection in the Prospector tree. A vertical line with a circular marker in the middle is inserted into the drawing. This is the assembly baseline location point, where you will attach one or more subassemblies.

8   Select a subassembly from a tool palette in the Tooltip Palette vista (page 1383), or from a tool catalog through the Content Browser.

   **NOTE** Not all subassemblies in AutoCAD Civil are located on a tool palette by default. All subassemblies are stored in the Content Browser, and you can add subassemblies (page 105)that you use frequently to a tool palette for easy access.

9  To attach the subassembly to the assembly baseline location, select the baseline point or the baseline marker. Typically, the baseline marker displays as a vertical line.

The subassembly name is displayed in the Subassemblies collection in the Prospector tree. A subassembly group (page 1401) is added to the assembly.

10  To add subassemblies to the subassembly just added, do any of the following:

- Select a subassembly in a tool palette, or in a tool catalog, and then select an appropriate marker point on the previously added subassembly.

- Select a subassembly that is already attached to an assembly and click ![icon] Copy To Assembly, ![icon] Move To Assembly, or ![icon] Mirror Subassemblies on the Modify Subassembly panel of the Subassembly tab. You can also select multiple subassemblies using these features.

When you add a set of subassemblies sequentially to a baseline (for example, lane, curb, sideslope, then ditch), they are all added to the same subassembly group. The next time you select the assembly baseline, a new group is created and subsequent subassemblies added belong to the new subassembly group.

For information about editing and managing assemblies, see Managing and Editing Assemblies (page 1387).

## Quick Reference

Menu

Corridors menu ➤ Create Assembly

Command Line

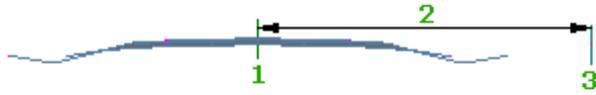
CreateAssembly

Dialog Box

Create Assembly (page 1784)

# Creating an Assembly Offset

Specify a controlling offset within an assembly.

An assembly with an offset is useful for a corridor section that has more than one definitive path, such as a highway with a service road on one or both sides. Create the offset (3) by placing it a distance (2) from the existing assembly baseline (1).


You then add subassemblies to the offset using the Subassembly Tool Palette.

The service road centerline(s) can be described by a specified offset line and offset point. The offset line is a vertical line that visually represents a secondary location that will follow an offset alignment when creating a corridor, and that subassemblies can attach to.

When assembly offsets are created, they are displayed on the Construction tab of the Assembly Properties dialog box. If desired, you can rename an offset on this tab by right-clicking the offset in the list, and selecting Rename.

You can also add or remove an offset, from the Assembly contextual menu, or the Assembly right-click menu. For more information, see Adding an Assembly Offset (page 1389) and Removing an Assembly Offset (page 1389)

**To create an assembly offset**

1  Click Home tab ➤ Create Design panel ➤ Assembly drop-down ➤ Add Assembly Offset .

2  Do one of the following:
   ■  Click an assembly in the drawing.

   ■  Press Enter to select an assembly from a list.

3  Click an offset location in the drawing.
   The offset location is displayed in the drawing.

For information, see Managing and Editing Assemblies (page 1387).

## Quick Reference

Ribbon

Home tab ➤ Create Design panel ➤ Assembly drop-down ➤ Add Assembly Offset

Command Line

AddAssemblyOffset

# Creating an Assembly from a Tool Palette

You can create an assembly object by adding it to your drawing from a tool palette.

Once selected in the tool palette, you can add the assembly to your drawing.

**To create an assembly from a tool palette**

1   To display the Tool Palettes window:

Click Home tab ➤ Palettes panel ➤ [icon] .

2   Open the tool palette containing the desired assembly.

3   On the tool palette, click the assembly, and then click a location in the drawing. Press Enter to end the command. You can also use drag and drop.

The assembly object is added to the drawing. The assembly name is displayed under the Assemblies collection in the Prospector tree.

## Quick Reference

Ribbon

Click Home tab ➤ Palettes panel ➤ [icon] .

Command Line

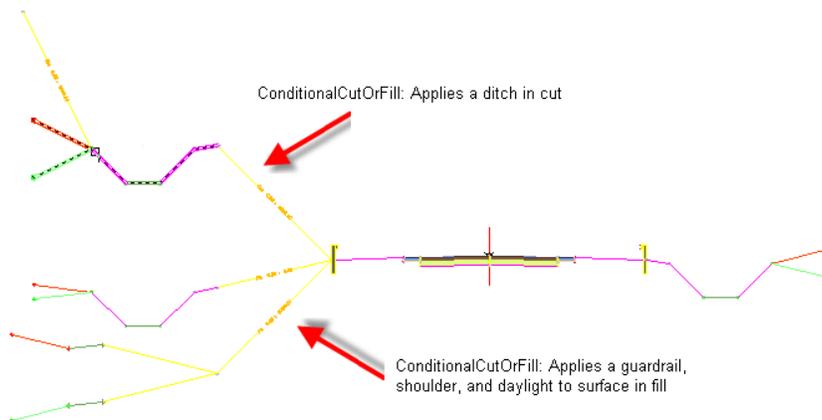
ToolPalettes

# Creating Assemblies with Conditional Subassemblies

You can create an assembly that contains conditional subassemblies.

An assembly that contains one or more conditional subassemblies can be referred to as a conditional assembly. When you have a conditional assembly in your drawing, specified subassemblies are automatically applied at stations when conditions exist.

For example, a conditional corridor assembly could contain two ConditionalCutOrFill subassemblies. The first ConditionalCutOrFill subassembly can be configured to apply a ditch subassembly when a cut condition exists. The second ConditionalCutOrFill subassembly can be configured to apply a guardrail, shoulder, and daylight to surface when a fill condition exists. Using conditional subassemblies enables you to reduce the number of corridor regions and assemblies that you have to maintain.

The following illustration shows an example of an assembly that contains a ConditionalCutOrFill subassembly that is configured to apply a ditch in cut situations, and another ConditionalCutOrFill subassembly that is configured to apply a guardrail, shoulder, and to daylight to surface in fill situations.


**To create a conditional assembly**

The following procedure describes how to add a conditional subassembly to an existing assembly.

1 Create an assembly containing at least one subassembly. For instructions on how to do this, refer to Creating an Assembly (page 1380).

2 In the tool palette, click the desired conditional subassembly. For example, you may want to select the ConditionalCutOrFill subassembly, which may be located on the Conditional tool palette.

3 In the Properties palette, set the subassembly's Side, Layout Width, Layout Grade, Type, and Minimum\Maximum Distance parameters to indicate the conditions under which they should be applied. For example, the table below shows how to set these parameters for the ConditionalCutOrFill subassembly in a fill situation. You may want to specify these settings differently, depending on the type of condition you want to configure.

| Parameter | Value | Description |
|---|---|---|
| Side | **Left** | Specifies which side of the assembly or corridor the subassembly is inserted towards. |
| Layout Width | **20.0000'** | Specifies the length of the line that is drawn to represent this subassembly in layout mode. This parameter, in combination with the Layout Grade parameter, allows you to position the ConditionalCutOrFill subassembly and subassemblies that are attached to it, but does not display or have any effect in the corridor model. |
| Layout Grade | **4.000:1** | Specifies the grade of the line that is drawn to represent this subassembly in layout mode. This parameter, in combination with the Layout Width parameter, allows you to position the ConditionalCutOrFill subassembly and subassemblies that are attached to it, but does not display or have any effect in the corridor model. |
| Type | **Fill** | Specifies the type of condition that when detected subsequent specified subassemblies will be applied to the assembly. |
| Minimum Distance | **0.0000'** | When the Cut or Fill (Type) depth is between these two values, the subsequent subassemblies will be applied to the assembly. |
| Maximum Distance | **5.0000'** | |

**NOTE** For the ConditionalCutOrFill subassembly, the Layout Width and Layout Grade parameters only affect the appearance of the subassembly in layout view. These parameters enable you to position the conditional subassembly and the subassemblies that are attached to it, but do not affect the corridor model.

4 If desired, you can add more conditional subassemblies to the same side of the assembly.

**5** Configure the opposite side of the assembly as desired. You can add conditional subassemblies to one or both sides.

**6** When you are finished adding subassemblies to the assembly, press Esc to exit subassembly placement mode.

The next step is to assign descriptive names to each of the subassemblies in the conditional assembly. Assigning meaningful names to the subassemblies makes it easier to identify them when you are assigning targets, and helps you to identify subassemblies in the Subassemblies collection in Prospector.

**7** For instructions on how to add meaning names to conditional subassemblies in an assembly, see Assigning Meaningful Names to Conditional Subassemblies (page 1386).

After assigning meaningful names to the conditional subassemblies, the final step is to set the corridor targets. For more information, see Setting and Editing Targets (page 1343).

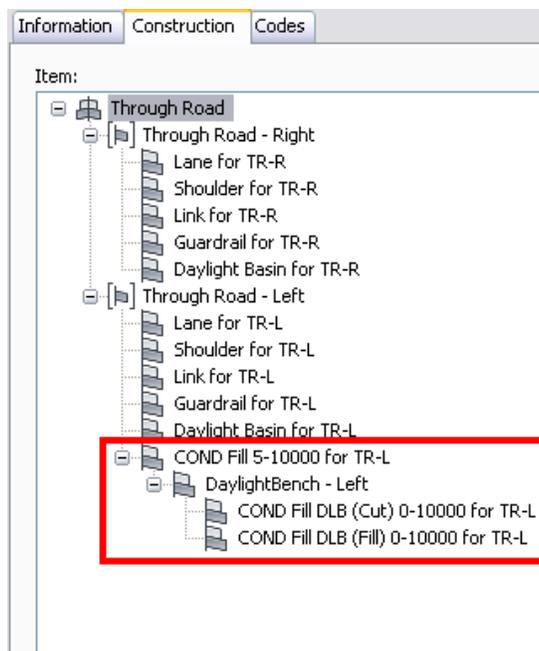
**To assign meaningful names to conditional subassemblies**

**1** In the drawing, right-click the conditional assembly and select Assembly Properties.

**2** In the Assembly Properties dialog box, click the Construction tab.

Subassemblies that are added to the one side of an assembly display the default names, followed by the side to which they were added.

**3** In the Item list, select the conditional subassembly that is located on the left side of the assembly. Click it again to highlight the text. Change the name so that it indicates the type of condition it is set to detect. In the following example, the name of the first conditional subassembly has been changed to **COND Fill 0-5 for TR-L**. In this example, **COND** indicates that this is a conditional subassembly. **Fill** indicates the type of condition that activates it. **0-5** indicates the minimum and maximum distance value of the fill condition it is looking for. In this example, **TR-L** is a reference to the name of the parent assembly this particular subassembly is associated with (in this case, "Through Road" or "TR" and "Left side" or "L".)



**4** Rename any other conditional subassemblies in the assembly to meaningful names.

**5** Click OK.

After assigning meaningful names to the conditional subassemblies, the final step is to set the corridor targets. For more information, see Setting and Editing Targets (page 1343).

Dialog Box

Construction tab (Assembly Properties) (page 1779)

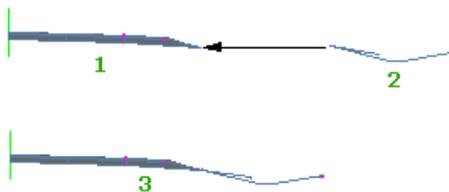
# Managing and Editing Assemblies

This section covers a variety of tasks you may perform while working with assemblies in AutoCAD Civil.

## Planning an Assembly

Before creating an assembly, identify the different types of subassemblies you need, make sure they are available, and decide how you want them to display.

The easiest way to access subassemblies is through a tool palette. Drag a subassembly (2) from a palette to add it to an assembly (1). You can add more subassemblies to the expanded assembly (3).



You can also add assemblies to a tool palette you create. For more information, see Understanding Subassemblies (page 1394).

You can design styles that control the appearance of the assembly components, such as the insertion point and baseline point, in the drawing. For more information, see Assembly Styles and Display (page 1389).

Use code set styles (page 1415) to control the appearance of subassembly components, such as points, links, and shapes. These components will display within your assembly object.

## Creating Assembly Sets

If you use the Create Intersection wizard to create intersections, you may want to create customized assembly set (page 2467)s for intersection creation. Assembly sets are XML files, used to organize assemblies for creating intersections. Assembly sets reference groups of existing assemblies and may reference null assemblies (page 2478). Null assemblies are used as placeholders, when complete assemblies are unavailable.

For more information on assembly sets, see Assembly Sets (page 1457).

For more information on null assemblies, see Null Assemblies (page 1460).

# Copying an Assembly

Copying an assembly creates a new assembly using the standard object naming convention.

If the assembly has subassemblies associated with it, new subassembly objects are also created. The new assembly is placed in the drawing and in the Assemblies collection in the Prospector tree. The new subassemblies are included in the assembly, and are also displayed in the Prospector tree as new subassembly objects.

When you copy an assembly, the new assembly is named using an incremental naming convention. For example if the original assembly that is copied is named "Assembly 1", the new assembly is named "Assembly 1 (1)". If assembly 1 is copied again, the new assembly is named "Assembly 1 (2)". If "Assembly 1 (1)" is copied, the new assembly is named "Assembly 1 (1) (2)".

This same naming convention also applies to any new subassemblies created when copying an assembly.

**To copy an assembly**

1 In the drawing area, right-click the assembly baseline and click Basic Modify Tools ➤ Copy.

   At the command line, you are prompted to specify a base point for the assembly.

2 Pick an insertion point in the drawing area.

   The assembly is copied in the drawing and added as a new assembly to Assemblies collection.

3 To edit the name of the assembly, right-click the assembly in the Prospector tree and click Properties.

   The Assembly Properties dialog box is displayed with the Information tab (page 1779) active. The Name field contains the name of the copied assembly, which is, by default " <assembly name> (1)."

4 Enter a new name in the Name field.

5 To edit the description of the assembly, enter a new description in the Description field.

6 Click Apply to accept the changes, or click OK to accept the changes and close the Assembly Properties dialog box.

## Quick Reference

Object Shortcut Menu

Right-click assembly baseline ➤ Basic Modify Tools ➤ Copy

Dialog Box

Information tab (Assembly Properties) (page 1779)

# Deleting an Assembly

Deleting an assembly erases it, and associated subassemblies, from the drawing and removes them from the Assemblies and Subassemblies collections in the Prospector tree.

You can delete a subassembly within an assembly, and it deletes the subassembly but not the assembly.

**To delete an assembly, do one of the following**

■ In the drawing area, right-click the assembly baseline, or select the entire assembly object, and click Basic Modify Tools ➤ Erase.

■ In the Prospector tree, right-click the assembly and click Delete.

The assembly is erased from the drawing and removed from the Assemblies collection in the Prospector tree.

### Quick Reference

Toolspace Shortcut Menu

Prospector tab: Assemblies ➤ Right-click <assembly name> ➤ Delete

## Adding an Assembly Offset

You can add an offset to an assembly object.

For more information on assembly offsets, see Creating an Assembly Offset (page 1382).

**To add an assembly offset**

1 In the drawing area, right-click the assembly baseline and click Add Offset.

2 Select an offset location in the drawing.
   The offset location is displayed in the drawing.

### Quick Reference

Object Shortcut Menu

Right-click assembly baseline ➤ Add Offset

## Removing an Assembly Offset

You can remove an offset from an assembly which erases the offset from the drawing.

For more information on assembly offsets, see Creating an Assembly Offset (page 1382).

**To remove an assembly offset**

1 In the drawing area, select the assembly baseline from which you want to remove the offset.

2 Right-click and click Remove Offset.

If there are multiple offsets associated with the assembly, you are prompted to select an offset. If there is only one offset associated with the assembly, it is removed.

### Quick Reference

Object Shortcut Menu

Right-click assembly baseline ➤ Remove Offset

## Assembly Styles and Display

Use assembly styles and code set styles to control the visual display of each assembly component.

# Using Assembly Styles

Use styles to control the visual appearance of the assembly object components.

You can create specific styles to use for the different phases of a project. For example, you can create one style to use in the design layout phase and another style to use for plotting.

Use assembly styles to control the appearance of assembly baseline location, profile grade reference point, controlling offset baseline location and profile point markers.

You can access assembly styles using the methods in the following table:

| To access assembly styles... | Then... |
| --- | --- |
| In the drawing | Right-click an assembly and then click Edit Assembly Style. |
| On the Settings tab in Toolspace | Right-click a style in the Assembly Styles folder and then click Edit. |

**NOTE** When you click New on the shortcut menu of a collection folder, the new style you create is based on installation defaults, not on the existing styles in the collection. To create a new style from an existing style, right-click the style, click copy, and then save the style with a new name.

Use the various tabs in the Assembly Style dialog box to set the following style information:

■ **Information**. Specifies name, description, and creation information.

■ **Marker**. Specifies the display of marker symbols (such as for the baseline point) within an assembly.

■ **Display**. Lists the assembly components and display options as well as the choice of 2D or 3D visibility. You can display components in a 2D plan view or a 3D view using other tools, such as Orbit or Vpoint.

■ **Summary**. Lists all the style properties.

# Copying or Editing Assembly Styles

Use the Settings tree to copy or edit an assembly style by clicking an existing style, making modifications and then saving it with a new name.

**To copy or edit an assembly style**

1 In Toolspace, on the Settings tab, expand the Assembly Styles collection and right-click an existing style.

2 Click Copy or Edit.

3 In the Assembly Style dialog box, click the Information (page 1781) tab and enter a new name and description for the assembly style.

4 To specify the display of marker symbols (such as for the baseline, baseline point, and insertion point), click the Marker (page 1781) tab and specify the marker properties for the assembly.

5 To define the display properties for the assembly style, click the Display (page 1782) tab and specify the display properties for the assembly.

6 To view a summary of information about the style, click the Summary (page 1783) tab.

7 Click Apply.

### Quick Reference

Toolspace Shortcut Menu

  Settings tab: Right-click Assembly Style item

Object Shortcut Menu

  Right-click Assembly object ➤ Copy or Edit Assembly Style

Dialog Box

  Assembly Style (page 1781)

## Previewing an Assembly

You can preview an assembly in the Prospector Item List View.

**To preview an assembly**

1   In Toolspace, on the Prospector tab, right-click the Assemblies collection and click Show Preview.

> **NOTE** A check mark is displayed next to the Show Preview menu item when the preview is enabled.

2   In the Prospector tree, click the assembly that you want to preview.
    The assembly is displayed in the Prospector item view.

> **NOTE** The preview of the assembly uses the same display styles as the assembly in the drawing area.

### Quick Reference

Toolspace Shortcut Menu

  Prospector tab: Right-click Assemblies ➤ Show Preview

## Sharing Assemblies

You can access and share assemblies using tool palettes, catalogs, or assembly drawings.

For example, you can create an assembly in your drawing, and then drag and drop it to a tool palette. Once it is in a tool palette, you can copy an assembly from a tool palette into a catalog. You can create a tool palette or a catalog that contains multiple assemblies, and then share that tool palette or catalog with others.

You can also save an assembly to a drawing file (.dwg), and then drag and drop that drawing file into your current drawing.

The following list summarizes ways you can share assemblies:

■   copy an assembly from the drawing area to a tool palette

■   copy an assembly from a tool palette to the drawing area

■   copy an assembly from a tool palette to a catalog

■   copy an assembly from a catalog to the drawing area

■   copy an assembly from a catalog to a tool palette

■   drag (copy) an assembly drawing (.dwg) into another drawing

**NOTE** You cannot copy an assembly directly from a drawing into a catalog. You must first copy the assembly to a tool palette. From a tool palette, you can copy an assembly to a catalog.

**To copy an assembly from the drawing area to a tool palette**

1 Display the Tool Palettes window.

 Click Home tab ➤ Palettes panel ➤ ![icon] .

2 Open the desired tool palette or create a new tool palette.

3 In the drawing area, zoom to the desired assembly.

4 Select the desired assembly, and click and hold down the mouse button to drag it onto the tool palette.

 **NOTE** To select an assembly, make sure that you click only on the assembly baseline (vertical line). Do not click on any grips on the assembly baseline.

The assembly is copied to the tool palette.

**To copy an assembly from a tool palette to the drawing area**

1 Display the Tool Palettes window.

 Click Home tab ➤ Palettes panel ➤ ![icon] .

2 Open the tool palette that contains the desired assembly.

3 In the tool palette, click the desired assembly, and then click a location in the drawing area.

The assembly is copied to the drawing area.

**To copy assemblies from a tool palette to a catalog**

1 To display catalogs:

 Click View tab ➤ Palettes panel ➤ ![icon] .

 **TIP** When working with both the AutoCAD Civil workspace and the Content Browser, you may find it useful to have the Content Browser window displayed at all times. To do this, right-click in the Content Browser title bar and select Always On Top.

2 To display tool palettes: Click Palettes panel ➤ ![icon] .

3 Open the tool palette that contains the desired assembly or assemblies.

4 In the tool palette, click on the desired assembly or assemblies, and hold down the mouse button to drag and drop them into the desired catalog.

The assemblies are copied to the catalog.

**To copy an assembly from a catalog to the drawing area**

You can copy an assembly from a catalog directly into the drawing area.

1 To display catalogs in the Content Browser: Click View tab ➤ Palettes panel ➤ ![icon] .

**2** Navigate to the catalog containing the desired assembly.

**3** Once you have located the desired assembly, click on the i-drop icon ⬤ that is located on the assembly image. When you do this the cursor image changes to an eye-dropper ⬖ .

**4** Drag the eyedropper icon into the drawing area.

The assembly is copied into the drawing area.

### To copy an assembly from a catalog to a tool palette

You can copy an assembly from a catalog directly onto a tool palette.

**1** To display catalogs in the Content Browser: Click View tab ➤ Palettes panel ➤ 🔲 .

**2** Navigate to the catalog containing the desired assembly.

**3** Once you have located the desired assembly, click on the i-drop icon ⬤ that is located on the assembly image. When you do this the cursor image changes to an eye-dropper ⬖ .

**4** Drag the eyedropper icon into the desired tool palette.

The assembly is copied into the tool palette.

### To drag (copy) an assembly from a drawing (.dwg) to another drawing

You can drag and drop an assembly drawing into another drawing. In this scenario, the assembly drawing that you want to copy (drag) must contain just the assembly that you want to copy, and no other data.

**1** Using Windows Explorer, navigate to the folder containing the assembly drawing file.

**2** Right-click on the assembly drawing file and drag and drop it into the AutoCAD Civil drawing area.

The assembly contained in the assembly drawing file is copied into the currently open AutoCAD Civil drawing.

The assembly is inserted as a block. Explode it to create the assembly object. When the assembly object is created, it appears in the Assemblies node in Prospector.

# Understanding Subassemblies

Subassemblies are the basic building blocks of a corridor design.

A subassembly is an AutoCAD drawing object (AECCSubassembly) that defines the geometry of a component used in a corridor section. Through the tool palette and tool catalogs, AutoCAD Civil provides preconfigured subassemblies for components such as travel lanes, curbs, side slopes and ditches. These subassemblies are defined by a set of points, links, and optionally closed areas referred to as shapes.

The subassemblies provided with AutoCAD Civil have built-in intelligent behavior. They can automatically adapt to conditions such as superelevation and cut or fill requirements. For example, a side slope subassembly has variable slopes that change automatically depending on the depth of cut along the corridor. In fill conditions exceeding a given depth, the shoulder automatically widens to include a guardrail or barrier.

After you determine the kinds of subassemblies to use, make sure they are available through an AutoCAD Civil tool palette or tool catalogs available through the Content Browser. For more information, see the Content Browser Help.

In addition to ready-to-use subassemblies, AutoCAD Civil also lets you create your own custom subassembly objects from polylines, or design more sophisticated ones using a .NET language. (See *AutoCAD Civil Developer's Guide*.)

### Layout and Modeling Modes

A subassembly that has not yet been applied to a corridor is considered to be in layout mode. After you create a corridor, all subassemblies included in the corridor model are considered to be in modeling mode.

### Conditional Subassemblies

You can use a special type of subassembly called a conditional subassembly that automatically inserts other specified subassemblies when certain conditions are met.

For example, a conditional corridor assembly could contain two ConditionalCutOrFill subassemblies. The first ConditionalCutOrFill subassembly can be configured to apply a ditch subassembly when a cut condition exists. The second ConditionalCutOrFill subassembly can be configured to apply a guardrail, shoulder, and daylight to surface when a fill condition exists. Using conditional subassemblies enables you to reduce the number of corridor regions and assemblies that you have to maintain.

An assembly that contains one or more conditional subassemblies can be referred to as a conditional assembly. For more information, see Creating Assemblies with Conditional Subassemblies (page 1384), or the tutorial exercise Creating an Assembly with Conditions.

# The Subassembly Object

A subassembly is an AutoCAD Civil drawing object (AECCSubassembly) that defines the geometry of a component used in a corridor section.

Add subassembly objects to an assembly object to create a road cross section. Through tool palette and tool catalogs, AutoCAD Civil provides preconfigured subassemblies for components such as travel lanes, curbs, side slopes and ditches.

For information on stock subassemblies, see Subassemblies at a Glance.

# Subassembly Styles

Use code set styles to control the appearance of subassemblies.

The subassembly object itself does not have its own style. However, since you will typically be working with sets of subassemblies, you can assign styles to subassembly components (point, links, and shapes) through code set styles. For more information, see Using Codes and Code Set Styles (page 1405).

# Subassembly Settings

Use subassembly settings to control the behavior of subassembly-related commands.

Work with subassembly settings the same way you work with other object settings in AutoCAD Civil, using the Toolspace Settings tree. You can control subassembly-related settings at both the object collection (feature) level and at the command level. For information about how the levels of settings work together, see Specifying Drawing Settings (page 63).

Right-click the Settings tree Subassembly collection to establish defaults for all subassembly-specific settings and to override the drawing ambient settings for all subassembly-related commands. Use the Commands collection in the Settings tree Subassembly collection to override subassembly-specific settings or drawing ambient settings for a specific command.

**NOTE** Overrides to the drawing ambient settings at the Subassembly collection level and the Subassembly Commands collection level affect only the specified level. The drawing level settings are not affected. For more information, see Understanding Settings (page 61).

# Subassembly Properties

Specify administrative, parameter and codes information using subassembly properties.

Subassembly properties specify all the information associated with a subassembly, including its code set style, input and output parameters, the name of the macro file it is derived from, and a list of the link, point, and shape codes associated with it.

Display the properties of a subassembly:

■ Right-click a subassemblies collection in the Prospector tree and click Properties.

■ Select a subassembly in the drawing, right-click and click Subassembly Properties.

For more information, see Subassembly Properties Dialog Box (page 1790) and The Toolspace Item View (page 82).

# Subassemblies Collection (Prospector Tab)

Use the Subassemblies collections in the Prospector tree to access the subassemblies in a drawing.

Right-click the Subassemblies collection to do the following:

■ Turn on or off the subassembly preview (page 1402).

■ Refresh the Subassemblies collection in the Prospector tree.

If a subassembly has been added to the current drawing, you can expand the Subassemblies collection to view the names of the subassemblies in the Prospector list view. For more information, see The Toolspace Item View (page 82).

Each subassembly in a site is displayed as a named object under the Subassemblies node of the site. Right-click a subassembly name to do the following:

■ Display subassembly properties (page 1395).

■ Delete the subassembly (page 1401) in the drawing.

■ Zoom or pan to the subassembly in the drawing.

■ Refresh the Prospector tree.

## Subassembly Collection (Settings Tab)

Use the Subassembly collection in the Settings tree to manage subassembly settings and commands.

Right-click the Subassembly collection to do the following:

■ Edit subassembly feature settings (page 1395).

■ Refresh the Settings tree.

Expand the Subassembly collection to display and edit the subassembly commands.

# Creating Subassemblies

Add subassemblies to a drawing using the subassemblies provided through the AutoCAD Civil tool palette or tool catalog, or create your own custom subassemblies.

When using the preconfigured AutoCAD Civil subassemblies, adding the subassembly to the drawing creates the subassembly object.

If you want to create a custom shape and use it as a subassembly, use the Create Subassembly from Polyline feature. For more information, see Creating Subassemblies From Polylines (page 1397).

Another approach to creating customized subassemblies is using scripts in a .NET language. This method provides you with the ability to create custom subassemblies with simple or complex conditional behavior built in. For more information, see Creating Custom Subassemblies Using .NET in the *AutoCAD Civil Developer's Guide*.

# Creating a Subassembly from a Tool Palette

You can create a subassembly object by adding it to your drawing from a tool palette.

Once selected in the tool palette, you can add the subassembly to an assembly baseline, or to a subassembly attached to an assembly. You can also just add the subassembly to your drawing and not associate it with an assembly. This is referred to as a detached subassembly.

**To create a subassembly from a tool palette**

1  Display the Tool Palettes window.

   Click Home tab ➤ Palettes panel ➤ [  ] .

2  On the Tool Palettes window, click the desired subassembly.

3  Do one of the following:
   ■ To add the subassembly to an assembly, select a marker point on an assembly in the drawing.

■ To add the subassembly to the drawing, and not associate it with an assembly, press Enter then click a location in the drawing.

The subassembly name is displayed under the Subassemblies collection in the Prospector tree.

If you subsequently move the subassembly from its original insertion point in an assembly, you can return it to that point by clicking Clear Offset in Assembly on the Modify Subassembly panel, or by entering SubassemblyClearOffset at the Command line.

The Clear Offset in Assembly button is only enabled if a selected subassembly is part of an assembly, and was moved away from its original insertion point.

CreateSubAssemblyTool
SubassemblyClearOffset

## Creating Subassemblies From Polylines

You can create customized subassemblies from AutoCAD polyline objects in a drawing.

To create a subassembly from a polyline object, first create the desired polyline object in the drawing. Add the new subassembly to an assembly by right-clicking it and clicking Add To Assembly.

Make sure the polyline object is free of drawing errors.

After you have created the subassembly from a polyline, add the desired point, link, and shape codes to the subassembly. If you do not add any codes to the subassembly, the subassembly does not display when you create the corridor. For more information, see Understanding Point, Link, and Shape Codes (page 1406) and Adding Codes to a Subassembly (page 1414).

Use code set styles (page 1405) to control the visual appearance of subassembly components. You can use existing code set styles or create your own.

**To create a subassembly from a polyline**

1 Create the desired polyline shape in the drawing.

2 Click Home tab ➤ Create Design panel ➤ ▼ ➤ Create Subassembly From Polyline .

3 Click the polyline object in the drawing and press Enter.

4 In the Create Assembly (page 1784) dialog box, for Name, enter a name for the subassembly.

   **NOTE** To name the subassembly, you can select its default name and enter a new name, or you can use the Name Template. For more information, see Name Template Dialog Box (page 1806).

5 For Description, enter an optional description for the subassembly.

6 In the Code Set Style list, select a Code Set Style or accept the default. For more information, see Using Codes and Code Set Styles (page 1405).

**7** Click ![layer icon] to select a layer. For more information about layers, see Object Layer Dialog Box (page 1985).

> **NOTE** If you do not select a layer, the subassembly is placed on the default layer.

**8** Optionally, select a mid-ordinate distance.

If this subassembly contains curves, they will be tessellated (converted into a finite number of segments). This value determines the length of the tessellated segments.

**9** In the Link Creation list, choose the behavior for link creation by selecting Multiple, Single, or None. Multiple is the default.

Multiple: Creates a new link for each segment created from the object selected. This is useful for assigning link codes to different components of the subassembly for creating surfaces, or other display features.

Single: Creates one link from all segments created from the selected object. This is provided to make creating shapes simpler. Using the Add Shape right-click command, you only need to perform one action.

None: Produces no links; only points will be created at the vertices.

**10** Optionally, you may clear Erase Existing Entities if you want to save the original polyline object selected to create the subassembly. By default, this option is checked and the polyline selected is automatically deleted.

**11** Click OK. The new subassembly is created and is displayed in the Subassemblies collection in the Prospector tree.

To add codes to the subassembly, see Adding Codes to a Subassembly (page 1414).

To add the subassembly to an assembly, see Creating Assemblies (page 1380).

Create Subassembly From Polyline (page 1784)

## Inserting Subassemblies on Right and Left Sides of a Corridor

Some subassemblies use a Side input parameter to specify inserting the subassembly on the right or left side of a corridor; other subassemblies allow you to do this by specifying a positive or negative value for the insertion point input parameter.

Subassemblies that contain a Side input parameter let you specify which side the subassembly is inserted by setting this parameter to Right or Left. By default, this parameter is typically set to Right. Change it to Left to insert the subassembly onto the left side.

Other subassemblies, such as LinkOffsetAndElevation, do not contain a Side input parameter. However, you can insert the subassembly onto the right or left side of a controlling baseline by entering a positive or a negative value for the insertion point input parameters. A positive value for this parameter inserts the subassembly onto the right side of a corridor, or of a controlling baseline. A negative value inserts the subassembly onto the left side. The insertion point input parameter could be named any of the following, depending on the function of the subassembly: Insert Point Offset, Sample Point Offset, Daylight Offset from Baseline.

The following are examples of subassemblies that do not contain an input parameter named Side. For these types of subassemblies, you specify the side by using positive and negative values for the insertion point input parameter.

■ DaylightToOffset

■ DaylightToRow

■ LinkOffsetAndElevation

■ LinkOffsetAndSlope

■ LinkOffsetOnSurface

■ OverlayMillAndLevel1

■ OverlayWidenMatchSlope1

■ OverlayWidenWithSuper

You can also use the Mirror option to automatically copy a subassembly, or multiple subassemblies, from one side of an assembly to the other. For more information, see Creating an Assembly (page 1380)

**To insert a subassembly on the left side of a corridor using the Side parameter**

1  Click Home tab ➤ Create Design panel ➤ Assembly drop-down ➤ Create Assembly 🏗 .

2  In the Create Assembly (page 1784) dialog box, accept the default settings. Click OK.

3  When you are prompted to specify the assembly baseline location, click a point in the drawing to insert the assembly.

4  In the Tool Palettes window, open the Imperial - Basic tool palette by clicking the Imperial - Basic tab. (To display the Tool Palettes window, click Home tab ➤ Palettes panel ➤ 🗔 .)

5  Click the BasicLane subassembly. The Properties dialog box is displayed for the BasicLane subassembly. Note that the Side parameter is set to Right by default.

6  Click on the assembly. The BasicLane subassembly is inserted onto the right side of the assembly.

7  On the tool palette, click the BasicLane subassembly again. Again the Properties dialog box is displayed.

8  In the Properties dialog box, in the Advanced section, click the value for the Side parameter and change it from Right to Left.

9  Click on the assembly. The BasicLane subassembly is inserted on the left side of the assembly.

**To insert a subassembly on the left side of a corridor using (negative) insertion point values**

1  Click Home tab ➤ Create Design panel ➤ Assembly drop-down ➤ Create Assembly 🏗 .

2  In the Create Assembly dialog box, accept the default settings. Click OK.

**3** When you are prompted to specify the assembly baseline location, click a point in the drawing to insert the assembly.

**4** In the Tool Palettes window, open the Imperial - Daylight tool palette by clicking the Imperial - Daylight tab. (To display the Tool Palette window, click Home tab ➤ Palettes panel ➤ ⬚ .)

**5** Click the DaylightToOffset subassembly. The Properties dialog box is displayed for the DaylightToOffset subassembly. Note that the Daylight Offset from Baseline parameter is set to 10 by default.

**6** Click on the assembly. The DaylightToOffset subassembly is inserted onto the right side of the assembly.

**7** On the tool palette, click the DaylightToOffset subassembly again. Again the Properties dialog box is displayed.

**8** In the Properties dialog box, in the Advanced section, click the value for the Daylight Offset from Baseline parameter and change it from positive 10 to negative 10.

**9** Click on the assembly. The DaylightToOffset subassembly is inserted on the left side of the assembly.

**To insert a subassembly on the left side of a corridor using Mirror**

**1** Click Home tab ➤ Create Design panel ➤ Assembly drop-down ➤ Create Assembly 🏭 .

**2** In the Create Assembly (page 1784) dialog box, accept the default settings. Click OK.

**3** When you are prompted to specify the assembly baseline location, click a point in the drawing to insert the assembly.

**4** In the Tool Palettes window, open the Imperial - Basic tool palette by clicking the Imperial - Basic tab. (To display the Tool Palette window, click Home tab ➤ Palettes panel ➤ ⬚ .)

**5** Click the BasicLane subassembly. The Properties dialog box is displayed for the BasicLane subassembly. Note that the Side parameter is set to Right by default.

**6** Click on the assembly. The BasicLane subassembly is inserted onto the right side of the assembly.

**7** On the assembly, right-click on the BasicLane subassembly and click Mirror. The BasicLane subassembly is inserted on the left side of the assembly. Note that the Mirror option is only available for subassemblies that contain a Side parameter.

# Managing and Editing Subassemblies

There are a variety of ways you can work with subassemblies in AutoCAD Civil.

## Deleting a Subassembly

Deleting a subassembly erases it from the drawing and removes it from the Subassemblies collection in the Prospector tree.

When you delete an assembly, and subassemblies associated with that assembly are also deleted.

**To delete a subassembly, do one of the following**

- In the drawing area, right-click the subassembly and click Basic Modify Tools ➤ Erase.

- In the Prospector tree, right-click the subassembly and click Delete.

The subassembly is erased from the drawing and removed from the Subassemblies collection in the Prospector tree. If the subassembly was attached to an assembly, it is removed from the assembly too.

### Quick Reference

Object Shortcut Menu

   Right-click subassembly ➤ Basic Modify Tools ➤ Erase

Toolspace Shortcut Menu

   Prospector tab: Subassemblies ➤ Right-click <subassembly name> ➤ Delete

## Managing Subassembly Groups

Each subassembly added to an assembly is automatically associated with a named group within the assembly.

Subassembly groups manage the order in which subassemblies are processed during corridor modeling. The first time you add a subassembly to an assembly, the subassembly is added to the first group. When you add a second subassembly by attaching it to the first subassembly, the second subassembly also gets added to the first subassembly group. The next time you select an assembly baseline, a new subassembly group is automatically created and subsequent subassemblies added to the assembly are added that group.

The Construction tab (page 1779) of the Assembly Properties dialog box displays the subassembly groups for a given assembly. The location of the groups on this tab reflects the order in which the subassemblies are processed. The group of subassemblies located at the very top of the list is processed first, in top-to-bottom order. The group of subassemblies located directly beneath the top group is processed second, and so on.

**NOTE** Subassembly groups are not processed according to the numeric order associated with their subassembly group name. For example, a subassembly group named Group (1) located at the bottom of the Item list is processed last, even though the group is named Group (1).

You can change the order of subassembly groups by moving them up or down. However, you cannot reorder subassemblies within a group. If you delete subassemblies or subassembly groups using this tab, the subassemblies are deleted from the drawing.

Subassemblies that are not associated with assemblies (detached subassemblies and subassemblies created from polylines) are not associated with groups.

**To move a subassembly group**

**1** In Toolspace, on the Prospector tab, expand the Assemblies collection and right-click an existing assembly.

**2** Click Properties.

**3** Click the Construction tab.

**4** In the Item list, right-click the name of a subassembly group and select Move up or Move down.

The group of subassemblies is moved up or down in the list.

## Previewing a Subassembly

You can preview a subassembly in the Prospector Item List View.

**To preview a subassembly**

**1** In Toolspace, on the Prospector tab, right-click the Subassemblies collection and click Show Preview.

**NOTE** A check mark is displayed next to the Show Preview menu item when the preview is enabled.

**2** In the Prospector tree, click the subassembly you want to preview.

The subassembly is displayed in the Prospector item view.

**NOTE** The preview of the subassembly uses the same display styles as the subassembly in the drawing area.

### Quick Reference

Toolspace Shortcut Menu

## Converting VBA Subassemblies to .NET

You can convert AutoCAD Civil stock subassemblies that are VBA-based to .NET.

In Civil 3D 2007, and in earlier versions of Civil 3D, the subassemblies that were included in the product were created using VBA.

In Civil 3D 2008, all of the subassemblies included in the product were created using .NET. This is because .NET versions of subassemblies provide faster performance than VBA-based subassemblies when generating corridor models. Civil 3D 2008, and later versions, still support VBA-based subassemblies. For example, in drawings, catalogs, and tool palettes, you can have a mix of VBA-based and .NET-based subassemblies. However, it is recommended that you convert VBA-based subassemblies to .NET using the following procedure to achieve optimal performance when generating corridor models.

**NOTE** This command only converts the VBA-based AutoCAD Civil stock subassemblies that were included with the product. It does not convert any VBA-based subassemblies that were created from user-defined (custom) VBA code.

To determine if a subassembly is VBA-based, .NET-based, or created from a polyline, use the Subassembly Properties dialog box or the Properties palette to display the subassembly definition.

For information on creating custom subassemblies, see the AutoCAD Civil Developer's Guide.

**To display the subassembly definition in the Subassembly Properties dialog box**

1 Right-click a subassembly in the drawing and click Subassembly Properties.

2 In the Subassembly Properties dialog box, click the Parameters tab.

The Defined From field displays .NET if the subassembly was created using .NET, VBA if it was created using VBA, and Entities if the subassembly was created from a polyline.

**To display the subassembly definition in the Properties palette**

1 Right-click a subassembly in the drawing and click Properties.

2 On the Properties palette, click the Design tab.

The Geometry Generate Mode property displays .NET if the subassembly was created using .NET, VBA if it was created using VBA, and Entities if the subassembly was created from a polyline.

**To convert subassemblies from VBA to .NET**

1 Click Modify tab ➤ Design panel ➤ ▼ ➤ Convert VBA Subassemblies To .NET ⬛ .

2 Do one of the following:

■ To convert all subassemblies in the drawing, at the command line, enter **A**, and then press Enter. All VBA subassemblies in the drawing are converted to VB.NET.

■ To convert all subassemblies in a selected assembly, select an assembly, and then press Enter. All VBA subassemblies in the selected assembly are converted to VB.NET.

# Sharing Subassemblies

You can access and share subassemblies using tool palettes, the AutoCAD Civil Corridor Modeling catalogs, or package files.

For example, you can create custom subassemblies in your drawing, and then drag and drop them onto a tool palette or catalog. You can create a tool palette or catalog that contains multiple custom subassemblies and then share that tool palette or catalog with others.

Custom subassemblies that have been created using .NET or VBA can be exported and imported using a package file. Subassemblies created from polylines cannot be included in a package file.

A package file contains all the files necessary for the custom subassemblies to work. Once the package file is created, users can import the package file contents into AutoCAD Civil using the ImportSubassemblies command, and copy the custom subassemblies directly into a tool palette or catalog. You can also share a package file with others. For example, you could attach a package file containing one or more subassemblies to an e-mail, or use other file transfer methods.

For more information on creating package files, see Exporting Custom Subassemblies Using a Package File in the *AutoCAD Civil Developer's Guide*.

For information on adding subassemblies to tool palettes, see Tool Palettes (page 105).

**To copy (import) subassemblies from a package file to a tool palette**

1   To display the Tool Palettes window:

    Click Home tab ➤ Palettes panel ➤ 　 .

2   Open the tool palette that you want to copy the subassemblies into. You may open an existing tool palette or create a new one.

3   Click Insert tab ➤ Import panel ➤ ▼ ➤ Import Subassemblies 　 .

4   On the Import Subassemblies (page 1787) dialog box, click the folder icon to navigate to and select the package file.

5   In the Import To section, click Tool Palette, and then select the desired tool palette in the drop-down list.

    **NOTE** You can import the subassemblies to a tool palette and to a catalog at the same time. When you import subassemblies to a catalog, they automatically get imported to the My Imported Tools catalog. If the My Imported Tools catalog does not exist, it is automatically created.

6   Click OK.

The subassemblies contained in the package file are copied to the tool palette. If you chose to copy the subassemblies to a catalog at the same time, the subassemblies are also copied to the My Imported Tools catalog.

**NOTE** Subassemblies created from polylines cannot be included in a package file. Package files are intended for sharing custom subassemblies that have been created using .NET or VBA.

**To copy (import) subassemblies from a package file to a catalog**

1   To display the corridor modeling catalogs:

    Click View tab ➤ Palettes panel ➤ 　 .

    **TIP** When working with both the AutoCAD Civil workspace and the Content Browser, you may find it useful to have the Content Browser window displayed at all times. To do this, right-click in the Content Browser title bar and select Always On Top.

2   Click Insert tab ➤ Import panel ➤ ▼ ➤ Import Subassemblies 　 .

**3** On the Import Subassemblies (page 1787) dialog box, click the folder icon to navigate to and select the package file.

**4** In the Import To section, click Catalog Library/My Imported Tools.

> **NOTE** You can import the subassemblies to a tool palette and to a catalog at the same time. When you import subassemblies to a catalog, they automatically get imported to the My Imported Tools catalog. If the My Imported Tools catalog does not exist, it is automatically created.

**5** Click OK.

The subassemblies contained in the package file are copied to the My Imported Tools catalog.

> **NOTE** When you import subassemblies to a catalog using this method (package files), you can only copy the subassemblies to the My Imported Tools catalog. If the My Imported Tools catalog does not exist, one is automatically created. Once the subassemblies are in the My Imported Tools catalog, you can then copy them to other catalogs.

If you chose to copy the subassemblies to a tool palette at the same time, the subassemblies are also copied to the selected tool palette.

> **NOTE** Subassemblies created from polylines cannot be included in a package file. Package files are intended for sharing custom subassemblies that have been created using .NET or VBA.

### Quick Reference

Import Subassemblies (page 1787)

# Using Codes and Code Set Styles

Codes can be associated with the point, link, and shape components of a subassembly.

Codes allow you to apply simple or complex rules governing the offset and elevation behavior of subassemblies. You can choose to add codes to certain subassembly components to implement presentation or annotation features to a corridor design.

A typical subassembly is comprised of the following components, which can have codes associated with them:

- **Point.** Define the basic subassembly structure.

- **Link.** Connect points to form planar structural surfaces of a corridor.

- **Shape**. Defined from links and define a closed region that represents materials used in a corridor model.

For a set of point, link or shape components, you can define a set of display characteristics and assign them to a code set style. You can then assign a code set style to a subassembly, assembly, corridor, or section view.

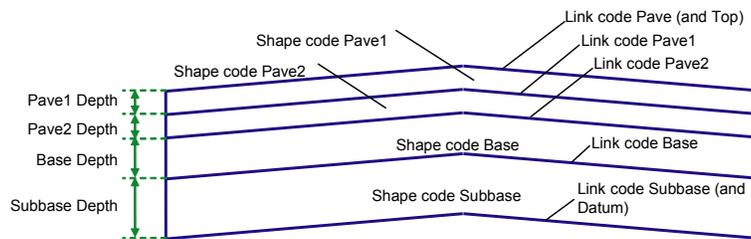
You can assign appropriate label styles to various code sets in the code set styles.

## Pavement Structure of Paved Sections

The AutoCAD Civil Corridor Modeling subassemblies that model paved components of a roadway, such as travel lanes and shoulders, allow multiple material layers to be defined.

These material layer sections are defined by sets of links. The typical structure is shown in the following diagram.

**Pavement Structure on Paved Sections**



The standard link codes from top to bottom are Pave, Pave1, Pave2, Base, and Subbase. The code Top is also assigned to all finish grade links, thus coinciding with the Pave links on paved sections. The code Datum is also assigned to the bottom of subbase. The shape codes for the material areas from top to bottom are Pave1, Pave2, Base, and Subbase.

The subassemblies that create paved sections have the depth or thickness of each layer as user-definable input parameters. Each subassembly that creates paved sections closes the layer areas to form a closed shape, even if those layers actually continue into the adjacent component. Layers can be omitted by setting the corresponding depth to zero. This collapses that layer so that the shape also has a zero area.

## Understanding Point, Link, and Shape Codes

The optional codes associated with a subassembly point, link, or shape components determine some of the behavior you will see in corridor modeling.

When designing custom subassemblies, you must consider not only the geometric shape of the corridor model that will ultimately be created by the subassemblies, but also how the model is used for post-modeling design operations. These operations include:

- Design surface modeling

- Combining the corridor model with grading models

- Earthwork and material volume analysis

- Design visualization and rendering

- Right-of-way acquisition

- Slopestake reporting

- Export to survey data recorders for construction stakeout

- Plans production

- Staged construction modeling

Nearly all of these operations depend on the codes assigned to points, links, and shapes in the corridor model. To create models that integrate into all of the operations listed above, the coding scheme must be carefully designed before creating the first subassembly. The best practice is to diagram all of the different roadway types and situations that can be anticipated for the users you are supporting. Next, devise and annotate codes for all critical points, links, and shapes. Use this diagram when documenting the codes for each subassembly. Note that it is difficult to design a single set of codes that meet needs of every operation. For this reason, AutoCAD Civil lets you assign any number of codes to each point, link, and shape. How these codes are utilized is described in the following sections.

### Creating Point, Link, and Shape Codes

You can create new point, link, and shape codes using a .NET language.

For more information about creating point, link, and shape codes using .NET languages, see *AutoCAD Civil Developer's Guide.*

For more information about assigning code set styles to point, link, and shape codes, see Using Codes and Code Set Styles (page 1405).

### Point Codes

Point codes are the feature codes assigned to the endpoints of the links that make up the subassembly component

| Operation | Description |
|---|---|
| Corridor Modeling | The corridor model is represented graphically by roadway cross sections at predetermined stations, with longitudinal strings connecting points between adjacent stations. Points with the same code and in the same region of the section are automatically connected with longitudinal lines. |
| Plans Production | Many organizations require that critical points be annotated on cross section drawings. For example, a given state's Department of Transportation may require the following: 1.) Elevations at ditch bottoms, 2.) Slopes (x:1) of ditch sides, clear zones, and cut/fill daylight links, 3.) % Slopes of lanes and shoulders, 4.) Offsets of the cut/fill daylight points. To create custom cross-section sheet utilities that meet these requirements, these points must be identifiable within the model. Another plans production operation is depicting the limits-of-construction in plan view, with different symbology and line types used for cut lines and fill lines. |
| Design Surface Modeling and Staged Design | Point codes make it possible to extract finish grade profiles at critical points on the corridor model surfaces. For example, a profile connecting the left edge-of-pavement points of a roadway can be used in drainage analysis and design, tying links from an adjacent road's model, and to combine corridor models with grading models. |

| Operation | Description |
| --- | --- |
| Right-of-Way Analysis | The limits-of-construction of the corridor model can be determined by extracting alignments or figures that connect the cut/fill daylight points on each side of the model. These are used to determine what property has to be acquired. |
| Slopestake reporting and construction stakeout | Identifying critical points on the different layers of the corridor model is essential to creating construction staking reports, or when exporting data to survey data recorders for construction stakeout. Since grading is nearly always done to the subbase line, not to the finish grade, it may be necessary to define distinct codes on both the finish grade and subbase surface links. For example, the edge-of-traveled-way may use code ETW on finish grade, and ETW_Sub on the subbase layer. |

The cut/fill daylight points are a good example of where two codes may be needed for the same point. If the daylight points for both cut and fill links have the code "Daylight", then it is easy to depict and extract a single figure defining the limit of construction on each side. If the same points have the code "Daylight_Cut" or "Daylight_Fill," depending on circumstances, it is also easy to annotate cut and fill daylight lines differently.

### Link Codes

Link codes are the feature codes assigned to each of the links that make up the roadway component. A link is defined as a single straight-line segment between endpoints.

| Operation | Description |
| --- | --- |
| Design surface modeling | Design surfaces can be built by extracting all links with a particular code. Link codes should be designed so that it is easy to extract the types of surfaces needed for surface modeling. Typically these are used for earthwork calculations, additional grading, visualization, and drainage analysis. Depending on the application, you may need to extract paved surfaces, all finish grade surfaces, or subbase surfaces. |
| Earthwork and material volume analysis | Different layers of the corridor model can be separated and used for volume calculations using tables that define materials in terms of which link codes are above, below, left, and right of the material layers. Simple cut and fill quantities are usually determined by comparing the existing ground to a combination of unpaved finish grade links and subbase links. Pavement layers, such as wearing course, asphalt base, and granular subbase, are determined based on the surface links defining those as closed areas. |
| Visualization and rendering | For realistic renderings of design surfaces, it is useful to distinguish between different surface materials such as pavement, gravel, grass, and concrete. |

To meet the requirements of these operations, it is usually necessary to assign multiple codes to links on certain portions of the roadway. A typical scheme:

| Link Code | Description |
| --- | --- |
| Top | Assigned to all links on the finished grade, whether paved or unpaved |
| Pave | A second code assigned to all paved links on the finished grade |
| Datum | Assigned to all unpaved finished grade links, and all links on the bottoms and sides of the subbase layers |
| Subbase | Assigned to all links on the bottoms and sides of the subbase layers |

Thus, the Top links can be used to build a surface model of the entire finished grade surface, which is used for visualization and drainage analysis. The Pave links can be used to render the paved portions of the finished grade surface with a particular color or texture. The Datum links can be used to model the surface that is graded with earth moving equipment, and is also used for simple cut and fill volume analysis. The Subbase links are used to define the bottom of the granular base material areas for material volume analysis.

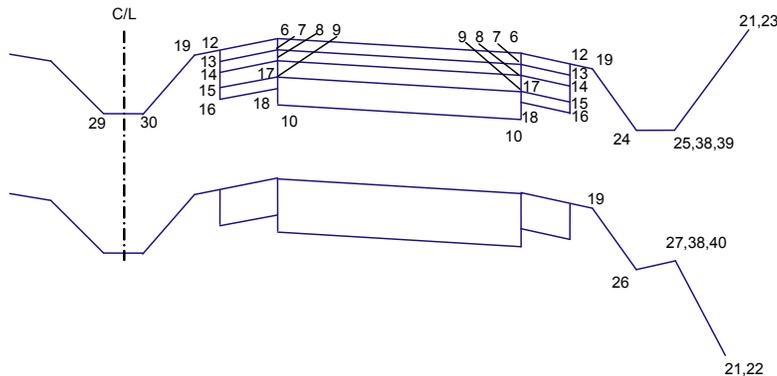
### Shape Codes

Shapes are closed cross-sectional areas created by a single subassembly. The primary use for shape codes; defining hatch patterns for different materials, and to extract areas for material volume tabulation. The codes should reflect how you want the materials identified in the earthwork reports.

# Standard Point Codes

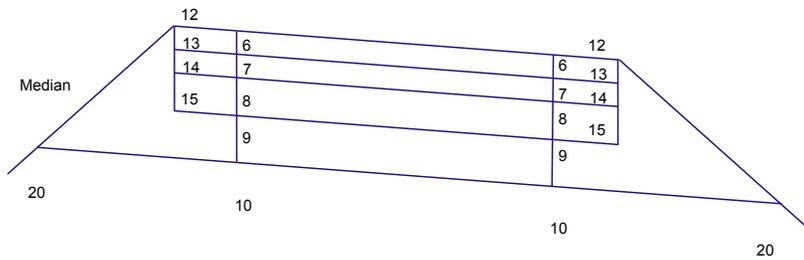
A set of standard codes define the display and behavior of the point components used in the AutoCAD Civil Corridor Modeling subassemblies.

The following illustration shows the location of the standard point codes on subassemblies defining a divided road with a depressed median and truncated shoulders.



**Divided Road with Depressed Median; Truncated Shoulders**

The table following the illustrations provides descriptions of the point codes used in the illustrated assemblies.

The following illustration shows the location of the standard point codes on subassemblies defining a divided road with a depressed median and extended shoulders:


**Divided Road with Depressed Median; Extended Shoulders**

The following illustration shows the location of the standard point codes on subassemblies defining an undivided road with a curb-and-gutter. Not all layers are shown.

**Undivided Road with Curb-and-Gutter; Not All Layers Shown**

The table below names and describes the standard point codes used in the example assembly illustrations.

**Point Codes**

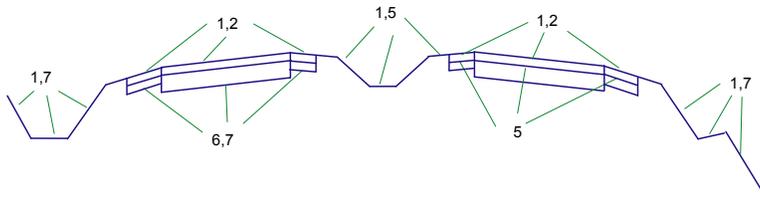
| No. | Code | Description |
| --- | --- | --- |
| 1 | Crown | Crown point between travel lanes on finish grade. |
| 4 | Crown_Base | Crown point between travel lanes on the base layer. |
| 5 | Crown_Sub | Crown point between travel lanes on the subbase layer. |
| 6 | ETW | Edge of traveled way; inside or outside edges of travel lanes on finish grade. |
| 7 | ETW_Pave1 | Edge of traveled way on the Pave1 layer. |
| 8 | ETW_Pave2 | Edge of traveled way on the Pave2 layer. |
| 9 | ETW_Base | Edge of traveled way on the base layer. |
| 10 | ETW_Sub | Edge of traveled way on the subbase layer. |
| 12 | Lane_Pave1 | Lane break point on Pave1. |
| 13 | Lane_Pave2 | Lane break point on Pave2. |
| 14 | Lane_Base | Lane break point on Base. |
| 15 | Lane_Sub | Lane break point on Subbase. |

| No. | Code | Description |
| --- | --- | --- |
| 16 | EPS | Edge of paved shoulder; outer edge of paved portions of shoulder on finish grade. |
| 17 | EPS_Pave1 | Edge of paved shoulder on the Pave1 layer. |
| 18 | EPS_Pave2 | Edge of paved shoulder on the Pave2 layer. |
| 19 | EPS_Base | Edge of paved shoulder on the Base layer. |
| 20 | EPS_Sub | Edge of paved shoulder; outer edge of paved portions of shoulder on the Subbase layer. |
| 21 | EPS_Base_In | Inside edge of paved shoulder on the base layer. |
| 22 | EPS_Sub_In | Inside edge of paved shoulder on the subbase layer. |
| 23 | ES_Unpaved | Edge of gravel shoulder; outer edge of unpaved portions of shoulder on finish grade. |
| 24 | Daylight_Sub | Subgrade intercept point; point where the subbase surface extends and intersects the finish grade. |
| 25 | Daylight | Daylight point for a cut or fill slope. |
| 26 | Daylight_Fill | Daylight point for a fill slope. |
| 27 | Daylight_Cut | Daylight point for a cut slope. |
| 29 | Ditch_Out | Outside edge of ditch. |
| 30 | Bench_In | Inside edge of bench. |
| 31 | Bench_Out | Outside edge of bench. |
| 32 | Flowline_Ditch | Flowline of a V-shaped ditch. |
| 33 | LMedDitch | Left edge of median ditch. |
| 38 | Bottom_Curb | Bottom of curb for a curb without gutter. |
| 39 | Back_Curb | Back of curb. |
| 40 | Sidewalk_In | Inside edge of sidewalk. |

To view all actual code numbers, the code names and brief code descriptions: In Notepad, open ..\Documents and Settings\All Users\Application Data\Autodesk\C3D2010\enu\C3DStockSubassemblyScripts.codes.

## Standard Link Codes

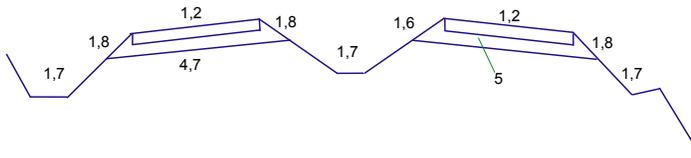
A set of standard codes define the display and behavior of the link components used in the AutoCAD Civil Corridor Modeling subassemblies.

The following illustration shows the location of the standard link codes on subassemblies defining a divided road with a depressed median and truncated shoulders.


**Divided Road with Depressed Median; Truncated Shoulders**

The table following the illustrations provides descriptions of the link codes used in the illustrated assemblies.

The following illustration shows the location of the standard link codes on subassemblies defining a divided road with a depressed median and extended shoulders.



**Divided Road with Depressed Median; Extended Shoulders**

The following illustration shows the location of the standard link codes on subassemblies defining an undivided road with a curb-and-gutter. Not all layers are shown.

**Undivided Road with Curb-and-Gutter; Not All Layers Shown**

The table below names and describes the standard link codes used in the example assembly illustrations.

**Link Codes**

| No. | Code | Description |
|---|---|---|
| 1 | Top | Traces all links on finished grade, including: <br> Unpaved finish grade links (clear zone, cut/fill slopes) <br> Top paved surface on paved sections. <br> Gutter, face of curb, and top of curb. <br> Top of sidewalk. <br> For most roadways, the Top links trace the finished grade surface from the left catch point to the right catch point. These links would build the finish grade surface. |
| 2 | Pave | Any finished grade surface on a paved section. |
| 5 | Base | All links on the base surface of paved sections. |

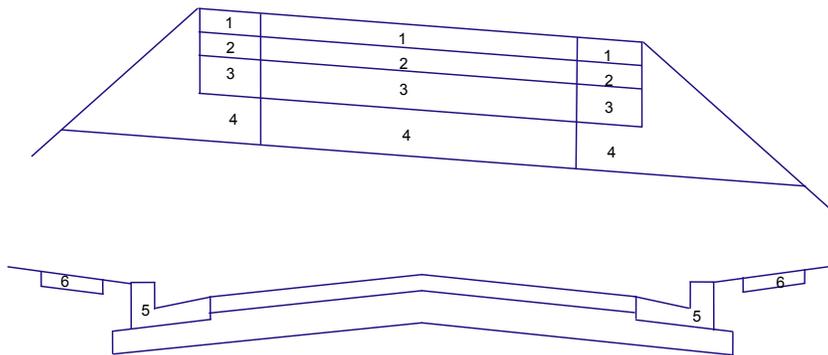
| No. | Code | Description |
|-----|------|-------------|
| 6 | SubBase | All links on the subbase surface of paved sections. |
| 7 | Datum | All finish grade links on unpaved sections, and all subbase links on paved sections. For most roadways, the Datum links trace the unpaved finished grade and subbase from the left catch point to the right catch point. These links would build the surface used to calculate cut and fill volumes. |
| 8 | Gravel | Finish grade surfaces above gravel shoulders with subbase. |
| 12 | Curb | All links comprising a curb or curb and gutter. |
| 13 | Sidewalk | All links comprising a sidewalk. |

To view all actual code numbers, the code names and brief code descriptions: In Notepad, open ..\Documents and Settings\All Users\Application Data\Autodesk\C3D2010\enu\C3DStockSubassemblyScripts.codes.

## Standard Shape Codes

A set of standard codes define the display and behavior of the shape components used in the AutoCAD Civil Corridor Modeling subassemblies.

The following illustration shows the location of some standard shape codes on subassemblies defining an undivided road with a curb-and-gutter:



**Undivided Road with Curb-and-Gutter**

The table below names and describes the standard shape codes used in the example assembly illustration.

**Shape Codes**

| No. | Code | Description |
|-----|------|-------------|
| 1 | Pave1 | Closed shape between the finish grade and first pavement surface on paved sections. |
| 2 | Pave2 | Closed shape between the first and second pavement surface on paved sections. |
| 3 | Base | Closed shape between the second pavement surface and the base surface on paved sections. |

| No. | Code | Description |
|---|---|---|
| 4 | SubBase | Closed shape between the base and subbase surfaces on paved sections. |
| 5 | Curb | Closed area within a concrete curb or curb and gutter. |
| 6 | Sidewalk | Closed area within a concrete sidewalk. |

To view all actual code numbers, the code names and brief code descriptions: In Notepad, open ..\Documents and Settings\All Users\Application Data\Autodesk\C3D2010\enu\C3DStockSubassemblyScripts.codes.

## Adding Codes to a Subassembly

Add codes to a subassembly created from a polyline.

After you create a subassembly from a polyline, the next step is to add the necessary codes to the subassembly. For more information, see Creating Subassemblies From Polylines (page 1397).

**To add a code to a subassembly created from a polyline**

1 In the drawing, select the subassembly, then right-click it and click Add Code.

2 Enter the code and press Enter.

> **NOTE** The code you enter must be an existing code, or, if it is a new code, you must make sure that it gets added to the codes file (*C3DStockSubassemblyScripts.codes*). For more information, see Adding a New Code to the AutoCAD Civil Stock Subassemblies (page 1419).

3 Select a point, link, or shape on the subassembly.

4 To see the code, in Toolspace, on the Prospector tab, right-click the subassembly and select Properties. Click the Codes tab. The code added is displayed in the Name column under the point, link, or shape collections.

**To remove codes from a subassembly created from a polyline**

1 In the drawing, select the subassembly from which you want to remove the code.

2 Click Subassembly tab ➤ Modify Subassembly panel ➤ Remove Code .

3 Click the point, link, or shape on the subassembly.
 The code is removed from the subassembly.

### Quick Reference

RemoveSubassemblyCodes

# Using Code Set Styles

Use code set styles to control the visual appearance of a code set (link, point, and shape codes). You can create specific styles to use for the different aspects of an assembly or corridor.

Since subassemblies can be displayed in a number of objects, code set styles are applicable to those objects as well. Below are the objects code set styles can be associated with:

■ Subassemblies

■ Assemblies

■ Corridors

■ Section views

An individual subassembly typically contains just a few points, links and shapes. Therefore, most subassemblies typically contain a relatively simple code list. Since an assembly manages a group of subassemblies, the code list for an assembly is comparatively larger. Furthermore, since a corridor can have multiple assemblies applied within it, the code list becomes larger and complex. The same holds true for the section views.

## Adding or Importing Codes to a Code Set Style

Add or import codes to a code set style. Both methods use the Codes tab of the Code Set Style dialog box. Click the Add button to add a new or existing code, or use the Import Codes button to import codes from a subassembly, assembly, or corridor object.

**To add a code to a code set style**

1   In Toolspace, on the Settings tab, expand the General collection, the Multipurpose Styles collection, then the Code Set Styles collection, and right-click an existing style.

2   Click either Copy or Edit.

3   In the Code Set Style dialog box, click the Codes (page 1783) tab.

4   Right-click a code collection (one of Link, Point, or Shape) in the Name column. Click Add.

5   In the Pick Style dialog box, select a style for the code.

6   In the Name column, click NEW CODE, enter the name of the code you want to add, and press Enter.

7   Click Apply.

**To import codes to a code set style**

1   In Toolspace, on the Settings tab, expand the General collection, the Multipurpose Styles collection, then the Code Set Styles collection, and right-click an existing style.

2   Click Copy or Edit.

3   In the Code Set Style dialog box, click the Codes (page 1783) tab.

4   Click Import Codes.

5   In the drawing, click on a subassembly, assembly, or corridor object, and press Enter. The codes are automatically displayed in the Codes tab list.

6   Click Apply.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: General collection ➤ Multipurpose Styles collection ➤ Code Set Styles collection ➤ Right-click <style name>

Dialog Box

Codes tab (Code Set Style) (page 1783)

## Copying or Editing Code Set Styles

Use the Settings tree to copy or edit a code set style by clicking an existing style, making modifications and then saving it with a new name.

**To copy or edit a code set style**

1   In Toolspace, on the Settings tab, expand the General collection, the Multipurpose Styles collection, then the Code Set Styles collection, and right-click an existing style.

2   Click Copy or Edit.

3   In the Code Set Style dialog box, click the Information (page 1783) tab and enter a new name and description for the code set style.

4   Click the Codes (page 1783) tab to define styles for each link, point (marker), or shape code associated with this code set.

5   Click Apply.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click <code set style item>

Dialog Box

Code Set Style (page 1783)

## Copying or Editing Link Styles

Use the Settings tree to copy or edit a link style by clicking an existing style, making modifications and then saving it with a new name.

**To copy or edit a link style for subassembly links**

1   In Toolspace, on the Settings tab, expand the General collection, the Multipurpose Styles collection, then the Link Styles collection, and right-click an existing style.

2   Click Copy or Edit.

3   In the Link Style dialog box, click the Information (page 1788) tab and enter a new name and description for the link style.

4   To define the display properties for the link style, click the Display (page 1788) tab and specify the display properties for the link.

5   To view a summary of information about the style, click the Summary (page 1788) tab.

**6**  Click Apply.

## Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click <link style item>.

Dialog Box

[Link Style](#) (page 1787)

## Copying or Editing Marker Styles

Use the Settings tree to copy or edit a marker style for subassembly points by clicking an existing style, making modifications and then saving it with a new name.

**To copy or edit a marker style for subassembly points**

**1**  In Toolspace, on the Settings tab, expand the General collection, the Multipurpose Styles collection, then the Marker Styles collection, and right-click an existing style.

**2**  Click Copy or Edit.

**3**  In the Marker Style dialog box, click the [Information Tab (Marker Style Dialog Box)](#) (page 1788)tab and enter a new name and description for the marker style.

**4**  To define the symbol used to display markers, click the [Marker](#) (page 1788) tab and specify the type of symbol, as well as the size, scaling and rotation, for the marker symbol.

**5**  To define the display properties for the marker style, click the [Display](#) (page 1789) tab and specify the display properties for the marker.

**6**  To view a summary of information about the style, click the [Summary](#) (page 1789) tab.

**7**  Click Apply.

## Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click <marker style item>

Dialog Box

[Marker Style](#) (page 1788)

## Copying or Editing Shape Styles

Use the Settings tree to copy or edit a shape style by clicking an existing style, making modifications and then saving it with a new name.

**To copy or edit a shape style for subassembly shapes**

**1**  In Toolspace, on the Settings tab, expand the General collection, the Multipurpose Styles collection, then the Shape Styles collection, and right-click an existing style.

**2**  Click Copy or Edit.

**3** In the Shape Style dialog box, click the Information (page 1790) tab and enter a new name and description for the shape style.

**4** To define the display properties for the shape style, click the Display (page 1790) tab and specify the display properties for the shape.

**5** To view a summary of information about the style, click the Summary (page 1790) tab.

**6** Click Apply.

Shape Style (page 1790)

# Localizing or Modifying Subassembly Codes

For localization purposes, the AutoCAD Civil stock subassemblies use an external codes file to define the point, link, and shape codes referenced in the subassemblies.

The external codes file is named C3DStockSubassemblyScripts.codes and is located in the same folder as the C3DStockSubassemblyScripts.dvb file and/or C3DStockSubassemblies.dll file. By default, on English-language based systems, this location is typically C:\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu. For non-English-language-based systems, the "enu" location corresponds to the appropriate language or region.

The codes file is associated with each subassembly with the CodesSpecific module in the .dvb file. The following sections explain the definition of the code files and how to edit it or add point, link, and shape codes to it.

The CodesSpecific module is in the CodesSpecific.vb file of the C3DStockSubassemblies VB project in the case of .NET subassemblies, and in the .dvb file in the case of VBA subassemblies.

### Understanding the C3DStockSubassemblyScripts.codes File

You can open the C3DStockSubassemblyScripts.Codes file with any text editor. Add comments in this file by adding // in front of a sentence. Do not leave any blank lines in the file. Each code line is separated with a return character. Each code definition is comprised of the following components, separated by commas:

■ Index Number: An integer value used (for a point, link, or shape as required) to assign a label to the subassembly module.

■ Localized Code: The value that will be displayed AutoCAD Civil in your Subassembly, Assembly, and or Corridor Properties Codes tab, and is used to set the style for the link.

■ Original Code: The code variable used by AutoCAD Civil. No matter what localized version of the subassembly is used, it is interpreted the same way to make drawings portable across different language versions.

■ Code Description: A localized description to further explain the functionality associated with this code. This text is displayed in the Description column of the Codes tab on the subassembly, assembly, and or corridor properties dialog box. This text is optional.

**NOTE** Codes files must be saved in Unicode format. For example, if you are using Notepad to update the codes file, when you save the file, the Save As dialog box lets you choose an encoding method. Make sure you choose Unicode.

The following is an example of a code definition line in the C3DStockSubassemblyScripts.codes file:

```
38,BottomCurb,BottomCurb,Bottom of curb for a curb without gutter.
```

The Index number is: `38`

The Localized Code is: `BottomCurb`

The Original Code is: `BottomCurb`

The Code Description is: `Bottom of curb for a curb without gutter.`

**Modifying Default Codes for AutoCAD Civil Stock Subassemblies**

To change or localize code display names, open the C3DStockSubassemblyScripts.codes file in a text editor and change the Localized Code and or corresponding code description.

For example, the display name of the Curb Bottom can be changed by editing the following bolded components in the C3DStockSubassemblyScripts.codes file as follows:

38,BottomKerb,BottomCurb,Bottom of kerb for a kerb without gutter

**Adding a New Code to the AutoCAD Civil Stock Subassemblies**

If you want to modify existing subassemblies to new codes, or add a new subassembly module, and you would like to use the same structure as default content, for .NET subassemblies you can do the following:

1 Add `<New Code>` at the end of the C3DStockSubassemblyScripts.Codes file, with a new index, localized name, original code, and optional description.

2 In the CodesSpecific.vb of the C3DStockSubassemblies VB project, add the following at the end of the AllCodes structure: `Public <New Code> as CodeType`

3 In the CodesSpecific.vb of the `With/End With` block of the `FillCodeStructure` routine, add the following at the end: `GetFromCollection colCodesAndDescriptionHashtable, n, .<NewCode>`

4 Declare the default value, in case the codes file is not found, for the `CodesDefault(<New Code Index>)` in InitializeDefaults() function of the `CodesSpecific` module.

5 Change the size of array `CodesDefault` in the `CodesSpecific` module in the `Dim` statement.

A new code added using these procedures can be used for any existing or new .NET-coded subassemblies in AutoCAD Civil Stock Subassemblies.

For VBA subassemblies, you can do the following:

1 Add `<New Code>` at the end of the C3DStockSubassemblyScripts.Codes file, with a new index, localized name, and optional description.

2 In the CodesSpecific module of C3DStockSubassemblyScripts.dvb file, add the following at the end of the AllCodes structure: `g_s<New Code> as CodeType`

3 In the CodesSpecific file, in the `With/End With` block of the `FillCodeStructure` routine, add the following at the end: `GetFromCollection colCodesAndDescriptionHashtable, n, .g_s<NewCode>`

4 Declare the default value, in case the codes file is not found, for the `g_arrDefaults(<New Code Index>)` in InitializeDefaults() function of the `CodesSpecific` module.

5 Change the size of array `g_arrDefault` in the `CodesSpecific` module.

A new code added using these procedures can be used for any existing or new VBA-coded subassemblies in AutoCAD Civil Stock Subassemblies.

**NOTE** The process of associating point codes is primarily done for easy localization of default content. If you are writing custom subassemblies, you do not have to follow this procedure. You can create a new module that contains a customized list of codes your subassemblies can reference. You can also bypass this process by hard-coding strings locally within each module.

**Localizing Subassembly Catalogs and Tool Palettes**

The default subassemblies are generally defined for a wide range of clients and geographical regions. You may want to change some of the display names of catalogs, palettes, tools, or tool variables as applicable to various situations and languages. These catalogs and tool palettes are composed in XML format, in *.atc* files, and can be edited.

**NOTE** By default, on English-language-based systems, the AutoCAD Civil subassembly tool catalog *.atc* files are installed to C:\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\Tool Catalogs\Road Catalog.

The following list identifies the data element values you can change in the subassembly tool catalog *.atc* file for localization purposes:

- The `<ItemName>` value is the descriptive name of the catalog, category, palette, or subassembly.

- The `<Description>` value describes the catalog, category, palette, or subassembly.

- The `<Keywords>` value contains a help string for subassemblies.

- The following attributes of the `<Params>` data element:
    - DisplayName: Name displayed in the AutoCAD Properties window for a selected subassembly.

    - Description: Descriptive text that is displayed at the lower left corner of the AutoCAD Properties window for a selected subassembly.

- The following data element values can be changed if needed:
    - The parameter values (such as Width in BasicLane subassembly) for any sub-element in `<Params>`.

    - The `<Units>` value which supports feet and meters in AutoCAD Civil.

    - The `<DotNetClass Assembly = ...>` (for .NET subassemblies), which can be modified to point to a different .NET class.

    - The `<Macro Module = ...>` (for VBA subassemblies), which can be modified to point to a different macro.

**NOTE** Only the values of a data element should be changed, not the data element name itself (such as Width in the BasicLane subassembly). These data elements are global variable names that are used in subassembly scripts.

**Installing Country Kits, Customized Codes Files, or Locale-specific Codes Files**

If you plan to install a country kit that contains a region-specific codes file, or, if you plan to install (use) a codes file that contains region-specific content, you must do the following before installing the country kit, or before installing the customized codes file.

Make a backup copy of the region-specific or customized codes file, rename it to the default name of your installed codes file (for example, for English version products, the default codes file is named C3DStockSubassemblyScripts_US.codes) and copy it to the following location: C:\Documents and Settings\All

Users\Application Data\Autodesk\Civil2010\enu. For non-English-language based systems, the "enu" location should correspond to the appropriate locale.

Note that when AutoCAD Civil is first installed on a new machine, the following two versions of the codes file are installed:

■ C3DStockSubassemblyScripts.codes

■ C3DStockSubassemblyScripts_US.codes

The C3DStockSubassemblyScripts_<locale>.codes file (in this example, C3DStockSubassemblyScripts_US.codes) is installed to provide a backup mechanism for securing codes file content.

When a country kit that contains a region-specific codes file is installed, the localized codes file is installed to C3DStockSubassemblyScripts.codes overwriting the existing file, and a copy is made at C3DStockSubassemblyScripts_<locale>.codes. If you have modified your C3DStockSubassemblyScripts.codes file, this is why it is important to make a backup of it before installing the country kit, or locale-specific codes file.

### Troubleshooting Codes File Issues

If you are experiencing unexpected results when using customized subassemblies, or when performing certain AutoCAD Civil corridor modeling tutorials, this may be due to the drawing attempting to reference codes file information that it cannot find. In some cases, these issues can be resolved by updating your existing codes file so that it contains the necessary information.

# Assembly and Subassembly Command Reference

You can use these commands to quickly access assembly and subassembly functionality.

The following table lists the assembly- and subassembly-related AutoCAD Civil commands and briefly describes their functionality.

| Command | Description |
| --- | --- |
| AddAssemblyOffset | Adds an offset assembly to an existing assembly (page 1383) |
| AddSubassemblyCode | Adds a code to a subassembly created from a polyline (page 1414) |
| ContentBrowser | Displays the Content Browser (page 106) |
| ConvertVBASAsToDotNET | Converts VBA subassemblies to .NET (page 1260) |
| CopySubssemblyTo | Copies a subassembly to or within an assembly (page 1380) |
| CreateAssembly | Creates an assembly (page 1381) |
| CreateSubAssemblyTool | Creates a subassembly from a tool palette (page 1396) |
| CreateSubFromPline | Creates a subassembly from a polyline (page 1397) |
| ImportTools | Imports subassemblies to a palette or catalog (page 1403) |
| MirrorSubssembly | Mirrors the selected subassembly or subassemblies within an assembly (page 1380) |

| Command | Description |
| --- | --- |
| MoveSubssemblyTo | Moves a subassembly to or within an assembly (page 1380) |
| RemoveSubassemblyCodes | Removes a code from a subassembly created from a polyline (page 1414) |
| SubassemblyClearOffset | Returns a moved subassembly to its insertion point in an assembly (page 1396) |
| ToolPalettes | Displays the Tool Palettes window (page 104) |

# Intersections

# 32

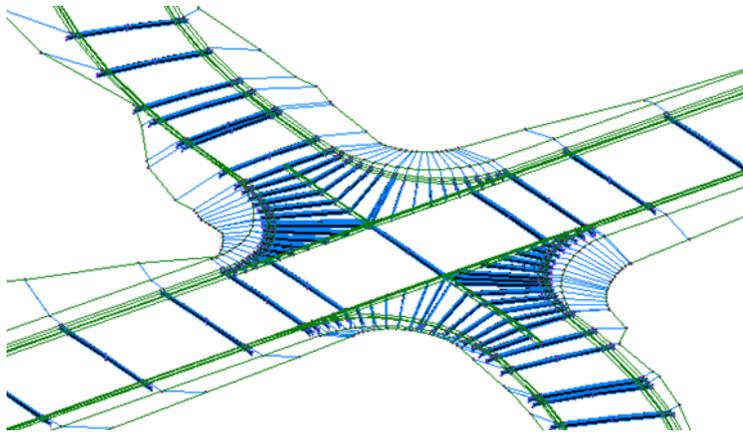
You can use AutoCAD Civil intersection design features to automatically create flexible 3D models of corridor intersections.

⟳ Intersection Design Workflow

## Understanding Intersections

An intersection object builds on and manages various object data, including alignments, profiles, corridors, assemblies, subassemblies, and surfaces.

In its simplest form, an intersection object can be created by selecting the location where two alignments intersect. This automatically creates an intersection object in the drawing, and this intersection object is also displayed in the Prospector tree.



Another approach to creating intersections is to first create roadway alignments, offset alignments, and profiles. Once these preliminary design items are in place, you can create an intersection object that utilizes the 3D aspects of these road design geometry components.

Intersections are created from and based on existing AutoCAD Civil objects, which include:

■ **Alignments** (horizontal). Used by an intersection to define the centerlines of the two roads that intersect. Three types of alignments are used in intersections: centerline alignments, offset alignments, and curb return alignments. The centerline and offset alignments are used to define the horizontal geometry aspects of an intersection object.

- **Profiles** (vertical alignments). Used to define surface and design elevations along a horizontal alignment.

- **Surfaces**. Used to build surface profiles, and for corridor grading in an intersection.

- **Corridors**. A corridor can be built automatically to represent the 3D aspects of the intersection. You can also add to this new corridor information to an existing corridor on the intersecting alignment(s).

- **Assemblies**. Roadway assemblies are required to build a corridor representing the intersection. To build an intersection corridor, you must be able to access appropriate assemblies to build the intersection model. AutoCAD Civil comes with a set of default intersection assemblies that you can use, or you can create your own custom assemblies that have been designed specifically to suit the needs of intersections you create.

- **Assembly set**. An intersection corridor requires an *assembly set*, which is a set of assemblies that are designed specifically for a specific type of intersection design. The assemblies included in an assembly set are defined in an .xml file that is referred to as the assembly set file. A default assembly set and assembly set file is included with AutoCAD Civil. You can create an intersection using this default assembly set, or you can create your own custom assembly sets.

- **Subassemblies**. Subassemblies define the geometry of a corridor section (through an assembly). For example, a typical roadway may be composed of paved lanes on either side of a centerline, a paved shoulder, a gutter and curb, and a roadside grading. These components are defined independently as subassemblies. You can add any type of subassembly to make up a typical assembly, and then apply that assembly for a station range along an alignment.

Intersection objects have their own display style that controls the intersection object marker. Intersection components, such as offset alignments, curb return alignments, and corridors, also each have their own display styles. Before creating intersections, you should be familiar with creating and managing styles (page 53) and command settings (page 97). For more information on intersection styles, see Intersection Styles and Display (page 1425).

**Intersection Object Considerations**

It is important to understand the following before you begin creating intersections:

- Using the Create Intersection wizard, you can create an intersection object that contains up to four quadrants.

- If the default intersection assembly mapping and target assignments does not meet your design requirements, you can create the intersection using these components, and then edit the intersection regions manually to satisfy your design requirements.

- If you create an intersection, and then manually edit the intersection corridor regions, those changes will be overwritten if the intersection is regenerated (by clicking "Recreate Corridors" button on the Intersection tab) or by rebuilding the intersection, using the Rebuild Intersection command.

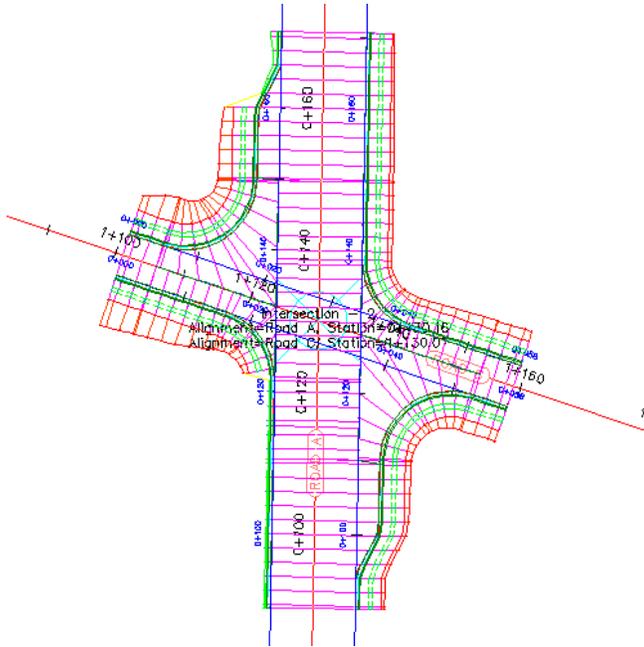
- When creating an intersection, targeting (both horizontally and vertically) is done automatically. If you want to change targets, you must manually modify the intersection corridor region(s) using the Corridor Properties dialog box.

- Typically, when an intersection object is created, the following objects are automatically added to the current drawing: intersection object, corridor(s), assemblies, subassemblies, offset alignments, and curb return alignments. However, assemblies, subassemblies, corridors, and profiles are only added if the appropriate options are selected.

# The Intersection Object

Intersection objects persist in an AutoCAD drawing as objects with the type AeccIntersection.

The intersection object allows you to create a 2D or 3D dynamic model of a T-shaped (3-way) intersection, or a four-way intersection.



Before creating an intersection object, you must have two alignments that intersect. If you want to create a three-dimensional intersection model, you must also have profiles associated with the intersecting alignments. Once you have the desired prerequisites, then you can create the intersection object using the Create Intersection wizard.

When the intersection object is created, a variety of tasks can be performed automatically, including the following:

■ creates offset alignments for the roads included in the intersection

■ creates curb return alignments (curb returns) in the intersection area

■ creates profiles for the offset alignments and curb return alignments created when the intersection was created (Note: An exception to this is that if you set pre-defined static alignments as offsets, it is expected that you will specify profiles too. No dynamic offset profiles will be created.)

■ creates new corridor regions for the existing corridors in the intersection area, or creates new corridor objects in the intersection area

■ locks the profile elevations of the secondary road to the main (primary) road profile

Some of these tasks are optional. They depend on options selected on the wizard dialog boxes.

For overview information about AutoCAD Civil objects, see Understanding Objects and Styles (page 51).

## Intersection Styles and Display

Intersection object display style is controlled both by a specific intersection object style, and the styles and labels associated with the objects used to create the intersection, such as the intersecting alignments.

Use the intersection object style to control the appearance of the intersection object marker. For more information, see Intersection Style Dialog Box (page 1925).

Other components associated with an intersection, such as offset alignments, curb return alignments, and profiles, each have their own object style to control their appearance.

Similarly, when you have corridor objects associated with the intersection, various components within the corridor are controlled by their own display styles and labels. For more information, see Corridor Styles and Display (page 1329).

To set default styles for components that are created through the intersection creation command, use the default styles collection in command settings. For more information, see Changing Intersection-Related Default Style Settings (page 1438).

The following table lists the components of the intersection and where they derive their styles from.

| Intersection Component | Display Style | Notes |
| --- | --- | --- |
| Main and secondary road alignments | Alignment style | Defined in the existing alignment style |
| Offset alignments | Offset alignment style | Defined in the Create Intersection command settings |
| Curb returns | Curb return alignment style | Defined in the Create Intersection command settings |
| Offset profile | Curb return alignment style | Defined in the Create Intersection command settings |
| Curb return profile | Curb return alignment style | Defined in the Create Intersection command settings |

For more information about styles, see Object Styles (page 53).

# Intersection Collection (Prospector Tab)

Use the Intersection collection in the Prospector tree to access the intersection objects in a drawing. As intersection objects are created, they are displayed in the Intersections collection.

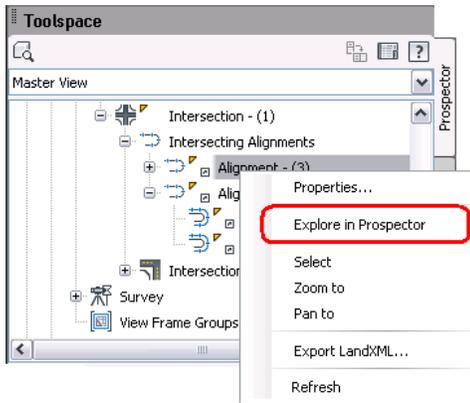
Expand the Intersections collection to view the names of the intersection objects included in the drawing. Expand an intersection object to display the Intersecting Alignments collection and the Intersection Quadrants collection. Click either of these collections to display a tabular list of the components in the Prospector list view. For more information, see The Toolspace Item View (page 82).

# Intersecting Alignments Collection

Use the Intersecting Alignments collection in the Prospector tree to access the alignments included in the intersection object.

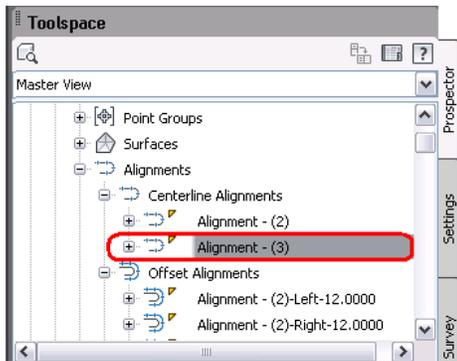
Expand the Intersecting Alignments collection to view the names of the alignments included in the intersection. You can also click this collection to display the alignments in the Prospector list view. You can edit the alignment style or assign a different profile using this view. For more information, see The Toolspace Item View (page 82).

**Exploring Intersection Alignments in Prospector**

Another feature available from the Intersecting Alignments collection is the Explore In Prospector command.


To use this command, right-click an alignment in the Intersecting Alignments collection, and select Explore In Prospector.

The same alignment is automatically displayed and selected in under the Alignments ➤ Centerline Alignments collection of the Prospector tree. Use this command to quickly find the location of an intersecting alignment in the Prospector tree.



The Explore In Prospector command is available for centerline alignments, offset alignments, and curb return alignments, and is available from the Intersecting Alignments collection as well as from the Intersection Quadrants collection.

## Intersection Quadrants Collection

Use the Intersection Quadrants collection in the Prospector tree to access details about the quadrants in the intersection object.

Expand the Intersection Quadrants collection to view the names of the quadrant included in the intersection. This collection also displays the names of the curb return alignments for each quadrant. You can also use this collection to display the names of the incoming and outgoing lane centerlines in the Prospector list view. The list view also displays the value of the intersecting angle between the incoming and outgoing lane centerlines. For more information, see The Toolspace Item View (page 82).

Right-clicking an intersection quadrant name in Prospector lets you do the following:

| Item | Description |
| --- | --- |
| Edit Curb Return Parameters | Displays the Intersection Curb Return Parameters dialog box. You can change the quadrant name, or edit the curb return type and geometry (such as simple curve |

| Item | Description |
|---|---|
| | type). You can also add widening, or edit widening parameters. |
| Edit Curb Return Profile Rules | Displays the Intersection Curb Return Profile Parameters dialog box. You can change whether to extend the profile along the incoming or outgoing lanes, and also change the length by which to extend the profile. Editable parameters have a white background in the Value column, while read-only parameters have a shaded background. |
| Recreate Corridor Regions | Recreates corridor regions for the currently selected intersection. It is important to note that using this option removes any manual edits that may have been made to the intersection corridor. |
| Refresh | Refreshes the display of items displayed in Prospector. |

## Intersection Collection (Settings Tab)

Use the Intersection collection in the Settings tree to manage intersection object settings, including intersection object styles, label styles, and command settings.

An intersection object has its own display style that controls the appearance of the intersection object marker. Components included within the intersection object, such as alignments, profiles, corridors, and so on, each have their own display styles.

An intersection object style controls the intersection object marker appearance. For more information, see Intersection Style Dialog Box (page 1925).

Right-click the Intersection collection to do the following:

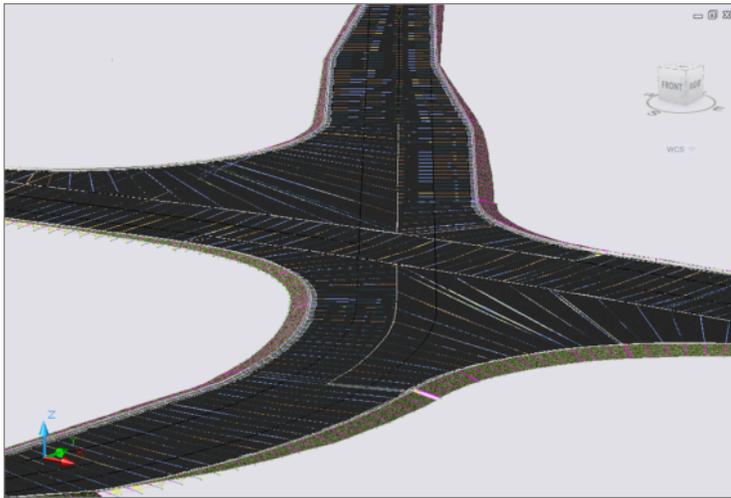
■ Edit the intersection feature settings. (page 1436)

■ Edit Intersection Label Style Defaults

■ Refresh the display of the settings tree.

Expand the Intersection collection to display and edit the intersection object style, label styles, and command settings that are available for the intersection feature.

## Creating Intersections

You can create an intersection using the Create Intersection wizard.


## Before You Begin

Before you can create a simple intersection, you must have at least two alignments that intersect each other only once in your drawing.

### Creating a Simple 2D Intersection

The simplest way to create a basic two-dimensional intersection object is to start with two alignments that intersect each other only once. You cannot use the Create Intersection wizard if the alignments do not intersect.

If your drawing has two intersecting alignments that meet this criteria, you can create a basic 2D intersection object using the Create Intersection wizard. Simply start the command, follow the prompts, and accept the default choices on the wizard dialog boxes.

### Creating a 3D Intersection with Corridor Objects, Alignments, and Profiles

To create a 3D intersection that includes a corridor, you will need to first create the road geometry (road centerline alignments and profiles) and existing ground surface in your drawing. Once these components exist in the drawing, you can proceed with using the Create Intersection wizard. The wizard prompts you to select the location in the drawing where the two road centerline alignments intersect.

You can start with the following data combinations:

■ two intersecting centerline alignments

■ two intersecting centerline alignments with one or more road edge offset alignments and or their profiles

You can have profiles defined already, or not. However, if profiles are not available, then features that are associated with 3D modeling will not be available on the wizard. For example, if you begin creating an intersection object with no profiles, then the following wizard options will not be available for selection: creating offset alignment and curb return profiles, as well as the ability to create a new corridor, or to add to an existing corridor in the intersection area.

With any of the scenarios just described, you can start the Create Intersection command, select the point where the centerline alignments intersect, and proceed with creating an intersection using the Create Intersection wizard.

If you need more information about creating the underlying objects required for creating 3D intersections, you can refer to the following table.

| For information about creating... | See... |
|---|---|
| Alignments | Creating Alignments (page 887) |
| Profiles | Creating Layout Profiles (page 1048) |
| Corridors | Creating Corridors (page 1330) |
| Assemblies | Creating Assemblies (page 1380) |
| Assembly Sets | Assembly Sets (page 1457) |
| Subassemblies | Creating Subassemblies (page 1396) |
| Surfaces | Creating Surfaces (page 601) |

# Setting Driving Direction

The Driving Direction option determines the direction in which curb returns are drawn when an intersection is created.

The options are Right Side of the Road and Left Side of the Road.

This setting should be set to **Left Side of the Road** when creating intersection objects for projects that have vehicles traveling on the left side of the road; for example, in countries such as the United Kingdom. In this case, curb return alignments in intersection objects are drawn starting on the left side of the outgoing road, and ending on the left side of the merging road.

When set to **Right Side of the Road**, curb return alignments in intersections are drawn starting from the right side of the outgoing road, and ending on the right side of the merging road.

**NOTE** You cannot change the "Driving Direction" setting on an intersection object that has already been created.

**To set driving direction**

1  In Toolspace, on the Settings tab, right-click the name of the drawing at the top of the Settings tree collection, and click Edit Drawing Settings.

2  Click the Ambient Settings tab, and expand the General collection.

3  Next to Driving Direction, click in the Value cell and select one of the two options (**Left Side of the Road** or **Right Side of the Road**.

## Quick Reference

Dialog Box

Ambient Settings Tab (Drawing Settings) (page 1856).

# Using the Create Intersection Wizard

To use the Create Intersection wizard, make sure you have the required data in your drawing before you begin.

As a minimum, you must start with a drawing that has two alignments that each have profiles and station data associated with them.

---

**NOTE** If you are creating a T-shaped (3-way) intersection, you must ensure that the alignments snap together precisely and do not overlap. If there is any overlap between the two alignments, a 4-way intersection will be created.

---

**To create an intersection using the Create Intersection wizard**

1 Do one of the following:

   ■ Click the Home tab ➤ Create Design panel ➤ Intersection ⊹ .

   ■ At the command line, enter CreateIntersection.

   You are prompted to pick an intersection point in the drawing.

   ---

   **NOTE** If you wish to create a 3-way intersection, it is important that the alignments meet precisely and do not overlap or undershoot. If the two alignments overlap, a 4-way intersect is created.

   ---

2 In the drawing, click the location in the drawing where two alignments intersect.

3 If you are creating a 4-way intersection, you will be prompted to select the alignment that will be identified as the primary road. If so, select the alignment by clicking the alignment in the drawing, or by pressing ENTER and selecting from the list of alignments in the drawing.

   If you are creating a T-shaped (3-way) intersection, then the alignment that passes through the intersection is automatically specified as the primary road (main road). In this situation, you are not prompted to specify which road is the primary road because this happens automatically. It is possible to change the road priority only during intersection object creation (on the Geometry Details page of the Create Intersection wizard). For more information, see Changing Road Priority (page 1433).

4 On the General page of the Create Intersection wizard, enter a name for the intersection object, or accept the default. You can also enter an optional description, and change defaults for marker styles, layer, and labels.

5 For the Intersection Corridor Type, select one of the following to specify the corridor grade options through the intersection area:

   ■ Primary Road Crown Maintained: When this options is selected, the primary road crown is maintained through the intersection.

   ■ All Crowns Maintained: When this options is selected, the crowns of both roads included in the intersection are maintained through the intersection.

   An illustration at the bottom of the wizard dialog box provides a conceptual graphic of the grade type selected.

6 Click Next to proceed to the next page of the wizard.

7 On the Geometry Details page, you may accept or change the defaults. For example, if desired you can perform the tasks listed in the following table:

| To perform this option... | do this... |
| --- | --- |
| Change the alignment priority | Select an alignment in the list and click the arrows. For more information, see Changing Road Priority (page 1433). |
| Select different profiles for the alignments | Select an alignment in the list and click in the Profile cell to select a profile from the |

| To perform this option... | do this... |
| --- | --- |
| | drop-down list of available profiles in the current drawing. |
| Choose to create or not create offset alignments and curb returns for the intersection | Place or remove the check mark from the appropriate box on this wizard dialog box. |
| Change parameters for the offset alignments, curb returns, lane slopes, curb return profiles | Click the appropriate Parameters button on this wizard dialog box. |

8   By default, new offset alignment objects will be created. However, if you want to specify an existing offset alignment from the drawing, click the Offset Parameters button, set Use An Existing Alignment to Yes, and select the alignment by clicking ⊡ next to the Alignment Name property.

9   When you are finished configuring the Geometry Details page, click Next to proceed to the next page of the wizard.

10  On the Corridor Regions page, you may accept or change the defaults. For example, if desired you can perform the tasks listed in the following table:

| To perform this option... | do this... |
| --- | --- |
| Create or not create a new corridor in the intersection area | Add or remove the check mark next to this option. For more information, see Creating Corridors in the Intersection Area (page 1435). |
| Add to an existing corridor | Select this option. If you do not have corridor objects in the drawing, this option is not available. For more information, see Creating Corridors in the Intersection Area (page 1435). |
| Select a surface to daylight | If a surface is available in the current drawing, you can select a surface to daylight. However, you cannot target a surface that is an output of another corridor. |
| Select an assembly set to import | Click Browse, select the assembly set, then ensure the assembly set is selected using the drop-down arrow under Select Assembly Set To Import. For more information, see Assembly Sets (page 1457). |
| Select different assemblies | If the desired assembly objects exist in the current drawing, you can select different assemblies by c licking ⊡ in the Assembly To Apply column. Otherwise, accept the default assemblies specified. |

11  Click the items listed under Corridor Region Section Type, and notice that the conceptual graphics update with each selection. The location where the assembly will be applied along the intersection is highlighted in the conceptual graphic.

**12** Click Create Intersection. The intersection is created.

### Quick Reference

Ribbon

Home tab ➤ Create Design panel ➤ Intersection 🔳

Command Line

CreateIntersection

Dialog Box

Create Intersection Wizard (page 1927)

## Changing Road Priority

When you create an intersection object, a Priority value is assigned to the main (primary) and secondary (side) road alignments .

The following table lists the value of the Priority property:

| Road (alignment) | Priority |
| --- | --- |
| Main (primary) road alignment | 1 |
| Secondary road alignment | 2 |

If you are creating a T-shaped (3-way) intersection, then the alignment that passes through the intersection is automatically specified as the primary road (main road). In this situation, the Priority is automatically set to a value of 1 for that alignment, and you are not prompted to specify which road is the primary road because this happens automatically.

You cannot change the priority of a road in an intersection after it has been created. However, if you want to change the priority of the alignments *during* the intersection creation, you can do so from the Geometry Details page of the Create Intersection wizard.

It is also important to note that typically, the secondary road (or lower priority) profile is automatically locked at the intersection location to the elevation of the main road (higher priority) main road. The profile of the main road is not modified.

**To change road (alignment) priority during intersection creation**

**1** Click the Home tab ➤ Create Design panel ➤ 🔳 Intersection.

**2** Advance to the Geometry Details page of the Create Intersection wizard.

**3** At the top of this dialog box, in the Intersecting Alignments section, select the road (alignment) you want to change by clicking the name of the alignment in the list.

**4** Click the up or down arrow to change the road priority.

> **NOTE** Once the intersection object is created, you cannot change the value of the road priority for an alignment.

**5** Continue creating the intersection. For more information, see Using the Create Intersection Wizard (page 1430).

**Quick Reference**

Dialog Box

Geometry Details Page (Create Intersection Wizard) (page 1929)

# Intersection Corridor Type

In AutoCAD Civil, the Intersection Corridor Type property identifies the type of grading that will be applied to roads in an intersection object.

There are two types of intersection grading options that are available with AutoCAD Civil intersection objects: Primary Road Crown Maintained and All Crowns Maintained. You must specify this type when you create the intersection, on the General page of the Create Intersection wizard.

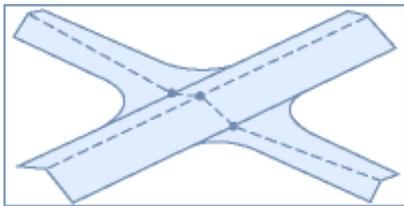
For existing intersections, the intersection corridor type is displayed on the Intersection Details tab of the Intersection Properties dialog box, in the Intersection Quadrants section. You can set the creation default for this option on the Edit Command Settings - CreateIntersection dialog box (page 1919).

Once the intersection is created, you cannot change the value of the Intersection Corridor Type property. If you do want to change this option after the intersection object is created, you must delete the intersection object, and create a new one with the desired Intersection Corridor Type.

### Primary Road Crown Maintained

In this type of intersection, the crown of the primary road is maintained, while the crown (profile) of the secondary road is adjusted to match the edge of the primary road and the intersection point. The crown (profile and edges) of the primary road are not affected.

The following conceptual graphic is displayed on the wizard dialog when you select this option:

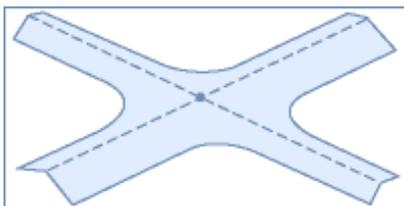


This represents how the grading occurs for the intersection object.

### All Crowns Maintained

In this type of intersection, the profile of the side road is adjusted to match the main road elevation at the intersection point. The main road profile is not affected. The edges are blended together along the curb returns (via the curb return profiles).

The following conceptual graphic is displayed on the wizard dialog when you select this option:



**NOTE** Once an intersection object is created, you cannot change the value of the intersection Corridor Type property.

# Creating Corridors in the Intersection Area

You can choose to create corridor objects within intersections, or add to existing corridors. You can also choose not to have corridor objects in the intersection.

In order to create the intersection corridor, the following must have already been done:

- Side road profile matching
- Creation or selection of offsets and profiles
- Creation of curb returns and profiles

If the above items have not been met, then the create corridor options on the Create Intersection wizard dialog box are not available.

The following table describes the options that are provided through the Create Intersection wizard dialog box:

| Option | Description |
| --- | --- |
| Create a New Corridor | Specifying this option creates a new corridor object in the intersection area. |
| Add to an Existing Corridor | Specifying this option lets you select an existing corridor object in the drawing to add to the intersection area. |
| No Corridors in the Intersection Area | When neither of the previouos two options are selected, no corridor object are created in the intersection area. |

You can specify these options during intersection object creation, using the Create Intersection wizard, or you can choose to edit these options after the intersection object has been created.

For example, you can select an existing intersection object, and click Recreate Corridor Regions from the shortcut menu. This displays the Intersection Corridor Regions dialog box which lets you edit corridor regions on the intersection. From this dialog box, you can change the options selected for corridor object creation. After making changes on this dialog box, you need to recreate the corridor regions for the intersection area.

**To create a new corridor in the intersection during creation**

This procedure describes how to create a new corridor in an intersection area during intersection object creation.

1. Start the Create Intersection wizard by doing one of the following:
   - Click the Home tab ➤ Create Design panel ➤ Intersection .
   - At the command line, enter CreateIntersection.

   You are prompted to pick an intersection point in the drawing.

2. Configure the first two pages of the wizard as desired, and advance to the Corridor Regions page. For more information, see Using the Create Intersection Wizard (page 1430).

3. On the Corridor Regions page, place a check mark in the Create Corridors in the Intersection Area check box.

4. Select the Create a New Corridor option.

**5** Proceed with configuring the rest of the wizard options.

**To add to an existing corridor in the intersection during creation**

This procedure describes how to add to an existing corridor in an intersection area during intersection object creation.

**1** Start the Create Intersection wizard by doing one of the following:

■ Click the Home tab ➤ Create Design panel ➤ Intersection 🔧.

■ At the command line, enter CreateIntersection.

You are prompted to pick an intersection point in the drawing.

**2** Configure the first two pages of the wizard as desired, and advance to the Corridor Regions page. For more information, see Using the Create Intersection Wizard (page 1430).

**3** On the Corridor Regions page, place a check mark in the Create Corridors in the Intersection Area check box.

**4** Select the Add to an Existing Corridor option.

**5** Select an existing corridor using the drop-down list or by picking from the drawing.

**NOTE** If you do not have corridor objects in the drawing, these options is not available.

**6** Proceed with configuring the rest of the wizard options.

**To create a new, or to add to an existing corridor in an intersection**

This procedure describes how to edit an existing intersection object to either add a new corridor object to it, or to add an existing corridor object to it.

**1** Select an intersection object, and then click Recreate Corridor Regions.

The Intersection Corridor Regions dialog box is displayed.

**2** On the Intersection Corridor Regions dialog box, select one of the following: Create a New Corridor or Add to an Existing Corridor.

**3** If you selected, Add to an Existing Corridor, select an existing corridor using the drop-down list or by picking from the drawing.

**NOTE** If you do not have corridor objects in the drawing, this option is not available.

**4** Configure the rest of the choices on this dialog box. For example, you may want to select a different assembly set, or select different assemblies. For more information, see Intersection Corridor Regions Dialog Box (page 1935).

**5** To apply the changes, click the Recreate button on this dialog box.

**NOTE** Because this command deletes and recreates the corridors in the intersection, if you made any changes to the corridors in the intersection object, those changes will be overwritten (discarded) when the new corridors are created. For more information, see Recreating Corridor Regions in Intersections (page 1454).

## Editing Intersection Settings

Use intersection settings to specify the default behavior for intersection-related commands.

Settings are handled in a standard way throughout AutoCAD Civil. You access settings using the Toolspace Settings tree. You can control settings at three levels: the drawing level, the object collection (feature) level, and the command level. For more information, see Understanding Settings (page 61).

In the Settings tree, use the Intersection collection's shortcut menu to establish defaults for all intersection-related commands. You can change intersection-specific settings at this level, or override the drawing ambient settings.

Use the Commands collection in the Intersection collection to change intersection settings for a specific command.

**NOTE** Overrides to the drawing ambient settings at the Intersection collection level and the Commands collection level affect only the specified (and subordinate) levels. The drawing level settings are not changed.

The topics in this section describe only those settings that affect intersection-related commands. They do not apply to the drawing ambient settings that you can change at the Intersection collection level. For more information about the drawing ambient settings, see Specifying Ambient Settings (page 68).

# Changing Intersection Creation Settings

Use the intersection creation and naming settings in the Edit Feature Settings - Intersections dialog box to change intersection-related settings before you create intersections.

For example, before creating an intersection, you may want to specify the default frequency for inserting assemblies along tangents, curves, or spirals. You may also want to set default parameters for curb returns, widening, or curb return profiles.

If a closed lock icon 🔒 is displayed in the Lock column for a property, the property is locked at a higher level of the Settings tree. It cannot be changed at this level.

If you change a property value, a check mark ✔ is displayed in the Override column. This override is also noted in the property table for related objects higher up the Settings tree, where an arrow is displayed in the Child Override column.

**To change intersection creation settings**

1  Do one of the following:

   ■ **To edit settings for all intersection-related commands**: In Toolspace, on the Settings tab, right-click the Intersection collection. Click Edit Feature Settings.

   ■ **To edit settings for a specific command**: In Toolspace, on the Settings tab, expand the Intersection collection. Expand the Commands collection. Right-click the name of the command and click Edit Command Settings. For example, right-click the CreateIntersection command and click Edit Command Settings.

   TheEdit Feature Settings - Intersection dialog box (page 1919) is displayed.

2  To specify defaults for intersection creation, right-click the CreateIntersection command and click Edit Command Settings. For example, to edit default frequencies for inserting assemblies along tangents, curves, and spirals, expand Assembly Insertion Defaults. For more information on intersection defaults, see the Edit Feature Settings - Intersection (page 1919) dialog box.

3  To edit the default naming format for intersection data, expand the Default Name Format property group. Edit the various name template settings.

4  Click Apply.

# Changing Intersection-Related Default Style Settings

Use the intersection settings to specify default styles and labels for intersection creation and for certain components that are create during intersection creation.

In addition to selecting a default style for the intersection object marker, you can also select default styles for the following objects that can be created when an intersection object is created:

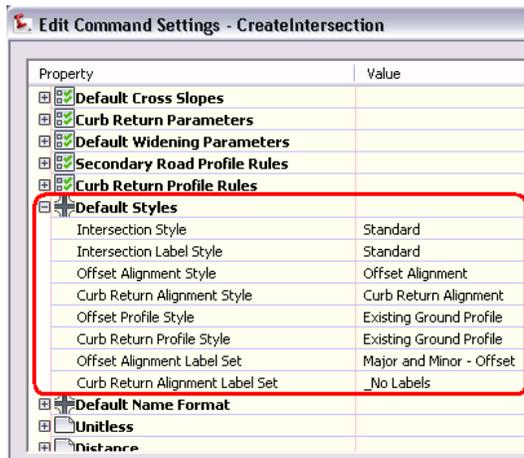
- Intersection label

- Offset alignment

- Curb return alignment

- Offset alignment profile

- Curb return alignment profile



You can also create label sets for offset alignments and for curb return alignments.

The default styles specified for these components are used to establish the default styles that are used when these items are created using the CreateIntersection command.

**To change the intersection-related style and label settings**

1  In Toolspace, on the Settings tab, right-click the Intersection collection. Click Edit Feature Settings to open the Edit Feature Settings - Intersection dialog box (page 1919).

2  Expand the Default Styles property group.

**3** To specify a default style for intersection output objects, such as offset alignments, curb returns, and profiles generated from intersections, click the corresponding field. Click ⋯ to open the Select Style dialog box.

**4** To specify a default intersection style, click Intersection Style. Click ⋯ to open the Select Style dialog box.

**5** To specify a default style for a label set, click the corresponding field. Click ⋯ to open the Select Label Set dialog box.

**6** Click Apply.

Edit Feature Settings - Intersection (page 1919)

# Editing Intersections

There are a variety of ways that you can edit intersections.

You can edit intersections using commands available from the ribbon, from right-click shortcut menus, or by editing the objects directly in the drawing using grips.

The following lists describe some of the ways that you may want or need to edit an intersection object after it has been created.

### Changes Managed by the Intersection Object

The following types of edits can be performed by making changes directly to components that are controlled by the intersection object:

■ Change the parametric values of the intersection object definition, such as nominal offsets/ cross slopes, curb return profile rules, and corridor regions

■ Change edge offsets from parametric (nominal offset) values to predefined alignments

■ Change edge offset profiles from parametric (nominal cross slopes) to predefined profiles

■ Change (intersection) rule-based dynamic offset alignments and dynamic profiles to static and then make edits to them

■ Change association of assemblies to one or more of "dynamic corridor regions"

■ Change the frequency that the assemblies are applied to the dynamic corridor regions

Typically you will need to update corridor regions after making these types of edits to intersection objects.

When an update is necessary, an out-of-date icon ⚠ is displayed in Prospector for the corridors in the intersection. If you have Update Regions Automatically turned on for the intersection object, then the corridor regions are updated automatically after these types of edits. For more information, see Updating Corridor Regions in Intersections (page 1452).

**Changes Not Managed by the Intersection Object**

While you can make the above types of changes by manipulating components that are controlled by the intersection object, it is also possible to make other types of changes that are not directly managed by the intersection object. For example, you can make the following types of changes that are not managed by the intersection object:

■ Change the intersection area corridor region extents and or add more regions within the intersection extents

■ Change the corridor targets in the intersection for the edge offsets and profiles

■ Edit corridor parameters in the intersection area regions using the Corridor Section View Editor

Because these last three types of changes do not modify the intersection object definition, it is important to understand that if you do make these types of changes, they could be overwritten or ignored if you update the corridor regions in the intersection, or if you recreate the intersection.

**NOTE** When you edit the horizontal or vertical geometry of the intersection object, the road that is specified as the secondary road is automatically adjusted to accommodate the horizontal and vertical position of the road that is specified as the primary road.

The sections that follow describe how to make various types of edits to intersection objects.

# Editing Basic Intersection Information

After creating an intersection, you can use the Prospector tree to edit basic intersection object information, such as object name and description.

**To edit basic intersection information**

1 In Toolspace, on the Prospector tab, expand the  Intersection collection. Right-click the intersection. Click Properties.

2 In the Intersection Properties dialog box, click the Information tab (page 1924).

3 To change the name of the intersection, enter a new name in the Name field.

4 To change the description of the intersection, enter a new description in the Description field.

5 To change the style of the intersection, click the Object Style list. You can also use the standard buttons to create, edit, or select a style.

6 Click Apply to make the changes, or click OK to make the changes and close the Intersection Properties dialog box.

  Intersection Properties

Dialog Box

  Intersection Properties - Information tab (page 1924)

# Editing Intersection Properties

You can change the intersection object name, style, alignment profiles, and view details about the alignments and quadrants in the current intersection using the Intersection Properties dialog box.

The Intersection Properties dialog box has the following tabs:

■ **Information**. Specifies intersection object name, description, and style.

■ **Intersection Details**. Displays information about the alignments and the quadrants included in the intersection. This tab displays the names of the alignments, the station of the point of intersection, and profile associated with each alignment. If multiple profiles are available, you can change the profile associated with the alignment by clicking in the Profile cell and selecting a new profile from the drop-down list. The Intersection Quadrants section displays the names of the alignments included in each quadrant, and identifies incoming and outgoing alignments, as well as the value for the intersection angle between the two alignments. This is for information only and cannot be edited in the properties dialog.

**See also:**

■ Intersection Properties dialog box (page 1924)

**To change intersection object name, description, or the intersection marker style**

1 Right-click an intersection in the drawing. Click Intersection Properties.

> **NOTE** The tab most recently opened in the Intersection Properties dialog box is displayed by default.

2 In the Intersection Properties dialog box, click the Information tab (page 1924).

3 Under Name, enter a name for the intersection object.

4 Under Description, enter an optional description for the intersection.

5 In the Object Style list, select an existing intersection style. Note that this only affects the intersection marker style.

6 Click the Style Detail button to open the Style Detail dialog box. Preview the intersection marker style.

**To change the profile associated with an alignment**

1 Right-click an intersection in the drawing. Click Intersection Properties.

> **NOTE** The tab most recently opened in the Intersection Properties dialog box is displayed by default.

2 In the Intersection Properties dialog box, click the Intersection Details tab (page 1925).

3 In the Alignment Details section, click a profile name in the Profile column. Select a profile from the drop-down list. If there are not multiple profiles in the drawing, no other profiles will be displayed.

4 Click Apply to apply the new profile.

5 After changing the profile, you may also need to rebuild the corridor, recreate corridor regions in the intersection, or rebuild the intersection. For more information see Rebuilding a Corridor (page 1360), Recreating Corridor Regions in Intersections (page 1454), or Updating Corridor Regions in Intersections (page 1452).

### Quick Reference

## Editing Intersection Styles

Use styles to control the visual display of each intersection component.

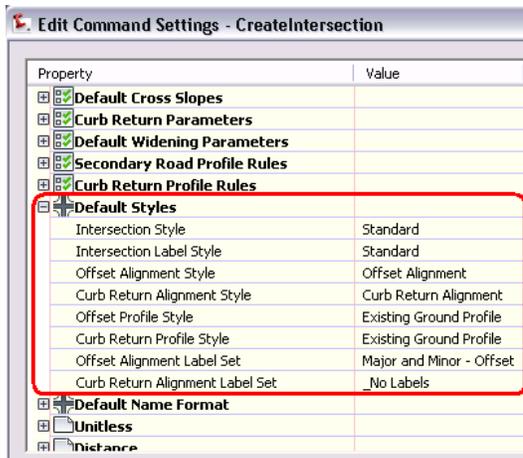
The intersection style controls the appearance of the intersection object marker. You can change the marker, as well as display parameters such as visibility, layer, and color used in plan and model views.

Access intersection styles using these methods:

| If you want to access intersection styles... | Then... |
| --- | --- |
| From the ribbon | Select an intersection ➤ Intersection tab ➤ Modify panel ➤ Intersection Properties drop-down ➤ Edit Intersection Style |
| In the drawing | Right-click an intersection ➤ Edit Intersection Style. |
| On the Settings tab in Toolspace | Right-click a style in the Intersection Styles folder ➤ Edit. |

**NOTE** When you click New in a collection folder, the new style you create is based on installation defaults, not on the existing styles in the collection. To create a style from an existing style, right-click the style. Click Copy and save the style with a new name.

Use the tabs in the Intersection Style dialog box to set style information. For more information, see Intersection Style Dialog Box (page 1925).

The following intersection components derive their styles from their own object styles: primary and secondary road alignments, offset alignments, curb return alignments, profiles, corridors.


Use the CreateIntersection command settings to set the default styles that will be used when creating some of these components.

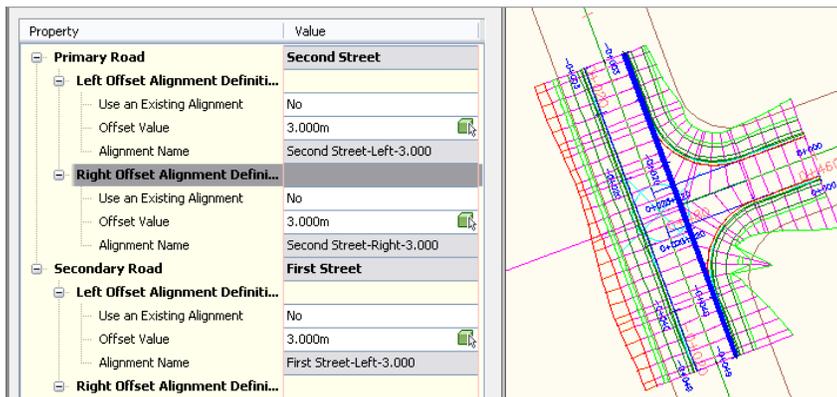
## Intersection Editing Visual Cues

Visual cues help you edit intersection components quickly.

Many of the dialog boxes that allow you to create or edit intersection object components have visual behavior built in to help you quickly identify the area of the intersection object being edited.

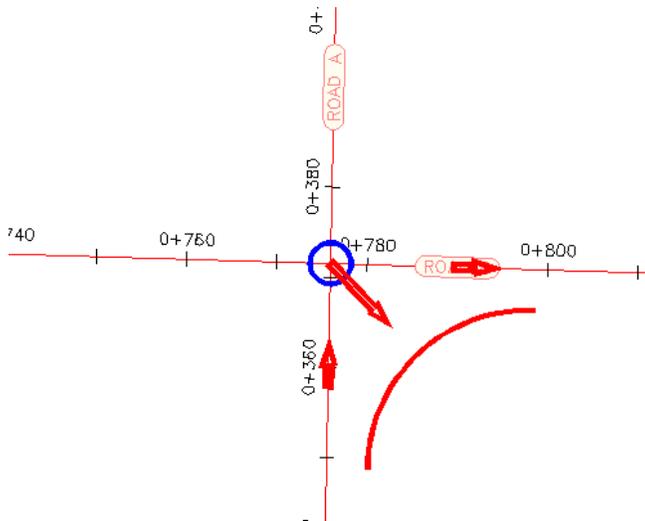
For example, editing dialog boxes, such as the Intersection Offset Parameters dialog box and the Intersection Curb Return Parameters dialog box, contain the following behaviors:

**Object Highlighting in Drawing:** When you select some items on an intersection editing dialog box, the affected object is highlighted in the drawing. For example, when you select an offset on the Intersection Offset Parameters dialog box, that offset alignment is highlighted in the drawing. This behavior is displayed in the following illustration.



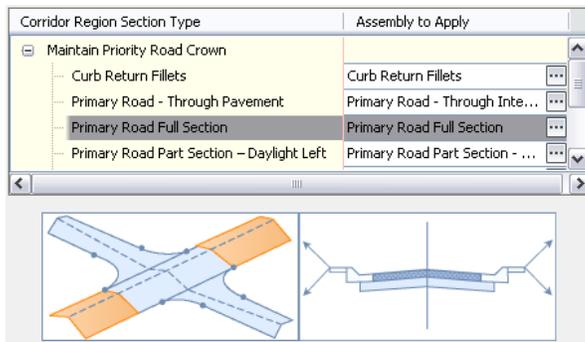
The right side offset alignment named First Street is selected in the Intersection Offset parameters dialog box, shown on the left. In the drawing, that offset alignment is highlighted.

Similarly, if you are editing intersection curb return parameters using the Intersection Curb Return Parameters dialog box, each time you select a quadrant or curb return in this dialog box, the selected quadrant or curb return is highlighted in the drawing.

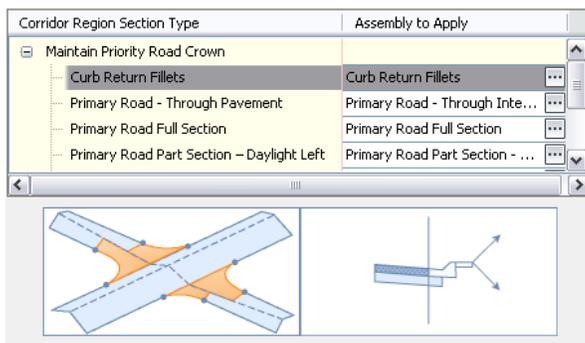
The following illustration shows temporary arrows along the alignments that indicate the direction of incoming and outgoing traffic. These arrows are displayed when you are specifying intersection curb return parameters.


**Conceptual Graphics on Dialog Boxes:** Each time you select a property or item to edit on intersection editing dialog boxes, the conceptual graphic is displayed at the bottom of the editing dialog box updates to indicate the location along the intersection affected by the edit.

For example, when you select the "Primary Road Full Section" corridor region on an intersection editing dialog box, the following conceptual graphic is displayed, indicating the location of this region along the corridor.



Similarly, when you select the "Primary Road Full Section" corridor region



This behavior also exists on the Create Intersection wizard dialog boxes.

**Shading of Non-editable Properties:** In editing dialog boxes, properties that are not editable are displayed with a gray (shaded) background color. Properties that are editable are displayed with a white (not shaded) background color.

# Editing Offsets in Intersections

There are several ways you can edit offset alignments in an intersection area.

You may need to edit offset alignments after an intersection is created. You can change the offset value, or select a different alignment to use as the offset.

For example, you can use the Edit Offsets command on an existing intersection object to change the parametric value of the intersection, or you can select a different offset alignment, using one from the current drawing. You can also grip edit the dynamic offset alignment after it is created.

It is also possible to edit offsets for incoming and outgoing roads by editing the corridor parameters, although this is not typically the preferred method. For example, the offsets can be changed by overriding offsets at one or more stations, or by overriding target parameters for incoming and outgoing lanes.

**Visual Cues**: When you select an item on this dialog box, the affected object is highlighted in the drawing, and the conceptual graphic on the dialog box updates to indicate the location of the edit. For more information, see Intersection Editing Visual Cues (page 1443).

**To edit offset alignments using the Edit Offsets command**

This procedure describes how to widen a road by editing the offset alignment definition on an existing intersection object.

1  Do one of the following:

   ■  In the drawing, click the intersection object. On the ribbon, click Edit Offsets ⊞ on the Modify panel of the Intersection contextual tab.

   ■  In the drawing, right-click the intersection object, and then select Edit Offset Parameters from the object shortcut menu.

   ■  In Prospector, expand the Intersections collection, right-click the intersection object, and then select Edit Offset Parameters from the Toolspace shortcut menu.

2  On the Intersection Offset Parameters dialog box, expand the collection for the alignment you want to edit.

   Notice that when the Use An Existing Alignment property is set to No, the Alignment Name property is read only. Notice also how the Offset Value property is set, and that it is currently editable.

3  Set the Use An Existing Alignment property to Yes, and notice that the Alignment Name property becomes editable.

4  Click ⊡ to select another alignment from the current drawing.

   Notice that the Offset Value is set to *Varies* if the alignment is not a dynamic offset alignment based on a centerline. Otherwise, the Offset Value specifies the offset value of the attached dynamic alignment. This control is disabled (read only) in both cases.

   **NOTE**  If you select another alignment in the Alignment Name field, the original offset alignment that was created during intersection object creation is not deleted.

**To specify offset alignment width during intersection creation**

This procedure describes how to widen a road by specifying a different offset alignment using the Create Intersection wizard.

1 Do one of the following:

■ Click Home tab ➤ Create Design panel ➤ Intersection 🔧 .

■ At the command line, enter CreateIntersection.

2 Pick the intersection point in the drawing.

3 In the wizard, click Next to proceed to the Geometry Details page.

4 Click Offset Parameters.

5 On the Intersection Offset Parameters dialog box, expand the collection for the alignment you want to edit.

6 Set the Use An Existing Alignment property to Yes, and notice that the Offset Alignment Name Format property is replaced with the Alignment Name property.

7 In the Value field for the Alignment Name property, click ⬚ to select an offset alignment from the current drawing.

Notice that the Offset Value is set to *Varies* if the alignment is not a dynamic offset alignment based on a centerline. Otherwise, the Offset Value specifies the offset value of the attached dynamic alignment.

---

**NOTE** When you assign an offset value to an existing alignment, either dynamic or static, the Intersection object does not remember the original dynamic object associated with it.

---

8 Click OK on the Intersection Offset Parameters dialog box, and proceed with using the wizard to create the intersection object. For more information, see Using the Create Intersection Wizard (page 1430).

**To edit offset alignments using grips**

This procedure describes how to widen a road by grip editing the offset alignment that is controlling an intersection.

1 In the drawing, select the desired offset alignment in the intersection object.

2 On the offset alignment, click and drag the Change Offset (triangle grip) to specify the new offset value. Notice that the intersection object and the associated curb returns update.

## Editing Curb Returns in Intersections

You can edit curb returns in an intersection.

You may need to edit curb returns after an intersection is created. For example, you can change the curb return type or dimension, or edit widening or transition details.

**Visual Cues**: When you select an item on this dialog box, the affected object is highlighted in the drawing, and the conceptual graphic on the dialog box updates to indicate the location of the edit. For more information, see Intersection Editing Visual Cues (page 1443).

**To edit curb returns in an intersection**

1   Do one of the following:

   ■ In the drawing, click the intersection object. On the ribbon, click Edit Curb Returns ⊞ on the Modify panel of the Intersection contextual tab.

   ■ In the drawing, right-click the intersection object, and then select Edit Curb Return Parameters from the object shortcut menu.

   ■ In Prospector, expand the Intersections collection, right-click the intersection object, and then select Edit Curb Return Parameters from the Toolspace shortcut menu.

2   Use the Intersection Curb Return Parameters dialog box to edit the following parameters associated with this component.

   ■ Intersection Quadrant: You can specify which quadrant of the intersection to edit.

   ■ Widen Turn Lane For Incoming\Outgoing Road: These options automatically add widening to the incoming or outgoing road in the intersection when the intersection is created.

   ■ Intersection Quadrant Name: Displays the name of the intersection quadrant. You can change the name here, if desired.

   ■ Incoming Road Centerline Name: Displays the name of the centerline alignment for the incoming road.

   ■ Outgoing Road Centerline Name: Displays the name of the centerline alignment for the outgoing road.

   ■ Intersection Quadrant Angle: Specifies the angle in degrees that is created by the two alignments that intersect, forming this intersection quadrant.

   ■ Curb Return Type: Specifies the type of curb return, either chamfer, circular fillet, or 3-centered arc.

   ■ Radius: When the curb return type is circular fillet or 3-centered arc, you can specify radius parameters for the curb return.

   ■ Copy These To All Quadrants: On this dialog box, you can right-click the Curb Return Parameters node in the Property column, and select Copy These To All Quadrants. When this option is selected, the curb return parameters currently selected are automatically applied to all quadrants in the intersection.

   ■ Widening At Incoming\Outgoing Lane: Specifies details for the widening at the incoming and outgoing lanes in the intersection.

- Transition Details: Specifies the transition details for the incoming or outgoing lanes in the intersection.

- Widening Details: Specifies the widening details for the incoming or outgoing lanes in the intersection.

## Editing Side Road Profiles for Intersections

You can edit the rules to adjust the profile of the side road in an intersection.

You may need to edit the profile for a side road after an intersection is created. For example, you can apply or not apply grade rules, or change the maximum grade.

This helps set reasonable grades coming in and out of the intersection on the side road.

**Visual Cues**: When you select an item on this dialog box, the affected object is highlighted in the drawing, and the conceptual graphic on the dialog box updates to indicate the location of the edit. For more information, see Intersection Editing Visual Cues (page 1443).

**To edit a side road profile in an intersection**

1 Do one of the following:

- In the drawing, click the intersection object. On the ribbon, click Side Road Profile  on the Modify panel of the Intersection contextual tab.

- In the drawing, right-click the intersection object, and then select Adjust Side Road Profile from the object shortcut menu.

- In Prospector, expand the Intersections collection, right-click the intersection object, and then select Adjust Side Road Profile from the Toolspace shortcut menu.

---

**NOTE** If one or more of the dynamic PVIs created by the intersection are unlocked, a task dialog is displayed prompting you to either relock the PVIs to match the primary road, or to continue the command without relocking the PVIs. If they do not match the primary road elevation, the corridor top surface in the curb return fillet areas will be uneven. Choose to either relock the PVIs, if possible, or to continue the command without relocking the PVIs.

---

**2** Use the Secondary Road Profile Rules dialog box to edit the following parameters associated with this component.

■ Apply Grade Rules: Specifies whether to apply grade rules for this secondary road profile.

■ Maximum Grade: Specifies the maximum grade that can be used for the tangents leading in to or leaving the intersection along the secondary road.

■ Maximum Grade Change: Specifies the maximum grade change between the intersection area and the tangent leading to the intersection along the secondary road.

■ Distance Rule to Adjust the Grade: Specifies to use a user-defined length or to the extents of the intersection, as lengths, for incoming and outgoing grades along the secondary roads.

■ Distance Value: When using the Distance Rule to Adjust the Grade option, this specifies the distance rule value used for the grade used for the secondary road in the intersection.

## Editing Lane Slopes for Intersections

You can edit lane slopes in an intersection.

You may need to edit lane slopes after an intersection is created. For example, you can change the cross slope from centerline, or select a different profile to use.

It is importnat to note that if you manually specify a lane slope by selecting a profile for the left edge (for example), then the lane slope is determined by that profile.

**Visual Cues**: When you select an item on this dialog box, the affected object is highlighted in the drawing, and the conceptual graphic on the dialog box updates to indicate the location of the edit. For more information, see Intersection Editing Visual Cues (page 1443).

**To edit lane slopes in an intersection**

**1** Do one of the following:

■ In the drawing, click the intersection object. On the ribbon, click Lane Slopes 🔁 on the Modify panel of the Intersection contextual tab.

■ In the drawing, right-click the intersection object, and then select Edit Lane Slope Parameters from the object shortcut menu.

- In Prospector, expand the Intersections collection, right-click the intersection object, and then select Edit Lane Slope Parameters from the Toolspace shortcut menu.

2 Use the Intersection Lane Slope Parameters dialog box to edit the following parameters associated with this component.

- Left or Right Edge Profile Definition: Specifies the parameters defining the left and right edge of the slope

- Use an Existing Profile: When Yes is selected, you can select a profile from the available profiles in the current drawing. When No is selected, this indicates that the profile was created during intersection creation.

- Cross Fall From Centerline: Specifies the slope of the grade from the centerline.

- Profile Name: Displays the name of the profile associated with this edge profile definition. When Use An Existing Profile is set to Yes, you can select a new profile from available profiles in the current drawing.

## Editing Curb Return Profiles for Intersections

You can edit curb return profiles in an intersection.

You may need to edit curb return profiles after an intersection is created. For example, you can extend or not extend the profile along the incoming or outgoing lanes.

**Visual Cues**: When you select an item on this dialog box, the affected object is highlighted in the drawing, and the conceptual graphic on the dialog box updates to indicate the location of the edit. For more information, see Intersection Editing Visual Cues (page 1443).

**To edit curb return profiles in an intersection**

1 Do one of the following:

- In the drawing, click the intersection object. On the ribbon, click Curb Return Profiles on the Modify panel of the Intersection contextual tab.

- In the drawing, right-click the intersection object, and then select Edit Curb Return Parameters from the object shortcut menu.

- In Prospector, expand the Intersections collection, right-click the intersection object, and then select Edit Curb Return Parameters from the Toolspace shortcut menu.

2 Use the Intersection Curb Return Parameters dialog box to edit the following parameters associated with this component.

- **Extend Profile Along Incoming (or Outgoing) Lane**: Specifies whether to extend the curb return profile along the incoming (or outgoing) lane of the intersection.

- **Length To Extend Along Incoming (or Outgoing) Lane**: When **Extend Profile Along Incoming (or Outgoing) Lane** is set to Yes, this option lets you specify the length to extend the curb return profile along the incoming (or outgoing) lane of the intersection.

# Editing Intersection Dynamic Profile Rules

# Widening Turning Lanes for Incoming and Outgoing Roads

# Changing Corridor Assembly Frequency

You can change the frequency of assemblies applied in corridors within intersection objects.

The frequency that assemblies are applied to corridors in an intersection is specified at intersection creation, and is controlled at the command settings level.

You can specify different frequencies for tangent, circular arcs, or spirals segments separately. Once the intersection is created, you can edit the corridor properties to change frequencies as needed. For example, suppose originally the curb return fillet is from station 1+00 to 3+00.

Then suppose that you change the frequency of assembly insertion for one or more of the corridor regions; for example, quadrant 2. Also perhaps you may add manual stations, for example, at station 2+05 and at 2+15 in the curb return fillet section of the corridor in quadrant 2.

Now suppose that you edit the intersection geometry so that the curb return fillet radius at quadrant 2 is increased. Suppose that due to this change, the curb return fillet station changed from 0+50 to 3+50 because of the increased length of arc. In this case, the intersection object will do the following:

■ Corridor region station for that curb return fillet area (in quadrant 2) will be updated as 0+50 to 3+50.

■ Frequencies for this region will be based on the newly set values.

■ Manual stations at 2+05 and 2+15 will still be in the list.

■ All other regions in other quadrants and region types will still have the frequencies set during the intersection object creation.

If the corridor is set to rebuild automatically, then the corridor will be updated with the changes noted above, including manual stations (which would remain at their previous station values).

If one of the manual stations is no longer part of the new curb return fillet area, then that manual station is removed from the list.

If the corridor is set with Rebuild Automatic turned off, then the intersection will still change the corridor regions to the new stations. However, the corridor is not rebuilt unless "Rebuild" is selected on the corridor object, either in the drawing, or in Prospector.

**NOTE** The above steps describe behavior when the corridor is set to rebuild automatically. If it is not set to rebuild automatically, this behavior occurs only when you explicitly click the Rebuild button.

**To change assembly frequency**

1 In Toolspace, on the Settings tab, expand the Intersection collection. Expand the Commands collection.

2 Right-click the CreateIntersection command and click Edit Command Settings.
   The Edit Feature Settings - Intersection dialog box (page 1919) is displayed.

3 Expand Assembly Insertion Defaults.

4 Click in the Value cell for the following frequency options, and specify the desired values: Frequency Along Tangents, Frequency Along Curves, Frequency Along Spirals, Frequency Along Profile Curves.

5 Click Apply.

Dialog Box

Edit Feature Settings - Intersection (page 1919)

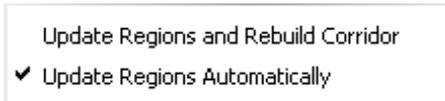
# Updating Corridor Regions in Intersections

You can update the corridor regions in an intersection manually or automatically.

If the intersection definition is out-of-date, 🛡 is displayed next to the intersection in the Prospector tree. This indicates that the corridor regions in the intersection need to be updated.

When you update corridor regions in an intersection, any manual edits that were made to the regions or targets within the intersection corridor are lost.

You can update corridor regions in an intersection manually, or you can specify that the intersection object update corridor regions automatically. When you configure the intersection object to update corridor regions automatically, a check mark is displayed next to the Update Regions Automatically option on the Toolspace shortcut menu.

```
  Update Regions and Rebuild Corridor
✔ Update Regions Automatically
```


The following two options are available for updating corridor regions in an intersection:

| Options | Description |
| --- | --- |
| Update Regions and Rebuild Corridor | Updates the corridor regions in an intersection object and rebuilds the corridors that are included in the intersection object. |
| Update Regions Automatically | Specifies that the intersection object automatically updates the corridor regions and rebuilds the corridors in the intersection object whenever certain types of changes are made to the intersection. |

When the Update Regions and Rebuild Corridor command is invoked, the corridor region stations in the intersection are updated (recalculated) in order to stay in synchronization with the intersection area geometry. The corridor properties are updated to reflect these new region station values.

**To manually update the corridor regions in an intersection**

■ In Toolspace, on the Prospector tab, expand the Intersections collection. Right-click the intersection. Click Update Regions and Rebuild Corridor.

**NOTE** If the intersection definition is out-of-date, 🛡 is displayed next to its node in the Prospector tree.

**To automatically update the corridor regions in an intersection**

■ In Toolspace, on the Prospector tab, expand the Intersections collection. Right-click the intersection. Click Update Regions Automatically.

**NOTE** When you toggle this option on, if AutoCAD Civil detects that changes have been made to the intersection that require the corridor regions to be updated, then the update occurs immediately when you toggle the option on.

A check mark is displayed next to the Update Regions Automatically option on the Toolspace shortcut menu, indicating that this option is turned on.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Intersections ➤ right-click <intersection name> ➤ Update Regions and Rebuild Corridor or Update Regions Automatically

Object Shortcut Menu

Update Regions and Rebuild Corridor or Update Regions Automatically

# Recreating Corridor Regions in Intersections

You can recreate corridor regions in an intersection after intersection geometry has changed, or after you have applied different assemblies.

You may need to recreate corridor regions if intersection components have been edited. For example, if you change the radius or length of curb return alignments, you must recreate corridor regions in the intersection area to ensure that no geometry gaps or overlaps exist.

Another scenario for recreating corridor regions is as follows:

You may want to discard all changes made to the intersection corridors, and recreate the corridors again using the original intersection creation logic.

For example, if you created an intersection object using a particular assembly set (page 2467), and then made changes to that intersection, such as changing curb return corridor stations, frequencies, and assemblies. You may also have changed the extents of the entire length of the primary road on either side of the intersection. Perhaps next you change the horizontal geometry and curb return parameters. If the corridor is set to rebuild automatically, it will update automatically. Otherwise, at this point the corridor will be displayed as out-of-date in Prospector.

Now you may want to discard all those changes and either reapply the original assemblies specified during intersection creation, or apply different assemblies. If so, you can use the Recreate Corridor Regions command to do this.

When you select the Recreate Corridor Regions command, the Intersection Corridor Regions dialog box is displayed. On this dialog box, you can change parameters if desired, including assemblies to apply, or you can leave the parameters on this dialog as specified, and click Recreate to recreate the corridor regions in the intersection object according to the parameters, and assemblies, that were specified when this intersection object was originally created.

The Recreate Corridor Regions command performs the following actions:

- All corridor regions in the selected intersection are deleted, and are recreated according to the parameters that were specified on the Intersection Corridor Regions dialog box.

- Any user-defined corridor regions within the extents of the intersection are deleted.

- A new set of corridor regions is created according to the assembly insertion frequency that is specified in the command settings.

Because this command deletes and recreates the corridors in the intersection, if you made any changes to the corridors in the intersection object, those changes will be overwritten (discarded) when the new corridors are created.

**To recreate corridor regions in an intersection**

1   In the drawing, select the intersection object.

2   Do one of the following:

   - In the Intersection tab on the ribbon, click the Modify panel ➤ Recreate Corridor Regions ⬚ .

   - Right-click and select Recreate Corridor Regions.

3   On the Intersection Corridor Regions dialog box, click Recreate.

**Quick Reference**

Ribbon

Click Intersection tab ➤ Modify panel ➤ Recreate Corridor Regions 

Toolspace Shortcut Menu

Prospector tab: Intersection ➤ right-click <intersection name> ➤ Recreate Corridor Regions

Object Shortcut Menu

Recreate Corridor Regions

# Deleting Intersection Objects

You can delete an intersection object, erasing it from the drawing and removing it from the Intersections collection in the Prospector tree.

When you delete an intersection object in the drawing, the following are deleted:

■ the intersection object, and its label, in the drawing

■ the intersection object in the Intersections collection in Prospector

The following components associated with an intersection object are *not deleted* when you delete an intersection object:

■ the following 2D geometry components associated with the intersection object: intersecting alignments, offset alignments, curb return alignments

■ the following other components associated with the intersection object: offset profiles, curb return profiles

■ If you created a new corridor object inside the intersection area, this corridor object is *not deleted* when you delete an intersection object. You must delete this corridor object manually, if desired.

You can use the following methods to delete an intersection object:

■ In the drawing, select the intersection object, and delete or erase it.

■ If you delete one or both of the intersecting alignments that create the intersection, then the intersection object is automatically deleted.

■ In the drawing, if you move one or both of the intersecting alignments that create the intersection so that the alignments no longer intersect, then the intersection object is automatically deleted.

**Deleting Intersection Object Dependent Components**

It is important to understand the following behavior associated with deleting objects that intersection objects depend on.

■ **Centerline Profiles**: If any of the centerline profiles associated with the intersection are deleted, then the curb return profiles will become static (no longer a dynamic profile). Accordingly, the intersection corridors will be updated. This behavior is similar to how a corridor reacts to its profile grade line, or when a centerline profile is deleted. In this scenario, the intersection object still exists (is not deleted), with just horizontal geometry.

■ **Offset Alignments**: If an offset alignment associated with an intersection object is deleted, and that offset alignment has a curb return alignment attached to it, the curb return attached to that offset alignment

is not deleted; however, the curb return alignment is no longer dynamic to the intersection object. It becomes a static curb return alignment, meaning that if you move the intersection object, the now static curb return alignment does not move. The same is true for the profile associated with the curb return alignment. It becomes a static (non-dynamic) profile.

- **Curb Return Alignments**: If the curb return alignments or profiles are deleted (using AutoCAD Delete), then the intersection area corridors based on those baselines are also deleted. If only the profile is deleted, then the corridors based on those profiles are moved to zero elevation. The intersection object still exists. Deleting the curb return does not automatically delete the profile associated with it; however, if you delete the curb return, the curb return profile becomes static.

- **Assemblies**: If any of the assemblies used the intersection are deleted, and the corridor is set to "Rebuild Automatic", then the corridor regions that use the deleted assemblies are set to <None>. This creates an empty corridor even though corridor regions still exist. You can use the Recreate Corridor command to download the assemblies from the source location into the current drawing, and this recreates the corridor regions.

**To delete an intersection object**

- In the drawing, select the intersection object, and use the AutoCAD Delete or Erase command.
  The intersection object, and its label, are erased from the drawing. The intersection object is also removed from the Intersections collection in the Prospector tree.

# Labeling Intersections

You can add labels to intersection objects.

There are three ways to add labels to intersection objects:

- during intersection object creation

- using the AddLabel command

- using the AddIntersectionLabel command

By default, the standard intersection object label contains the name of the intersection object, the names of the intersecting alignments, and the station value locations where the alignments intersect.

There is no placement option available for an intersection label. The label is always placed at the intersection point. If that point is already labeled, then a second label is placed on top of the existing label.

For more information, see Understanding Labels in AutoCAD Civil (page 1466).

**To label intersection objects**

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Add Intersection Label 🏷️ .

2 Select the intersection object to be labeled.

## Quick Reference

Ribbon

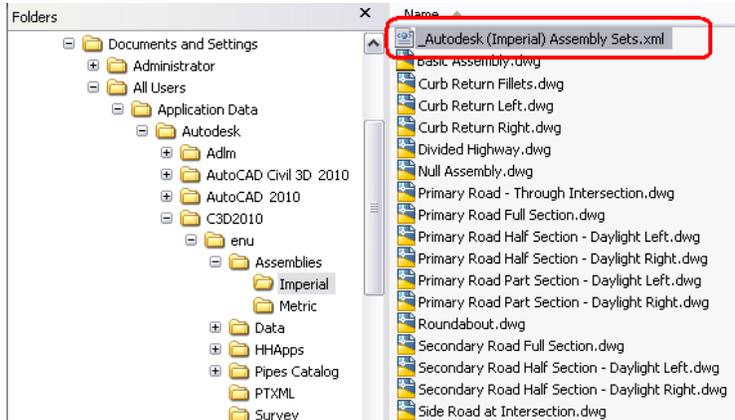
Command Line

AddIntersectionLabel

# Assembly Sets

An assembly set is a group of assemblies used to create a corridor in an intersection object.

Assembly sets are used only with intersection object creation. A default assembly set is included with AutoCAD Civil. You can create an intersection using this default assembly set, or you can create your own custom assembly sets to suit the needs of specific intersection design.



When you apply the assembly set, and create or update the intersection object corridors, the referenced assembly objects are imported into the current drawing, if they are not already there.

The following table describes the components that are associated with an assembly set:

| Component | Description |
| --- | --- |
| assembly set | A group of assemblies that have been designed for use in specific type of intersection design. An assembly set is defined in an assembly set file. |
| assembly set file | An .xml file containing information that defines the assemblies that are included in an assembly set. An assembly set file contains the names of the assembly objects, the location (path) where the individual assembly drawings exist, and other information about the assemblies included in the set. This .xml file serves primarily as a pointer (reference mechanism). It does not contain the actual assembly drawing data. |
| assembly object names | The name of each assembly object referenced in the set is maintained in the assembly set file. Note that the assembly object data itself is not contained in the assembly set file, just the information that enables AutoCAD Civil to locate the assembly object data (a reference to the assembly name, and the name of the drawing file that contains the assembly object.) |
| assembly drawings | Each assembly object referenced in an assembly set is also saved to an assembly drawing file. An assembly drawing file contains a single assembly object. The assembly drawing file typically has the same name as the assembly object. For example, the assembly drawing file for an assembly object named Secondary_Road_Half_Section _Daylight_Left is named Second- |

| Component | Description |
|---|---|
| | ary_Road_Half_Section _Daylight_Left.dwg. The assembly drawing file associated with each assembly object referenced in the assembly set is also stored (referenced) in the assembly set. |

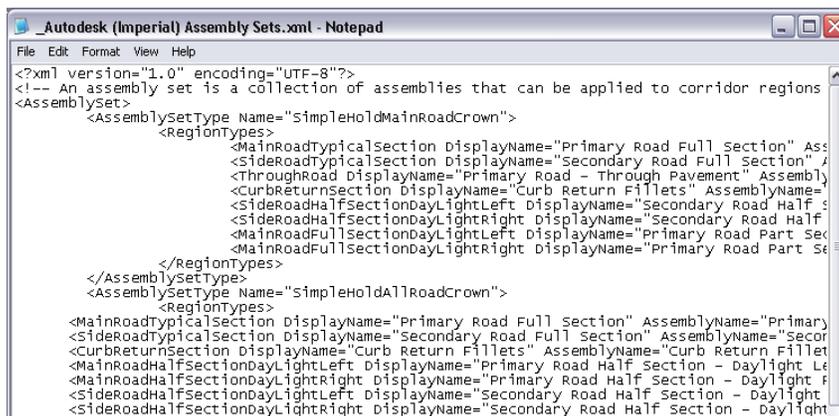
The fist time you use the Create Intersection wizard, it is recommended that you accept and use the assembly set that is referenced by default on the wizard. As you become more familiar with creating intersections, you will want to create your own customized assembly sets. For instructions see, To Create an Assembly Set (page 1458).

The assembly set that is included with AutoCAD Civil is typically located by default in the following location:

*C:\Documents and Settings\All Users\Application Data\ Autodesk\Civil2010\enu\Assemblies\Imperial (or Metric)*

**NOTE** If the assembly set file references an assembly name that cannot be found, then a null assembly (page 2478) will be used to in its place to create the intersection object. For more information, see Null Assemblies (page 1460).

The following illustration shows the contents of the default assembly set file that is included with AutoCAD Civil.



### Modifying Assemblies Referenced in Assembly Sets

It is important to note that if you modify an assembly that is referenced in an assembly set, and that is already used in the current drawing, and you do not change the name of the modified assembly, this does not change the intersection area corridor definition.

In such cases, if you try to create a new intersection, or recreate an existing intersection, the intersection corridor will continue to use the assembly of the same name in the current drawing, and will not use the modified assembly that is referenced in the assembly set folder.

If you want to apply the updated assembly that is referenced in the assembly set to the intersection corridor, you must delete (or rename) the assembly with the same in name in the current drawing first.

**To create an assembly set**

1   Ensure that the assemblies that you intend to save to the new assembly set exist in the current drawing.

 You can perform this procedure using the Create Intersection wizard, or by editing an existing intersection object.

2   Do one of the following:

 ■ **Using the Create Intersection Wizard**: You can create an assembly set during intersection creation, using the Corridor Regions page of the Create Intersection wizard. To do so, start the CreateIntersection comand, select the new assemblies in the Assemblies To Apply section of the

Corridor Regions page, and then proceed to Step 3 below. If desired, you can click Cancel on the Create Intersection wizard after you have saved the new assembly set. This allows you to create a new assembly set without creating a new intersection object.

- **Edit an Existing Intersection**: Select an existing intersection, and then click Recreate Corridor Regions on the Modify panel of the Intersection contextual tab. On the Intersection Corridor Regions dialog box, select the assemblies in the Assemblies To Apply section of this dialog box.

3 After selecting the desired assemblies, click Save As a Set.

4 On the Select Assembly Set File dialog box, enter a name for the new assembly set file, and then click Save.

---

**NOTE** At this point, the new assembly set file is created. You may or may not want to proceed with applying the new assembly set to the current intersection. If you do want to apply the new assembly set to the current intersection, follow the next step.

---

5 To apply the assembly set to the intersection, do one of the following:
- If you selected the assemblies from the Corridor Regions page of the Create Intersection wizard, click the Browse button, select the newly created assembly set file, and then click Create Intersection.

- If you selected the assemblies from the Intersection Corridor Regions dialog box, click the Browse button, select the newly created assembly set file, and then click Recreate.

**To apply a different assembly set to an intersection**

1 In the current drawing, create the desired assemblies. You can edit the existing assemblies, or create new ones from scratch.

2 Do one of the following:
- If you are creating an intersection, on the Corridor Regions page of the Create Intersection wizard, select the new assemblies in the Assemblies To Apply section of this dialog box.

- On an existing intersection, select the intersection, and then click Recreate Corridor Regions on the Modify panel of the Intersection contextual tab. On the Intersection Corridor Regions dialog box, select the assemblies in the Assemblies To Apply section of this dialog box.

3 After specifying the desired assemblies, click Save As a Set.

4 On the Select Assembly Set File dialog box, specify the name and location for the assembly set file, and click Save. If desired, you can select an existing assembly set file and save (update) it with the information about the newly specified assemblies.

5 Click Browse to navigate to and select the desired assembly set file.

6 Use the drop-down arrow on the Select Assembly Set To Import field to ensure that the desired assembly set file is specified on this dialog box.

7 To apply the new assembly set to the intersection, do one of the following:
- If you are creating a new intersection, click Create Intersection on the Corridor Regions page of the Create Intersection wizard.

- If you edited an existing intersection, click Recreate on the Intersection Corridor Regions dialog box.

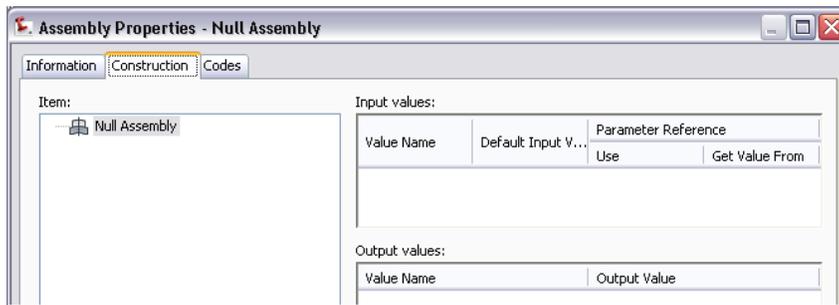
# Null Assemblies

A null assembly is created in an intersection object during creation when an assembly name referenced in the assembly set file cannot be found.

AutoCAD Civil automatically creates a null assembly when you create an intersection that references an assembly name that cannot be found in any of the assembly drawings referenced in the selected assembly set (page 2467) file. The null assembly serves as a placeholder object so that the intersection object can still be created even though an assembly cannot be found.

If the assembly name is not found in the assembly drawings referenced by the assembly set file, AutoCAD Civil then searches for the assembly name in the current drawing. If the assembly is found in the current drawing, then AutoCAD Civil proceeds with creating the intersection using that assembly, and creating the external assembly drawing for the assembly, if one does not already exist.

A null assembly allows AutoCAD Civil to continue with intersection creation even though all of the referenced assemblies are not found.



After the intersection is created, you can assign appropriate assemblies, or a different assembly set. If you do, you will need to recreate the intersection corridor regions, as well as rebuild the intersection, to apply the new assembly or assemblies to the intersection. You may also need to rebuild corridors. For more information on recreating intersection corridor regions, or on rebuilding an intersection, see Updating Corridor Regions in Intersections (page 1452) and Recreating Corridor Regions in Intersections (page 1454).

# Intersection Command Reference

You can use commands to quickly access intersection functionality.

The following table lists the intersection-related AutoCAD Civil commands and briefly describes their functionality.

| Command | Description |
| --- | --- |
| AddIntersectionLabel | Adds a label to an intersection object (page 1456) |
| CreateIntersection | Creates an intersection (page 1430) |
| EditIntersectionProperties | Displays the Intersection Properties dialog box which lets you edit Intersection object properties (page 1441) |

| Command | Description |
|---|---|
| EditIxCorridorRegions | Edits corridor regions in an intersection (page 1452) |
| EditIxCurbReturns | Edits curb returns in an intersection (page 1447) |
| EditIxCurbReturnProfiles | Edits curb return profiles associated with an intersection object (page 1450) |
| EditIxOffsetProfiles | Edits offset alignment profiles associated with an intersection object (page 1449) |
| EditIxOffsets | Edits offset alignments in an intersection (page 1445) |
| EditIxSideRoadProfile | Edits side road profiles associated with an intersection (page 1448) |

# Labels and Tags

# 33

You can annotate AutoCAD Civil objects with labels that update dynamically when the drawing objects change.

Labels can contain single or multiple lines of text, blocks, ticks, lines, and direction arrows.

Labels have two modes: label mode and tag mode. Use tags to mark drawing objects with numbers so you can insert detailed information in tables.

In AutoCAD Civil, tag settings are a drawing-wide setting. See Creating Label Tags (page 1544) for more information.

Labels and Tables Workflow

Label Styles Best Practices

## Label Objects

AutoCAD Civil includes independent label objects. Most labels in AutoCAD Civil are implemented as label objects that reside on their own layer.

**NOTE** Points, surface watershed, and all corridor labels are not object type labels. They are sub-entities of a parent object and their properties are managed in the Label Properties dialog box.

- Label objects are not highlighted when the parent object is selected as they are separate independent objects.

- Labels can include references to other AutoCAD Civil objects by including Referenced Text (page 1509) components.

- You can label external reference (xref) data objects. When you insert xref objects from a source drawing into your current drawing, you can annotate them as you would other objects. For more information, see Labeling External References (Xrefs) (page 1531).

- You can use alignment label styles to label superelevation critical points (page 877).

- Label text can be overridden by using the Edit Label Text (page 1535) command on the shortcut menu.

- Group Label Properties (page 1533) such as such as layer, linetype, and color are changed with the AutoCAD Properties palette. You have the ability to simultaneously edit group labels with the Properties palette.

- Label object properties are separate from the parent object. Use the Label List command (page 1486) to display the label properties (including its designation as a single or group label object).

- Label visibility (page 1487) can be controlled with label style settings or through layer management.

- New label styles can reference the layer in the style, or the layer that the label(s) resides on. This gives you the option of managing labels with styles (page 1492) or the use of layers.

- Labels that are part of a group can be selected individually and changed using "Ctrl+click" selection (page 1534).

- A label's default layer (page 1488) can be specified and changed with the Properties palette, or other AutoCAD layer manipulation tools.

- Alignment label styles are edited in the Alignment Labels Dialog Box (page 1739).

- Use the Mapcheck Analysis command to determine values from label objects based on the precision of the annotation of the label object. Click Analyze tab ➤ Ground Data panel ➤ Survey drop-down ➤ Mapcheck 🗹 . For more information, see Performing a Mapcheck Analysis (page 1608).

- This release of AutoCAD Civil features label leader line enhancements for improved control and flexibility when grip editing labels. See Editing Line, Arc, and Polyline Labels with Grips (page 1538), and Managing Leader Vertices (page 1520) for more information.

- Use the Label Stagger options to avoid densely populated graph views. These options allow you to stagger labels for profile views, section views, and data bands for improved visibility. For more information, see Staggering Profile and Section Labels (page 1527) and Staggering Data Band Labels (page 1528).

- Data band labels are now object labels that can be edited, dragged, and reset like other label objects. See Editing Data Band Labels (page 1529), Deleting Band Labels (page 1545), and Restoring Band Labels (page 1546) for more information.

- This release of AutoCAD Civil include projected object label styles for profile and section views. See Adding Profile View Labels (page 1037)and Using Section View Labels (page 1139)for more information.

The label objects are listed in the table below. Note that the label objects include two distinct object types: group and single labels.

Group label objects and single label objects behave differently with respect to screen interaction and AutoCAD object management. The selection of the group label objects is limited to the group (the entire group is highlighted when selected), which means the context menu no longer applies to the perceived selected label.

This group selection functionality allows you to simultaneously edit an entire group of labels. As group type labels have an object controlling the creation and application of the label within a group, the AutoCAD Properties palette lists information regarding the annotated object.

Single type labels do not list this information, but both types display Standard AutoCAD properties and Label properties with the Properties palette. See Modifying Labels in a Drawing (page 1533) for more information.

The label objects are listed in the table below and are identified as either group or single labels.

| Feature / Label Type | Group or Single Label |
| --- | --- |
| Note | Single |
| Segment | Single |
| Surface Slope | Single |
| Surface Spot Elev | Single |
| Surface Contour - Major, Minor, User | Group (no sub-entity selection) |

| Feature / Label Type | Group or Single Label |
|---|---|
| Alignment Major Stations | Group |
| Alignment Minor Stations | Group |
| Alignment Geometry Point | Group |
| Alignment Station Equation | Group |
| Alignment Design Speed | Group |
| Alignment - Profile Geometry Point | Group |
| Alignment Station Offset - Fixed Point | Single |
| Alignment Station Offset | Single |
| Alignment Line | Single |
| Alignment Curve | Single |
| Alignment Spiral | Single |
| Alignment Tangent Intersect | Single |
| Parcel Line | Single |
| Parcel Curve | Single |
| Parcel Area | The first area label is part of the parcel object (to select the parcel). Additional area labels can be added, but they are single. |
| Profile Major Stations | Group |
| Profile Minor Station | Group |
| Profile Horizontal Geometry | Group |
| Profile Grade Breaks | Group |
| Profile Line | Group |
| Profile Sag Curves | Group |
| Profile Crest Curves | Group |
| Profile View Depth | Single |
| Profile View - Station Elevation | Single |
| Sample Line | Group |
| Section Major Offset | Group |

| Feature / Label Type | Group or Single Label |
| --- | --- |
| Section Minor Offset | Group |
| Section Grade Break | Group |
| Section Segment | Group |
| Section View Grade | Single |
| Network Pipe in plan | Single |
| Network Pipe in profile | Single |
| Network Pipe in section | Single |
| Network Structure in plan | Single |
| Network Structure in profile | Single |
| Network Structure in section | Single |
| Network Pipe - Spanning pipe | Single |
| Plans Production - View Frame | Single |
| Plans Production - Matchline | Group |
| Profile Data Band | Group |
| Section Data Band | Group |

# Understanding Labels

In AutoCAD Civil, labels and tags are controlled by label styles.

In the Toolspace Settings tree, most feature collections, such as parcels, alignments, and surfaces, contain their own unique label styles. When you define a label style, you determine the purpose of the label and set up a relationship with the object that uses it. Labels always remain associated with the object they are annotating.

General line and curve label styles can be used for parcel segments labels, and alignment line/curve labels. Previously, general line label styles could modify only lines, curves, and polylines. For more information, see Editing Label Styles (page 1482).

The general line label styles are available for the parcel, alignment, grading, and survey labeling commands. Parcel tables now support general line/curve label types. Parcel tables display either general/line curve labels or parcel segment labels. For more information, see Adding Parcel Tables (page 845).

There are three levels of label settings in addition to settings that you define in the label styles themselves. For more information, see The Hierarchy of Label Settings (page 1468).

As you create AutoCAD Civil objects in a drawing, they are labeled automatically using specified label styles. However, after an object is created, you can add more labels manually.

Labels are defined by the following properties:

■ **Location**. Label location in a drawing depends on the object using the label.

For example, a parcel area label is usually placed at the center of the parcel, and surface contour labels are usually placed on the contour line.

- **Appearance and Visibility**. Whether a label is visible, and how it appears in a drawing, can be specified in the label style or by managing the AutoCAD properties. You can define different display settings, such as color, lineweight, and linetype, for each label component.

- **Mode**. Many label styles have two modes: label and tag. Tags are used to identify labeled objects within a table. For more information, see Setting Up Label Styles To Be Used as Tags (page 1485).

- **Behavior**. Labels behave according to their association with objects. For example, if you move an object in a drawing, the label moves with it.
  Also, behavior can also depend on how a label is positioned in a drawing.

- **Placement**. A label is placed in relation to an object or another label style component. For more information, see Anchor Points and Attachment Points (page 1492).

- **Plan-Readable text**. Labels can be placed at any angle, but you can select a plan-readability setting to maintain legibility. For more information, see Using Plan-Readability (page 1489) and Changing Label Insertion (page 1490).

- **Orientation**. Label orientation refers to the rotation angle of the labels in 3D space. For more information about label orientation, see Changing Label Orientation (page 1488).

The commands used to add single and multiple label types from the parcels, alignments and line/curve menus support each of the three object types. For example, if you click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Line And Curve ➤ Add Single Segment Line/Curve Label 🏷 and then select a parcel in the drawing, a parcel segment (line or curve) label is created.

The following object type/segments are supported by these commands:

- line

- arc

- polyline line segment

- feature line, line segment

- feature line, arc segment

- parcel line segment

- parcel curve segment

- alignment line segment

- alignment curve segment

- alignment spiral segment

The following table lists what determines the default style/style type when you use the add label command from particular menus.

| | General Line/Curve Menu | Parcel Line/Curve Menu | Alignment Line/Curve Menu |
| --- | --- | --- | --- |
| Create label on line, curve, pline, or feature line | Styles come from line/curve settings (General line/curve style type). | Styles come from Parcel settings (General line/curve style type, or parcel types supported). | Styles come from line/curve settings (General line/curve style type). |

|  | **General Line/Curve Menu** | **Parcel Line/Curve Menu** | **Alignment Line/Curve Menu** |
|---|---|---|---|
| Create label on Parcel Segment | Styles come from line/curve settings (General line/curve style type). | Styles come from Parcel settings (General line/curve style type, or parcel types supported). | Styles come from Parcel settings (General line/curve style type, or parcel types supported). |
| Create label on Alignment Segment | Styles come from line/curve settings (General line/curve style type). When labeling using "Multiple" or "Single," and any spirals are labeled they use the alignment settings for the spiral style. | Styles come from Alignment settings (General line/curve style type, or Alignment types supported). When labeling using "Multiple" or "Single," and any spirals are labeled, they use the alignment settings for the spiral style. | Styles come from Alignment settings (General line/curve style type, or Alignment types supported). |
| Create label on Line, Curve, Pline or Feature Line | Styles come from Add Labels dialog | Styles come from Add Labels dialog | Styles come from Parcel settings (General line/curve style type, or parcel types supported). |
| Create label on Alignment Segment | Styles come from Add Labels dialog. When labeling using "Multiple" or "Single," and any spirals are labeled, they use the alignment settings for the spiral label style. | If current style referenced in label tool is line/curve type, then that style is applied. If style is parcel type, get styles from alignment settings. When labeling spirals using "Multiple" or "Single," and any spirals are labeled, they use the alignment settings for the spiral style. | Styles come from Add Labels dialog. |

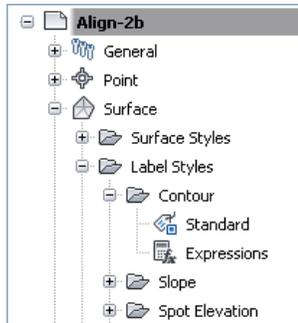
# The Hierarchy of Label Settings

You can manage label style settings in a drawing at different levels using the Settings tree in Toolspace.

The hierarchy that label style settings use can be best viewed in the tree structure in Toolspace, shown in the following illustration.

**Edit label settings at the Drawing level, object level (such as Surface),**

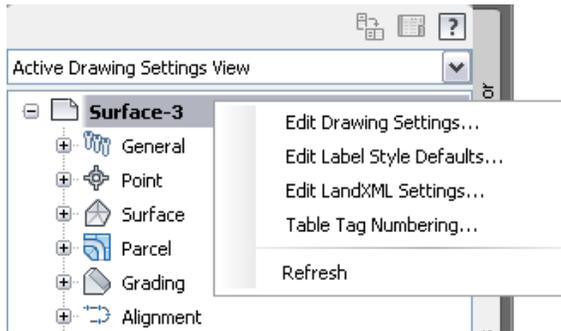
**and label-style-type level (such as Contour)**



**At each level, right-click and click Edit Label Style Defaults**

Each level of settings controls the characteristics in subordinate levels, unless a setting has been specifically changed or overridden in the subordinate.

At the drawing level you can determine how table tags are numbered. Click the drawing name, right-click and click Table Tag Numbering to access the Table Tag Numbering Dialog Box (page 1971). For more information, see Creating Label Tags (page 1544).



**Tag numbering settings are drawing-wide settings**

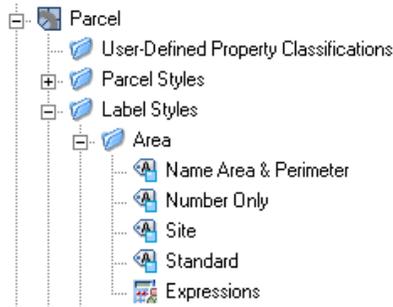
# Overview of Label Styles

Use a label style to define the behavior, appearance, and content of labels.

Every label in the drawing has a style associated with it, and edits to the label styles are immediately reflected in the labels in the drawing.

In the Toolspace Settings tree, Label Styles collections contain one or more *types* of label styles that represent a unique aspect of the object using it. The following illustration shows the hierarchy of the label style collection, the label style types, and the individual label styles:

**Parcel Area label style type collection**



Each label type has a Standard label style. The AutoCAD Civil drawing templates also contain several other label styles you can use.

You can create *child* styles that are based on an existing style. For more information, see Defining Children of Existing Label Styles (page 1478).

## Viewing and Selecting Available Label Styles

Use the Toolspace Settings tree to view available label styles in a drawing.

**NOTE** You can identify a label style in the Settings tree by  next to it. If a label style is in use in the drawing, then  is displayed when the Drawing Item State icons are visible in Toolspace.

**To view available label styles**

1   In Toolspace, click the Settings tab.

> **TIP** From the View Control list, select Active Drawing Labels Only View. Or, if you have more than one drawing open, select Labels Only View.

2   Expand the Settings tree by clicking ⊞ next to a drawing name.

3   Expand a feature collection, such as the Surface collection.

4   Expand the Label Styles collection to display the label style types inherent to that object.
    In the Alignment, Profile, and Section collections, you can also view any label sets (page 1547) for that feature.

5   Expand the label style type collection to view the available label styles.

6   Right-click a label style to access commands for working with the style. You can edit, delete, or copy the style, or create a new child style.

> **NOTE** Right-click the label style type collection and click New to create a new label that is not a child style of an existing style.

OR

1   In the drawing, select the label to edit. Right-click and select Edit Label Style.

2   In the Label Style Control (page 1965) box, click the Select a Style arrow to display a list of available styles.

OR

**1** Select a label, right-click and select Properties or Label Properties.

**2** In the Properties palette, click Line or Curve label style to display a list of available styles.

Select the Edit/Create option to access the Label Style Control (page 1965) dialog box with which you can create a new style, copy the currently selected style, create a child style, or edit the currently selected style with the Label Style Composer.

OR

**1** In the drawing, select the label to edit.

**2** Select the Labels tab ➤ Label Properties drop-down menu ➤ Edit Label Style to access the Label Style Control (page 1965) dialog box.

### Quick Reference

Ribbon

Click Labels tab ➤ Modify panel ➤ Label Properties drop-down ➤ Edit Label Style

Toolspace Shortcut Menu

Settings tab: <drawing name> ➤ <object collection> ➤ Label Styles ➤ <label style type name> ➤ <label style name>

## Predefined Label Styles in Templates

Use drawing templates provided with AutoCAD Civil to access predefined label styles for each feature.

Use these styles as-is or use them as a basis for creating your own styles.

## Standard Label Styles

By default, all label style types have a Standard label style.

When you create a new drawing without a reference to a template (*.dwt*), the label style types in the Label Styles collections in the Settings tree contain a Standard label style based on default settings. You can use the Standard style as-is, or you can use it as a basis for a new style by changing its properties and renaming it.

You can delete a Standard label style only when it is not referenced in a drawing or if it is not a "parent" label style with a subordinate "child" label style. For more information, see Defining Children of Existing Label Styles (page 1478).

## Working with Label Styles in Toolspace

Use the Settings tree to create or edit label styles.

Right-click either a label style type or a specific label style to display a shortcut menu with options for working with label styles.

| Select this command… | If you want to… |
| --- | --- |
| Right-click label style ➤ New (page 1478) | Create a label style that is based on the settings of a parent label style. This command displays |

| Select this command... | If you want to... |
| --- | --- |
| | the Label Style Composer and contains "Child of..." as the label style name. |
| Right-click label type ➤ New (page 1477) | Create a label style that is not a child of an existing label style. The new label style is a parent-level style and obtains its defaults from the label type settings. |
| Right-click label style ➤ Edit (page 1473) | Edit a label style in the Label Style Composer. |

## Using Label Styles From Other Drawings

Use a label style from any open drawing by dragging the style from one drawing to another in the Settings tree. You can also drag the style from the Settings tree into the drawing window to copy it into that drawing.

When you attempt to copy a named label style to a location where a matching named label style exists, you are prompted with a warning, and you can choose one of the following options:

■ **No**: Leaves the existing style and cancels the operation.

■ **Yes**: Copies the style to the new drawing and renames the style using the format <source drawing name>.<style name>.1

### Using Child Label Styles From Other Drawings

If you copy a child label style to another drawing, its parent style is also copied.

---

**TIP** Because you can only drag one label style at a time into another drawing, it is more efficient to set up your commonly used label styles in a DWT file that you can use for each new drawing you create.

---

### To use label styles from other drawings

1  Open the drawing that contains the styles you want to copy (Drawing1, for example), and the drawing you want to copy styles to (Drawing2, for example).

2  In Toolspace, click the Settings tab.

3  From the View Control list, select Labels Only View to see the labels in all open drawings.

4  In the Settings tree, expand the Drawing1 collection and select the label style that you want to copy.

5  Drag and drop the label style to Drawing2 in the Settings tree. You must drag the style over the drawing name in the Settings tree before releasing the mouse button.

    ■ A valid drag and drop operation will display a ⬚ cursor.

    ■ An invalid drag and drop operation will display a ⊘ cursor.

## Previewing Label Styles

Use the preview window to view how a label style will appear in the drawing. When you make modifications to the label style, the preview window updates.

The preview window is located on the General, Layout, and Dragged State tabs of the Label Style Composer (page 1473). You can select a different preview by selecting it in the Preview list.

To change the view in the Preview window, you can use AutoCAD commands on the shortcut menu, such as Pan and Zoom.

Previews are actually stored as DWG files in the \Data\Preview folder. If you would like to add your own preview drawings that contain specific label styles, you can place the drawings in the Preview folder.

**NOTE** Do not rename the Preview folder or its sub-folders. Any changes to the folder structure prevents AutoCAD Civil from accessing the preview drawings.

**To add preview drawings to the Preview folder**

1 Create a new drawing, create one or more label styles, and label an object with the label styles you want to preview.

2 Click App Frame ➤ Save As.

3 Navigate to the Data\Preview folder and save the drawing file.

**NOTE** The \Data folder path is set up during installation.

**To view a preview drawing in the Preview pane**

1 On the General, Layout, or Dragged State tabs of the Label Style Composer (page 1942), click the Preview arrow in the upper-right corner of the dialog box to display a list of preview drawings.

2 Select the preview drawing you want to view.

3 Right-click in the preview pane to access commands you can use to change the display of the preview drawing.

# Overview of the Label Style Composer

Use the Label Style Composer to edit a style or to set up a new label style

**Access the Label Style Composer by selecting any of the following commands:**

■ Right-click an existing style and click Edit.

■ Right-click an existing style and click New.

■ Right-click a label style type and click New.

**NOTE** You can also access the Label Style Composer from the Label Style Control, which is available in many dialog boxes. For more information, see Label Style Control (page 1965).

**Access the Label Style Composer from the Ribbon**

1 Select the label. Click Labels tab ➤ Modify panel ➤ Label Properties drop-down ➤ Edit Label Style  .

2 In the Label Style Control, click Edit Current Selection.

The Label Style Composer contains the following five areas for settings:

**Information tab (page 1942)** Defines the name and description of the label style.

**General tab (page 1942)** Defines general display and behavior of the label, such as layer and visibility settings. For more information, see Managing General Properties for Label Styles (page 1486).

**Layout tab (page 1944)** Defines specific components of a label, and their display, behavior, and relationship to the feature that uses them. For more information, see Managing Layout Properties for Label Styles (page 1492).

**Dragged State tab (page 1958)** Specifies how label text displays when it is dragged away from its original position. For more information, see Managing Dragged Properties for Label Styles (page 1517).

**Summary tab (page 1959)** Displays all settings and overrides in a label style, as well as parent/child relationships. For more information about working with overrides, see Managing Overrides in Label Style Dialog Boxes (page 1960).

# Scaling Labels in Drawings

Labels are scaled relative to the drawing scale in model space, and are scaled to the assigned text height in paper space, regardless of the viewport scale.

**Model space scaling**

In model space, label text height is controlled by the drawing scale and the text height as specified in the label style.

For example:

- In a 1:50 scale drawing, with the label text height 0.1, the labels are created at a height of 5'.

- In a 1:100 scale drawing, with the label text height 0.1, the labels are created at a height of 10'.

**Paper space scaling**

In paper space, label text always appears at the same height regardless of the paper space viewport scale.

For example, label text height set to 0.1 appears as 0.1 inch on the plotted sheet, regardless of viewport scale or zoom level.

You must use the REGENALL command to update the label display onscreen when you either change the paper space viewport scale or zoom.

**Scaling of Xrefs**

Labels in drawings that you xref also respect the scale of paper space viewports, so you can create project documentation in paper space at the correct scale for several drawings at the same time.

**NOTE** In order to label an xref object, the scale of the inserted xref is must be 1,1,1.

**Recommendations for managing AutoCAD Civil labels in a viewport**

When working with labels in a viewport, do not use the Annotation Scale at the bottom of the drawing window as this will change the viewport scale.

When working with labels in a viewport, you should use one of the following methods:

- Use the Standard Scale in the View Port Properties Palette window. This will not change the Annotation Scale.

- Use the zoom command in the viewport to get the desired viewport zoom scale.

# Defining Label Settings

You can define default label settings at three different levels. Each level controls default characteristics in subordinate settings and in the label styles.

At subordinate levels you can override the default settings. However, you can lock the default settings so that they cannot be changed.

## Default Settings for All Label Styles in a Drawing

Label style defaults that you set at the drawing level can affect every label style in the drawing.

**To specify default label style settings for a drawing**

1   In Toolspace, on the Settings tab, right-click a drawing name, and click Edit Label Style Defaults.

2   In the Edit Label Style Defaults - Drawing (page 1941) dialog box, define defaults for all labels in a drawing by changing the settings in the Value column.

> **TIP** Using the Visibility setting in the drawing-level label settings is a quick way to turn off all labels in a drawing.

If you want a different setting for an individual label style, you can override the default in a subordinate setting.

3   Optionally, lock any setting by clicking ⬔ to change it to 🔒 .

4   Click OK.

### Quick Reference

Toolspace Shortcut Menu

   Settings tab: Right-click <drawing name> ➤ Edit Label Style Defaults

Dialog Box

   Edit Label Style Defaults - Drawing (page 1941)

## Default Settings for All Label Styles in a Feature

Label style defaults that you set at the feature level can affect every label style defined for that specific feature.

**To specify default label settings for all label styles in a feature**

1   In Toolspace, on the Settings tab, right-click a feature collection and click Edit Label Style Defaults.

2   In the Edit Label Style Defaults <Feature Name> (page 1941) dialog box, define defaults for all label styles belonging to the feature by changing the property settings in the Value column.

When you change a value at the current level, the check box ☑ is selected in the Override (page 1960) column.

**3** Optionally, lock any setting by clicking 🔓 to change it to 🔒 .

**4** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: <drawing name> ➤ Right-click <object collection> ➤ Edit Label Style Defaults

Dialog Box

Edit Label Style Defaults <Feature Name> (page 1941)

# Default Settings for All Labels in a Label Type

Label style defaults that you set at the label-style-type-level can affect every label style defined for that specific label style type.

**To specify default settings for all labels in a label type**

**1** In Toolspace, on the Settings tab, right-click a label style type and click Edit Label Style Defaults.

> **NOTE** Label style types are the lowest-level collection within the Label Styles collection. For example, under Alignment, expand Station to display the label style types Major Station, Minor Station, Geometry Point, and so on.

**2** In the Edit Label Style Defaults <Style Type> (page 1942) dialog box, define defaults for all label styles belonging to that label type collection by changing the property settings in the Value column.

When you change a value at the current level, the check box ☑ is selected in the Override (page 1960) column.

**3** Optionally, lock any setting by clicking 🔓 to change it to 🔒 .

**4** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: <drawing name> ➤ <object collection> ➤ Label Styles ➤ Right-click <label style type name> ➤ Edit Label Style Defaults

Dialog Box

Edit Label Style Defaults <Style Type> (page 1942)

# Changing Command Settings for Labeling Lines, Arcs, and Notes

Specify the default styles to use when inserting Note and Line and Curve labels.

**To specify default styles for Note and Line and Curve Labels**

**1** In Toolspace, on the Settings tab, expand the General collection.

**2** Expand the Commands collection.

**3** Right-click a command item and click Edit Command Settings.

**4** Expand Default Styles.

**5** Specify the styles for each label type.

**6** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: <drawing name> ➤ General ➤ Commands ➤ Right-click <command name> ➤ Edit Command Settings

Dialog Box

Edit Feature Settings - General Dialog Box (page 1799)

# Creating and Editing Label Styles

You can create new label styles that are derived from existing styles and styles that are independent of existing label styles. When you edit a label style, all labels in the drawing that use that style are updated.

**NOTE** Label style names are case-sensitive. For example, the label name "Standard" is not the same as "standard".

# Creating New Label Styles

Define the settings for a new or existing label style by using the Label Style Composer.

## Defining an Independent Label Style

You can define a label style that has no dependencies on another existing label style.

**To define an independent label style**

**1** In Toolspace, on the Settings tab, right-click a label style type and click New.

**NOTE** Label style types are the lowest-level collection within the Label Styles collection. For example, under Alignment, expand Station to display the label style types Major Station, Minor Station, Geometry Point, and so on.

**2** In the Label Style Composer, click the Information (page 1942) tab and enter a name in the Name box.

**3** Use the other tabs in the Label Style Composer (page 1942) to change the settings.

**4** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: <drawing name> ➤ <object collection> ➤ Label Styles ➤ right-click <label style type name> ➤ New

Dialog Box

Label Style Composer (page 1942)

## Defining New Label Styles by Copying Existing Label Styles

Create a copy of a label style.

**To copy label styles**

1   In Toolspace, on the Settings tab, right-click a label style and click Copy.

2   In the Label Style Composer, click the Information (page 1942) tab and enter a name in the Name box.

3   Use the other tabs in the Label Style Composer (page 1942) to change the settings.

4   Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: <drawing name> ➤ <object collection> ➤ Label Styles ➤ <label style type name> ➤ right-click <label style name> ➤ Copy

Dialog Box

Label Style Composer (page 1942)

## Defining Children of Existing Label Styles

You can define a new child label style that derives its default settings from an existing label style, or parent.

**To create a child of a label style**

1   In Toolspace, on the Settings tab, right-click a label style, and click New.
    In the Label Style Composer, "<name of parent style> [Child]" is displayed in the title bar.

2   Click the Information (page 1942) tab, and enter a name in the Name box.

3   Use the other tabs in the Label Style Composer (page 1942) to change the settings.

4   Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: <drawing name> ➤ <object collection> ➤ Label Styles ➤ <label style type name> ➤ right-click <label style name> ➤ New

Dialog Box

Label Style Composer (page 1942)

## Automatically-Created Child Styles

To be displayed in a table, the labels must be converted to tag display mode. Tag and label mode are style-wide settings. However, when you manually select labels that are in label mode, AutoCAD Civil generates a child style that is set to tag mode and changes only the selected label to this new child style.

**Selecting Labels to Add to a Table**

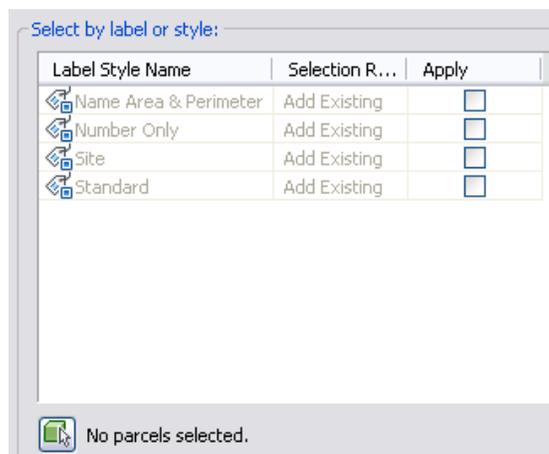
When you insert a table, you can specify the contents of the table in two ways:

■ The table can contain all labels of a particular label style.

■ You can select the labels to add to the table from the drawing.

When you use the second method, you are prompted to create a child style if the selected labels are currently in Label display mode.

The following illustration shows the Selection section of the Add Table dialog box:



To add all labels of a particular label style name to a table, select the Apply check box next to the label style name. When you use this method, all the labels are switched to tag mode, and a child style is not created.

To add selected labels of a particular style to a table, click and click the labels. When you select a label in the drawing that is not in Tag display mode, a dialog box is displayed informing you that the label is not currently in tag mode and asking whether you want to create a new child style.

Click Yes to continue (if you click No a child style is not created and the label is not added to the table). Clicking Yes creates a child style of the current label style in the format <style name>.Tag.1.

If you want to avoid generating child styles when creating a table, then you can do either of the following:

■ Always use the style-based selection method when creating tables. You can specifically set up "tag" label styles to use for this purpose, and use the tag label styles to label only those entities you want to insert into the table. For more information, see Setting Up Label Styles To Be Used as Tags (page 1485).

■ Before creating a table, switch the label style display mode to Tag. Then when you use the Select In Drawing method when tags are displayed, child styles are not created. For more information on switching to tag mode, see Displaying Labels as Tags (page 1487).

# Creating Label Styles for Lines, Curves, and Polylines

Line, Curve, and Polyline labels use the styles that are defined in the General ➤ Label Styles collection in the Settings tree.

Polylines use Line label styles for straight segments and Curve label styles for curved segments. You can set up the Line and Curve label styles to label the total length and area of polylines by using the "Overall" label properties.

**To create a line or curve label style**

1  In Toolspace, on the Settings tab, expand the General ➤ Label Styles collection.

2  Right-click the Line or Curve collection and click New.

3  Use the tabs on the Label Style Composer  (page 1942)to set up the label style.

> **NOTE** From the Layout tab, you can add or edit label components to include the overall length of lines and polylines and the total area of polylines. Follow the steps in Adding Text Components to Labels (page 1503) and use the General Overall Length and General Overall Area properties.

4  If you have multiple components in the label style, be sure to specify appropriate Anchor Points and Attachment Points (page 1492) so the components do not overlap. You can use the Preview window to check the label layout.

> **NOTE** Specify the default layer for Line and Curve labels on the Layers tab (page 66) of the Drawing Settings dialog box. You can also change the layer of these labels by using the AutoCAD Properties palette (right-click label and select Label Properties or Properties).

## Quick Reference

Toolspace Shortcut Menu

Settings tab: <drawing name> ➤ General ➤ Label Styles ➤ right-click Line or Curve ➤ New

Dialog Box

Label Style Composer (page 1942)

# Creating Note Labels

Note label styles are inserted at selected points in the drawing, and are not physically attached to specific objects. They can use Referenced Text components to contain references to other objects in the drawing.

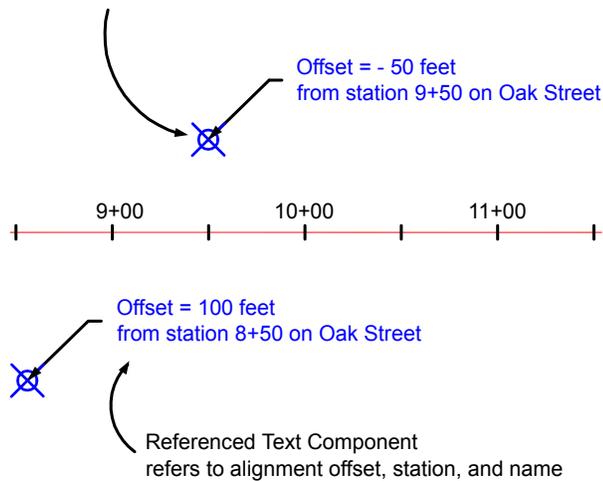
The insertion point of a Note label can be used to identify location-based Referenced Text data. For example, in the following illustration, the insertion point determines the station and offset values that appear in the label.

Note insertion point determines offset and station values

Offset = - 50 feet
from station 9+50 on Oak Street

9+00        10+00        11+00

Offset = 100 feet
from station 8+50 on Oak Street

Referenced Text Component
refers to alignment offset, station, and name


This component would be set up as follows in the Text Component Editor:

```
Offset = <[Offset(Uft|P3|RN|Sn|OF|AP)]> feet
```

```
from station <[Station Value(Uft|FS|P2|RN|AP|Sn|TP|B2|EN|W0|OF)]> on <[Name(CP)]>
```

**To create a note label style**

1   In Toolspace, on the Settings tab, expand the General ➤ Labels collection.

2   Right-click the Note collection and click New.

3   On the Information tab of the Label Style Composer dialog box, specify a name for the new style.

4   Click the Layout tab (page 1944).

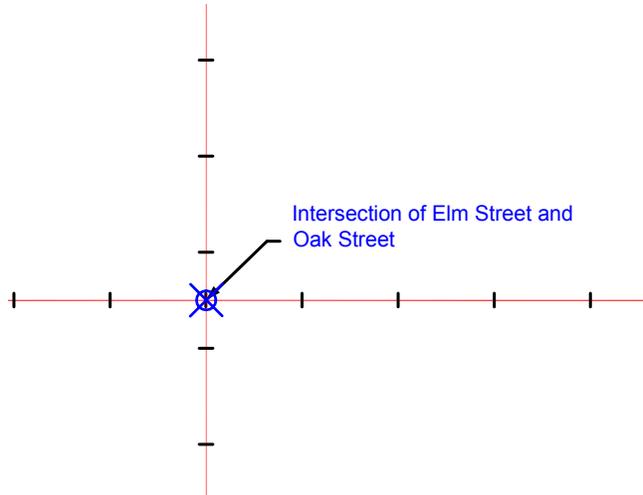
5   A default text component is created by default. To change the text string, under Text, click the Contents row. Then click ⋯ .

6   In the Text Component Editor (page 1961), edit the text for the note as needed. You can type directly into the window.

7   Close the Text Component Editor window.

8   If you want to reference objects in the drawing, create a Referenced Text (page 1509) component for each object you want to reference.

For example, you can create a note label with two Referenced Text components, each which refers to an alignment name. You can then insert that label at the intersection of two alignments, and select the intersecting alignments as the object data.

Intersection of Elm Street and Oak Street


**9** If you have multiple components in the label style, be sure to specify appropriate Anchor Points and Attachment Points (page 1492) so the components do not overlap. You can use the Preview window to check the label layout.

**10** Use the other tabs on the Label Style Composer  (page 1942)to set up the label style.

---

**NOTE** Specify the default layer for Note labels on the Layers tab (page 66) of the Drawing Settings dialog box. You can also change the layer of these labels by using the AutoCADProperties palette (right-click label and select Label Properties or Properties).

---

**See also:**

■ Inserting Note Labels (page 1530)

Dialog Box

  Label Style Composer (page 1942)

## Editing Label Styles

Use the Edit Label Style command to specify a label style for an object, to create a new style, or to copy or edit an existing label style.

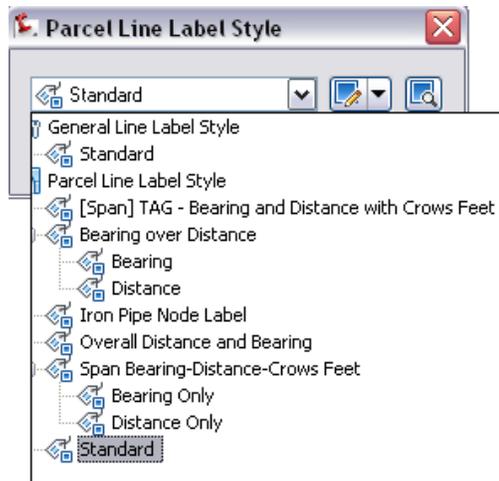
When you edit a label style, all labels in the drawing that reference that style are updated.

Edit an existing label style by using the Label Style Composer. You can access the Label Style Composer from Toolspace Settings tab or from the label object's context menu.

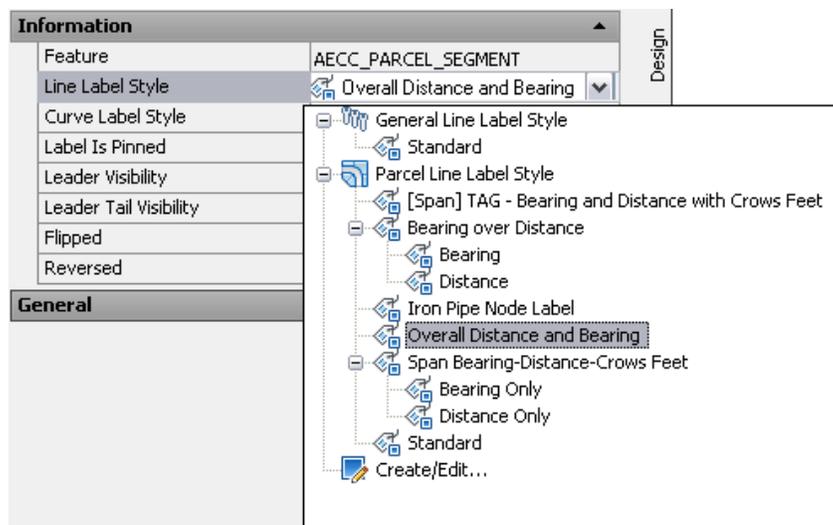
The Label Style Composer can also be accessed from the AutoCAD Properties palette by selecting Create/Edit from the available style drop-down menu. In the Label Style Control (page 1965) dialog box, select Edit Current

Selection. You can use the Style Selection pull-down menu in the AutoCAD Properties palette to bulk edit label properties for labels placed in the drawing. This is a convenient method of editing label styles without having to navigate to the Prospector Settings tab.

Notice in the following example that in addition to the Parcel Line Label Styles, the General Line Label Style is available for use when editing a Parcel Line Label.



**Use right-click Edit Label Style option to access Style Selection dialog**



**AutoCAD Properties palette list of available label styles**

**To edit an existing label style**

1 In Toolspace, on the Settings tab, right-click the label style you want to edit and click Edit.

2 Use the Label Style Composer (page 1942) to edit the label style.

3 Click OK.

OR

1 In the drawing, select a label, right-click and select Properties or Label Properties.

2 In the Properties palette, click Line or Curve label style to display a list of available styles.

Select the Edit/Create option to access the Label Style Control (page 1965) dialog box with which you can create a new style, copy the currently selected style, create a child style, or edit the currently selected style with the Label Style Composer.

OR

1   In the drawing, select the label to edit.

2   Right-click and select Edit Label Style.

3   In the Label Style Control (page 1965) dialog box, specify a label style, create a new style, or copy or edit an existing style. Press  to access the Label Style Composer.

### Quick Reference

Ribbon

Select the label. Click Labels tab ➤ Modify panel ➤ Label Properties drop-down ➤ Edit Label Style 

Toolspace Shortcut Menu

Dialog Box

Label Style Composer (page 1942)

# Modifying Label Style Content

Label content contains information that is linked directly to an object and consists of text, symbols, blocks, lines, ticks, and direction arrows. Set up this content by using the Label Style Composer.

**To modify the content of a label style**

1   In the Settings tree, right-click an existing label style and click Edit.

> **TIP** Create a new drawing using one of the default AutoCAD Civil drawing templates, which contain a set of pre-defined label styles.

2   In the Label Style Composer dialog box, click the Layout tab.

3   Click the Component Name list to see which components have been defined for the label style. The components control the label content.

4   To modify the content of a label component, select its name in the Component Name list.

5   Under Text, click in the Value column of the Contents row to display the Browse button , as shown in the following illustration:

6   Click  to display the Text Component Editor, where you can change the label properties. For more information, see Adding Text Components to Labels (page 1503).

**7**  You can also edit the static text in the label. For more information, see Editing Text in the Text Component Editor (page 1507).

# Setting Up Label Styles To Be Used as Tags

If a label style supports the use of tags and tables, there are a few unique properties you can manage in the style by changing settings in the Label Style Composer.

■  **Display Mode**. Controls whether the labels are currently displayed as labels or tags. This switches to tag mode automatically when a table is inserted into the drawing using the style-based selection method.

■  **Table Tag Component**. A unique component that is defined on the Layout tab of the Label Style Composer and is required for labels that support tables.

■  **Label "Used In" Property**. Controls whether label style components (such as text or blocks) are used in label mode, tag mode, or both.

A single label style can contain settings for both the label mode and the tag mode. You do not have to have separate label styles set up for tags. However, it may help you manage your drawings (and prevent additional styles from being created automatically) if you set up a style with its default state set to tag mode and give the style an explicit name. For more information, see Automatically-Created Child Styles (page 1479).

**To set up a label style for tags**

**1**  Create a new label style and give the style a unique name. For more information, see Creating and Editing Label Styles (page 1477).

**2**  With the new style open in the Label Style Composer dialog box, click the General tab.

**3**  Under Label, set the Display Mode to Tag. This sets the default state of this label style to tag mode. Then, when you label an object with this style, tags are created rather than full labels. For more information, see Displaying Labels as Tags (page 1487).

**4**  Click the Layout tab and select the Table Tag component in the Component Name list. This component is required for labels that support tables. You cannot delete or change the name of this component.

**5**  Under General, set the value of Used In property. For Table Tag components, the tag can be displayed in tag mode or in label and tag modes. For more information, see Layout Tab (Label Style Composer Dialog Box) (page 1944).

**6**  Under Text, click the Value column for Contents and then click ⊡ to display the Text Component Editor.

**7**  Note the property listed in the Properties list. Table tags support only the Segment Number property field. For more information, see Property Fields (page 1507).

**8**  In the Text Component Editor, edit the static text as needed. You can change "C" to "Curve" for example. Do not alter the property field itself. For more information, see Editing Text in the Text Component Editor (page 1507).

**9**  You can click the Format tab to change the tag justification or color, for example. For more information, see Formatting Text (page 1505).

**10**  Click OK in the Text Editor window and the Label Style Composer to close them.

**11**  Use the new label style for tagging objects, and then insert an object table into the drawing. For more information, see Adding Labels to Drawings (page 1522).

# Managing General Properties for Label Styles

Use the General tab of the Label Style Composer dialog box to define label style layer, visibility, display mode, and text style. The General properties also include behavior rules regarding how a label is oriented to an object, and whether it is plan-readable.

# Specifying Label Text Style

Each label style has one AutoCAD text style associated with it.

**To specify the text style to use for a label style**

1   In the Label Style Composer dialog box, click the General (page 1942) tab.

2   Under Label, click the Value column for the Text Style property, and then click ![...] .

3   In the Select Text Style dialog box, select a text style.

4   Click OK.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: <drawing name> ➤ <object collection> ➤ Label Styles ➤ <label style type name> ➤ right-click <label style name> ➤ Edit

Dialog Box

Label Style Composer (page 1942)

# Displaying Label Properties with the List Command

Use the AutoCAD List command to display label property information.

**To display the AutoCAD Text Window**

1   In the drawing, select a label.

2   In the command line, enter List.

3   The AutoCAD Text Window dialog box displays the label type, entity type, and layer.

Group type labels display "GROUP" at the end of the entity type, as well as the parent object and the default label style. For example, **AECC_ALIGNMENT_STATION_LABEL_GROUP Layer:** "**0**". In this case, the entity type is alignment station. The label type is group, and the layer is set to zero.

4   Single type labels differ from group labels as they do not display "GROUP" at the end of the entity type listing, and the label style is displayed.

> **NOTE** The alignment label type vertical geometry point label does not include "GROUP" at the end of the entity type listing. It is called: AECC_ALIGNMENT_VAGEOMPOINT_LABELING.

Dialog Box

 AutoCAD Text Window

# Hiding and Displaying Labels in the Drawing

The label style Visibility setting controls whether the labels are visible in the drawing. You can use this setting to quickly hide and display all labels of a particular label style.

In previous releases of AutoCAD Civil 3D, most labels were sub-entities of the parent object. If the parent object was frozen, the labels would disappear with the frozen parent object. The independent label objects are no longer sub-entities of the parent object but still behave as previously. You also have the option of controlling label visibility independently through layer manipulation (with either the label style layer references, label visibility switches, or the layer that the label object itself resides on).

### To hide or display labels in a drawing

**1** In the Label Style Composer dialog box, click the General (page 1942) tab.

**2** Under Label, change the Visibility value to True or False.

**3** Click OK.

## Quick Reference

Toolspace Shortcut Menu

Dialog Box

 Label Style Composer (page 1942)

# Displaying Labels as Tags

Display labels as tags when you want label content to be in a table.

Tags contain an identifier number that is displayed in the first column in an associated table. The other columns of the table display the object data as defined in the table style. For more information about creating tables, see Tables (page 1555).

General line and curve label styles can be displayed as tags. Tag display mode is also supported by parcel and alignment segments labels as well as curve labels. You can specify the tag start number and increment numbers in the Table Tag Numbering Dialog Box (page 1971).

**NOTE** By setting label styles to Tag display mode before creating tables, you can avoid creating unnecessary child styles. For more information, see Automatically-Created Child Styles (page 1479).

### To display labels as tags

**1** In the Label Style Composer dialog box, click the General (page 1942) tab.

**2** Under Label, change the Display Mode value to Tag.

> **NOTE** Some label types (such as parcel area labels and alignment station labels) cannot be displayed in tag mode and therefore do not have the Display Mode property.

**3** Click OK.

### Quick Reference

Toolspace Shortcut Menu

Dialog Box

Label Style Composer (page 1942)

## Specifying the Label Style Layer

Each label style can be assigned to its own layer. The independent label objects reside on their own layer. You can also specify reference layer within the label style.

> **NOTE** Specify the default layer for labels on the Object Layers tab (page 66) of the Drawing Settings dialog box. You can also change the layer of these labels by using the AutoCAD Properties palette (right-click label and select Label Properties or Properties), or any other object layer manipulation tool.

**To specify the label reference style layer**

**1** In the Label Style Composer dialog box, click the General (page 1942) tab.

**2** Under Label, click the Value column for Layer and then click ⊡ .

**3** In the Layer Selection dialog box, select a layer, or create a new one.

**4** Click OK.

### Quick Reference

Toolspace Shortcut Menu

## Changing Label Orientation

Labels are composed relative to a zero angle (the default X axis), and are placed in a drawing based on an orientation setting.

Label offsets and rotation values are measured relative to the orientation setting.

**To change the orientation of labels**

**1** In the Label Style Composer dialog box, click the General (page 1942) tab.

**2** Under Behavior, change the Orientation Reference value to the desired item.

**3** Click OK.

## Quick Reference

Toolspace Shortcut Menu

Settings tab: <drawing name> ➤ <object collection> ➤ Label Styles ➤ <label style type name> ➤ right-click <label style name> ➤ Edit

Dialog Box

Label Style Composer (page 1942)

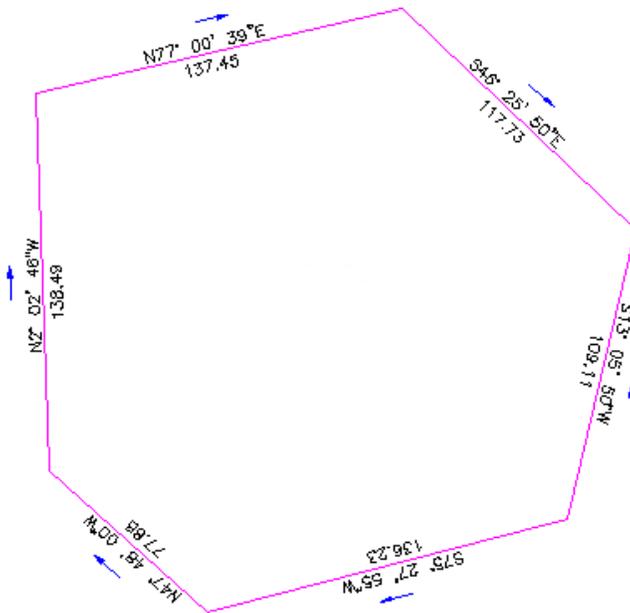
# Using Plan-Readability

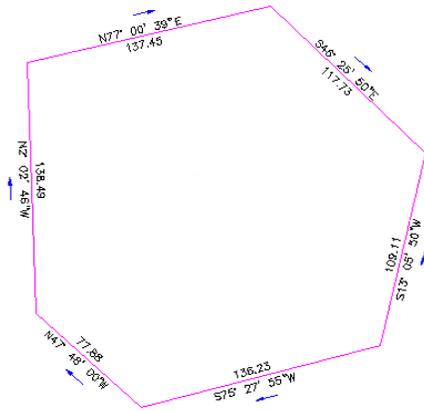
Use the plan-readability settings to make label text readable in a normal plan view.

When you select the *plan-readable* option, label text is rotated to a consistent readable angle.

You can specify the angle at which to start flipping labels. By default this angle is set to 110 degrees. That means that as soon as the angle of the text goes beyond 110 degrees, the label will flip 180 degrees to remain plan-readable.

The following illustration shows labels with Plan Readable set to False. Note the label at the bottom of the illustration:



The following illustration shows labels with Plan Readable set to True:


**To make a label style plan-readable**

1  In the Label Style Composer dialog box, click the General (page 1942) tab.

2  Under Plan Readability, change the Plan Readable value to True.

3  Change the Readability Bias angle to the angle at which you want the labels to start flipping. For example, an angle of 110 degrees means that label text inserted at an angle greater than 110 degrees is flipped.

> **NOTE** The labels are flipped again when they reach 180 degrees from the Readability Bias angle. For example, if the bias angle is 90, the labels are flipped at 90 degrees, and then are flipped again at 270 degrees.

4  Set the Flip Anchors With Text setting to False to flip labels so they are mirrors of the original labels. Set this setting to True if you also want to flip the label's anchor point.

> **NOTE** In most cases, it is not desirable to have this setting set to True. However, there are cases where it is needed, such as with a station label with a plus sign located always at the station tick.

5  Click OK.

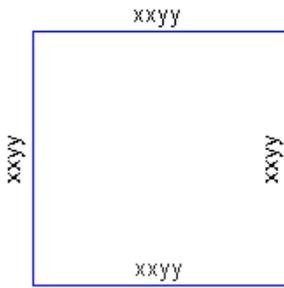
Dialog Box

Label Style Composer (page 1942)

# Changing Label Insertion

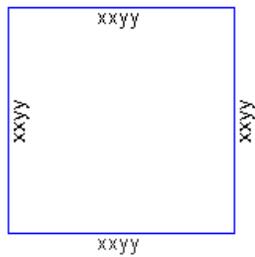
You can force labels to the top or bottom of objects or to the inside of curves.

**Top**

This setting ensures that the label is always placed on top of the object, regardless of the relationship to the zero angle of an object. The Top setting determines label placement based on the same calculation used for Plan Readability. For more information, see Using Plan-Readability (page 1489).


### Bottom

This setting ensures that the label is always placed beneath the object, regardless of the relationship to the zero angle of an object. The Bottom setting determines label placement based on the same calculation used for Plan Readability.

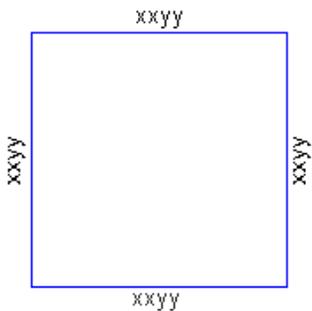


### Force to Inside of Curve

This setting ensures that the label is always placed in the inside of a curve regardless of the zero direction of the curved object.

### None

This setting places labels as they relate to the calculated zero angle of an object. It does not change label composition and, in essence, ignores any label placement rules.



### To change label insertion

1   In the Label Style Composer dialog box, click the General (page 1942) tab.

2   Under Behavior, change the Forced Insertion value to either None, Top, or Bottom.

3   Click OK.

**To change label insertion for curves**

1   In the Label Style Composer dialog box, click the General (page 1942) tab.

2   Under Behavior, change the Force Inside Curve value to either True or False.

3   Click OK.

Dialog Box

Label Style Composer (page 1942)

# Managing Layout Properties for Label Styles

You use the Layout tab of the Label Style Composer dialog box to control text and border settings, display properties, and content.

Layout properties are controlled independently for each label *component*. A label component can be text, a block, a line, a tick, or a direction arrow.

For example, a parcel line "Bearing Over Distance" label may have four components:

■   **Bearing**. A text component that labels the line's angle.

■   **Distance**. A text component that labels the line's distance.

■   **Table Tag**. A text component. Used only for table insertion. Required for labels that can be inserted into tables.

■   **Direction Arrow**. A direction arrow component that is positioned relative to the Bearing.

You can use the Layout properties to control each of these components separately.

**NOTE** For more information about defining new label components, see Adding Content to Labels (page 1502).

**NOTE** This section describes the Layout Properties for Text Components. Many of the same properties are available for Block, Tick, Line, and Direction Arrow components. Additional layout properties are described in Blocks (page 1513), Ticks (page 1514), Lines (page 1512), and Direction Arrows (page 1515).

## Anchor Points and Attachment Points

Label component position is defined by specifying an anchor component, an anchor point, and an attachment point. Rotation angles and X and Y offsets are applied in relation to the anchor component and anchor point.

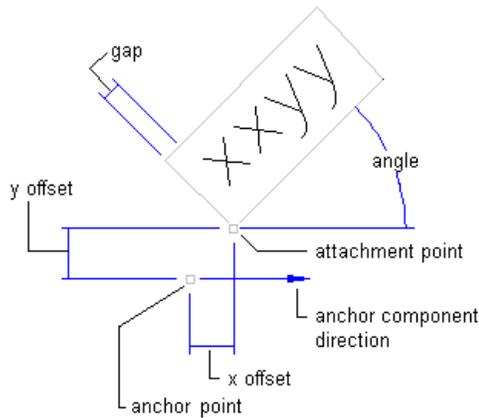
■   **Anchor Component**. The *anchor component* is the item that the *label component* is positioned relative to. It can be the object that is labeled, or it can be another label component.

■   **Anchor Point**. The *anchor point* is the location on the anchor that is attached to the label component's *attachment point*. It can be the label location (when the anchor component is set to Feature) or it can be

one of several locations on the label component (when the anchor component is set to a specific label component).

■ **Attachment Point**. The *attachment point* is the location on the label component that is attached to the anchor point.

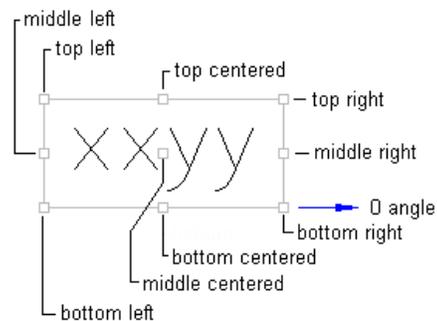
The following illustration shows how these points work together to position the label component (the rotated text in the illustration):



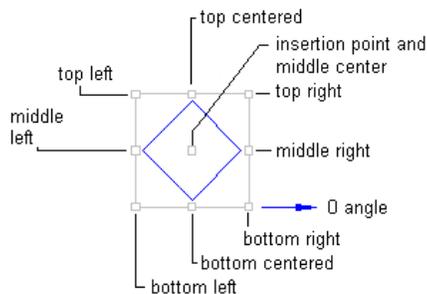
**Anchor and attachment points for text component**

The anchor is on a line (the anchor is set to Feature and the anchor point to Label Location). The attachment point on the text is set to Bottom Left. Note how the *X* and *Y* offsets, angle, and border gap all affect how the label is positioned relative to the attachment and anchor points

The following illustrations show the different points on label components that can be used either as anchor points or attachment points.

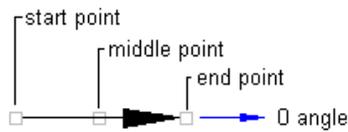


**Anchor and attachment points on text component**



**Anchor and attachment points on a block component**

**NOTE** The location of the insertion point is defined in the block itself. The anchor and attachment points are the same on blocks and ticks.



**Anchor and attachment points on a direction arrow component**

**NOTE** The anchor and attachment points are the same on direction arrows and lines.

**To specify anchor and attachment points for a label component**

1 In the Label Style Composer dialog box, click the Layout (page 1944) tab.

2 Select a component from the Component Name list.

3 Under General, specify the Anchor Component value for the component.

The Anchor Component defines what the selected component should be "anchored to" — or positioned relative to—in the label.

For example, if you are setting up a Direction Arrow component for a direction label, you might want to specify the Bearing as the Anchor Component so that you can position the arrow in relation to the bearing label text.

4 Change the Anchor Point value to specify the location of the anchor point.

This value specifies precisely where on the Anchor Component you want to place the anchor.

5 Under Text, change the Attachment value to specify the location on the label component that will be attached to the anchor point.

6 Optionally, specify X and Y offsets and a Rotation Angle. For example, you may want to specify X or Y offsets from the anchor point to add some space between the components. For more information, see Offset (page 1497) and Rotation (page 1498).

**TIP** Refer to the Label Preview window when editing the label layout properties. This preview dynamically shows the effect of each of these settings.

7 Click OK.

## Quick Reference

Toolspace Shortcut Menu

Settings tab: <drawing name> ➤ <object collection> ➤ Label Styles ➤ <label style type name> ➤ right-click <label style name> ➤ Edit

Dialog Box

Label Style Composer (page 1942)

# Specifying Anchor Points

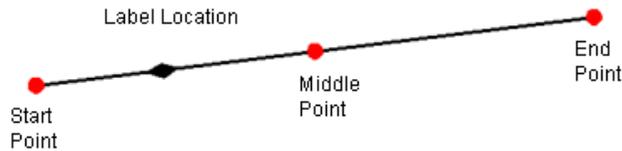
You can attach labels to specified geometry point locations.

Line and curve label anchors allow you to create much more graphic type label styles. For example, you can display crow's feet to indicate where segments start and end.

**NOTE** Anchor points do not support the spanning option for parcel segment labels.

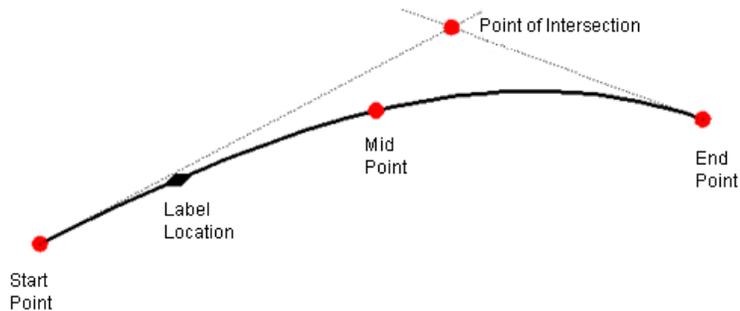
These anchors apply to the following segment labels: parcel lines and curve Label, general line and curve labels, alignment line, and curve and spiral labels.

There are four line label anchor points that you can use to attach labels to: start, end, middle points and label location. The label location anchor can be dragged anywhere along the line.

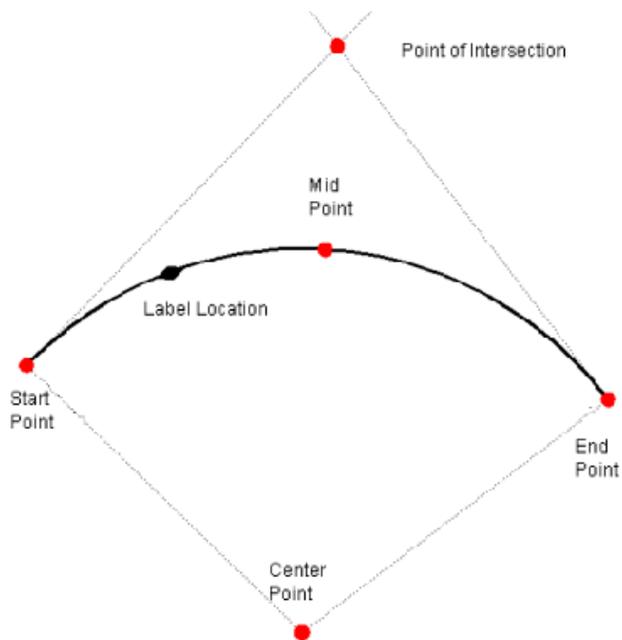


**Line label anchor points**

For spiral labels, in addition to the label location, start, end, and middle points anchors, there is a Point of Intersection anchor.



**Spiral label anchor points**

With curve label anchors, you can attach a label to the center point of the arc.


**Curve label anchor points**

**To specify label anchor point**

1  In the Label Style Composer dialog box, click the Layout tab.

2  Select an anchor point from the Anchor Point list.

3  Click Apply and then OK.

# Background Mask

Use a background mask for Text and Referenced Text components to mask the background of a label component.

The size and shape of the mask is configured using the border settings. For example, if you specify a rectangular border with a gap of 0.1, the mask respects those settings, even if the border visibility is set to False.

You can use the AutoCAD Properties palette to include a background mask for surface contour labels

**To include a background mask**

1  In the Label Style Composer dialog box, click the Layout (page 1944) tab.

2  Select a Text or Referenced Text component from the Component Name list.

**3** Under Border, change the Background Mask property to True.

**4** Configure the other Borders (page 1502) settings to adjust the mask and border size and shape.

**5** Adjust the label component Draw Order (page 1517) as needed.
Any label component that is drawn before the mask may be covered if it is within the mask boundary.

**To set the background mask setting for surface contour labels in AutoCAD Properties**

**1** In the drawing, right-click a surface contour label and select Properties.

**2** In the AutoCAD Properties palette, under Labels  change the Masking property to From Label Style.
This sets the contour label to the label background mask setting from the assigned label style.

OR

**3** Under Labels, change the Masking property to Contour Line Only.

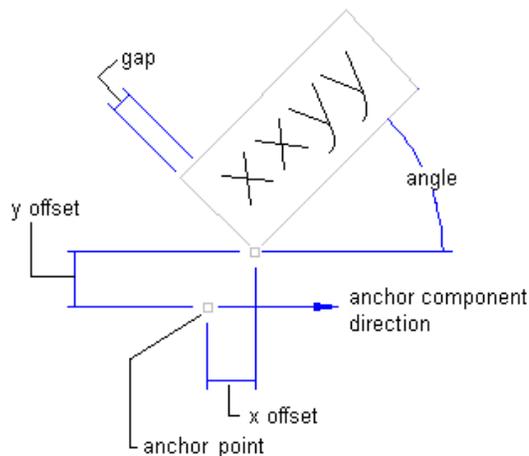
Dialog Box

Label Style Composer (page 1942)

# Offset

Specify X and Y offsets to define the distance between the anchor point of the anchor component and the attachment point of the label component.



**X and Y offsets in a text component**

Offsets are dependent on the Orientation Reference of the label style:

■ Label Orientation Reference set to Object. X and Y offset values are relative to the X and Y coordinate system as defined by the anchor component direction. In the preceding illustration, the anchor component direction is zero (0) degrees, so X, and Y offsets are measured relative to zero (X direction = 0° and Y

direction = 90°). If the anchor component direction changed to 45°, then the X direction is measured at 45°, and the Y direction is measured at 135°.

- Label Orientation Reference set to World. X and Y offset values are relative to the world coordinate system (X direction = 0° and Y direction = 90°).

- Label Orientation Reference set to View. X and Y offset values are relative to the current view (X direction = bottom of screen and Y direction = 90° from bottom of screen).
  For more information about these settings, see General Tab (Label Style Composer Dialog Box) (page 1942).

**To define offset values**

1 In the Label Style Composer dialog box, click the Layout (page 1944) tab.

2 Select a component from the Component Name list.

3 Change the X and Y offset values. If the label component type is a line, you must define X, Y start and endpoints.

4 Click OK.

Dialog Box

Label Style Composer (page 1942)

# Rotation

Specify a rotation angle for a label component.

Rotation angles are dependent on the Orientation Reference of the label style:

- Label Orientation Reference set to Object. The rotation angle is measured relative to the X and Y coordinate system as defined by the anchor component direction. For example, if the anchor component direction is 45°, then the rotation angle is measured relative to 45°.

- Label Orientation Reference set to World. The rotation angle is measured relative to the world coordinate system (X direction = 0° and Y direction = 90°).

- Label Orientation Reference set to View. The rotation angle is measured relative to the current view (X direction = bottom of screen and Y direction = 90° from bottom of screen).

**To change the rotation of a label component**

1 In the Label Style Composer dialog box, click the Layout (page 1944) tab.

2 Select a component from the Component Name list.

3 Change the Rotation Angle value.

4 Click OK.

### Quick Reference

# Colors

Assign colors to individual components in a label.

Use the Select Color dialog box to assign a standard AutoCAD color or use one of the following options:

■ **ByLayer**. Labels obtain their color from the label style's layer (defined on the General tab of the Label Style Composer).

■ **ByBlock**. Labels obtain their color from the parent object's AutoCAD properties. The object is first examined for any property overrides. If none are found, then the color property of the object layer is used.

#### To specify colors for label components

1 In the Label Style Composer dialog box, click the Layout (page 1944) tab.

2 Select a component from the Component Name list.

3 Click the Value column for Color, and then click ⊞.

4 In the Select Color dialog box, select a color or select ByLayer or ByBlock.

5 Click OK.

### Quick Reference

# Linetypes

Assign linetypes to individual components in a label.

Use the Select Linetype dialog box to assign a specific linetype or use one of the following options:

■ **ByLayer**. Labels obtain their linetype from the label style's layer (defined on the General tab of the Label Style Composer).

■ **ByBlock**. Labels obtain their linetype from the parent object's AutoCAD properties. The object is first examined for any property overrides. If none are found, then the linetype property of the object layer is used.

**To specify linetypes for label components**

1 In the Label Style Composer dialog box, click the Layout (page 1944) tab.

2 Select a component from the Component Name list.

> **NOTE** Text components do not have a Linetype option.

3 Click the Value column for Linetype, and then click ⊡ .

4 In the Select Linetype dialog box, select a linetype or select ByLayer or ByBlock.

5 Click OK.

Dialog Box

Label Style Composer (page 1942)

# Lineweights

Assign lineweights to individual components in a label.

Use the Select Lineweight dialog box to select a specific lineweight or use one of the following options:

■ **ByLayer**. Labels obtain their lineweight from the label style's layer (defined on the General tab of the Label Style Composer).

■ **ByBlock**. Labels obtain their lineweight from the parent object's AutoCAD properties. The object is first examined for any property overrides. If none are found, then the lineweight property of the object layer is used.

**To specify lineweights for a label component**

1 In the Label Style Composer dialog box, click the Layout (page 1944) tab.

2 Select a component from the Component Name list.

3 Click the Value column for Lineweight, and then click ⊡ .

4 In the Select Lineweight dialog box, select a lineweight, or select ByLayer or ByBlock.

5 Click OK.

Toolspace Shortcut Menu

Settings tab: <drawing name> ➤ <object collection> ➤ Label Styles ➤ <label style type name> ➤ right-click <label style name> ➤ Edit

Dialog Box

Label Style Composer (page 1942)

# Adding Content to Labels

You can use the Layout tab of the Label Style Composer to define *label components*, which define the content of labels. Label components include text, referenced text, blocks, direction arrows, lines, and ticks.

# Text

Use the Text Component Editor to format and define label text components.

■   To define dynamic text, select and add label *property fields*.

■   To define static text, enter text directly into the Text Component Editor window.

All text components are based on the AutoCAD text style that is defined on the General tab (page 1942) of the Label Style Composer.

## Adding Text Components to Labels

By adding text components to labels, you can create new label styles that label specific features, such as parcel area, name, and perimeter.

Text components make use of dynamic label properties that you can assign in the Text Component Editor. Each object type has several properties you can use to build the label style components.

For example, when setting up parcel line segment labels, you can choose among the following label properties:

■ Segment length

■ Segment start and end northings and eastings

■ Segment direction

■ Parcel line number

When you label a parcel using the label style, the labels are generated based on the parcel object's properties. If the parcel properties change, then the labels are updated dynamically.

There are two basic strategies you can use when adding text components to a label. If you want more precise control over the label's appearance, you can either add several properties to one text component or define a separate component for each piece of text in the label.

### Adding Multiple Properties to a Text Component

You can add multiple properties to one text component.

The advantages of this strategy include

■ Fewer text components to define

■ Fewer placement rules to define

■ The ability to place one border around the entire label

### Adding a Single Property to a Text Component

Alternately, you can add a single property per text component, and define multiple text components.

The advantages of this strategy include

■ More precise control over the placement of each piece of text

■ More property formatting options

■ The ability to turn off the visibility of one or more of the text components while leaving others visible

### To add a text component to a label

1 In the Label Style Composer dialog box, click the Layout tab.

2 Click the Down arrow in $A_+$ , and then click $A_+$ .

The component automatically receives a default name, Text.1.

3 Enter a name in the Name box.

_____

**TIP** Use a descriptive name that describes the content of the text component.

_____

4 Under Text, click the Value column for Contents and then click ⊡ :

**5** In the Text Component Editor, on the Properties (page 1962) tab, select a property from the Properties list. This list contains a set of properties applicable to each label style type.

When you select a property, Modifiers and their Values are displayed in the grid below it. These modifiers control such things as the units and precision of the labels.

**6** Change the modifier values in the Value column as needed.

**7** Click . This inserts a property field into the Text Component Editor window.

For example, if you are setting up a parcel area label, and you insert the Parcel Area property, the following property field is inserted:

<[Parcel Area(Usq_m|P2|RN|AP|Sn|OF)]>

**WARNING** You cannot edit the label property fields after you have inserted them into the Text Component Editor window. If you alter anything about the field itself, such as using the shortcut menu to change capitalization, the label style will not function correctly.

For more information about property fields, see Property Fields (page 1507).

**WARNING** To later change any of the modifier values you specified, delete the property field from the Text Component Editor window and then reinsert the property by clicking . Simply changing a modifier value and clicking OK does not update the label style.

**8** Add static text as needed in the Text Component Editor window.

For example, you might want to add "Area =" before the parcel area property field, and "square meters" after the property field.

To do this, click in the Text Component Editor window and enter the text directly. You can also insert a paragraph return after a property field and then insert additional properties to create a multi-line label.

You can use the formatting options on the Text Component Editor window shortcut menu to modify the text that you manually enter.

**9** If you want to add additional properties to the text component, select them from the Properties list and insert them, as shown in Step 7.

**10** If you want to specify different justification, fonts, or colors for the label component, click the Format (page 1963) tab in the Text Component Editor. For more information, see Formatting Text (page 1505).

**11** Click OK to close the Text Component Editor.

## Quick Reference

## Formatting Text

Use the formatting options on the Format tab in the Text Component Editor to determine how text is displayed in a label.

Some options require you to select text in the Text Component Editor window first.

**To format label text**

1  In the Label Style Composer dialog box, click the Layout tab.

2  Select a component from the Component Name list.

3  Under Text, click the Value column for Contents, and then click ⚬⚬⚬ .

4  In the Text Component Editor dialog box, click the Format tab (page 1963).

5  Format the text as desired.

6  Click OK.

### Quick Reference

## Creating Stacked Characters

Add fractions or any other type of stacked text to label styles in the Text Component Editor.

**To create stacked characters in label styles**

1  In the Label Style Composer dialog box, click the Layout tab.

2  Select a component from the Component Name list.

3  Under Text, click the Value column for Contents, and then click ⚬⚬⚬ .

4  In the Text Component Editor dialog box, click the Format tab (page 1963).

5  In the Text Component Editor window, enter the text you want to stack separated by one of the following characters:

   ■  Slash (/) stacks text vertically, separated by a horizontal line.

   ■  Pound sign (#) stacks text diagonally, separated by a diagonal line.

   ■  Carat (^) creates a tolerance stack, which is not separated by a line.

   For example, if you want to create a fraction of 1 over 2, enter **1/2**.

6  In the Text Component Editor window, select the text that you want to stack, and then click [a/b] on the Format tab.

**NOTE** If you enter numbers separated by stack characters and then either enter a nonnumeric character or press Spacebar or Enter, the Multiline Text - AutoStack Properties dialog box is displayed. In the Multiline Text - AutoStack Properties dialog box, you can select to automatically stack numbers (not nonnumeric text) and to remove leading blanks. You can also specify whether the slash character creates a diagonal fraction or creates a vertical fraction. If you do not want to use AutoStack, click Cancel to exit the dialog box.

**7**  To unstack text, select it and click $\frac{a}{b}$ again.

**8**  To edit stacked text properties, select the stacked text, right-click, and click Properties to display the AutoCAD Stack Properties dialog box.

You can edit the upper and lower text separately. The Appearance options control the stack style, position, and text size of the stacked text.

## Adding Special Characters

Use the Symbol option to add symbols to label text.

**To add symbols or special characters**

**1**  In the Label Style Composer dialog box, click the Layout tab.

**2**  Select a component from the Component Name list.

**3**  Under Text, click the Value column for Contents, and then click ![...] .

**4**  In the Text Component Editor dialog box, click the Format tab (page 1963).

**5**  Click in the Text Component Editor window in the location where you want to add the symbol or special character.

**6**  Click Symbol.

**7**  From the list, select a symbol, such as degree, diameter, or plus/minus, or a non-breaking space.

The symbol is added to the label text at the cursor location.

**8**  To select a special character, click Other to display the Character Map dialog box.

**9**  Select a character, click Select, and then click Copy.

**10**  In the Text Editor window, place the pointer in the location where you want to add the special character.

**11**  Paste the copied character by either right-clicking and clicking Paste or pressing Ctrl+V.

## Editing Text in the Text Component Editor

Use a shortcut menu in the Text Component Editor window to edit the format of text content you have manually entered.

**WARNING** You cannot edit the label property fields. If you alter anything about the field itself, such as using the shortcut menu to change capitalization, the label style will not function correctly.

Right-click in the Text Component Editor window to display the shortcut menu.

The lower part of the shortcut menu contains specific formatting options. If you have selected stacked text, then options that are specific to stacked text are added to the menu.

■ **Select All**. Selects all text in the editor window.

■ **Change Case**
   ■ **UPPERCASE**. Changes all selected text to uppercase characters.

   ■ **lowercase**. Changes all selected text to lowercase characters.

■ **Remove Formatting**. Removes any formatting, such as underline, bold, and italic.

■ **Combine Paragraphs**. Removes all line returns.

■ **Stack**. Stacks selected text. Available only when text separated by stack characters is selected. For more information, see Creating Stacked Characters (page 1505).

■ **Unstack**. Unstacks text. Available only when stacked text is selected.

■ **Properties**. Displays the AutoCAD Stack Properties dialog box. Available only when stacked text is selected.

# Property Fields

Use property fields to control the label content. You add property fields to label text components to act as placeholders for the label or tag content.

## Adding Property Fields to Label Text Components

Insert property fields in text components to add content that is linked directly to drawing components.

Label text generated by most property fields is dynamic and is updated whenever changes are made to a drawing.

**NOTE** You cannot edit the property fields in the edit pane of the Text Component Editor window. You can only add or delete a property field or add static text.

As you view the property field in the edit pane of the Text Component Editor, the characters are defined and separated by the following symbols:

| Character | Description |
|---|---|
| <[ | Begin property field |
| ( | Begin modifier list |
| \| | Modifier separator |
| ) | End modifier list |
| ]> | End property field |

For example, the property field format may look like this:

```
<[Attribute(Unit|Precision|Rounding|Sign|Capitalization|Format|Direction|Output)]>
```

Property fields attributes are formatted with predefined modifiers, such as measurement units (acres, feet, and meters), precision, and rounding.

For more information about the modifiers for feature property fields in AutoCAD Civil, see Property Field Modifiers (page 1509).

**To add property fields to label text**

1  In the Label Style Composer dialog box, click the Layout tab.

2  Select a component from the Component Name list, or create a new text component.

3  Under Text, click the Value column for Contents, and then click ⋯ .

4  In the Text Component Editor dialog box, click the Properties tab (page 1962).

5  From the Properties list, select a property.

> **NOTE**  If you have defined user-defined property classifications, these are displayed in the Properties list for you to select and add to certain label styles. For more information, see User-Defined Property Classifications (page 416).

The modifier values are displayed in the grid below the property.

> **NOTE**  Because certain label style types have many possible properties, an additional filtering feature is provided for these types so you can restrict the list. Click to display the Property Filter (page 1963) Property Filter dialog box. A filter remains active until you turn it off.

6  In the Value column, change the modifier values.

7  Click to insert the property into the text window.

8  Click OK.

### Quick Reference

## Property Field Modifiers

Most label styles associated with AutoCAD Civil objects contain property fields with modifiers. These modifiers are abbreviations for the values you specified for the label property.

The following is a key to the modifier codes:

| | | | | |
|---|---|---|---|---|
| U = | Units | | S = | Sign |
| F = | Format | | D = | Direction |
| P = | Precision | | C = | Capitalization |
| R = | Rounding | | O = | Output |
| A = | Decimal character | | | |

For example, the following is a parcel area property field:

<[Parcel Area(Usq_m|P2|RN|AP|Sn|OF)]>

The following lists each of the modifiers for this label property:

- **Usq_m**: Units = square meters

- **P2**: Precision = 2

- **RN**: Rounding = Normal

- **AP**: Decimal Character = Period

- **Sn**: Sign Negative = '-'

- **OF**: Output = Full

# Referenced Text

Use Referenced Text components in label styles to include references to other objects in a label. You can insert references to surfaces, profiles, parcels, and alignments.

Referenced Text components are supported for most object label types. See Label Objects (page 1463) for a list of label objects supported by Referenced Text.

---

**NOTE** Referenced Text is supported for most label object types in AutoCAD Civil. Label types for points, parcel face, parcel segment, corridor labels, and surface watershed do not support reference text.

---

Each Referenced Text component can refer to only one AutoCAD Civil object. For example, you can format a Referenced Text component to include an alignment name and its description, but it cannot refer to two different alignment names. To include references to two different alignments you need to include two Referenced Text components in the label style, one for each different alignment.

> **NOTE** You can format a Referenced Text component to include an expression. Note that if you have referenced an expression with a property that is not supported through the referenced text property field this results in questions marks (???) inserted into the label .

**To create a Referenced Text component**

1   In the Label Style Composer dialog box, click the Layout tab.

2   Click the Down arrow in $A_+$ , and then click $A_+$ Reference Text.

3   In the Select Type (page 1949) dialog box, select the type of object data to include in the Referenced Text component. Click OK.

    You are returned to the Label Style Composer dialog box. The type of object data you selected is listed as the Reference Text Object Type in the General section.

4   Under Text, click the Value column for Contents, and then click ⋯ .

5   In the Text Component Editor dialog box, ensure the Properties tab (page 1962) is selected.

6   From the Properties list, select a property. The list of properties available reflects the object you selected in step 2 previously.

7   In the Value column, change the modifier values as needed.

8   Click ⇨ to insert the property into the text window.

9   Add other properties or descriptive text as needed. Click OK to return to the Label Style Composer dialog box.

10  Set up the other Layout settings the Referenced Text component using the same settings that are available for text components (page 1503).

> **NOTE** If the Visibility setting is set to True for the Referenced Text component in the label style, and you do not select an object for the reference when you insert the label, question marks (???) are inserted into the label. This is because the reference text component is not yet connected to an object. You can specify an object by editing the label properties and the question marks will be replaced with the object data.

Dialog Box

Label Style Composer (page 1942)
Text Component Editor (page 1961)

# Text-For-Each

Use the Text Component Editor to format and define text-for-each components for a variety of object types.

*Text-for-each* components label each object associated with a parent object (the object you are labeling). For example, you can use a text-for-each component in a structure label style to include labels for pipes associated with that structure. These components are only used in structure label styles and structure tables.

Text-for-each components are formatted just like text components, except that you select which child objects to label when you first create a text-for-each component. For example, you can add labels for all the pipes that enter or exit a structure, or only for invert-in or invert-out pipes. These label components are dynamic, so that if you remove or add a child object, the labels are updated.

The following shows an example of a structure label where the first three lines of the label contain structure data. The last three lines of the label contain data about the pipes that connect to the structure:

MH - 54 TYPE "B"

STA. 20+11.35, 6.00' RT

TOP ELEV. = 62.91

INV. IN = 47.08 (N)

INV. IN = 54.42 (SE)

INV. OUT = 47.08 (W)

You would set up this label style by including two text-for-each components. One component is for all pipes in, which lists invert in values. The other component is for all pipes out, which lists the one invert out value.

**To create a text-for-each component**

1   In the Label Style Composer dialog box, click the Layout tab.

> **NOTE** The text-for-each component type is available only for structure label styles.

2   Click the Down arrow in ![A+ icon], and then click ![icon].

3   In the Select Type (page 1949) dialog box, select the type of data to include in the text-for-each component and click OK.

4   Set up the other Layout settings the text-for-each component using the same settings that are available for text components (page 1503).

For example, if you are setting up a label for invert in pipes, you could use the Text Component Editor to add static text (INV. IN =), and also add a dynamic property field that labels the pipe elevation.

## Quick Reference

Settings tab: <drawing name> ➤ <object collection> ➤ Label Styles ➤ <label style type name> ➤ right-click <label style name> ➤ Edit

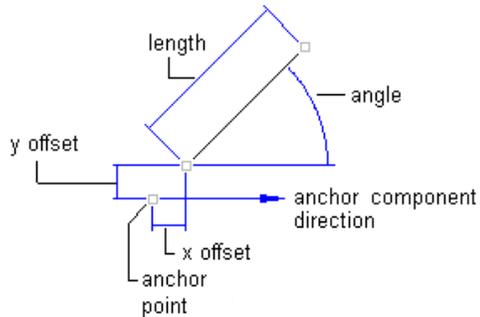
Dialog Box

Label Style Composer (page 1942)
Text Component Editor (page 1961)

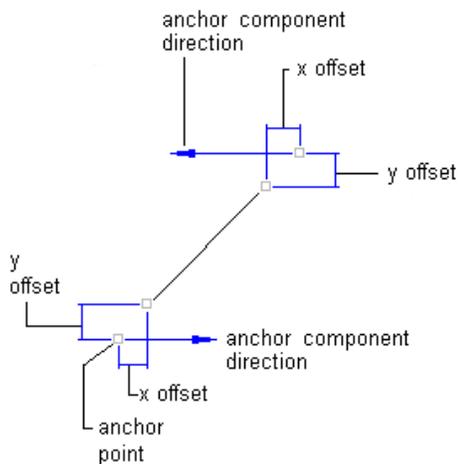
# Lines

Add line components to a label style using one of two methods.

■ **Start Point, Length, and Angle**: Use this method to anchor the start point of the line component to the anchor component. Then, specify the length and angle. The following illustration shows a line defined using this method:



■ **Start Point and End Point**: Use this method to anchor the start and end point of the line component. The length and angle of the line are determined by the position of the anchor objects, and adjust if the anchor components are edited. The following illustration shows a line defined using this method:



**To add lines**

1 In the Label Style Composer dialog box, click the Layout (page 1944) tab.

2 Click the Down arrow in ![icon], and then click ![icon].
The component automatically receives a default name, Line.1.

3 Enter a new name in the Name box.

4 Specify the desired settings in the General and Line categories.
To define a line, either specify a start and end point anchor or define a start point anchor, a length, and a direction.
For more information, see Managing Layout Properties for Label Styles (page 1492).

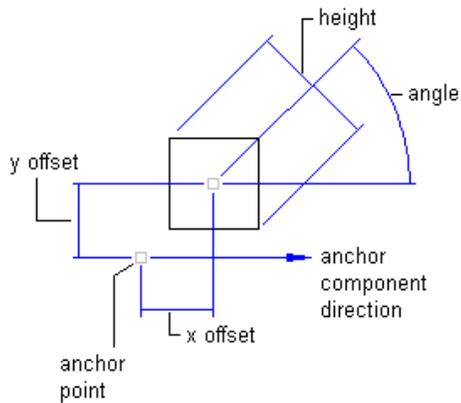
5 Click OK.

### Quick Reference

Dialog Box

# Blocks

Add block components, such as a custom arrowhead or symbol, to a label style.



**Block component properties**

**To add blocks**

1   In the Label Style Composer dialog box, click the Layout (page 1944) tab.

2   Click the Down arrow in  , and then click  .
    The component automatically receives a default name, Block.1.

3   Enter a new name in the Name box.

4   Under Block, click the Value column for Block Name, and then click  ⌷ .

5   In the Select A Block dialog box, select the block to use, and then click OK.

    **NOTE** The AutoCAD Civil drawing templates contain several blocks you can use.

6   Specify the desired settings in the General and Block categories.
    For more information, see Managing Layout Properties for Label Styles (page 1492).

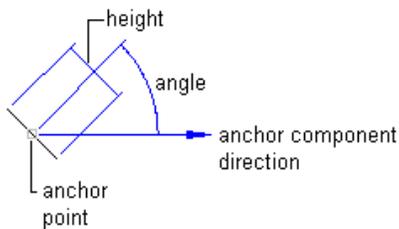
7   Click OK.

### Quick Reference

# Ticks

You can add tick components, which are short lines inserted at a perpendicular angle to another object, to a label style. For example, ticks can be used to mark the location of a station label on an alignment.

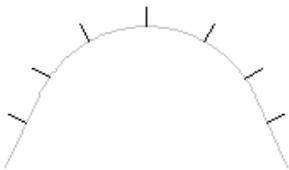
Ticks cannot be edited with grips or moved from the object on which they are inserted. They are always anchored to the object.



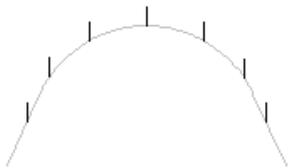
**Tick component properties**

The following illustrations show the effect of the Align With Object setting for ticks:

■ **True**. Inserts the tick at an angle relative to the object, as shown in the following illustration:



■ **False**. Inserts the tick at an angle relative to the UCS setting, as shown in the following illustration:



**To add ticks**

1 In the Label Style Composer dialog box, click the Layout (page 1944) tab.

2 Click the Down arrow in ![icon], and then click ![icon].

The component automatically receives a default name, Tick.1.

**NOTE** This option is not available in label style types that do not support ticks.

**3**  Enter a new name in the Name box.

**4**  Under Tick, click the Value column for Block Name, and then click ⬚ .

**5**  In the Select A Block dialog box, select the block to use, and then click OK.

> **NOTE**  The AutoCAD Civil drawing templates contain several blocks you can use.

**6**  Specify the desired settings in the General and Tick categories.

For more information, see Managing Layout Properties for Label Styles (page 1492).

**7**  Click OK.

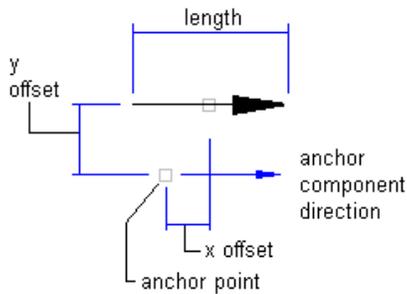
Dialog Box

Label Style Composer (page 1942)

# Direction Arrows

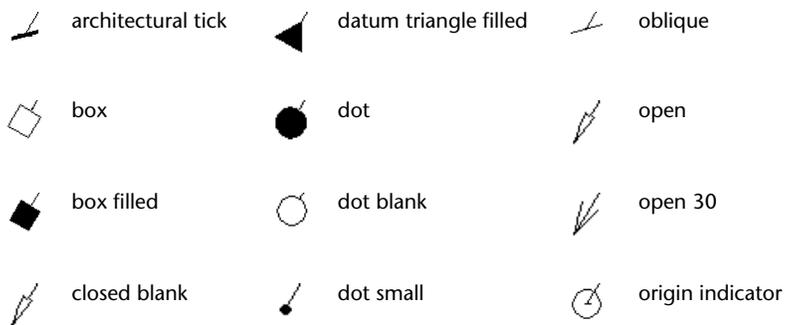
Add an arrow to a label style to indicate direction.

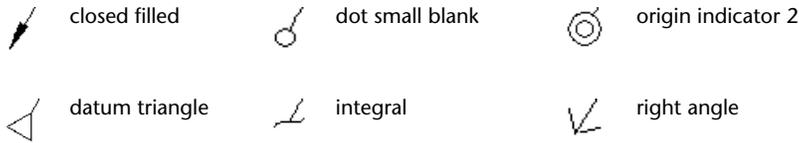


**Direction arrow properties**

The standard AutoCAD arrowheads are used in AutoCAD Civil:

| | | | | | |
|---|---|---|---|---|---|
| | architectural tick | | datum triangle filled | | oblique |
| | box | | dot | | open |
| | box filled | | dot blank | | open 30 |
| | closed blank | | dot small | | origin indicator |

| | | | | | |
|---|---|---|---|---|---|
| ∤ | closed filled | ⅃ | dot small blank | ◎ | origin indicator 2 |
| ◁ | datum triangle | ⌐ | integral | ⋁ | right angle |




**To add direction arrows**

1 In the Label Style Composer dialog box, click the Layout (page 1944) tab.

2 Click the Down arrow in ![A+ icon] , and then click ![arrow+ icon] .

The component automatically receives a default name, Arrow.1.

> **NOTE** This option is not available in label style types that do not support direction arrows.

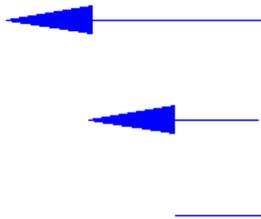
3 Enter a new name in the Name box.

4 Under Direction Arrow, select an Arrow Head Style.

5 Specify the desired settings in the General and Direction Arrow categories.

> **NOTE** The direction arrow length must be at least twice that of the specified arrow head size. If not, the arrow head is not displayed. For example, if you specify an arrow head size of 0.2, the arrow length must be at least 0.4. This behavior is similar to AutoCAD leaders.

**Arrow head is not displayed when
arrow length is decreased**



6 Click OK.

For more information, see Managing Layout Properties for Label Styles (page 1492).

# Changing Label Component Draw Order

You can change the label component draw order to control which label components are drawn on top of other components.

This is useful if you want to use a mask in a label style to cover drawing entities and then have another component appear on top of the mask.

**To change label component draw order**

**1** In the Label Style Composer dialog box, click the Layout (page 1944) tab.

**2** Click ⬚ Draw Order.

**3** In the Component Draw Order (page 1958) dialog box, select a label component in the list and click the Up or Down arrows to move it up or down in the display order. The item at the top of the list is drawn last, so it will appear on top of all other objects.

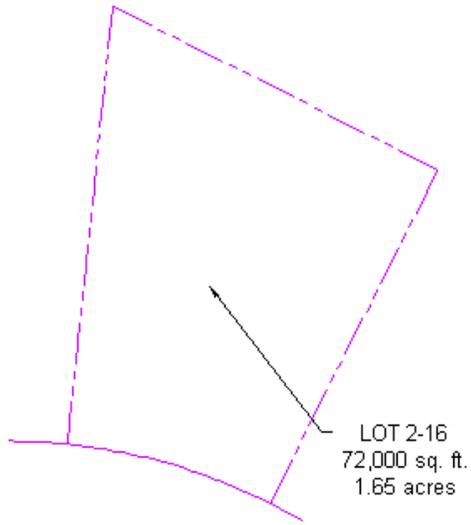
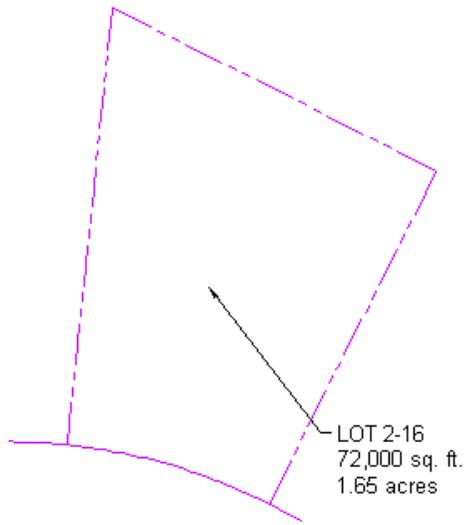
# Managing Dragged Properties for Label Styles

Use the Dragged State tab of the Label Style Composer dialog box to define leader visibility and properties for dragged label text.

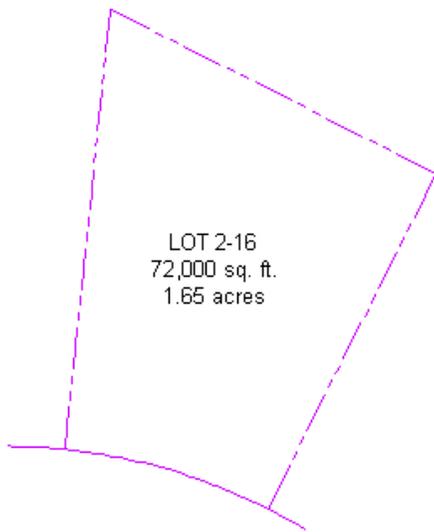
You can display dragged label text as you composed it originally, or as stacked text, as shown in the following illustrations:


**Label "As Composed"**

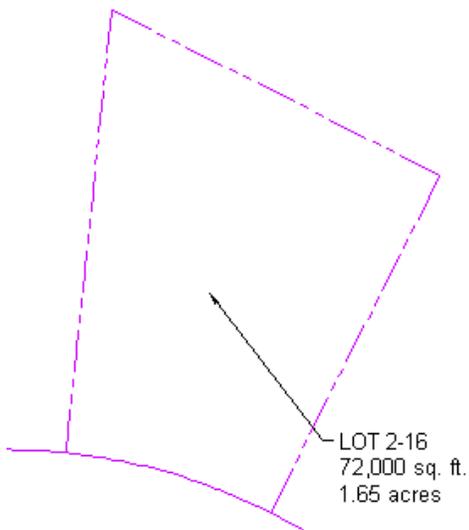


**Stacked label**

# Managing Leader Properties for Label Styles

Leaders can be displayed when you drag a label away from its default location.


**Default label location**



**Dragged label with leader**

A leader line remains attached to the original insertion point of the label and stretches to the label's new location. A leader can be drawn with an arrowhead and can be a straight line or a spline curve.

**Straight leader**

**Spline leader**

Text in a dragged label is stacked according to settings that you specify in the Dragged State (page 1958) tab of the Label Style Composer.

**To manage leader properties**

**1** In the Label Style Composer dialog box, click the Dragged State (page 1958) tab.

**2** Under Leader, change the Visibility value to True to display leaders when you move a label away from its original placement.

**3** Specify the leader arrow head style and size.

**4** Specify the leader type, either Straight Leader or Spline Leader.

**5** Specify color, linetype, and lineweight properties.

**To display/hide the leader**

■ Right-click a label and click Toggle Leader.

**To display/hide the leader tail**

■ Right-click a label and click Toggle Leader Tail.

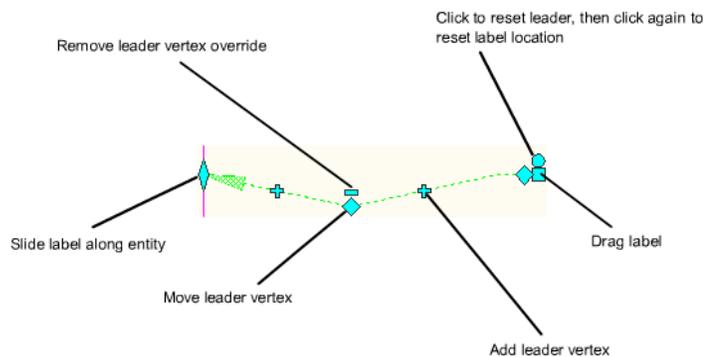
Dialog Box

Label Style Composer (page 1942)

# Managing Leader Vertices

Leader vertices can be added, moved, or removed.

Use the leader vertex grips to add, move, and reset leader vertices. You can add as many leader segments as desired.



**To add a leader vertex**

**1** Click on a dragged label and select the ✚ grip.

**2** Move the grip to the new location. A vertex is created. Note that new ✚ grips display on the resulting leader lines. Use these grips to create additional vertices.

**NOTE** If the leader type in label style dragged state is set to spline, an AutoCAD spline fit is made passing through the vertex points.

**To move a leader vertex**

1 Click on a dragged label that has at least two leader lines.

2 Select the grip and select a new vertex location.

**To remove a leader vertex**

1 Click on a dragged label that has at least two leader lines.

2 Select the grip and the adjacent vertex is reset.

**To reset leaders**

1 Click on a dragged label that has at least two leader lines.

2 Select the grip and the leader line is reset to its original state.

**NOTE** Click the grip a second time to reset the dragged label to its undragged state.

# Managing How Label Text Appears when Dragged

Dragged label text can be displayed as composed, which means that it is displayed the same way when dragged as when it is originally inserted, or it can be stacked. When stacked, all blocks, lines, and direction arrows are removed.

You can add borders around stacked label text, and specify how the text is justified. Label text is left-justified when the leader is on the left side of the text and is right-justified when the leader is on the right, as shown in the following illustration.

LOT 2-16
72,000 sq. ft.
1.65 acres

LOT 2-16
72,000 sq. ft.
1.65 acres

However, you can set the label text to be always left-justified regardless of the location of the leader, as shown in the following illustration.

LOT 2-16
72,000 sq. ft.
1.65 acres

LOT 2-16
72,000 sq. ft.
1.65 acres

You can also define the leader attachment position, which defines where the leader appears in relation to the label content.

**NOTE** If you set the display of a dragged label component to As Composed, then all the Dragged State Components properties are unavailable for editing. To control leader placement for "as composed" labels, edit the text attachment, anchor point, and offset settings on the Layout tab.

**To control how label text appears when dragged**

1 In the Label Style Composer dialog box, click the Dragged State (page 1958) tab.

2 Under Dragged State Components, change the Display value to either As Composed or Stacked Text.

> **NOTE** When you use the As Composed setting, you may need to adjust the text attachment point on the Layout tab to prevent the leader from crossing the text. For more information, see Anchor Points and Attachment Points (page 1492).

3 If you select Stacked Text, specify the border and leader values, including the Leader Justification value:

- **True**. Text is right-justified when the leader is on the left side of the text and is left-justified when the leader is on the right.

- **False**. Text is always left-justified regardless of the location of the leader.

Dialog Box

Label Style Composer (page 1942)

# Inserting and Managing Labels in Drawings

You can add labels to drawing objects, change label properties, flip and pin labels, and renumber label tags.

# Adding Labels to Drawings

You usually add labels to drawings when you create objects such as points, alignments, or parcels. You can also add labels after you create the objects.

- You specify the label styles to use when creating objects, and these labels are created automatically. For more information, see the Help about creating individual features.

- You can also insert labels using the Add Labels (page 1970) dialog box, and by using other feature-specific commands, such as the surface contour label command.

- You can also insert labels using the Annotate tab. This tab provides an efficient work environment for when you are ready to label objects that you have created. This tab provides quick access to all AutoCAD Civil feature-specific commands. Before using this tab, set your default label settings for best results as you are able to quickly label objects in rapid succession.

The labels that are created when you create objects can be deleted. Specifically, you can erase a whole group of labels and restore them by resetting the label group. You can also hide a single label and restore its visibility by resetting the label group. You can also explode labels and delete the labels that you manually insert.

**To manually add labels to drawings**

1 Click Annotate tab ➤ Labels & Tables panel ➤ Add Lables Drop-down ➤ Add <feature-specific label> .

2 In the Add Labels (page 1970) dialog box, select the desired label type and style.

**3** Click Add and select the label location in the drawing.

### Quick Reference

Ribbon

Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ <Feature ➤ Add <Feature> Labels

Menu

<Feature> menu ➤ Add <Feature> Labels

Dialog Box

Add Labels (page 1970)

#### To add feature specific labels to drawings

➤    Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels drop-down ➤ Add <feature-specific label> .

OR

**1** Click <feature> tab  ➤  Labels & Tables panel  ➤ <command>.

**2** Select the object to add the label to.

# Labeling Lines and Arcs

You can label lines, arcs, 2D polylines, feature lines, parcels, and alignments with AutoCAD Civil label styles. The general line label styles are available for lines, arc, 2D polylines, feature lines, lot lines, and alignments. You can also convert these general line labels to tags.

When creating or editing line labels, you can select both parcel label/alignment label styles as well as general line and curve label styles. The commands to add single and multiple label types support each of the three object types (line/curve, parcel, and alignment).

#### To label lines, arcs, polylines, feature lines, parcel, and alignments with general line label styles

**1** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Line and Curve  ➤  Add Line and Curve Labels ✎ .

**2** In the Add Labels (page 1970) dialog box, under Feature, select Line and Curve.

**3** Under Label Type, select Single Segment or Multiple Segment. Multiple Segment labels all segments on a selected polyline or feature line.

**4** Select the Line and Curve label styles to use. For more information, see Creating Label Styles for Lines, Curves, and Polylines (page 1479).

Note that you can select parcel, alignment, and general line and curve label styles to annotate lines.

**5** If the label styles use Referenced Text (page 2481), specify the Reference Text Object Prompt Method to use.

**6** Click Add. Then select the object to label.

**Quick Reference**

Ribbon

Menu

General menu ➤ Add Labels

Command Line

AddSegmentLabel
AddSegmentLabels (for multiple segments)

Dialog Box

Add Labels (page 1970)

# Labeling the Overall Length of Parcels

AutoCAD Civil contains label properties that you can use to label the overall length on the outside of contiguous parcels.

**To label the overall length of parcel segments**

1 Create a new parcel line label style or open an existing style to edit.

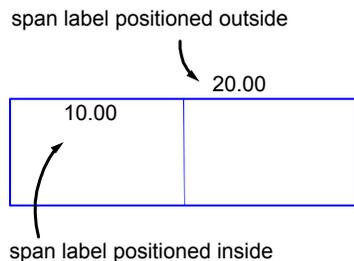
> **NOTE** You can also set up parcel curve label styles to span multiple segments.

2 On the Layout tab of the Label Style Composer, select or create the label component that you want to span multiple segments.

3 In the Properties list, under General, change the Span Outside Segments property to True.

Specify this setting for each component that you want to span multiple segments.

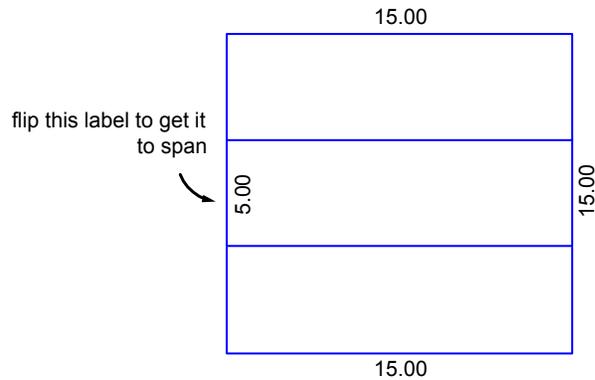
> **NOTE** The Span Outside Segments option works only on outside segments. If you have this option specified for a component, but it is positioned so that it appears inside a parcel, it will label the individual segment, not the spanned segment.

**Even if a label is set to Span Outside Segments, it must be positioned outside the parcel to label the span**


**4** Make sure that the components are all set up to display on the outside of the parcel line.

- On the Layout tab, adjust the Anchor Component, Attachment position, and Y Offset values as needed.
  For example, if the Anchor Component is Feature, set the Attachment to Bottom Center adjust the Y Offset to a positive number so the label will appear above the feature.

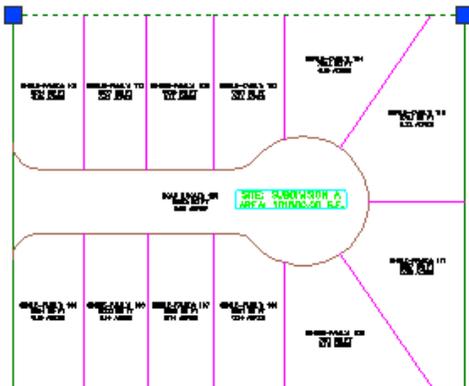
- On the General tab, set the Orientation Reference setting to Object and the Forced Insertion setting to None.
  The None setting forces the label component to the outside of most segments. However, on some segments, you may need to use the Flip Label command to flip the label to the outside.

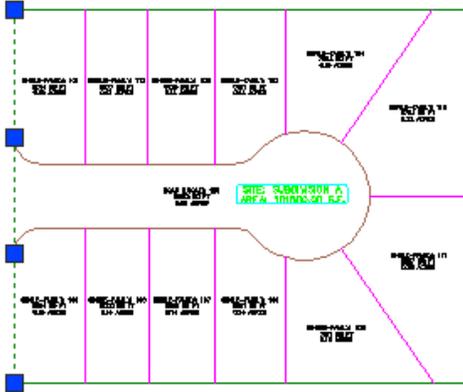


**5** To insert the labels, use the Parcels ➤ Add Labels command, select Single Segment as the label type, and select the label style that you set up to span.

The span label is inserted at the location you click, and the values contain the overall data for the contiguous parcels.

The parcel segment to label with the span must be one unbroken entity. For example, in the tutorial drawing Parcel-3.dwg, you can see that the top of the parcel group is one segment, so a span label can be successfully applied.



However, the left side of the parcel group is broken up into three segments, as shown below. The span label will not label all three. If you want to label the overall distance of that side, you would need to redraw the left side as one parcel entity.


# Setting Up Profile and Section View Labels

Because profile views and section views can contain more than one profile or section, certain profile and section labels require that you specify which profile or section data to use for the labels.

Specify which profile or section data to use by modifying the label properties after you add the label to the drawing. The label styles that use this feature are

■ Profile view Station Elevation labels

■ Section view Station Offset labels

The following workflow describes how to set up the profile view labels, and the same concepts can be applied to setting up the section view labels.

**To create profile view labels that contain data for multiple profiles**

1   Create a profile view that contains multiple profiles.

   **NOTE** The *Profile-3.dwg* file in the *\AutoCAD Civil 2010\Help\Civil Tutorials\drawings* folder contains a profile view you can use for experimenting.

2   Create a new profile view Station Elevation label style, or open an existing profile view Station Elevation label style for editing. For more information, see Creating and Editing Label Styles (page 1477).

3   With the style open in the Label Style Composer dialog box, click the Layout tab.

4   Verify that the Station Elevation Data component is selected in the Component Name list.

5   Under Text, click the Value column for Contents, and then click ⋯ to display the Text Component Editor.

6   Expand the Properties list. Note the following properties you can specify:
   ■ Profile 1 Name

   ■ Profile 1 Elevation

   ■ Profile 1 Elevation Difference

   ■ Profile 2 Name

   ■ Profile 2 Elevation

   ■ Profile 2 Elevation Difference

- Profile 1 Elevation minus Profile 2 Elevation

- Profile 2 Elevation minus Profile 1 Elevation

Because there may be multiple profiles in a profile view, you can assign any of those profiles to be "Profile 1" or "Profile 2." After you add these property fields to the label style and label the profile view, you can edit the label properties to specify which profiles you want to use.

7   In the Text Component Editor window, place your cursor at the end of the existing property fields and press Enter to create a new row.

8   In the Properties list, select a Profile 1 or Profile 2 property to add, and then click ⇨ to insert the property field. For more information, see Adding Text Components to Labels (page 1503).

For example, you could insert the "Profile 1 Name" property, enter a colon, and then insert the "Profile 1 Elevation" property, enter a paragraph return, and then insert similar properties for Profile 2.

9   Click OK to save your changes and close the dialog boxes.

10   Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Profile View ➤ Add Profile View Labels 🏷 .

11   In the Label Type list, select Station Elevation.

12   In the Station Elevation Label Style list, select the new style you created or the style you edited.

13   Click Add, and then select the profile view to label.

14   Specify the station and the elevation, and then press Enter to end the command.

The label is inserted with question marks (???) as placeholders for the profile 1 and profile 2 data.

15   Select the label, right-click, and click Label Properties.

16   In the Label Properties dialog box, click the Profile 1 Object column, and then click ⊡ .

17   In the Profile 1 Object dialog box, select the profile that you want to use as Profile 1, and then click OK.

18   Repeat Steps 14 and 15 for the Profile 2 Object.

19   Click OK to close the Label Properties dialog box.

The label is updated with the profile data.

---

**NOTE** If the label does not update immediately, enter Regen at the command line.

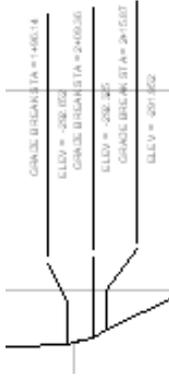
---

20   Use the label staggering options to avoid label collisions and to improve readability. For more information, see Staggering Profile and Section Labels (page 1527).

# Staggering Profile and Section Labels

Staggers profile and section labels for improved visibility.

Use the label height staggering options to avoid collisions in densely populated graph views in order to improve legibility. The staggering options are available through the AutoCAD Properties palette or the Properties dialog boxes.

Specify the height of the stagger lines so that label components have adequate spacing.


**Profile with staggered labels to avoid collisions**

**To stagger profile labels**

1   Right-click a profile object and select Edit Labels.

2   In the Profile Label Set (page 2167) dialog box, specify the Stagger Labels settings as required.

3   Specify the height of the stagger lines.

**NOTE** Layer, linetype and other AutoCAD properties of the stagger lines are determined by the leader settings in the Dragged State tab of the corresponding label style.

OR

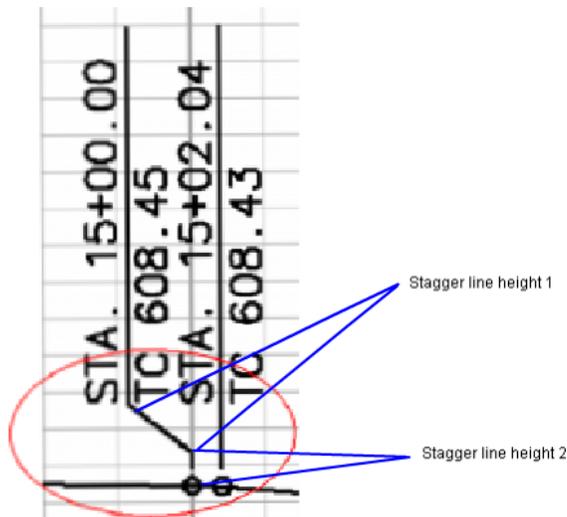
1   Right-click a profile label and select Properties

2   In the AutoCAD Properties palette under Staggering, specify the stagger label settings as required.

# Staggering Data Band Labels

Staggers data band labels for improved visibility.

Data band labels are objects that can be manipulated like other AutoCAD Civil label objects. Use the label height staggering options to avoid label collisions in densely populated data bands. The staggering options are available through the Profile View Properties or the AutoCAD Properties palette.

**NOTE** Data band labels can also be grip edited like other label objects.


**You set the stagger label line height**

**The staggering options are available for the following label types**

- Grade breaks (profile labels)

- Major/minor stations (profile labels)

- Horizontal geometry points (profile labels)

- Major/minor offsets (section labels)

- Grade breaks (section labels)

The following workflow describes how to stagger profile view labels, and the same concepts can be applied to setting up the section view labels.

**To stagger data band labels**

1 Right-click a data band label and select Profile View Properties.

2 In the Profile View Properties dialog box, click the Bands (page 2181) tab. Specify the Stagger Labels setting as required.

3 Specify the height of the stagger lines.

OR

1 Right-click a data band label and select Properties.

2 In the AutoCAD Properties palette under Staggering, specify the stagger label settings as required.

# Editing Data Band Labels

You can edit data band label objects with the Label Style Composer.

Use the Label Style Composer to specify a label style for an band, to create a new style, or to copy or edit an existing label style.When you edit a label style, all band labels in the drawing that reference that style are updated.

**To edit data band label styles**

**1** Right-click a data band label and select Edit Band Style.

**2** In the Profile Data Band Style dialog box, click the Band Details (page 2165) tab. Select the Compose Label button.

**3** Use the Label Style Composer Dialog Box (page 1942) to edit the data band label style.

**4** Click OK.

# Inserting Note Labels

You can insert Note labels that are not anchored to a specific object.

Note labels can contain text strings as well as Referenced Text (page 2481), which refers to other objects in the drawing.

It is important to remember that although the Referenced Text components in a Note label will update if a referenced object changes, a Note label itself is not attached to a specific object. Therefore, it does not move if you move a referenced object or an object that you have snapped it to. You must manually move a Note label to reposition it.

You can edit (or override) Note labels in a drawing to change the text for unique information. That way you do not have to have a separate label style for each note you want to insert. For more information, see Overriding Label Text (page 1535).

**To insert note labels**

**1** Specify the layer for Note labels on the Layer tab (page 66) of the Drawing Settings dialog box.

**2** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Notes � .

**3** In the Add Labels (page 1970) dialog box, under Feature, select Note.

**4** Select the Note label style to use. For more information, see Creating Note Labels (page 1480).

**5** Optionally, select a Marker Style to use. Using a Marker Style places a symbol at the Note label insertion point. If you do not select a Marker Style now, you can specify one later by editing the Label Properties.

---

**NOTE** You can set up new Marker Styles from the Toolspace Settings tab. Expand the General collection ➤ Multipurpose Styles ➤ Marker Styles.

---

**6** If the label style uses Referenced Text (page 2481), specify the Reference Text Object Prompt Method to use.

**7** Click Add.

**8** Select the location in the drawing where you want to insert the note.

**9** If the label uses Referenced Text, select the object(s) to reference by doing one of the following:

■ If you specified Command Line as the prompt method: Refer to the command line prompts to select the objects.

■ If you specified Dialog as the prompt method: The Label Properties (page 1966) dialog box is displayed. Click the Value column next to the Referenced Text item (where <none> is listed). Then click ⋯ and select the object from the Property Field Object dialog box.

**NOTE** If the Visibility setting is set to True for the Referenced Text component in the label style, and you do not select an object for the reference when you insert the label, question marks (???) are inserted into the label. You can specify an object by editing the label properties.

**NOTE** See Referenced Text (page 1509) for a list of other label types that support Referenced Text.

Dialog Box

Add Labels (page 1970)

# Labeling External References (Xrefs)

You can label xref objects as you would native objects.

The process to label xref objects is the same as if you were labeling an object in the current drawing. If the xref object is modified in the source drawing, then the corresponding label updates dynamically.

Labels you add to an xref exist in the current drawing. If you detach the xref, labels created in the current drawing will be lost. Xref data is read-only in the current drawing and can only be edited in the source drawing.

**For Xref labels to be created**

1    The xref must be inserted into the current drawing at 0, 0, 0.

2    The xref must be scaled at 1,1,1.

3    The xref must not be rotated.

Objects in an xref cannot be individually context selected. Xref commands, such as detach, bind, and unload, can alter the association between a label and the object within an xref. For more information, see Xref Label Behavior (page 1532).

If a drawing containing AutoCAD Civil objects and labels is inserted as an xref into another drawing, the labels will not be altered. It is recommended that if you insert xrefs that include labels, you should set the labels on layers that can be frozen.

**NOTE** Xrefs can only be used to create parcel and alignment tables. Other xref objects are not currently supported by tables.

**To add Xref labels**

1    Click Insert tab ➤ Reference panel ➤ Attach .

**2** In the Select Reference File dialog box, select the DWG to insert into the current drawing.

**3** In the External Reference dialog box, set the Insertion Point values (X, Y, and Z) to 0.00.

**4** Set the Scale values (X, Y, and Z) to 1.00.

**5** Set the Rotation angle to 0. Press OK.

The xref object displays in the current drawing. Now you can label the xref data.

**6** Click Annotate tab ➤ Labels & Tables panel ➤ Add Labels menu ➤ Notes ✎ .

**7** Select the label style to use.

> **NOTE** Labels for View Frames and Matchlines are NOT supported through xrefs.

**8** Click OK and pick the label locations.

Dialog Box

Add Labels (page 1970)

## Xref Label Behavior

Existing Xref labels are affected by edits to the xref object.

When an xref is modified, the xref label can be affected and/or removed.

The following describes the behavior of existing xref labels if the xref is modified through xref or AutoCAD commands.

| Command | Result |
| --- | --- |
| Xref Unload | While unloaded, the labels temporarily disappear, but still exist. When the xref is reloaded, the labels reappear. |
| Broken (Xref not found) | This occurs when an xRef file is renamed, deleted or path to it changed. While not found, the labels temporarily disappear, but still exist. When the xref is reloaded, the labels reappear. |
| Xref Detach (or erase) | The labels are erased and cannot be restored. |

| Command | Result |
|---|---|
| Xref Reload | The labels updated accordingly to the xref. If the xref has been modified, the label updates. If the xref has been removed, the label is erased. |
| Bind Xref | The label is erased. |
| Explode Xref | The label is erased. |
| AutoCAD command that alters the size or position of the xref. Such as move, rotate, or stretch. | Labels are converted to a single line of text "???", at the new insertion point. When the xref is altered back to meet the insertion requirements listed previously, the labels regenerate and appear as designed. When an xref is moved, the label displays xref moved. |

You cannot select a pick-sensitive context (right-click) menu for an object within an xref. Some labeling commands are available in <object> feature menus so they can be used with xref objects. Commands for editing alignment station labels (page 973), profile labels (page 1033), sample line (page 1136), and section labels (page 1137) are now available in their respective label menus on the Annotate tab.

# Identifying and Selecting Xrefs

Xrefs are easy to identify when selecting reference text objects for label styles or objects for inclusion in tables.

The name of the xref object uses this convention: **<XRef DWG Name>|<Object name in XRef>**. Note that the XRef DWG Name does not include the file extension or path. This is the same convention that AutoCAD uses for xref layer names.

# Modifying Labels in a Drawing

You can modify label object properties by right-clicking a label and selecting Label Properties or Properties to open the AutoCAD Properties palette. Use Ctrl+click to select individual labels within a group for editing. You can also grip edit label components, flip, pin, and reset labels.

## Changing Group Label Object Properties

Turn off the visibility of a group of labels, change the label style, and specify other properties depending on the type of label selected.

**To change group label properties**

1   Select a label in a drawing (the entire group is selected), right-click, and select Label Properties or Properties.

2   In the Properties palette, change the desired properties.

3   Click OK.

Ribbon

Select the label. Click Labels tab ➤ Modify panel ➤ Edit Label Group 

Object Shortcut Menu

Right-click label ➤ Label Properties or Properties

## Changing Single Label (single label within a group) Properties

To turn off the visibility of the label, change the label style, and specify other properties depending on the type of label selected, you can select sub-entities (single labels) within a group label using Ctrl+click.

**To change sub-entities (single labels) within a group label**

 **1**  Press Ctrl+click to select labels in a drawing.

 **2**  Right-click and select Label Properties or Properties.

 **3**  In the Properties palette, change the desired properties.

 **4**  Click OK.

OR

 **1**  In the drawing, select the label to edit.

 **2**  Right-click and select Edit Label Style.

 **3**  In the Label Style Control (page 1965) box, specify a label style, create a new style, or copy or edit an existing style. Press  to access the Label Style Composer.

### Quick Reference

Object Shortcut Menu

Press Ctrl and right-click label ➤ Label Properties or Properties

## Changing Non-Object Type Label Properties

Properties for points labels, all corridor labels, and surface watershed labels are modified with the Label Properties dialog box. Turn off the visibility of the label, change the label style, and specify other properties depending on the type of label selected.

**To change label properties**

 **1**  Select a label in a drawing, right-click, and click Label Properties or Properties.

 **2**  In the Label Properties (page 1966) dialog box, change the desired properties.

 **3**  Click OK.

### Quick Reference

### Quick Reference

## Overriding Label Text

Use the Edit Label Text command to override content of individual labels.

For certain label object types, you can override the content of individual labels. This override is useful if you want to add additional text specific to a certain label.

If you have edited the label text, this allows you to clear those edits. The label will only display what is in the style.

Overrides are supported for the following label types:

- Line
- Curve
- Note
- Profile View Station Elevation
- Surface Spot Elevation
- Section View Offset Elevation
- Segment
- Surface Slope
- Surface Contour - Major, Minor, User
- Alignment Major Stations
- Alignment Minor Stations
- Alignment Geometry Point
- Alignment Station Equation
- Alignment Design Speed
- Alignment - Profile Geometry Point
- Alignment Station Offset - Fixed Point
- Alignment Station Offset
- Alignment Line
- Alignment Curve
- Alignment Spiral

- Alignment Tangent Intersect

- Profile Major Stations

- Profile Minor Station

- Profile Horizontal Geometry

- Profile Grade Breaks

- Profile Line

- Profile Sag Curves

- Profile Crest Curves

- Profile View Depth

- Profile View - Station Elevation

- Sample Line

- Section Major Offset

- Section Minor Offset

- Section Grade Break

- Section Segment

- Section View Grade

- Network Pipe in plan

- Network Pipe in profile

- Network Pipe in section

- Network Structure in plan

- Network Structure in profile

- Network Structure in section

- Network Pipe - Spanning pipe

- Plan Production - View Frame

After you have overridden a label component, any changes you make to the text content in the label style are not applied until you clear the label text overrides. Changes you make to the non-text content in the label style (such as border, visibility, or color) are still applied to the overridden label.

**To override label text**

1  Select the label in the drawing. Right-click and click Edit Label Text.

2  The Text Component Editor (page 1961) is displayed.

3  Edit the label component as needed. Click OK.

**To clear label overrides**

1  Right-click the label and click Clear Label Text Override.

If multiple text components have been overridden for the label, you are prompted to select the text component to clear.

**2** Do one of the following:

**To clear all label overrides**

**1** Select the label(s) that contain the overrides.

**2** Right-click and click Clear All Label Text Overrides.

# Moving Labels in a Drawing

Use grips to move labels. Each label in a drawing contains a single, primary grip that can be used to drag a label from its position.

The Dragged State settings within the label style control how labels appear when dragged. If the Stacked Text option is selected, text components in dragged labels are stacked vertically based on the order in which the text components were created in the label style. Dragged labels can display a leader pointing from the text to the label's original location. For more information about stacked text, see Managing How Label Text Appears when Dragged (page 1521).

**To move a label in a drawing**

**1** Click the label to be moved and select the square grip.

**2** Move the label to the new location.

---

**NOTE**

To return the label to its original position, if the leader is not modified from its original state, click the
🔵 reset grip or right-click the label and click Reset Label. For group labels, click the 🔵 reset grip or right-click the label and click Reset All Group Labels.

If the leader has been divided into multiple segments, a single click will restore the leader to its original state. Click the 🔵 reset grip twice to reset the label to its original location.

---

## Editing Point Label Components with Grips

Move each component of a point label independently by using component grips.

The following illustration shows the round and diamond-shaped component grips on a point label:

**To edit point label text with grips**

1   Click the point label to display the round and square grips.

2   Click the round grip to display the diamond-shaped grips.

3   Click a diamond-shaped grip and move the label component to the new location.

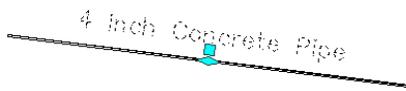
## Editing Line, Arc, and Polyline Labels with Grips

Use the square grip on line, arc, and polyline labels to drag the label off the entity. Use the diamond grip to slide the label along the entity.

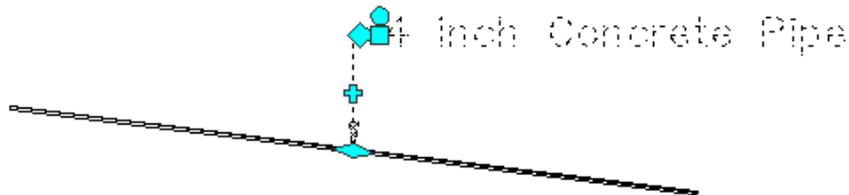
If you slide a label along a polyline from one type of segment to another (such as a line to a curve), the label style changes.

**To move line, arc, and polyline labels away from the entity**

1   Click the label to be moved and select the ▢ grip.



2   Move the label to the new location. A leader is created and the label is displayed using the Dragged State settings defined in the label style. A ⬭ grip is also displayed on the label.



> **NOTE** If no additional leader line vertices have been added, click the ⬭ grip store a dragged label to its undragged state. If there are multiple leader lines, click the ⬭ grip once to restore the leader to its original state. Click the ⬭ grip twice to restore a dragged label to its undragged state.

**To move line, arc, and polyline labels along the entity**

1   Click the label to be moved and select the diamond grip.

2   Slide the label along the entity.

## Editing Unanchored Labels with Grips

Single point type labels such as note and station offset labels are not anchored to any specific object. You can move them freely about the drawing.

**To move a Note label**

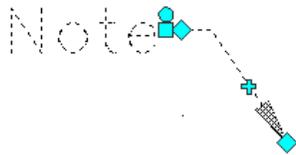
1 Click the label to be moved and select the diamond grip.

2 Move the label to the new location.

**To drag a Note label away from its insertion point and create a leader**

1 Click the label to be moved and select the ■ grip.

2 Move the label to the new location. A leader is created and the label is displayed using the Dragged State settings defined in the label style. A ⬭ grip is also displayed on the label.



**NOTE** If no additional leader line vertices have been added, click the ⬭ grip to restore a dragged label to its undragged state. If there are multiple leader lines, click the ⬭ grip once to restore the leader to its original state. Click the ⬭ grip twice to restore a dragged label to its undragged state.

## Editing Data Band Labels with Grips

Edit data band label objects with grips.

Use the ■ grip on data band labels to drag the label off of the entity.

**To move a band label**

1 Click the label to be moved and select the ■ grip.

2 Move the label to the new location. A leader is created and the label is displayed using the Dragged State settings defined in the label style.

3 Manage the label leader as you would for other label objects. For more information, see Managing Leader Vertices (page 1520).

4 **NOTE** If no additional leader line vertices have been added, click the ⬭ grip to restore a dragged label to its undragged state. If there are multiple leader lines, click the ⬭ grip once to restore the leader to its original state. Click the ⬭ grip twice to restore a dragged label to its undragged state.

## Resetting Group Label Location

Returns dragged group labels to their original position.

Use the Reset All Group Labels command to return dragged group labels to their original position.

**To reset group label location**

1  Select one of the labels in the group.

2  Right-click the label, and click Reset All Group Labels.

> **NOTE** To reset a single sub-entity of a group label, the available command is Reset Label.

> **NOTE** You can also click the ⬤ grip to restore a dragged label to its default state. Click once to reset the leader to its original state if vertices have been added. Click twice to reset the label to its undragged state.

### Quick Reference

Ribbon

Select the label. Click Labels tab ➤ Modify panel ➤ Reset Label Group 🔲

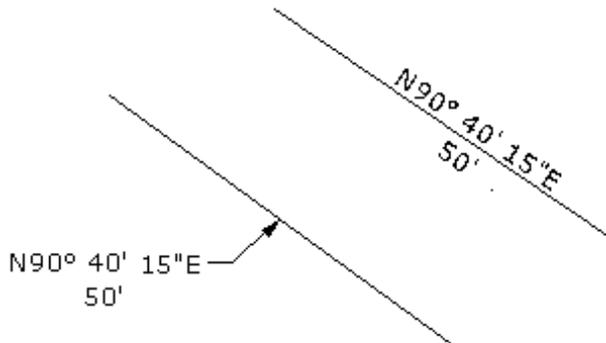
Right-click label ➤ Reset All Group Labels

## Resetting Single Label Location

Resets single labels to their original position.

Use this command to return dragged single labels to their original position. You can also reset a single, dragged sub-entity of a group label.



**To reset single label location**

1  Select the label you want to reset.

2  Right-click the label, and click Reset Label.

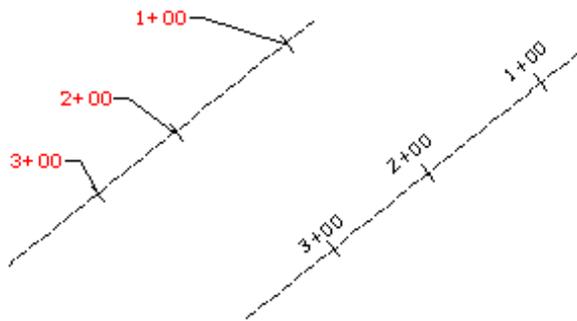
> **NOTE** You can also click the ⬤ grip to restore a dragged label to its default state. Click once to reset the leader to its original state if vertices have been added. Click twice to reset the label to its undragged state.

## Quick Reference

## Resetting Label Properties

Resets group labels.

Use this command to reset dragged group labels group back to their original position, as well as remove any style overrides.



**NOTE** You can also reset dragged labels per viewport.

**To reset label group properties**

1 Select one of the labels in the group.

2 Right-click the label, and click Reset All Group Labels .

## Quick Reference

## Exploding Labels

Use the Explode command to convert labels to AutoCAD MText, line, and block entities without affecting the parent object.

If the label has a leader, then it is converted to an AutoCAD leader entity.

**To explode labels**

**1** Click Home tab ➤ Modify panel ➤ Explode  .

**2** Select the label to explode and press Enter.

## Quick Reference

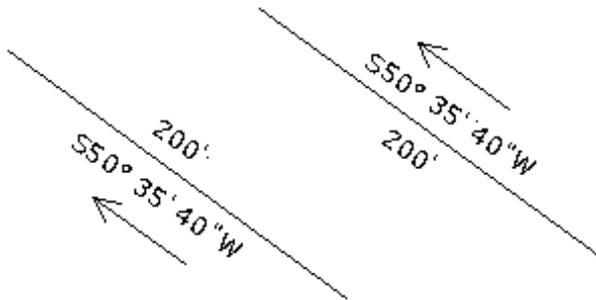
# Flipping Labels

Flip a label in its location to reverse the placement order of the label components. You can flip labels for lines, curves, and spirals.

For example, flipping a bearing over distance label moves the bearing and distance to the other sides of the line or arc.



**To flip labels**

■ Right-click a label, and click Flip Label.

> **NOTE** To return the label to its original position, right-click the label and select Reset Label.

## Quick Reference

Ribbon

Select the label. Click Labels tab ➤ Modify panel ➤ Flip Label 

Object Shortcut Menu

Right-click label ➤ Flip Label

Command Line

  LabelFlip

## Pinning Labels

Pins labels to their current location.

After you have dragged a label to another location, you can force (pin) labels to remain in the current location, regardless of edits that are made to the parent object.

**To pin labels**

■  Right-click a label, and click Toggle Label Pin.

### Quick Reference

LabelReverseBearing

# Creating Label Tags

Control label tags with the Table Tag Numbering dialog box. You can set the default starting number and increment options for table tags.

General line and curve labels can be used alone or with parcel segment labels to create a table.

**To control table tag starting numbers and increments**

■ In the Toolspace Prospector tab, right-click the drawing name, and click Table Tag Numbering.

■ In the Table Tag Numbering (page 1971) dialog box, specify the default tag starting number and the increment number. No duplicate tags are created unless you manually create them with the Renumbering label tags tool. If there is a duplicate with the starting number, the number increments up by the specified amount. If there is still a duplicate, it increments up, until an unused tag number is found and applied. The starting number is then set to the next number according to the increment (even if it is a duplicate).

### Quick Reference

Object Shortcut Menu

Right-click drawing name ➤ Table Tag Numbering

# Renumbering Label Tags

Label tags are numbered sequentially according to the order in which they are created, but you can renumber them to remove gaps in a sequence, or to change the starting number or increment value.

By default, newly created tags are unique. Duplicate tags are only created manually. Specify tag starting and increment numbers in the Table Tag Numbering Dialog Box (page 1971). You can create a duplicate by opening an existing drawing that contains duplicates across sites/alignment collections or with the renumber command. You can create or avoid duplicate tags as desired.

Table tags support the following tag mode labels: general line, general curve, parcel line, parcel curve, alignment line, alignment curve, and alignment spiral.

**To renumber tags**

1 Click <Object Name> tab ➤ Labels & Tables panel ➤ Renumber Tags .

2 Do one of the following:

■ In the drawing, select a tag to renumber. The starting number is determined by the Table Tag Renumbering settings. If there is a duplicate in the drawing, you are prompted to skip to the next

available number or to create a duplicate. By default, duplicates are not created unless you allow it. You can select multiple tags to renumber. Select the tags in the sequential order that you want them numbered. If you selected a label that is not a valid type or is not in tag mode, you are prompted to try again.

■ At the command line, enter **S**. In the Table Tag Numbering (page 1971) dialog box, set the starting number and increment for the label types, either line, curve or spiral. Then press OK.

**3** Enter **end** to end the command.

### Quick Reference

Renumbering (page 2444)

## Deleting Labels From Drawings

You can delete some labels from drawings.

Labels that you can delete include all label types that you can add manually, after an object is created. You can also delete group labels. Labels that you cannot delete include some of the label types that are added to an object automatically when it is created, such as parcel area labels.

**NOTE** You can also explode labels, and then erase the exploded entities. For more information, see Exploding Labels (page 1541).

If you delete an object, all labels that are associated with it are also deleted.

**To delete labels from drawings**

■ To delete manually-added labels, right-click a label and click Erase.

**NOTE** Some labels cannot be deleted, but can be hidden. For more information, see Hiding and Displaying Labels in the Drawing (page 1487).

### Quick Reference

Object Shortcut Menu

Right-click label ➤ Basic Modify Tools ➤ Erase

## Deleting Band Labels

You can delete band labels from drawings.

Band label objects can be deleted individually or as part of a group.

**To delete band labels as a group**

■  Right-click a band group label and click Erase.

**To delete individual band labels**

■  Ctrl-click a band label and click Erase.

### Quick Reference

Object Shortcut Menu

Right-click label ➤ Basic Modify Tools ➤ Erase

## Restoring Band Labels

You can restore band labels that have been deleted from drawings.

When the complete set of band group labels are deleted, the band displays without labels. You can use the Bands tab in the Profile View Properties dialog box to restore deleted band group labels.

The following workflows describe how to restore deleted profile view band labels, and the same concepts can be applied to restoring section view band labels.

**To restore deleted band group labels**

1  Right-click the profile view and select Profile View Properties.

2  In the Profile View Properties dialog box, click the Bands tab.

3  Select the Show Labels check box. Click OK.

**To restore deleted individual band labels**

■  Right-click a band label and click Reset All Group Labels
All previously deleted labels display on the bands.

## Deleting a Label Style

You can delete a label style if it is not being used in a drawing.

**To delete a label style**

1  In Toolspace, on the Settings tab, right-click the label style you want to delete.

2  Click Delete.

> **NOTE** You cannot delete a label style that is referenced by an object or by another label style.

3  Click Yes to confirm the deletion.

# Creating a Label Set

Defines new label sets.

This allows you to modify the set of labels by adding or removing label types or parameters.

**To define a new label set**

1   In Toolspace, on the Settings tab, expand a drawing's Alignment, Profiles, or Section object collection, and then expand Label Styles.

2   Right-click Label Sets, and click New.

3   In the <Feature Name> Label Set (page 1968) dialog box, click the Information tab.

4   Enter the label set name and description information.

5   Click the Labels tab.

6   Under Type, select a label style type from the list.

7   Under <label style name> Label Style, select a specific label style from the list.

8   Click Add to add the style to the label set.

    The label style is displayed in a row in the window section.

9   Repeat Steps 7–8 for each label style that you want to add to the set.

10  Specify values for the label properties, such as the Increment value for station labels. For more information, see Labels Tab (Label Set Dialog Box) (page 1968).

11  Click OK.

**Quick Reference**

Dialog Box

<Feature Name> Label Set (page 1968)

# Expressions

Set up mathematical expressions to use in label styles.

Label styles are composed of property fields that display information about an object. Expressions allow you to convert the object information using a formula, then insert the result into a label style component.

Expressions are stored in the Settings tree, within the label style type folders. They are not available for label style types that do not have relevant properties, such as Note label styles.

You insert expressions into label styles using the Text Component Editor when you are editing a label style text component.

You can use design data to determine how a label style is drawn using text, lines or block components. You can insert expressions into label styles by selecting expressions in place of static values for text, line, and block component modifiers. For example, in the Layout tab of the Label Style Composer dialog box, you can insert an expression in place of a static value when determining the text height of a label. This expression could increase the text height of a spot elevation label to coincide with the elevation height.

You can insert expressions in label styles to create custom graphics. For example, you can create a graphical profile band, in which the graphics of the vertical grades are relative to the actual grades in order to visually reinforce the data representation, or match graphical standards. A PVI can be represented by a symbol, where the lines/values representing the grade in and grade out change quadrants based on the sign of the grades.

# Setting Up Expressions

Expressions make use of the same properties that you can add to label styles, such as Point Elevation, Northing, and Easting. By using expressions, you can set up separate mathematical formulas using the existing properties. For example, you could subtract a value from a point elevation, and display that number along side the actual elevation in a point label.

After you set up expressions, they are available in the Properties list in the Text Component Editor so you can add them to label styles. In effect, expressions become new properties that you can use to compose a label style.

Expressions are unique to a particular label style type. Only those properties that are relevant to the label style type are available to choose from in the Expressions dialog box.

### Brackets and Parentheses

When you insert a property into an expression, it appears in curly brackets if it contains spaces. For example:

```
{Segment Length}
```

Do not insert anything else into the curly brackets, and do not remove them. If the property name does not have any spaces (like Northing), then curly brackets are not required.

For expression grouping, use parentheses. For example:

```
0.567*({Segment Length} + 56)
```

### Restrictions

Expressions are mathematical formulas that are used to compute a value. No text can be added directly to them. Any text you want to include can be added to the label style. For example, to convert feet to meters, you could set up the following expression:

```
{Segment Length} *.3084
```

If you want to add "meters" to the end of this string, you must add it later when you set up the label style.

### To set up an expression

1   In Toolspace, on the Settings tab, expand a label style type collection.

    For example, expand Parcel ➤ Label Styles ➤ Line.

2   Right-click Expressions and click New.

3   In the Expressions dialog box, enter a name and description for the expression.

**NOTE** It is recommended that you use a clear naming convention such as "Parcel line expression: Length in meters" so you can distinguish them when composing a label style.

**4** Click the Insert Property button and select a property from the list.

The property appears in the editor box.

**5** Add functions, constants, and logical operators to complete the equation.

**NOTE** Do not insert anything into the curly brackets that surround the property fields.

■ Use the calculator buttons or click in the editor field and use your keypad to enter numbers and mathematical operators like **\*** (multiply) or \ (divide).

■ Use the Insert Function button to insert mathematical functions like TAN.

**NOTE** For a complete list of operators and functions, see Expressions Dialog Box (page 1973).

**6** Specify how the expression should be formatted by selecting a format from the Format Result As list.

**7** Click OK.

See Inserting Expressions into Label Styles as Properties (page 1551)

### Quick Reference

Dialog Box

Expressions (page 1973)

# Expression Examples

Following are some examples of expression syntax.

### Converting Northings and Eastings to Polar Coordinates

You can create expressions for point labels to convert northings and eastings to polar radius and polar angle values. These expressions compute the radius and angle from the coordinate system origin to the point.

**Polar Radius Expression Syntax:**

SQRT (Northing^2 + Easting ^2)

Format as Distance.

**Polar Angle Expression Syntax:**

ATAN2 (Northing, Easting)

Format as Angle.

### Converting Astronomic Direction to Magnetic Direction

All internal angle calculations in AutoCAD Civil are done in radians. You can take this into account when you apply a formula to an angle, such as when you label a line with both a true direction and a magnetic direction.

To subtract a 15d 30' 15" magnetic declination from an astronomic direction to derive the magnetic direction, you can set up the following expression:

**Known:**

PI = 3.141592654

360 degrees = 2(pi) radians

1 radian = 57.29577951 degrees

**Given:**

15d 30' 15" = 15.50417 degrees

**Expression Syntax:**

{Segment Direction} - (15.50417**\***((2**\***pi)/360))

Or alternatively using the built-in functions as follows:

{Segment Direction} - DEG2RAD(15.50417)

Format the result as Direction.

### Tower Top Elevation

You can create expressions for surface spot elevation labels to calculate the sum of the height of a structure such as an airport control tower with the ground elevation.

**Tower Top Expression Syntax:**

{Surface Elevation+ 228.5}

In this example, 228.5 is the height of the structure.

# Editing Expressions

After you create an expression, it is listed in the Settings tree item view.

Click the Expressions collection to display the list of defined expressions in the Toolspace item view. Right-click an expression to access commands.

**To edit an expression**

1  Select the Expressions collection that contains the expression you want to edit.

2  Ensure the Toolspace item view (page 82) is visible.

3  Right-click an expression in the item view and click Edit Expression.

4  Edit the expression using the Expressions (page 1973) dialog box.

# Inserting Expressions into Label Styles as Properties

Expressions are listed in the Properties list of the Text Component Editor. You can insert them into label styles like any other property.

**To insert an expression into a label style**

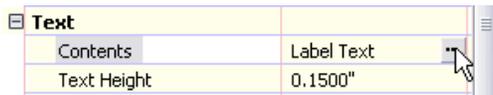
1  Set up an expression (page 1548) for a label style type.

2  Open an existing label style in the Label Style Composer or create a new label style. The type of this label style must match the type of the expression you created.

   For example, if you created an expression for a parcel line, you can only add that expression to a parcel line label style.

3  In the Label Style Composer dialog box, click the Layout tab and select or create a text, line, tick, or block component to which you want to add the expression. For more information, see Text (page 1502).

4  Under Text, click the Value column for Contents click [...]



5  In the Text Component Editor, on the Properties (page 1962) tab, click the Down arrow on the Properties list.

   This list contains a set of properties and expressions applicable to each label style type.

6  Select the expression and click ➪. This inserts the expression into the Text Component Editor window.

7  Add any descriptive label text before or after the expression as needed. For example, add descriptive information about the expression, such as units, that will distinguish it in the label.

   **WARNING** Expressions have the same editing restrictions as property fields. If you alter anything about the expression, such as using the shortcut menu to change capitalization, the expression will not function correctly.

8  Click OK to close the Text Component Editor and the Label Style Composer dialog boxes.

### Quick Reference

Dialog Box

# Inserting Expressions into Label Styles as Values

You can insert expressions as values to modify components in the Label Style Composer.

**To insert an expression as a value into a label style**

1  In Toolspace, on the Settings tab, expand a label style collection. For example, expand Parcel ➤ Label Styles ➤ Line.

2  Right-click Line and click Edit.

3  In the Label Style Composer dialog box, click the Layout tab and click a component modifier to access a drop-down list of compatible expressions. You can also type in a new value.

4  Click OK.

> **NOTE** When inserting expressions as values for text, line, block or tick components, any non-number, or "double" type property cannot be used and will not appear in the drop-down list. Height, length, or size modifiers must be absolute numbers, so that the property is converted to an absolute value. For example, if the entered value for text height is zero, the default height from drawing label style defaults will be used.

The tables below list the Label Style Composer component modifiers that support expressions.

**Text Components**

Text Height

Rotation Angle

X Offset

Y Offset

**Line Components**

Length

Angle

Start Point X Offset

Start Point Y Offset

End Point X Offset

End Point Y Offset

**Block Component**

Block Height

# Labels Command Reference

The following table lists label commands and briefly describes their functionality. For more information about a command, follow the link in the Description column.

| Command | Description |
| --- | --- |
| AddLabels | Adds labels with the Add Labels dialog box (page 1522) |
| AddNoteLabel | Adds a note label (page 1530) |
| AddSegmentLabel | Adds line, arc, and polyline segment labels (page 1523) |
| FlipLabel | Flips a label to reverse the placement order of th e label components. (page 1542) |
| LabelReverseBearing | Reverses bearing direction in labels that support bearing direction. (page 1543) |
| LabelTogglePin | Pins labels to their current location. (page 1543) |

# Tables                                                          34

You can insert tables into a drawing to document the geometry of selected objects.

## Understanding Tables

Each row in a table contains information about a single object component, such as a line. Tables are supported for points, parcels, alignments, surfaces, pipes, and structures.

■ The first column of data in a table is reserved for the tag number or identifier.

> **NOTE** For point tables, the point number is used as the identifier. For parcel tables, the parcel ID is used as the identifier for the area and tag numbers are used for lines and curves.

■ Additional columns display the object data.

**Adding Object Tables**

Add a table to a drawing by doing the following:

■ Set up a table style for the object. The table style specifies the type of data that is inserted into the table.

■ Label the objects whose data you want to add to a table.

Select table data by using the following methods:

■ By selecting individual labels

■ By specifying a label style

■ By selecting point groups (for point tables)

■ By selecting an alignment (for alignment segment tables)

When you insert a table into a drawing, most labels are required to be displayed in tag mode (the exceptions to this rule are parcel area tables and point tables).

If the labels are currently set to label mode, they are automatically switched to tag mode when you insert the table. Although it is not required, you may prefer to set the label styles to tag mode before inserting a table to avoid the creation of unwanted styles. For more information, see Setting Up Label Styles To Be Used as Tags (page 1485).

After creating tags, you can renumber them to reset their sequential order. For more information, see Renumbering Label Tags (page 1544).

**Adding Surface Legend Tables**

When you perform a surface analysis, the data is separated into ranges that are assigned different colors. Legend tables display these colors and range values.

Add a surface legend table to a drawing, by doing the following:

- Perform a surface analysis. For more information, see Analysis Tab (Surface Properties Dialog Box) (page 2349).

- Modify the surface style so that it displays the analysis type. For more information, see Display Tab (Surface Style Dialog Box) (page 2345).

- Set up a surface legend table style to display the surface data. For more information, see Table Styles (page 1556).

# Table Styles

Edits table content and style.

Table styles define which data is displayed in the table, and control the table appearance.

# Defining a New Table Style

Right-click a table style type and click New to create a new table style.

**To define a new table style**

1 In Toolspace, on the Settings tab, right-click a table style type name, and click New.

2 In the Table Style dialog box, click the Information tab (page 2437).

3 Enter a name.

4 Click OK.

# Table Title

The title is displayed in the first row of a table.

---
**NOTE** Except for Alignment tables, you cannot define property fields as a table title.

---

**To define the table title**

**1** In the Table Style dialog box, click the Data Properties (page 2437) tab.

**2** Under Structure, double-click the table title element in the top row of the table heading. The Text Component Editor opens.

**3** Enter the title.

**4** Format the text using the editing options.

**5** Click OK.

# Table Data

Properties control which data is inserted in table columns.

Available properties are specific to the table type. For example, point table properties include only those properties that are relevant to points, such as point number.

Surface legend table styles contain a Surface Range Color property that displays the color swatch in the specified column.

**To link property fields to table rows**

1   In the Table Style dialog box, click the Data Properties (page 2437) tab.

2   Under Structure, double-click a Column Value cell to open the Text Component Editor.

3   Click the Properties tab.

4   In the Properties list, select a property, and enter the Modifier values.

5   Click  to insert the property into the window.

6   Click OK.

### Quick Reference

# Table Format

Manage table size and appearance.

## Column Size

Set columns to either a specific or an automatic width.

■ You can set the column width to Manual and specify the number of characters allowed in a string. Strings over the specified amount are truncated unless word wrapping is selected.

■ You can set the column width to Automatic, which adjusts the width to accommodate the longest string in the column.

**To define column size**

1 In the Table Style dialog box, click the Data Properties (page 2437) tab.

2 Under Structure, click a Column Width icon ⬚ to display the selections.

3 Click either Automatic or Manual.

4 If you select Manual, enter the number of characters.

5 Click OK.

### Quick Reference

## Rearranging Columns

Rearrange and move columns in the table by dragging them.

**To move columns**

**1** In the Table Style dialog box, click the Data Properties (page 2437) tab.

**2** Under Structure, click the column to be moved in its title cell and drag it to the new position.

---

**NOTE** You cannot move the first table column.

---

## Splitting Tables

Split tables into smaller sets and customize the display of the headers.

**To set up a split table**

1   In the Table Style dialog box, click the Data Properties (page 2437) tab.

2   Under Table Settings, you can select the following options:
   - Repeat Title In Split Tables.
   - Repeat Column Headers In Split Tables.

3   Click OK.

**NOTE** When you create a table, or edit table properties, you can specify both whether the table should be split and how many rows each section should contain. For more information, see Table Properties Dialog Box (page 2443).

# Using Table Styles from Other Drawings

Drag and drop table styles from other drawings to copy the styles.

Drag a style from one drawing to another in the Settings tree, or drag the style from the Settings tree into the drawing window to copy the style into that drawing.

When you attempt to copy a table style to a location where a matching table style exists, you are prompted with a warning, and have the following options:

■ **No**. Leaves the existing style and cancels the operation.

■ **Yes**. Copies the style to the new drawing and renames the style using the format <source drawing name>.<style name>.1

**To copy table styles from other drawings**

1 Open the drawing that contains the styles you want to copy (Drawing1, for example), and the drawing you want to copy styles to (Drawing2, for example).

2 In Toolspace, click the Settings tab.

3 In the View Control list, select Master View.

4 In the Settings tree, expand the Drawing1 collection and select the table style to copy.

5 Drag and drop the table style to Drawing2 in the Settings tree. You must drag the style over the drawing name in the Settings tree before releasing the mouse button.

■ A valid drag and drop operation will display a ⬚ cursor.

■ An invalid drag and drop operation will display a ⊘ cursor.

# Deleting a Table Style

Use the Settings tree in Toolspace to delete a table style.

**To delete a table style**

■ In Toolspace, on the Settings tab, expand the object collection, expand the table style type collection (if applicable), right-click the table style name, and click Delete.
For example, to delete the surface direction table style named 'Standard':

NOTE A style that is used in the drawing cannot be deleted.

### Quick Reference

# Adding Tables to Drawings

Add tables to a drawing.

# Adding Object Tables to Drawings

Specify table data differently for each object type.

- **Point tables**. Select points, point groups, or label styles.

- **Alignment tables**. Select an alignment, individual labels or tags, or label styles.

- **Parcel tables**. Select individual parcel labels or tags, or label styles.

- **Survey figure tables**. Select survey figure labels or tags, or label styles.

When creating parcel tables, you can select any general line/curve label types and/or parcel segment labels including any line or curve label, applied to a line, curve, feature line, or polyline.

You can create an alignment segment label that references a general line or curve style for inclusion in a table.

General line and curve label styles have a Tag Mode which supports general line and curve labels, parcel segment labels that reference a general line or curve style, and alignment segment labels that reference a general line or curve style.

The Add Table commands are available from the Annotate tab.

**To add tables to a drawing**

1   Do the following:
    ■   Click Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ <feature> ➤ Add <feature-specific> Table ⊞ .

2   In the Table Creation dialog box, select the table style, layer, and behavior properties. For more information, see Table Creation Dialog Box (page 2441).

3   Select the data for the table:
    ■   For all types of tables, select the check boxes next to the style name to select label styles to include in the table.

    ■   For alignment segment tables, select By Alignment and click ⬛ to select an alignment. Or, select Multiple Selection and select the check boxes or click ⬛ to select tags.

    ■   For alignment line, curve, or spiral tables, click ⬛ to select tags.

    ■   For point tables, click ⬕ to specify a point group or click ⬛ to select points from the drawing.

    ■   For parcel tables, click ⬛ to select tags or area labels. Note that you can select line and curve labels within the drawing, just as you would select parcel segment or alignment labels. These labels go into tag mode when selected. If they are selected in the drawing, you are prompted to create a child style in tag mode for the selected label.

    **NOTE** To avoid creating child label styles, set up label styles to be used as tags. For more information, see Setting Up Label Styles To Be Used as Tags (page 1485).

4   Click OK.

5   Select an insertion point.

## Quick Reference

Dialog Box

Table Creation (page 2441)

# Adding Surface Legend Tables to Drawings

Surface tables are created in a legend style and do not use label styles or tags.

To add a surface legend table to a drawing, first do the following:

■ Perform a surface analysis. For more information, see Analysis Tab (Surface Properties Dialog Box) (page 2349).

■ Modify the surface style so that it displays the analysis type. For more information, see Display Tab (Surface Style Dialog Box) (page 2345).

■ Set up a surface legend table style to display the surface data. For more information, see Table Styles (page 1556).

**To add surface legend tables**

1 Annotate tab ➤ Labels & Tables panel ➤ Add Tables menu ➤ Add Surface Legend Table ⊞

2 Select a surface in the drawing.

3 At the Command prompt, enter the table type.

4 At the Command prompt, enter Dynamic to enable the table to be updated automatically if the surface analysis is updated. Enter Static to require manual updating.

5 Select an insertion point.

# Changing Table Data

Add, remove, or replace data in a table.

___

**NOTE** The Table Selection shortcut commands are not available for surface legend tables and alignment segment tables.

___

**To add data to a table**

1   Right-click a table, and click Selection ➤ Add.

2   In the Selection dialog box, select the data by doing the following:

  ■ **All table types**: Select label styles by selecting the Apply check box and then selecting Add Existing or Add Existing And New from the Selection Rule list.

  ■ **Point tables**: Click  and select point groups, or click  and select points in the drawing.

  ■ **Alignment tables**: Click  and select alignment tags in the drawing.

  ■ **Parcel tables**: Click  and select parcel tags in the drawing.

3   Click OK.

**To remove data from a table**

1   Right-click a table, and click Selection ➤ Remove.

2   In the Selection dialog box, select the data by doing the following:

  ■ **All table types**: Select label styles by selecting the Apply check box, or click  and select table rows.

  ■ **Point tables**: Click  and select point groups.

3   Click OK.

**To replace data in a table**

1   Right-click a table, and click Selection ➤ Replace.

**2** In the Selection dialog box, select the data by doing the following:

- **All table types**: Select label styles by selecting the Apply check box and then selecting Add Existing or Add Existing And New from the Exclusion Rule list.

- **Point tables**: Click ⊞ and select point groups, or click ⊞ and select points in the drawing.

- **Alignment tables**: Click ⊞ and select alignment tags in the drawing.

- **Parcel tables**: Click ⊞ and select parcel tags in the drawing.

**3** Click OK.

# Reports

# 35

In AutoCAD Civil 2010, all reports are consolidated within the Reports Manager. The Reports Manager is displayed on the Toolbox tab of Toolspace.

## Understanding the Reports Manager

Use the Reports Manager to access all the report types that are available in AutoCAD Civil. You can add custom reports to the Reports Manager so even your custom reporting can be done through the same interface.

Reports in AutoCAD Civil are of two types: LandXML and .NET. Depending on the type of report, different dialog boxes are displayed after you select the report to run.

The LandXML reports use LandXML data output for report generation, and use predefined or custom XSL style sheets to format the report data.

The .NET reports use custom dialog boxes for selecting the data and options for the report.

The LandXML Reporting tool is included with AutoCAD Civil as a program that you can run independently of AutoCAD Civil. To use this tool, you export a LandXML file and then open it within LandXML Reporting. Access LandXML Reporting from the desktop icon or by selecting it from the AutoCAD Civil 2010 Program Group from the Start ➤ Programs menu. For more information about exporting LandXML data, see LandXML Import and Export (page 1673).

## Specifying Report Settings

Use the Edit Report Settings dialog box to specify report settings. These settings are used for all reports.

**To specify report settings**

1 Click View tab ➤ Palettes panel ➤ 🧰 Toolbox.

2 On the Toolbox tab, click 🧰 .

3 In the Edit Report Settings (page 2212) dialog box, expand the tree view and edit the values in the Value column.

4 Click OK.

Edit Report Settings (page 2212)

# Generating a Report

Generate reports by double-clicking a report in the Reports Manager.

**To generate a report**

1 Click View tab ➤ Palettes panel ➤  Toolbox.

2 Expand Reports Manager ➤ <Report Type> to see the available reports.

3 Double-click a report, or right-click a report and click Execute.

4 Do one of the following:

■ **LandXML Reports**: In the Export To LandXML (page 1983) dialog box, select the data to include in the report and click OK.

> **NOTE** If you are running a points report, for example, only the points that are selected are used in the report. You can clear the selection of other objects, but that is not necessary. All objects other than points are filtered out.

"LandXML export complete" and "Generating XSLT Report..." are displayed at the command line. The report is then displayed in the default Internet browser window.

> **NOTE** LandXML reports are not saved automatically. To save a LandXML report, see Saving Report Files (page 1575).

■ **.NET Reports**: Select the data to include and specify the location to save the report. For more information on the specific dialog boxes, see Reports Dialog Boxes (page 2211). Click Create Report. The report is then displayed in the default Internet browser window and saved to the specified location.

# Saving Report Files

You can save your report for future use.

**NOTE** .NET reports are saved automatically to the specified location in the report dialog box.

**To save report files**

1  In the Internet browser window, click File menu ➤ Save As.

2  Change the folder to an appropriate location, or use the default, which is the last folder used.

3  Enter the file name and specify the file type for the report.

4  Click Save.

**NOTE** If you do not want to save the entire report, select the area of the report you want to save, copy it and paste the data into Microsoft Word, Microsoft Excel, or another editor. If you save your files as comma or space delimited files you can successfully import them into Microsoft Excel spreadsheets.

# Editing Toolbox Content

The Reports Manager is displayed on the Toolbox tab of Toolspace. You can add custom reports to the Reports Manager, or other custom tools to the Toolbox.

**To edit Toolbox content**

1  Click View tab ➤ Palettes panel ➤ 🧰 Toolbox.

2  On the Toolbox tab, click 📝 .

3  To edit the Reports Manager items, in the Toolbox Editor vista (page 2211), expand the Reports Manager item.

4  Do one of the following:

■  To add a new collection for reports, right-click the Reports Manager item and click New Category. You can specify a name and description for the category by selecting the new category and editing the values displayed in the right pane.

■ To add a new report, right-click a collection and click New Tool.
A new tool is inserted into the category with a default name. Expand the collection and click the New Tool item to select it. Specify the properties for the new tool by editing the values in the right pane.

# Object Rendering

# 36

You can create realistic rendering of AutoCAD Civil objects using render materials.

A render material corresponds to a specific material in a civil model, such as asphalt, concrete, or gravel. It consists of a pointer to a material and settings that control the material properties when it is rendered.

You can apply render materials to several objects, including surfaces and surface masks, corridor surfaces and corridor surface boundaries, pipes and structures, and interferences.

For more information about render materials, including how to create custom render materials, modify render materials, add render materials to the drawing, and apply render materials to objects, see *Materials and textures* in the AutoCAD User's Guide.

## Creating Render Materials

Create render materials for enhancing the rendered views of surfaces, corridor models, pipes, structures, and interferences.

You use a render material to add a realistic look to an object in AutoCAD Civil. The material you select for visualization must exist in the current drawing.

After you create a render material, you can save it to a drawing template or copy it to other drawings.

If, at rendering time, the material specified as the render material cannot be found in the drawing, the AutoCAD GLOBAL material is used.

**To create a render material**

- To open the Materials window, click View menu ➤ Render ➤ Materials.

For instructions about how to create a render material, see *Create Materials* in the AutoCAD User's Guide.

### Quick Reference

  View menu ➤ Render ➤ Materials

Command Line

  MATERIALS

# Adding Materials to Drawings

To use a material in a rendering, the material must exist in the current drawing.

A Material Library is installed with AutoCAD Civil by default. You can open the Tools Palette and either drag a render material into a drawing or insert the material by using the Add to Current Drawing command.

**To add materials to the current drawing**

1   Click Home tab ➤ Palettes panel ➤ Tool Palettes Window.

2   In the Tool Palettes window, right-click the Tool Palettes Window button, and choose Civil Materials from the list.

---

**NOTE** In addition to civil-specific render materials, you can access and use all the render materials contained in the AutoCAD Materials Library palette. Choose one of the Materials Library palettes from the Tools Palettes Window shortcut menu.

---

3   In the Civil Materials palette, do one of the following:
   ■   Right-click the swatch representing the chosen render material and select Add to Current Drawing.

   ■   Drag and drop a render material swatch into the drawing.

   The selected render material is added to the drawing. For more information, see "Materials Dashboard and Tools Palettes" in AutoCAD Help.

# Applying Render Materials to Objects

You can apply a render material to AutoCAD Civil objects.

You can specify a default render material to use for surfaces in the Surface Feature Settings (page 2329). After you create a surface or a surface mask, you can assign a different render material by changing the surface properties or surface mask properties.

Define the render material for corridor surfaces on the Surfaces tab (page 1818) of the Corridor Properties dialog box.

Specify the style for corridor boundaries on the Boundaries tab (page 1820).

Specify the styles for pipe network parts by using the Render Material option on the Pipe Properties Information tab (page 2039) or the Structure Properties Information tab (page 2052). Specify the styles for interferences by using the Interference Properties Information tab. (page 2073).

---

**TIP** Use corridor boundaries to apply different render materials to one corridor surface. For more information, see Rendering Corridor Models (page 1374).

---

**To apply a render material to an object**

**1** Click Home tab ➤ Palettes panel ➤ Tool Palettes Window.

**2** In the Tool Palettes window, click the Properties button, and choose Civil Materials from the list.

---

**NOTE** In addition to civil-specific render materials, you can access and use all the render materials contained in the AutoCAD Materials Library palette. Choose Materials Library from the Propertied menu.

---

**3** Do one of the following:

■ Right-click on the swatch representing the chosen material and select Apply Material to Objects.

■ Drag and drop a render material swatch onto the object in the drawing.

The selected render material is added to the drawing. For more information, see *Materials Tool Palettes* in the AutoCAD Help.

# Transparent Commands

# 37

Use AutoCAD Civil transparent commands to enter a value based on known information when you are prompted for a point, a distance, or a radius.

Most AutoCAD Civil transparent commands are used to specify point locations within a larger operation, such as the creation of an alignment or a parcel lot line. Using these transparent commands, you can calculate the location for a point from information, such as angle and distance, or from point object information, such as a point number.

**NOTE** For more information about AutoCAD transparent commands see AutoCAD Help.

Some of the AutoCAD Civil transparent commands require a Z coordinate for the point elevation. For more information, see Transparent Command Settings (page 1581).

## Transparent Command Settings

Use Transparent Command settings to control how you are prompted when you use a Civil transparent command.

The Transparent Command settings are specified on the Ambient Settings tab in the Edit Drawing Settings dialog box. In addition to the specific Transparent Command settings, many of the transparent commands are affected by other settings on the Ambient Settings tab.

**NOTE** Angle, Direction, and Lat Lon ambient settings are set to a single unit type (degree, grad or radian) and format (digital or various degree/minute/second formats for degrees). You will have to change these settings, if you wish to use a different unit/format for angles, bearings or latitudes/longitudes.

You can use the Transparent Command settings to control the following prompts for transparent commands:

■ Whether you are prompted for 3D points

■ The prompt order for X/Y

■ The prompt order for northing/easting

■ The prompt order for latitude/longitude

The Transparent Command settings are drawing ambient settings that can be overridden at either the object (feature) level or at the individual command level. For more information, see Ambient settings (page 68).

# Activating a Transparent Command

You can activate transparent commands by entering a command or by using a toolbar.

■ Enter the name of the transparent command at the command line. A transparent command always begins with an apostrophe (').

■ Select the command from the toolbar. To display the toolbar for accessing transparent commands, right-click any toolbar and select Transparent Commands.

# Using Transparent Commands Within a Running Command

You can use transparent commands within a main command that requires the entry of multiple point locations.

When you enter a transparent command within a running command that accepts more than one point location (for example, the AutoCAD LINE command), you can enter a series of points in the same format without having to re-enter the transparent command. At any time, you can press Esc to terminate the transparent command and return control to the main command, where you can switch to another transparent command. Also, you can end the transparent command by terminating the main command.

### Using Previously Entered Points in a Running Command for Relative Data Input

When you use a transparent command that requires baseline data from which to calculate a relative location, you must enter the required data before specifying the command parameters. If you use a transparent command within a running command, the transparent command remembers the last points entered during the running command and uses them to calculate new relative locations.

For example, when you use the Bearing Distance ('BD) transparent command, you must first identify a baseline point from which the bearing and distance are measured. If you initiate the Bearing Distance command before you enter any points, you are prompted for the baseline point before you are prompted for quadrant, bearing, and distance. If you use the Bearing Distance command after you have entered at least one point, the last point you entered is used as the baseline.

### Transparent Command Point Filters

When you are working within a transparent command and you are prompted to specify a point location, you can use point filters to specify known point information by doing one of the following:

■ Entering a point number

■ Entering northing and easting

■ Selecting a point in a drawing

For more information, see Using Point Filters Within Transparent Commands (page 1599).

# Using Angle and Distance to Specify a Point Location

You can specify a point location using an angle and a distance from a reference line.

The last two entered points define the reference line, or you must define a line. From the reference line (1-2), specify an angle (3), and distance (4), to specify a point (5).

If you have already entered one point in the command, you are prompted to enter a second point to define the reference line.

A transparent command can only be used within a running command. The reference line is updated each time you enter a point.

**To specify a point location using angle and distance**

1   When you are prompted to enter a point within a command, do one of the following:
    ■   Enter '**ad**.

    ■   Activate the Transparent Commands toolbar and select  .

2   If you have not yet entered any points in the main command, you must specify a temporary reference line by doing one of the following:
    ■   Select a line.

    ■   Enter **p**, then specify a start point and endpoint for the line.

3   If you have entered one point in the main command, that point is used as the starting point for the temporary reference line. Specify the ending point for the temporary reference line.

4   Specify the angle by doing one of the following:
    ■   Click in the drawing to specify the angle.

    ■   Enter a positive or negative numeric value for the angle.

    ■   Enter **c** to switch the angle between counterclockwise and clockwise, and then specify the angle.

5   Specify the distance by either clicking in the drawing or entering a distance.

6   If you are prompted, enter an elevation. For more information, see Entering an Elevation for a Transparent Command (page 1599).

---

**NOTE** Elevation prompting for transparent commands is controlled by the Transparent Command setting Prompt For 3D Points. For more information, see Transparent Command Settings (page 1581).

# Using Deflection and Distance to Specify a Point Location

You can specify a point location using a deflection angle and a distance from a reference line.

The deflection angle is measured from the reference line's extension beyond the endpoint, and the distance is measured from the line's endpoint

The extension of the last two entered points defines the reference line, or you must define a line. From the reference line (1-2) and start point (2), specify a deflection angle (3), and distance (4) to specify a point (5).

A transparent command can only be used within a running command. The reference line is updated each time you enter a point.

**To specify a point location using deflection and distance**

1 When you are prompted to enter a point within a command, do one of the following:
   ■ Enter '**dd**.

   ■ Activate the Transparent Commands toolbar and select ◹ .

2 If you have not yet entered any points in the main command, you must specify a temporary reference line by doing one of the following:
   ■ Select a line.

   ■ Enter **p**, then specify a start point and endpoint for the line.

3 If you have entered one point in the main command, that point is used as the starting point for the temporary reference line. Specify the ending point for the temporary reference line.

4 Specify the angle by doing one of the following:
   ■ Click in the drawing.

   ■ Enter a positive or negative numeric value for the angle.

   ■ Enter **c** to switch the angle between counterclockwise and clockwise, and then specify the angle.

5 Specify the distance by either clicking in the drawing or entering a distance.

6 If you are prompted, enter an elevation. For more information, see Entering an Elevation for a Transparent Command (page 1599).

**NOTE** Elevation prompting for transparent commands is controlled by the Transparent Command setting Prompt For 3D Points. For more information, see Transparent Command Settings (page 1581).

Command Line

ʻZD

Toolbar

Transparent Commands toolbar ➤

# Using Side Shots to Specify a Point Location

You can specify a point location using an angle (bearing, azimuth, angle, or deflection) and a distance from a reference point.

Before you can specify an angle and distance within the Side Shot command, you must define a temporary reference line from which all the subsequent points are calculated.

The last two entered points define the reference line, which is reused if you take multiple shots within the command. Specify an angle and distance to the next point. From the reference line (1-2) and start point (2), specify points (3, 4, 5) by side shot.

To define a line, you can either select an existing line in the drawing or enter two points. If you have already entered one point in the command, you are prompted to enter a second point to define the reference line.

A transparent command can only be used within a running command. In this command, the reference line is not updated; it remains the same for all points entered.

**To specify side shot point locations**

1 When you are prompted to enter a point in a command, do one of the following:

■ Enter ʼ**ss**.

■ Activate the Transparent Commands toolbar and select .

2 If you have not yet entered any points in the main command, you must specify a temporary reference line by doing one of the following:

■ Select a line.

■ Enter **p**, then specify a start point and endpoint for the line.

3 If you have entered one point in the main command, that point is used as the starting point for the temporary reference line. Specify the ending point for the temporary reference line.

**4** Enter an angle by doing one of the following:

- Enter an angle in angular units for the drawing.

- Enter **b**, then specify the angle by specifying a quadrant and a bearing.

- Enter **d**, then specify a deflection angle.

- Enter **z**, then specify an azimuth.

- Enter **c** to switch the direction of the angle between clockwise and counterclockwise.

**5** Specify a distance by either clicking in the drawing or entering a distance.

**6** If you are prompted, enter an elevation. For more information, see Entering an Elevation for a Transparent Command (page 1599).

---

**NOTE** Elevation prompting for transparent commands is controlled by the Transparent Command setting Prompt For 3D Points. For more information, see Transparent Command Settings (page 1581).

---

**7** If you are working within a running command, do one of the following:

- To enter another side shot using the same angle type, enter the angle and repeat Steps 5 and 6.

- Press Esc to end the Side Shot transparent command.

Additional side shot locations are calculated using the reference line established at the start of the transparent command.

■ Enter '**sse**.

■ Activate the transparent command toolbar and select  .

**2** In plan view, select the parent alignment of the profile view.

**3** Select the surface from which you want to derive elevation data.

**4** Select a point on the surface.

**5** Select the profile view again.

**6** Do one of the following:

■ Select additional locations on the surface to create additional points with the corresponding alignment station and elevation values.

■ Press Esc to end the transparent command.

# Using an Alignment and COGO Point to Specify a Point Location

You can specify the X and Y coordinates for a point by identifying an alignment and COGO point.

COGO points can be used to define a layout profile include points along an alignment, survey points, or corridor points.

Define profile layout entities by specifying a station and elevation based on plan view objects. Examples of COGO points that may be used to define a layout profile are points along the parent alignment or other alignment, survey points, or points derived from a corridor.

A transparent command can only be used within a running command.

**To specify a point location in a profile view using an alignment and a COGO point**

1  When you are prompted to enter a point in a command, do one of the following:
   - Enter '**spe**.

   - Activate the transparent command toolbar and select  .

2  In plan view, select an alignment.

3  Select a COGO point.

4  Select the profile view again.

5  Do one of the following:
   - Select additional points in plan view to create additional points with the corresponding alignment station and elevation values.

   - Press Esc to end the transparent command.

# Entering an Elevation for a Transparent Command

After you use a transparent command to establish the X and Y coordinates of a point location, you can specify the Z coordinate.

Specify an elevation using any of the following methods:

■ Accept the default elevation

■ Enter an elevation value

■ Specify a grade

■ Specify a slope

■ Take the elevation from the current surface

The default elevation, displayed at the prompt, is determined by the transparent command in use. If the current transparent command is 'PN (point number), 'PO (point object), or 'PA (point name), the default elevation is taken from the specified point. In all other cases, the default elevation is the AutoCAD default elevation.

A transparent command can only be used within a running command.

**NOTE** Elevation prompting for transparent commands is controlled by the Transparent Command setting Prompt For 3D Points. For more information, see Transparent Command Settings (page 1581).

**To enter an elevation for a transparent command**

1 Run a transparent command until you are prompted to enter an elevation.

2 Do one of the following:

■ To accept the default elevation that is displayed on the command line, press Enter.

■ Enter **g**. The elevation is calculated using the entered grade and a previously entered point.

■ Enter **s**. The elevation is calculated using the entered slope and a previously entered point.

■ Enter **y**. The elevation is taken from the X, Y location on the current surface.

■ Enter **t**. If there is more than one surface in the drawing, you are prompted to select the surface from which the elevation is read.

**NOTE** During a running command, the default prompts for elevation change, depending on how the previous elevation was entered. Enter **e** to reset the prompts back to the defaults described above.

# Using Point Filters Within Transparent Commands

Use Civil point filters to enter known point information when you are prompted for a point location within a transparent command.

A point filter offers you three ways to specify a point location:

■ enter a point number

■ enter northing and easting values

■ select a point in the active drawing

To activate a point filter, do one of the following:

■ Enter the point filter on the command line. You must always begin a transparent command point filter with a period (.).

■ Select the point filter from the transparent command filter toolbar. If the toolbar is not displayed, right click any toolbar and select Transparent Command Filters.

The following table lists the point filters available within the Civil transparent commands.

| To specify a location using this information... | Enter this point filter... | Or click this icon on the Transparent Command Filter Toolbar... |
| --- | --- | --- |
| point number | .p |  |
| a point in a drawing | .g |  |
| known northing and easting | .n |  |

A point filter is active only while you enter a single point location. Control then returns to the main transparent command.

Point filters are available for use only when you are prompted for a point location during the following transparent commands:

■ Angle Distance ('AD)

■ Bearing Distance ('BD)

■ Deflection Distance ('DD)

■ Azimuth Distance ('ZD)

■ Station Offset ('SO)

■ Side Shot ('SS)

When you are working with the .p (point number) point filter, the system searches for the point first within the active drawing, then within the project, if the drawing is attached to a project.

**To use a point filter within a transparent command**

1 When you are prompted for a coordinate location from within a transparent command, do one of the following:

■ To specify a point using a point number, enter **.p** and enter the point number.

■ To specify the coordinates from a point object in a drawing, enter **.g** and select the point.

■ To enter a known northing and easting, enter **.n** and enter the northing and easting values.

2 Continue with the transparent command.

# Transparent Command Reference

| an object's radius (page 1598) | 'MR | |

# Utilities

# 38

You can use the AutoCAD Civil Utilities to perform operations not related to a specific object or command.

## Coordinate Geometry (COGO)

Use coordinate geometry to enter accurate geometry when creating objects and find out accurate geometry for existing objects.

## Overview of Coordinate Geometry

Use coordinate geometry commands to input and extract locations in coordinate geometry.

Use the transparent commands to create objects using accurate geometry. For example, you can create parcel boundaries from legal documents or survey data. The COGO input commands expand the normal object creation commands by letting you use coordinate geometry to specify the points for the object.

Use the inquiry commands to get accurate geometric information about objects in your drawing. For example, you can determine the coordinates of a manhole or the centerline of a new road.

## Using Coordinate Geometry to Specify Points

Use the transparent input commands to create objects using accurate geometry. For example, you can create parcel boundaries from legal documents or survey data. For more information, see Transparent Commands (page 1581).

## Measuring Coordinate Geometry

Use the COGO inquiry commands to extract geometric information from objects such as lines, curves, closed polylines, and polygons. This information is useful if you want to verify the accuracy of your data.

**NOTE** The COGO inquiry commands use the World Coordinate System (WCS) and ignore current User Coordinate System (UCS) settings. Therefore, north is always considered to point along the WCS positive Y axis, and inquiry results are reported in WCS coordinates.

## Adding Distances

You can calculate the total of several disjunct distances on your drawing.

Specify the distance by selecting points in your drawing, enter distances on the command line, or select numeric text, such as measurements, in your drawing.

Select all the distances you want to add. When you press Enter, AutoCAD Civil displays the total of all the distances.

**To add distances**

1   Click Analyze tab ➤ Inquiry panel ➤ Add Distances $\Sigma_{\blacksquare}$ .

2   Specify the first distance by doing one of the following:

   ■   Enter the distance on the command line.

   ■   Select two locations in the drawing.

   ■   Enter s. Select numeric text in the drawing, such as a measurement.

3   Enter as many additional distances as you want.

4   When you finish selecting distances, press Enter to view the total of the distances.

## Displaying Continuous Distance

You can add and display the distance between one point and a number of other points, or between a series of points.

The Base option measures the distance from the starting point to each of the points you select.

The Continuous option measures the distance from the starting point to the next point in a continuous line.

**TIP**   To add distances that are not continuous, see Adding Distances (page 1604).

**To display the distance between points**

1   Click Analyze tab ➤ Inquiry panel ➤ Continuous Distance ⇔ .

2   Select Base or Continuous.

   ■   Base: Always measures the distance from the first point you select to each of the additional points you select.

   ■   Continuous: Measures the distance from one point to the next.

3   Select two points to display the distance between the points.

4   Select another point. If you selected Base, AutoCAD Civil displays the distance from first (or base) point to the new point. If you selected Continuous, AutoCAD Civil displays the distance from the last point to the new point.

5   When you finish selecting points, press Enter to view the total of the distances.

### Quick Reference

## Displaying Angle Information

You can display the acute and obtuse angle between points or intersecting lines.

This command uses the Angle settings as specified on the Ambient tab (page 68) in the Drawing Settings dialog box.

**To display angle information**

1 Click Analyze tab ➤ Inquiry panel ➤ Angle Information ◹⃰ .

2 Select two lines, or enter p to specify points.

3 If you entered p, specify a starting point, a vertex, and an ending point.

### Quick Reference

## Displaying COGO Information for Lines and Arcs

You can display coordinate geometry for lines and arcs. This information includes line and curve details, area, and coordinates.

This command uses the Angle, Distance, and Direction settings as specified on the Ambient tab (page 68) in the Drawing Settings dialog box.

**To display COGO information**

1 Click Analyze tab ➤ Inquiry panel ➤ Line And Arc Information ⌐ .

2 Select the line or arc, or enter p to specify the points for a line.

3 If you entered p, specify a starting point and an ending point for the line.

### Quick Reference

## Listing the Slope or Grade between Points

You can display the slope, grade, and horizontal distance between two points.

This command uses the Elevation, Distance, and Grade/Slope settings as specified on the Ambient tab (page 68) in the Drawing Settings dialog box.

**To display the slope between two points**

1  Click Analyze tab ➤ Inquiry panel ➤ List Slope .

2  Select a line or an arc, or enter p to specify points.

3  If you entered p, specify a starting point and an ending point for the line.

### Quick Reference

# Mapcheck Analysis

Perform a Mapcheck Analysis by selecting AutoCAD Civil line and curve labels to determine values from label objects based on the precision of the annotation of the label object, or enter mapcheck data manually.

A mapcheck analysis is typically performed for each labeled polygon that represents a parcel, a labeled parcel object, or survey figure to ensure that errors and omissions are minimized. If error is introduced and accumulated, the coordinates of the last segment endpoint will not equal that of the point of beginning (POB) which creates the 'error of closure'.

The report is computed based on the start and end coordinates of each parcel segment, relative to the coordinates of the POB and the previous segment.

In the Survey Command Window you have the option to list mapcheck information that computes the error of closure for a figure based on the precision settings for direction and distance values which you specify in the  Survey Database settings (page 2378) For more information, see Listing Mapcheck Information for a Figure (page 356).

In the Parcel Properties you can specify Inverse Analysis and Mapcheck Analysis. For more information, see Exporting a Parcel Inverse or Mapcheck Report (page 830).

# Performing a Mapcheck Analysis

Use the Mapcheck Analysis command to perform a mapcheck that is based on the precision of the annotation of the label object.

The Mapcheck Analysis command computes mapcheck calculations directly from the selected labels. To perform a mapcheck you must specify a point of beginning (POB) for each parcel. For each segment within the parcel, you select a label containing a direction, direction and distance, distance label, or curve label until the requirements to compute the next vertex of the current segment are met.

As you perform a mapcheck, temporary graphics are displayed in the drawing to indicate the sides that have been entered for each parcel. The current side is displayed in bold indicating origin and direction for that side. The temporary graphics also provide a visual confirmation of possible errors, or indicate that the direction of a line or curve needs to be flipped or reversed.

**NOTE** The mapcheck report data is stored in the drawing database so you can continue a mapcheck from a previous AutoCAD Civil session. The Mapcheck Analysis window must be open to enable the display of the temporary graphics.

From the POB, the annotation for each side in the parcel is used to calculate the coordinates of the endpoint of the side. As you enter data for each parcel, the Output View in the Mapcheck Analysis window updates to indicate error of closure and area based on the previously entered sides. Entering the information for the last side closes to the POB. The Mapcheck Analysis output view contains the following information:

■ POB coordinates

■ A sequential list of each course, direction and distance, or curve data, and end point coordinates

■ An error of closure summary: Error of closure: 1 part in <X parts>

■ Error of closure direction: <bearing or azimuth>

■ Error of closure distance: <distance>

■ Perimeter distance: <total distance around the parcel>

■ Area: <area units (acres/hectares, and square feet/meters>

For each parcel or survey figure, the area annotation is compared to the mapcheck area. If the error of closure is acceptable, for example a closure that exceeds one part in 10,000 parts and the area annotation matches, the annotations are considered to be mathematically correct.

📖 Tutorial Exercise: Performing a Map Check Analysis with Parcel Labels

**To perform mapcheck analysis from AutoCAD Civil label objects**

1  Click Analyze tab ➤ Ground Data panel ➤ Survey drop-down ➤ Mapcheck 🗹 .

2  In the Mapcheck Analysis window, click 📄 New Mapcheck Report.

3  Enter a name for the Mapcheck, for example LOT 1.

4  Click 🖥 to Use Command Line Interface and follow the prompts at the command line.

5  Specify a Point of Beginning. The interactive graphics display the POB in the drawing.

---
**NOTE** Colors displayed in the temporary graphics are controlled by the Mapcheck command settings. For more information, see Mapcheck Command Default Settings (page 1615).

---

The following illustration shows the Point of Beginning:

6  At the command line you are prompted to select a label. After selecting a label, the interactive graphics display in the drawing. If you need to make a change, at the command line you have options to do the following:

- Clear: Clears the current side.

- New: Starts a new mapcheck report.

- Flip: Changes the direction of the curve to either clockwise or counter-clockwise.

- Reverse: Changes the direction of the line or curve.

---
**NOTE**  If the mapcheck requires more information to make the calculation, a red circle displays in the drawing and you are prompted at the command line.

---

The following illustration shows how the Reverse command can be used to change the direction of the mapcheck line:

The following illustration shows an example of using the Flip command:

**7** Continue to follow the command line prompts by selecting labels until you return to the Point of Beginning.

The following illustration shows the continuation of the mapcheck towards the POB:

**8** Click ![icon] New Mapcheck to add a new mapcheck to the existing Mapcheck Report. Repeat steps 5 through 7.

**9** Click ![icon] Output View to review the mapcheck analysis report. Click ![icon] to return to the input window.

**10** Optionally, in either the Input View or the Output View, click ![icon] Insert Mtext to insert either the current mapcheck or all mapchecks into the drawing. Specify an insertion point in the drawing and insert the Mapcheck Report.

## Manually Entering Mapcheck Data

Create a mapcheck report by manually entering data.

You can enter data from a paper drawing into the Mapcheck Analysis window to create a mapcheck report. For each mapcheck, you can create a polyline which can then be used to create AutoCAD Civil objects such as a survey figure.

![icon] Tutorial Exercise: Performing a Map Check Analysis by Manually Entering Data

**To create a mapcheck report by manually entering data**

---

**NOTE** To manually enter mapcheck data, ensure that the 🖳 Use Command Line Interface is toggled off.

---

**1** Click Analyze tab ➤ Ground Data panel ➤ Survey drop-down ➤ Mapcheck ✅.

**2** In the Mapcheck Analysis window, click 🗋 New Mapcheck Report.

**3** Enter a name for the Mapcheck, for example LOT 1.

**4** Enter the Easting and Northing values for the Point of Beginning or click ⬛ and select a point in the drawing.

**5** Click ⬛ to create a New Side. Specify the values for the side.

For a line side, enter the following:

■ Side Type: Select Line from the drop-down list.

■ Angle Type: Select Direction, Angle, or Deflection Angle from the drop-down list.

■ Angle: Enter the angle value.

■ Reverse Direction: Specify Yes or No.

■ Distance: Enter the distance value.

For a curve side, enter the following:

■ Side Type: Select Curve from the drop-down list.

■ Curve Direction: Select Clockwise or Counter-clockwise from the drop-down list.

■ Traverse Method: Select Across Chord or Through Radius from the drop-down list.

> **NOTE** This option is used to specify how the error of closure is calculated and displayed in the Output View. If you select Across Chord, the endpoint of the curve is calculated from the Chord direction and distance. If you select Through Radius, the endpoint of the curve is calculated based on the direction to the radius point, the radius length, the delta angle, and the direction from the radius point to the point of tangency. If this option is selected, additional information is displayed in the Output View.

■ Radius: Specify the radius value.

■ Arc Length: Specify the arc length.

■ Delta Angle: Specify the delta angle.

■ Tangent: Specify a tangent.

■ Angle Type: Select Direction, Angle, or Deflection Angle from the drop-down list.

■ Chord Angle: Specify a chord angle.

■ Reverse Direction: Specify Yes or No.

■ Chord Distance: Specify the chord distance.

**6** Click ⬅ Insert Side Before, or ➡ Insert Side After, if you have omitted a side before or after the current selected side in the mapcheck. Specify values as shown in the previous step.

**7** Click ✅ New Mapcheck to add a new mapcheck to the mapcheck report. Repeat steps 3 through 6.

**8** When you have completed entering data, click  Output View to view the mapcheck analysis. Click  Input View to return to the input window.

**NOTE** You can switch between input and output views at any time.

**9** Optionally, click  Create Polyline to create a polyline for the current mapcheck. The polylines can be converted to AutoCAD Civil objects.

**NOTE** If there is no current mapcheck then a polyline for all mapchecks are inserted into the drawing. Press ESC to clear a selection in tree view.

**10** Optionally, click  Copy To Clipboard to copy the contents of the input view or output view to the Windows Clipboard of the current mapcheck.

**NOTE** If there is no current mapcheck then all mapchecks are copied to the clipboard. Press ESC to clear a selection in tree view.

**11** Optionally, in either the Input View or the Output View, click  Insert Mtext. Specify an insertion point in the drawing and insert the mapcheck analysis report.

# Using the Object Viewer

The Object Viewer displays objects you select in your drawing, based on the current view that is set in the drawing.

Civil objects are displayed in the Object Viewer using the Plan or Model settings specified in their styles. For example, in a 3D view, objects are displayed using their Model settings.

You can manipulate the viewing angle and then set the drawing view equal to the view in the Object Viewer by clicking ⊕ .

The Object Viewer contains the ViewCube and the SteeringWheel. For more information, see Use ViewCube and Navigation Wheels in the AutoCAD Help.

**To display objects from your drawing in the Object Viewer**

**1** Click View tab ➤ Palettes panel ➤ Object Viewer 🔍 .

**2** Select the objects you want to view.

**3** Press Enter.

The Object Viewer is displayed.

**4** From the View Control list at the upper right of the Object Viewer, select any of the following.

- **Top, Bottom, Left, Right, Front, or Back:** Sets the current view to the selected view.

- **SW Isometric, SE Isometric, NE Isometric, or NW Isometric:** Sets the current view to the selected isometric view.

**5** From the Visual Style list, select one of the following object appearance styles.

- **3D Hidden** To display objects in the current view in a 3D wireframe representation with all visible lines displayed as continuous and all hidden lines displayed as dashed.

- **3D Wireframe** To display objects in the current view in a 3D wireframe representation with all lines displayed, including those objects hidden by other objects.

- **Conceptual** To display objects in a transparently shaded 3D view with all lines visible.

- **Realistic** To display objects in a shaded 3D view.

**6** Choose from the following zoom options from the Object Viewer to increase or decrease the apparent size of objects in the current viewport:

**7** Click  to set the view in the drawing to match the current view in the Object Viewer.

> **NOTE** AutoCAD Civil supports only the Standard Display Configuration.

# Performing Inquiries on AutoCAD Civil Objects

Use the Inquiry Tool to run inquiries on AutoCAD Civil objects. You can extract information from the design model to aid in design, validation, and analysis. See Inquiry Types (page 1620) for a list of available inquiries.

The Inquiry Tool is in a window you can keep open on screen while you do other work. Like the Toolspace, you can dock the window or turn on the AutoHide feature so it displays only when you move your mouse over it to save desktop space.

The Inquiry Tool consolidates and replaces some of the listing and inquiry commands that were in previous releases of AutoCAD Civil.

For more information, see Inquiry Tool Dialog Box (page 2462).

# Performing an Inquiry

Use the Inquiry Tool to run a selected inquiry on drawing objects.

Choose an inquiry type and follow prompts to select the data. After the inquiry completes, you can copy the data to another file such as a Microsoft© Excel spreadsheet.

There are two ways to select the data for an inquiry. When you first select the inquiry to run, you are prompted to select the data required for the inquiry. If there is only one object of that type in the drawing, it is selected automatically. After the inquiry is complete, you can use the object select buttons. Click  or  in the Inquiry Tool window to change the selection of data.

You can also run an inquiry by selecting an object in the drawing and accessing the Inquiry command from the shortcut menu. In this case you are not prompted for the main object, but you are prompted for any additional object input the inquiry requires.

**To perform an inquiry**

1   Click Analyze tab ➤ Inquiry panel ➤ Inquiry Tool  .

2   In the Inquiry Tool window, under Select An Inquiry Type, click the Down arrow and select the inquiry to run.

   After you select an inquiry type, you are prompted to select the objects that are required for the inquiry.

   ---
   **NOTE** To run Corridor queries, a corridor section view must be active. Select a corridor. Click Corridor tab ➤ Modify panel ➤ Corridor Section Editor  . Then select the station to query. Use the Zoom command to zoom closer to the view.
   ---

3   Select the objects and locations for the inquiry. You can use Osnaps and transparent commands to select the objects.

   The data is displayed in the Inquiry Tool window.

4   To change selected objects or locations, click  or  in the Inquiry Tool window next to a value and select the new object or location in the drawing.

# Copying Inquiry Data

After you run an inquiry, you can copy the data to the clipboard, or you can send the inquiry data to the AutoCAD text window and copy the data from there.

The option to copy the inquiry to the AutoCAD text window continually sends the data to the text window as the inquiry proceeds.

**To copy inquiry data to the clipboard**

➤   Right-click in the Inquiry Tool results area and click Copy To Clipboard. Or click 📋 .

**To copy an individual value to the clipboard**

1   Right-click the value in the Inquiry Tool.

2   Click Copy Value To Clipboard.

**To send a running copy of inquiry data to the AutoCAD text window**

1   Click 📋 Copy To Text Screen.

As you run the inquiry, the data is sent to the text window.

2   Press F2 to expand the text window and view the data.

# The Coordinate Tracker

You can use the Coordinate Tracker to view and capture X, Y, and Z drawing coordinates.

The Coordinate Tracker displays the X and Y coordinates of the cursor in the drawing. If the cursor is within the boundary of a specified surface, the surface elevation at the location of the cursor is displayed as the Z coordinate.

You can send the coordinate information to the command line for use in the active command, or you can copy the information for use in another application.

Because the Coordinate Tracker is an AutoCAD palette, you can use Auto-hide to minimize the display space it requires. You can also dock, move, and resize it. For more information about Auto-hide and AutoCAD palettes, see Working with AutoCAD Civil Windows (page 78).

# Viewing Cursor Coordinates Using the Coordinate Tracker

Use the Coordinate Tracker to view the drawing X and Y coordinates of the cursor and a Z coordinate value read from a specified surface.

**To view cursor coordinates using the Coordinate Tracker**

1 Click View tab ➤ Palettes panel ➤ Coordinate Tracker $\overset{\text{XYZ}}{\text{Q}}$ .

2 In the Coordinate Tracker (page 2462), in the Surface list, select the surface from which Z values (elevations) are read.

 If the drawing contains only one surface, it is automatically selected.

3 Move the cursor within the boundary of the selected surface.

 The drawing X and Y coordinates are updated from the cursor position within the drawing. The Z coordinate value is read from the specified surface when the cursor is within the surface boundary. If you move the cursor outside of the surface boundary, the Z value is not shown.

4 To suspend cursor tracking and capture the current X, Y, and Z coordinate values, do the following:

 ■ Enter the keys listed in the Coordinate Capture Keys edit box by pressing, and not releasing, each key in the specified order until you are holding all the specified keys down.

■ Release all keys.

Coordinate tracking is suspended and the current X, Y, and Z coordinates are captured.

5 Optionally, send the X, Y, and Z coordinates to the command line for use in the current command. You can edit the values before you send them. For more information, see Sending Coordinate Tracker Values to the Current Command (page 1624).

6 To resume cursor tracking, click ⇨ .

7 To hide the Coordinate Tracker, click ✕ .

Dialog Box

Coordinate Tracker (page 2462)

## Sending Coordinate Tracker Values to the Current Command

Use the Coordinate Tracker to capture and send drawing X, Y, and Z coordinate values to the current command.

You can send any of the following:

■ X and Y values only

■ Z (elevation) value only

■ X, Y, and Z values

Send the value required by the current command. If the current command requires a 3D (X, Y, and Z) value, an error occurs if you send a 2D (X and Y only) value.

Send a value by first moving the cursor to the desired location and entering the coordinate capture keys. This suspends tracking and captures the X, Y, and Z values. You can edit one or more of the values before you send them.

You send the values to the command line using the buttons directly beneath the X, Y, and Z values. The buttons are shown in the following illustration:

**TIP** Move the cursor over each button to view a tooltip that tells you what value the button sends to the command line.

**To send Coordinate Tracker values to the current command**

**1** Display the Coordinate Tracker. Select a surface if required. For more information, see Viewing Cursor Coordinates Using the Coordinate Tracker (page 1623).

**2** Run any command until you are prompted at the command line for a 2D point, a 3D point, or an elevation.

**3** Move the cursor until the Coordinate Tracker displays the desired coordinate and elevation values.

**4** To suspend cursor tracking and capture the current X, Y, and Z coordinate values, do the following:

- Enter the keys listed in the Coordinate Capture Keys edit box by pressing, and not releasing, each key in the specified order until you are holding all the specified keys down.

- Release all keys.

Coordinate tracking is suspended and the current X, Y, and Z coordinates are captured.

**5** Optionally, edit the coordinate information before sending it. In the Coordinate Tracker (page 2462), click in either the X:, Y:, or Z: edit box and enter a new value.

---

**TIP** Move the cursor over each button to view a tooltip that tells you what value the button sends to the command line.

---

**6** Do one of the following:

- To send the X and Y values, click [_____] .

- To send the Z value only, click [_____] .

- To send X, Y, and Z values, click [_____] .

**7** After you send a value, cursor tracking is automatically resumed. To resume cursor tracking without sending a value, click ⇨ .

Coordinate Tracker (page 2462)

# Changing the Coordinate Tracker Coordinate Capture Keys

Change the capture key sequence that suspends coordinate tracking and captures the current X, Y, and Z values.

The *coordinate capture keys* are the keys you press to capture the current X, Y, and Z drawing coordinates. Then you can either send the values to the command line or copy them for use in another application. For more information, see Sending Coordinate Tracker Values to the Current Command (page 1624).

The capture key sequence always consists of any combination of Ctrl, followed by Alt and/or Shift, followed by a single character key. The following are examples of valid capture key combinations:

- *Ctrl+Shift+Z*
- *Ctrl+Alt+Z*
- *Ctrl+Shift+Alt+Z*

The default coordinate capture key sequence is *Ctrl+Shift+Z*.

You change the coordinate capture keys by clicking ⌨ and entering the new key sequence.

**To change the Coordinate Tracker coordinate capture keys**

1 Click View tab ➤ Palettes panel ➤ Coordinate Tracker.

2 In the Coordinate Tracker (page 2462), click ⌨ .

3 Press and hold down Ctrl.

4 While holding down Ctrl, press and hold down Alt and/or Shift.

5 While holding down the other keys, press and hold down a single character key.

6 Release all keys.

The Coordinate Capture Keys edit box displays the sequence of keys that you entered. If the Coordinate Capture Keys edit box is not updated, the sequence of keys that you entered is not valid. This can occur if the sequence does not begin with Ctrl followed by either Shift or Alt, or if the sequence is reserved for another function on your computer.

# The Event Viewer Vista

You can use the AutoCAD Civil Event Viewer to view event messages that are logged during an AutoCAD Civil drawing session.

The display of the Event Viewer can be controlled by changing the Show Event Viewer setting in the drawing's Ambient Settings (page 1856).

The Event Viewer is a Panorama vista. Each drawing can have a different Event Viewer session associated with it. When you change the active drawing, the Event Viewer session changes. If you do not activate the Event Viewer for a drawing, the Event Viewer is not displayed when that drawing becomes active. For information about Panorama vistas, see The Panorama Window (page 102).

The Event Viewer displays the *event tree* in the left pane and the *event list* in the right pane.

You use the event tree to control the events that are listed in the event list. For example, if you click the top collection in the tree, Event Viewer, all events are listed in the event list. If you expand the event tree and click either the Event Subsystem collection or Surfaces collection, only the events that were logged by either the Event Subsystem (which is the Event Viewer) or the Surfaces feature are listed in the event list.

When you first open the Event Viewer, the event list is empty if no events have been logged to the Event Viewer. When an event is logged to the Event Viewer, the appropriate collection is created, and the event is added to the event list.

You can save the event list to a log file as a permanent record, and open a previously created log file to view it in the Event Viewer. You can also export an event list to a comma-delimited or tab-delimited text file.

# Customizing the Event Viewer

You can control the content and appearance of the Event Viewer, including the columns displayed in the event list and the events listed there.

## Controlling the Columns Displayed in the Event Viewer

Control the columns that are displayed in the event list and the order in which they are displayed.

Columns that you can add or remove include Date, Time, Source, User, and Description.

You cannot remove the Type column from the display.

**To control the columns displayed in the Event Viewer**

1 Click View tab ➤ Palettes panel ▼ Event Viewer ⟁ .

2 To change the location of a column in the event list, in the Event Viewer Vista (page 2455), click and drag the heading right or left.

3 To add columns or remove columns, do the following:
   ■ In the Event Viewer, on the View menu, click Choose Columns.

   ■ In the Choose Columns (page 2459) dialog box, specify columns to be added or removed.

### Quick Reference

Ribbon

View tab ➤ Palettes panel ▼ Event Viewer ⟁

View ➤ Choose Columns

Dialog Box

Choose Columns (page 2459)

## Controlling the Events Displayed in the Event Viewer

Control which events are displayed in the event list and the order in which they are displayed.

When you change the display of the event list by filtering, the events are hidden, but they are not deleted from the event list. However, when you use the Clear All Events command, the events are permanently deleted from the list.

For information about changing the columns that are displayed in the event list, see Controlling the Columns Displayed in the Event Viewer (page 1627).

For information about locating an event that matches specified criteria, see Finding a Specific Event in the Event Viewer (page 1630).

**To control the events displayed in the Event Viewer**

1  Click View tab ➤ Palettes panel ▼ Event Viewer ◁ᐞ .

2  In the Event Viewer (page 2455), do one of the following in the event tree:
   - Click the Event Viewer collection to display all the events in the event list.
   - Expand the Event Viewer collection and click a collection to display the events in that collection.

3  Click View menu ➤ Filter. Use the Filter Events (page 2457) dialog box to filter the event list to meet only specified criteria.

4  To display the event list by date, on the View menu, click one of the following:
   - Newest First: Displays the event list with the most recent event at the top.
   - Oldest First: Displays the event list with the least recent event at the top.

5  To sort the event list using a column heading, click the column heading.

6  Click Action menu ➤ Clear All Events to permanently remove all events from the event list.

Dialog Box

Filter Events (page 2457)

## Working With Log Files in the Event Viewer

Open and create log files that contain event lists.

You can save the current event list to a binary log file, and also open an existing log file to view it.

For information about saving an event list to a comma-delimited or tab-delimited text file, see Exporting an Event List to a Text File (page 1630).

## Creating a Log File in the Event Viewer

Use the Save Log File As command to create a log file from the event list.

When you create a log file, all the events in the current event viewer session at the time the file is created are written to the file. Events that have been logged during the session, but that are not displayed in the event list due to filtering, are also written to the file. For more information about using filters to limit the events displayed in the event list, see Controlling the Events Displayed in the Event Viewer (page 1628).

**To create a log file in the Event Viewer**

1 Click View tab ➤ Palettes panel ▼ Event Viewer ⬠ .

2 In the Event Viewer (page 2455), on the Action menu, click Save Log File As.

3 In the Save As dialog box, browse to the folder where you want the log file to be located, enter a file name, and click Save.

The current event list is saved to the log file.

### Quick Reference

# Multi-View Blocks

A multi-view block is an AutoCAD Civil object that can have different representations in different view directions. You create a multi-view block from AutoCAD blocks that represent the different views of the custom object that you are creating.

# Understanding Multi-View Blocks

A multi-view block can represent different types of objects in AutoCAD Civil, such as the following:

■ Plantings, such as trees and shrubs

■ Utilities, such as fire hydrants

■ Vehicles

■ Signage

Multi-view blocks can be displayed differently in each view direction and each display representation. For example, the top view of a multi-view block representing a traffic sign shows the top of the sign. The bottom view shows the bottom of the sign, and there are representations for left, right, front, and back views. Additionally, you can define a different group of displays for each display representation. You can have one set of views for plan view and another one for reflected view.

The top and profile view blocks representing a pine tree might look like:

# Predefined Multi-View Blocks

The content folders of AutoCAD Civil contain a large number of predefined multi-view blocks for a number of design purposes. These contain multi-view blocks of building footprints, landscape symbols, annotation symbols, site-related symbols, and other useful elements.

You can access these multi-view blocks from the AutoCAD Civil MV Blocks Tool Palette. You can also use DesignCenter™ to insert the blocks.

Predefined multi-view blocks are located by default in the *\\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\data\Symbols\Mvblocks* folder.

# Creating Multi-View Block Definitions

Each multi-view block in a drawing is based on a multi-view block definition. The multi-view block definition specifies the display representations in which the block can be viewed, and the views available in each representation. From a multi-view block definition, you can create as many actual multi-view block references as you need.

Multi-view blocks typically represent 3D Civil objects. For example, you can create a customized, multi-view fire hydrant representation by drawing plan, elevation, and model views, and save each view as an individual AutoCAD block. You assign each block to a view when you create the multi-view block definition. The blocks

(top, bottom, front, back, left, right, and model views) are used to define the custom object as a single multi-view block. By adding points to your views on the defpoints layer prior to defining the block, you can identify additional insertion points for the view block. You set the display representations and view directions when you define the multi-view block.

You can see the individual blocks of your custom object in plan, elevation, and isometric views as one assembly after inserting them in the drawing as a multi-view block. For more information about working with blocks, see the online *AutoCAD User's Guide*.

## Process Overview: Creating Multi-View Block Definitions

There are four general steps for creating a multi-view block:

1 Create a set of view blocks for each view direction in each display representation that you need.

2 Create a multi-view block definition where you assign the view blocks to view directions in individual display representations.

3 If you want the new multi-view block definition to be available in DesignCenter, add the definition to DesignCenter.

4 If you want the new multi-view block definition to be available from a tool palette, add it to a palette.

## Creating View Blocks

Create AutoCAD blocks and use them to represent each view of the multi-view block definition.

**Creating individual blocks for multi-view block definition**

**To create the AutoCAD blocks used to represent each view of the multi-view block**

1   Draw the views you need for a specific display representation:

   ■   To create views for the front and back directions, draw them on the XZ plane.

   ■   To create views for the left and right directions, draw them on the YZ plane.

   ■   To create views for the top and bottom directions, draw them on the XY plane.

2   Specify additional insertion points on the defpoints layer in the AutoCAD point command, if necessary.

   **NOTE** The points added to view blocks are cumulative. For example, if you add one point to a view block used for the top view and two points to the view block used for the model view, you have a total of four points to cycle through. The fourth point is the regular basepoint defined during the creation of the block.

3   Make sure the current coordinate system is the world coordinate system before making blocks from these individual views.

   For more information about coordinate systems, see "Use Coordinates and Coordinate Systems" in the online *AutoCAD User's Guide*.

4   Define each view as a block, and specify the location of the insertion base point as you define each block.

   For example, if you specify the insertion base point of the model view block as the dead center of the top side, the front, back, left, and right view blocks will all have an insertion base point at the midpoint of the bottom edge. In the following illustration, the insertion points for the top, front, and side view blocks are indicated by an "X". For more information about blocks, see "Create and Use Blocks" in the online *AutoCAD User's Guide*.

**TIP** It is helpful to have a naming convention as you save your views as blocks. For example, name the plan view block hydrant-p, and name the right view block hydrant-r.

## Creating a New Multi-View Block Definition

Create a multi-view block definition from existing view blocks created to represent different views of a custom object.

**To create a multi-view block definition**

1   Click Insert tab ➤ Blo ck panel ⬇ Edit Multi-View Block Definition.

   **NOTE** If there is already a multi-view block in the drawing, press Enter when the prompt Select Multi-View Blocks is displayed.

2   In the New Multi-View Block Definition dialog box, enter a name for the new multi-view block definition. Click OK.

3   In the Multi-View Block Definition Properties dialog box, set up the new multi-view block definition:

   ■   To connect view blocks representing different display representations, see Adding View Blocks to the Multi-View Block Definition (page 1635).

   ■   To add notes and files to the multi-view block definition, see Attaching Hyperlinks, Notes, or Files to a Multi-View Block (page 1642).

4   Click OK.

Dialog Box

Multi-View Block Definition Properties Dialog Box (page 2459)

## Adding View Blocks to the Multi-View Block Definition

Add view blocks corresponding to individual display representations.

You can specify different settings for plan and profile views, for example.

**To add view blocks**

1 Click Insert tab ➤ Block panel ▼ Edit Multi-View Block Definition.

2 In the Multi-View Block Definition Properties dialog box, select the multi-view block definition from the Multi-View Block Name list.

3 Under Multi-View Block Components, select the display representation to which you want to connect view blocks.

There are two display representations available for multi-view blocks:

■ Select 2D for all Plan views.

■ Select 3D for all other views.

4 Click the add button.

5 Use the Select A Block dialog box to select a view block.

6 To specify view blocks in other display representations, repeat steps 4 - 5.

7 Click OK.

## Adding a Multi-View Block Definition to DesignCenter

Add a multi-view block to DesignCenter. When you add a multi-view block definition to DesignCenter, you can create new multi-view blocks by dragging and dropping them from DesignCenter to your drawing. To add a multi-view block definition to DesignCenter, you need to first create a DWG file that contains a multi-view block definition.

**NOTE** A side effect of this process is that the multi-view block, when inserted using DesignCenter, will be embedded in an enclosing block reference and must be exploded before it will be recognized by AutoCAD Civil as a multi-view block object.

**To add a multi-view block to DesignCenter**

1  Click View tab ➤ Palettes panel ➤ Design Center.

2  In DesignCenter, click the Folders tab.

3  Browse to and select the folder where you would like to place the multi-view block.

4  At the command prompt, enter WBLOCK.

5  In the Write Block dialog box, select the Block option.

6  In the Block list, select the name of the multi-view block definition that you would like to add to the folder selected in DesignCenter.

7  Under Destination, browse to the folder specified in DesignCenter. Click Save in the Browse For Drawing File dialog box.

8  Verify the insert units for the multi-view block drawing file.

**NOTE** When using DesignCenter, the insert units will be used to convert the units assigned to the multi-view block to the units specified for the active drawing.

9  Click OK in the Write Block dialog box to write the multi-view block to the drawing file.

10  In DesignCenter, press the F5 key to refresh the contents. The multi-view block is placed in the selected DesignCenter folder.

# Inserting Multi-View Blocks into a Drawing

Insert multi-view blocks into a drawing by dragging and dropping them from the AutoCAD Civil - MVBlocks Tool Palette, or by referencing their definitions using DesignCenter.

After a multi-view block has been inserted into the drawing, additional references can be added by using the Insert tab ➤ Block panel ▼ Add Multi-View Block command.

Predefined multi-view blocks are located in the \\*Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\data\Symbols\Mvblocks* folder by default.

## Inserting a Multi-View Block Using the Tool Palette

Use the Civil Multiview Blocks Tool Palette to insert a multi-view block into a drawing.

**To insert a multi-view block into a drawing using the Tool Palette**

1 Click Home tab ➤ Palettes panel ➤ Tool Palettes Window.

2 Right-click anywhere on the Tool Palette's vertical bar, and click Civil Multiview Blocks.

3 Locate the block to insert by clicking the named tabs.

4 Click the block and drag it into the drawing window.

5 Specify the insertion point and rotation angle.

**NOTE** Multi-view blocks are embedded in an enclosing block reference when they are initially inserted and must be exploded before they can be recognized by AutoCAD Civil as a multi-view block object.

## Inserting a Multi-View Block Using DesignCenter

Use DesignCenter to insert a multi-view block into a drawing.

**NOTE** Multi-view blocks are embedded in an enclosing block reference when they are initially inserted and must be exploded before they can be recognized by AutoCAD Civil as a multi-view block object.

**To insert a multi-view block into a drawing using DesignCenter**

1 Click View tab ➤ Palettes panel ➤ Design Center.

2 In DesignCenter, select the folder containing the DWG file or files (do not select individual blocks within the DWG files).

3 From the DesignCenter preview pane, drag the image representing the multi-view block DWG file into the drawing.

4 Specify the insertion point, if prompted.

5 Specify the scale, if prompted:
   - To specify a scale value, enter a value at the Command prompt.

   - To dynamically set the scale, use the pointing device, and click when you see the appropriate scale.

6 Specify the rotation angle, if prompted:
   - To specify a rotation value, enter a value at the Command prompt.

■ To dynamically set the rotation, use the pointing device, and click when you see the appropriate rotation

**7** To insert additional references to the multi-view block, repeat steps 3 - 6. 3.

**8** Press Enter to finish inserting blocks.

## Inserting Additional Instances of Multi-View Blocks into a Drawing

After one instance of a multi-view block has been inserted into the drawing, additional instances can be added.

The block must already exist in the current drawing to use this command. Insert the original block using the Civil Multiview Blocks Tool Palette.

**To add another instance of a multi-view block into a drawing**

**1** Click Insert tab ➤ Block panel ▼ Add Multi-View Block.

**2** Use the AutoCAD Properties Palette to select the multi-view block to insert. All available blocks are listed in the Definition list on the Design tab.

> **NOTE** If you do not see the block you want to insert, add it to the drawing by dragging it from the Tool Palette or by adding it from the DesignCenter.

**3** Specify the insertion point, rotation, and other settings. You can enter these values in the Properties Palette, or you can use the command line options.

## Modifying Multi-View Blocks

Change the attributes of a multi-view block in a drawing. For example, you can change the rotation or the scaling factor.

There is a multi-view block contextual ribbon in AutoCAD Civil 2010 that you can use to access commonly-used commands. Select the multi-view block in the drawing to display this ribbon tab.

> **NOTE** If you select a multi-view block in a drawing and the multi-view block contextual ribbon is not displayed, use the EXPLODE command to explode the multi-view block. Multi-view blocks are embedded in an enclosing block reference when they are initially inserted and must be exploded before they can be recognized by AutoCAD Civil as a multi-view block object.

## Changing the Rotation of a Multi-View Block

**To change the rotation of a multi-view block**

1 Click View tab ➤ Palettes panel ➤ Properties.

2 Select the multi-view block.

3 On the Properties palette, expand Basic. Expand Location.

4 Enter a value for Rotation.

## Changing the Associated Multi-View Block Definition

Change the multi-view block definition associated with the multi-view block. For information about the relationship between multi-view blocks and multi-view block definitions, see Creating Multi-View Block Definitions (page 1632).

**To change the multi-view block definition associated with the multi-view block**

1 Click View tab ➤ Palettes panel ➤ Properties.

2 Select the multi-view block.

3 On the Properties palette, expand Basic. Expand General.

4 Click Definition. Select a new multi-view block definition for the multi-view block.

## Changing the Scale Factor of a Multi-View Block

**To change the scale factor of a multi-view block**

1 Click View tab ➤ Palettes panel ➤ Properties.

2 Select the multi-view block.

3 On the Properties palette, expand Basic. Expand Scale.

4 Enter new values for the X, Y, and Z scale factors.

## Changing the Offset of a Multi-View Block

Change the offset of a multi-view block from its insertion point.

When you first add a multi-view block to a drawing, the offset value is set to 0. Change the position of the multi-view block by offsetting it from its original insertion point.

You can also change the offset of a multi-view block using the Properties palette.

**To change the offset of a multi-view block from its insertion point**

1 Select the multi-view block.

2 Click Multi-View Block tab ➤ Modify panel ➤ Edit View Block Offsets.

> **NOTE** If you select a multi-view block in a drawing and the multi-view block contextual ribbon is not displayed, use the EXPLODE command to explode the multi-view block.

**3** Select the Location grip.

In Model view, the Location grip has three possible edit modes: Edit Along XY Plane, Edit Along XZ Plane, and Edit Along ZX Plane. Press Ctrl to cycle among modes until you are in the desired mode. The default is Edit mode along the XY plane. In Plan view, the Location grip is restricted to movement in one plane.

**4** Offset the multi-view block to the desired location and click once, or enter a value and press Enter.

If you want to enter a specific value for the second direction in any edit mode (for example, in the Y direction when editing along the XY plane), press Tab to cycle to the second direction.

You can also lock the movement of the multi-view block along a specific direction. If you enter a value for either of the dimension directions in the current edit mode and then press Tab, the movement of the multi-view block is constrained to the second dimension direction. When editing along the XY plane, for example, you can enter a value for the X dimension, and then press Tab. The X dimension is locked at that value, and movement of the multi-view block is constrained to the Y dimension direction.

**5** Right-click and click Exit Edit View Block Offsets.

The selected view block is offset from the original insertion point.

## Changing the Location of a Multi-View Block

Relocate an existing multi-view block by changing the coordinate values of its insertion point. In Model view, the Location grip has three possible edit modes: Edit Along XY Plane, Edit Along XZ Plane, and Edit Along ZX Plane. Press Ctrl to cycle among modes until you are in the desired mode. The default is Edit mode along the XY plane. In Plan view, the Location grip is restricted to movement in one plane

You can also change the location of a multi-view block using the Properties palette.

**NOTE** This procedure can only be done in Model view.

**To relocate an existing multi-view block by changing the coordinate values of its insertion point**

**1** Select the multi-view block you want to relocate.

**2** Select the Location grip.

Location
Press Ctrl to cycle between:
 - Edit Along Object's XY Plane
 - Edit Along Object's YZ Plane
 - Edit Along Object's XZ Plane

**3** Move the multi-view block to the desired location and click once, or enter a value and press Enter.

If you want to enter a specific value for the second direction in any edit mode (for example, in the Y direction when editing along the XY plane), press Tab to cycle to the second direction.

You can also lock the movement of the multi-view block along a specific direction. If you enter a value for either of the dimension directions in the current edit mode and then press Tab, the movement of the multi-view block is constrained to the second dimension direction. When editing along the XY plane, for example, you can enter a value for the X dimension, and then press Tab. The X dimension is locked at that value, and movement of the multi-view block is constrained to the Y dimension direction.

Polar: < 45.00, Endpoint: < 60.00
Edit Along Object's XY Plane

**4** Right-click and click Deselect All to turn off grips.

## Attaching Hyperlinks, Notes, or Files to a Multi-View Block

Attach hyperlinks, enter notes, or attach reference files to a multi-view block in a drawing. You can also edit notes and edit or detach reference files from a multi-view block.

**To attach hyperlinks, enter notes, or attach reference files to a multi-view block in a drawing**

1 Click View tab ➤ Palettes panel ➤ Properties.

2 Select the multi-view block.

3 On the Properties palette, click the Extended Data tab.

4 To add a hyperlink, click 🔲 next to Hyperlink, and specify the link.

5 To add or edit a note, click 🔲 next to Notes. Enter text. Click OK.

6 Click 🔲 next to Reference documents. Attach, detach, or edit a reference file:

■ To attach a reference file, click 🔲 . Select a file. Click Open.

■ To edit the description of a reference file, enter text under Description.

■ To edit a reference file, double-click the reference file name to start its application.

■ To detach a reference file, select the file name. Click ✖ .

## Editing the Attributes of a Multi-View Block

**To display the attributes defined for a multi-view block**

1 Click View tab ➤ Palettes panel ➤ Properties.

2 Select the multi-view block.

3 On the Properties palette, click the Design tab. Expand Advanced.

4 Click Attributes.

5 Edit attributes as needed.

6 Click OK.

**NOTE** You can also select the multi-view block to display the Multi-View Block ribbon tab, and then use the Edit Attributes command on the Modify panel to edit the attributes.

## Updating Multi-View Block Attributes

Use this procedure to update the attributes of blocks in your drawing, using the current attributes defined for the view blocks upon which each multi-view block is based. You need to do this if you change attribute definitions in one or more of the block definitions on which the multi-view block is based.

**To update attribute definitions**

1 Select the multi-view block.

**2** Click Multi-View Block tab ➤ Modify panel ➤ Update 🖼️.

**3** Enter **y** (Yes) to include text style properties (for example, width factor, oblique, mirroring) when updating attributes, or **n** (No) to update all attributes properties except those relating to text style.

**4** Press Enter to end the update process.

# Drafting Tools

You can perform a variety of editing operations on linework components and certain Civil objects using the AEC Modify Tools.

This suite of tools can be used on any of the following objects and is available on the shortcut menu regardless of whether any of these objects of these types are selected:

■ Hatches

■ Polylines

■ Circles

■ Arcs

■ Text/Multiline text (Mtext)

■ Any of the above when embedded in blocks

Although the modify tools can only be applied to the types of objects listed, objects of any type can be used as reference points or boundaries for the editing operations. For example, linework can be trimmed or extended in relation to Civil objects. Likewise, Civil objects can be used to define a cropping boundary to subtract from linework. For more information about the applicability of the various tools, refer to the individual procedures.

# Trimming Linework Objects

You can trim hatches, lines, polylines, arcs, circles, or any block-based content created from these types of linework or objects.

**To trim linework**

**1** Select the linework, object, or block you want to trim.

**2** Right-click and click AEC Modify Tools ➤ Trim.

**3** Specify two points to establish the trim line.

The trim line changes color after the second point is selected, as does all linework (except hatches) on the side of the trim line where the cursor is positioned.

**4** Click the side of the trim line where the region you want to remove is located.

All linework on the selected side of the trim line is removed. Boundaries for any closed polylines on the other side of the trim line are redrawn along the trim line.

existing block

select block

specify first trim
line point

specify second trim
line point

specify side to trim

result

**Trimming a block**

# Trimming Linework Objects to an Edge

Trim one or more lines, polylines, arcs, circles, or hatches precisely to a selected edge or side of any straight segment of linework.

**TIP** If you need to trim linework to the edge of an arced segment of an object, use either the Crop option (see Cropping Linework Objects (page 1650)) or the Subtract option (see Subtracting from Linework Objects (page 1647)). The Crop option removes linework outside the implied boundary of the arc, while the Subtract option removes linework inside the implied boundary of the arc.

**To trim one or more objects to an edge**

1  Select the linework or object you want to trim.

2  Right-click and click AEC Modify Tools ➤ Trim.

3  Press Enter.

4  Move the cursor over the edge or line to which you want to trim the selected linework or object.

5  Click when the trim line is displayed.

6  Click the side of the trim line you want trimmed.
   All selected linework is trimmed to the edge you selected.

existing wall
and polyline

select polyline

specify trim edge

specify side
to trim

result

**Trimming linework to the
edge of a wall**

# Extending Linework to an Edge

Extend one or more lines, open polylines, or arcs precisely to an implied edge of a straight or arced segment
of any object, or to an implied extension of that segment.

**To extend linework to an edge**

1 Select the linework you want to extend.

2 Right-click and click AEC Modify Tools ➤ Extend.

3 Move the cursor over the edge or line to which you want to extend the selected linework. Click when a temporary line is displayed extending along and beyond the edge/line in both directions.

4 Click any point on the linework you want to extend or click the edge or line to which you want to extend the linework.

The linework is extended to the edge. If you selected multiple lines, clicking on any one of them extends them all.

existing wall
and polyline

select polyline

specify trim edge

select point near
end to extend

result

**Extending linework to the
edge of a wall**

# Dividing Linework Objects

Divide linework or a block containing linework into two (or more) parts defined by a dividing line you draw. You can then select the parts on either side of the line. If a closed-boundary object is divided into two parts using this option, both parts are recreated as closed. If an open polyline in a zigzag pattern is divided along its length, many selectable segments are created.

**To divide linework**

1 Select the linework, object, or block you want to divide.

2 Right-click and click AEC Modify Tools ➤ Divide.

3 Specify two points to establish the dividing line. In the case of a closed-boundary object, the points can be inside or outside the boundaries. The dividing line is automatically extended until it intersects all boundaries of the selected object.

You can select the divided parts of the linework or object on either side of the divide line. The divide line is not visible after you select the second point.

existing space

select space

specify divide line
start point

specify divide line
endpoint

result

**Dividing a space object**

# Subtracting from Linework Objects

Subtract a selected part from linework or from a block containing linework without having to redraw any of the remaining components. The part to be subtracted can contain or be delineated by lines, polylines

(closed or open), arcs, circles, text, or hatches. If the subtraction removes part of a closed polyline, the polyline is recreated as closed. If the subtraction bisects a closed polyline, both parts are recreated as separate closed polylines. However, when the subtraction bisects a hatch, the hatch remains a single linework entity that you can select by clicking either part.

---

**NOTE** Anything subtracted by this operation is actually deleted from the drawing. If you want to hide linework from view, you may want to use the Obscure command instead. For more information, see Obscuring Regions of Linework (page 1648).

---

**To subtract a selected part from an object**

1   If it does not already exist, draw the linework that delineates what you want to subtract.

2   Select the linework or object from which to subtract the delineated part.

3   Right-click and click AEC Modify Tools ➤ Subtract.

4   Select the linework delineating the part you want to subtract. Press Enter.

5   Press Enter to retain the selected linework. Enter y (Yes) to erase it.

existing block
and polyline

select block

select object
to subtract

result with
linework retained

result with
linework erased

**Subtracting part of a block**

# Obscuring Regions of Linework

Obscure or "hide" a region of linework in relation to other linework. Use this feature when you want to indicate that one entity extends behind or beneath another entity that is displayed in the foreground. The obscured linework is placed on the layer specified by the Hidden layer key.

**To obscure a region of linework in relation to other linework**

1 Select the linework you want to obscure.

2 Right-click and click AEC Modify Tools ➤ Obscure.

3 Select the foreground linework that will obscure the linework selected in step 1.

4 Press Enter.

The obscured region is delineated with a dashed line. You can select it (or its component segments) separately from the linework it was part of before being obscured.

existing blocks

select linework
to hide

select obscuring
linework

result

**Obscuring linework with a block**

# Merging Linework Objects

Merge contiguous closed polylines, circles, hatches, or blocks into a single closed-boundary object or linework entity.

**To merge linework**

1 Select the linework or object to which you want to add one or more other linework entities or objects.

2 Right-click and click AEC Modify Tools ➤ Merge.

3 Select the linework/object(s) you want to merge with the originally selected linework/object, and press Enter.

4 Press Enter to retain the selected linework. Enter y (Yes) to erase it.

All selected linework and/or objects are merged into a single entity.

existing block
and polyline

select block

select object
to merge

result with
linework retained

result with
linework erased

**Merging a region with a block**

# Cropping Linework Objects

Crop linework to a smaller area using a boundary you define. You can crop hatches, lines, polylines, arcs, circles, or blocks. Neither the linework to be cropped nor the linework that defines the new boundary needs to have closed boundaries. For example, you can either use a v-shaped polyline to crop a circle or a circle to crop a v-shaped polyline.

**To crop linework using a boundary**

1  Draw the linework that defines the new boundary to which you want to crop the existing linework.

2  Right-click and click AEC Modify Tools ➤ Crop.

3  Select the linework to crop and press Enter.

4  Select the linework you want to use to define the new boundary (the linework you drew in Step 1), and press Enter.

5  Press Enter to retain the selected linework (the crop boundary), or enter y (Yes) to erase it.

   All of the originally selected linework outside the crop boundary is erased. If you choose to erase the crop boundary, boundaries are redrawn for any closed-boundary entities inside the crop area. But any open-boundary objects that have been cropped remain open.

linework erased

# Utilities Command Reference

You can use commands to quickly access AutoCAD Civil utility functionality.

The following table lists the utility-related AutoCAD Civil commands and briefly describes their functionality.

| Command | Description |
| --- | --- |
| AeccMvBlockDefEdit | Edits a multi-view block definition (page 1632) |
| AecMvBlockEditAttributes | Edits the attributes defined for a multi-view block (page 1642) |
| AecMvBlockEditViewBlockOffsets | Changes the offset of a multi-view block from its insertion point (page 1639) |
| CgADist | Calculates the total of several disjunct distances (page 1604) |
| CgAng | Displays the acute and obtuse angle between points or intersecting lines (page 1606) |
| CgCDist | Displays the distance between points (page 1605) |
| CgList | Displays coordinate geometry for lines and arcs (page 1606) |
| CgSList | Displays the slope, grade, and horizontal distance between two points (page 1607) |

| Command | Description |
|---|---|
| ContentBrowser | *Opens the Content Browser, which is a library of tool catalogs, including subassembly catalogs* |
| DockCT | Docks the Coordinate Tracker utility (page 1623) |
| DockInquiry | Docks the Inquiry utility (page 1618) |
| FloatCT | Changes the Coordinate Tracker utility from docked to floating (page 1623) |
| FloatInquiry | Floats the Inquiry utility (page 1618) |
| HideCT | Hides the Coordinate Tracker utility (page 1623) |
| HideEventViewer | Hides the Event Viewer utility (page 1626) |
| HideInquiry | Hides the Inquiry utility (page 1618) |
| Mapcheck | Displays the Mapcheck Analysis utility (page 1607) |
| MvBlock Update | Updates the attributes of blocks in your drawing (page 1642) |
| MvBlockAdd | Inserts a multi-view block definition into a drawing (page 1637) |
| Notes | Adds notes to a drawing (page 1616) |
| ObjectViewer | Displays the Object Viewer utility (page 1617) |
| ShowCT | Displays the Coordinate Tracker utility (page 1623) |
| ShowEventViewer | Displays the Event Viewer utility (page 1626) |
| ShowInquiry | Displays the Inquiry utility (page 1618) |

# File and Data Sharing

# Sharing Drawings and Data With Other Applications

# 39

AutoCAD Civil provides many utilities for sharing your drawings and data with other applications.

## Comparing Sharing Methods

To share an AutoCAD Civil drawing data with people who do not have AutoCAD Civil, you can use proxy graphics, the Object Enabler, the Export To AutoCAD commands.

The following table lists the features of each method:

| Data Sharing Method | Use of objects in other AutoCAD-based applications | Status of objects in other applications | 2D and 3D style display settings honored in different viewports | Objects still exist when reopened in AutoCAD Civil |
|---|---|---|---|---|
| **Proxy Graphics** | View/plot objects and design data; no manipulation of objects. | Objects are displayed as proxy graphics with no intelligence. | No | Yes |
| **Object Enabler** | View, plot, copy, and manipulate object labels. Design data is not editable. | Objects are maintained as intelligent objects. | Yes | Yes |
| **Export To AutoCAD (DWG or DXF)** | Objects are exploded to AutoCAD primitives. The visual integrity of the model is preserved. Object design data is not available. | No objects in other applications. Only AutoCAD primitives. | No | No |

| Data Sharing Method | Use of objects in other AutoCAD-based applications | Status of objects in other applications | 2D and 3D style display settings honored in different viewports | Objects still exist when reopened in AutoCAD Civil |
|---|---|---|---|---|
| Export to SDF | Points, parcels, alignments, pipes and structures are exported to the SDF file. Can be used in applications that can read SDF. AutoCAD Map can import this data. | Primarily a format for AutoCAD Map. | SDF is a separate file. Original drawing is not affected. | SDF is a separate file. Original drawing is not affected. |
| Export to 3D DWF | Uses the 3D display representations of the objects for display. Some objects do not have a 3D display component so are not displayed in 3D DWF. There is also object meta-data exported with 3D DWF. All of the objects export the meta-data. | Autodesk Design Review or DWF Viewer is required. | Autodesk Design Review or DWF Viewer is required. 3D DWF uses the 3D display component when exported. | Original drawing is not affected. |

# Using Proxy Graphics

Proxy graphics store the last viewed image of AutoCAD Civil objects, which lets users view your drawing without modifying the original objects. Proxy graphics store only the display representation for the current active viewport.

**NOTE** Depending on the complexity of the drawing, a drawing saved with proxy graphics can become extremely large, slowing drawing performance. It is recommended that you make a copy of the drawing without proxy graphics before turning them on in the drawing you want to share with other users.

**To generate proxy graphics**

1 Set up the drawing to display the view for which you want to create proxy graphics.

2 At the command line, enter **Proxygraphics**.

3 Enter **1**.

4 Save the drawing.

5 To turn off proxy graphics, enter **Proxygraphics**, and then enter **0**.

Command Line

Proxygraphics

# Using the Object Enabler

Users who do not have AutoCAD Civil but who have an AutoCAD 2010-based product can install the Object Enabler and view your drawing exactly as you created it.

The Object Enabler is available on the AutoCAD Civil installation CD and on the Autodesk web site at *www.autodesk.com/aecobjenabler*.

After a user installs the Object Enabler, the user can open the drawing and view, plot, manipulate, and copy AutoCAD Civil objects using standard AutoCAD commands. AutoCAD Civil objects are maintained as intelligent objects, and the drawing can be re-used in AutoCAD Civil.

# Exporting a Drawing to AutoCAD

You can export a drawing created in AutoCAD Civil to AutoCAD®. This process creates either a new AutoCAD 2010, 2007, 2004, 2000 or R14 format drawing with all civil objects exploded to AutoCAD primitives. The original drawing is not affected.

When you open the resulting drawing, the primitive objects are not restored to their original state.

The following format compatibility rules apply.

| Format ... | Compatible with AutoCAD ... |
|---|---|
| 2010 | 2010 |
| 2007 | 2007-2009 |
| 2004 | 2004-2006 |
| 2000 | 2000-2003 |
| R14 | R14 |

The Export To AutoCAD commands respect the current display settings of the objects in your drawing. For example, if a surface in the drawing is set up to display the border and contours only, the drawing created with the ExportTo Auto CAD command will contain primitives that represent the surface border and contours only.

If the current drawing contains multiple viewports, the Export To AutoCAD commands create the primitives based on the view of the objects in the active viewport.

---

**TIP** For information about the Save As AutoCAD DWG command and how it is different from the Export To AutoCAD commands, see *Save A Drawing* and *Save As* in the AutoCAD Help.

---

**To export a drawing to AutoCAD**

1  Verify that the drawing's Model tab is selected.

2  At the command line, enter **UCS**, and then enter **World**.

**3** Click  ➤ Export ➤ AutoCAD DWG, and then click the version you want to use.

**4** Enter a filename, and specify a path, if necessary.

The default filename includes any prefix or suffix that you specified on the AEC Editor tab of the Options dialog box. For more information, see Changing the AEC Editor Settings (page 1658).

To change export options, such as how the command handles xrefs, use the command line version of this command. For more information, see Exporting a Drawing to AutoCAD (page 1657).

**5** Click Save.

---

**TIP** You can use the Autodesk Civil Batch Drawing Converter Utility to convert multiple drawings to a legacy AutoCAD drawing format. See Using the Civil Batch Drawing Converter (page 1287).

---

When converting AutoCAD Civil drawings to legacy AutoCAD drawing formats, the application does not convert AutoCAD Civil objects to the previous version.

### Quick Reference

Application Menu

## Exploding AutoCAD Civil Objects

All AutoCAD Civil objects support the AutoCAD Explode command. In addition, labels on objects can be individually exploded.

For more information on the Explode command, see *Explode*.

A setting in the AutoCAD Options dialog box affects how AutoCAD Civil objects are exploded. For more information, see Changing the AEC Editor Settings (page 1658).

## Changing the AEC Editor Settings

You can specify settings for the Export To AutoCAD commands, including how the commands handle XRefs.

**To change the AEC Editor Settings**

**1** At the command line, enter **Options**.

**2** In the AutoCAD Options dialog box, click the AEC Editor tab (page 2453).

**3** Under Block Properties Of Exploded Objects, select Maintain Resolved Layer, Color, Linetype to maintain the layer, color, and linetype of objects when you explode them.

**4** Under Export To AutoCAD, select Bind Xrefs if you want to bind the xrefs to the host drawing when exploding, thus creating local block definitions. If you select this option, all xrefs and their dependent named objects become a part of the exported drawing.

**5** If you select the Bind Xrefs check box, then either select or clear the Use Insert Method When Binding Xrefs check box.

**6** Enter a prefix or a suffix to be added to the drawing filename when the drawing is exported with the Export To AutoCAD commands.

---

**NOTE** The other options on the AEC Editor tab are not supported by AutoCAD Civil.

---

**7** Click OK.

AEC Editor Tab (Options dialog box) (page 2453)

# Exporting a Drawing to a DXF File

You can export a drawing created in AutoCAD Civil to AutoCAD. This process creates either a new AutoCAD 2010, 2007, 2004, 2000, or R12 DXF format drawing with all civil objects exploded to AutoCAD primitives. The original drawing is not affected.

A DXF file is a text file that contains drawing information that other CAD systems can read. When you open the DXF file, the exploded objects are not restored to their original state.

You can export drawings to the following DXF formats:

■ AutoCAD 2010 DXF

■ AutoCAD 2007 DXF

■ AutoCAD 2004 DXF

■ AutoCAD 2000 DXF (including 2000i and 2002)

■ AutoCAD Release 12 DXF

This process creates a new DXF file with all AutoCAD Civil objects exploded to AutoCAD primitives. The original drawing is not affected.

---

**NOTE** When you use the Export To AutoCAD commands, all AutoCAD Civil objects are exploded to AutoCAD primitives. Opening the drawing in AutoCAD Civil does not restore these primitive objects to AutoCAD Civil objects.

---

**To export a drawing to a DXF file**

**1** Verify that the drawing's Model tab is selected.

**2** At the command line, enter **UCS**, and then enter **World**.

**3** Click  ➤ Export ➤ AutoCAD DXF.

**4** Enter a filename, and specify a path, if necessary.

The *.dxf* extension for the file name is specified by default. The default file name also includes any prefix or suffix that you specified on the AEC Editor tab of the Options dialog box. For more information, see Changing the AEC Editor Settings (page 1658).

**5** Click Save.

# Exporting Civil Data to SDF Files

Use the Export to SDF command to export AutoCAD Civil data to Spatial Data Format (SDF) files.

Spatial data format files can be used in AutoCAD Map 3D and Autodesk MapGuide Enterprise. The alignment, point, parcel, and pipe network data are converted to data objects with attributes.

The AutoCAD Civil alignment, point, parcel, and pipe network data is converted to data objects with attributes. SDF files store data as features, which means that you are dealing with real-world objects rather than geometry.

| AutoCAD Civil Object | Exported Attributes |
|---|---|
| Alignment | ■ Alignment Name |
| | ■ Length |
| | ■ Design Speed |
| | ■ Starting Station |
| | ■ Ending Station |
| Point | ■ Point Number |
| | ■ Point Name |
| | ■ Elevation |
| | ■ Description |
| | ■ Raw Description |
| | ■ Latitude |

■ Longitude

| Parcel | ■ Parcel Name |
| | ■ Parcel Number |
| | ■ Area |
| | ■ Perimeter |

| Pipe | ■ Network Name |
| | ■ Length |
| | ■ Slope |
| | ■ Inside Diameter |
| | ■ Outside Diameter |
| | ■ Shape |
| | ■ Elevation at Start |
| | ■ Elevation at End |
| | ■ Structure Start |
| | ■ Structure End |

| Structure | ■ Network Name |
| | ■ Rim Elevation |
| | ■ Structure Name |

**To export AutoCAD Civil drawing data to an SDF file**

1  Click Output tab ➤ Export panel ➤ Export Civil Objects To SDF  .

2  In the Export To SDF (page 2463) dialog box, specify a name for the SDF file.

3  Specify the coordinate system.

> **NOTE** If the drawing already has a coordinate system specified, it is used automatically and the Select Coordinate System controls in the Export To SDF dialog box are grayed out.

4  Click OK to export the file.

# Exporting a Drawing to a 3D DWF File

You can export a drawing created in AutoCAD Civil to 3D DWF format.

A Design Web Format (DWF) file is a set of drawings or images that is compressed into a single, smaller file, making sharing across the Web faster and more secure.

The Export to 3D DWF command creates a DWF file with all or the selected AutoCAD Civil objects and AutoCAD primitives. The command uses the 3D display representations of the objects when displaying them in the DWF file. Some objects do not have 3D display components (for example, profile views), so they are not displayed in the 3D DWF.

Object metadata is also exported with 3D DWF. For example, the maximum surface elevation information is available when you view the 3D DWF in the DWF Viewer or Autodesk Design Review.

**NOTE** To export to 2D DWF format, use the Plot feature. For more information see *Create and Modify a Drawing Set for Publishing*.

For more information on 3D DWF publishing, see *3DDWFPublish*.

**To export a drawing to a DWF file**

1  Verify that the drawing's Model tab is selected.

2  At the command line, enter **UCS**, and then enter **World**.

3  Click ➤ Export ➤ Other Formats.

4  In the Files of Type drop-down, click 3D DWF, enter a filename, and specify a path, if necessary.

   The *.dwf* extension for the file name is specified by default.

5  Optionally, click Tools ➤ Options and modify the publishing options. For more information, see DWF Publishing Options Dialog Box (page 2464).

6  Click OK to close the DWF Publishing Options dialog box and click Save to generate the DWF file.

# Other Data Sharing Methods

Share AutoCAD Civil data using additional utilities and commands.

The following section list additional methods for sharing AutoCAD Civil data.

### Exporting to Google Earth

Use the Export to Google Earth utility to publish and view your design data in Google Earth. For more information, see Publishing Civil Data to Google Earth (page 1669).

### Exporting to DEM

Use the Export Surface to DEM utility to export surface data to a DEM file. The file can be of type USGS (*.dem*) or GeoTIFF (*.tiff*). For more information, see Exporting to DEM (page 714).

### Exporting to LandXML

Use the LandXML export commands to export drawing data to LandXML format. For more information, see Understanding LandXML Import and Export (page 1673).

### Exporting Points

Use the Points export command to export drawing points to an ASCII (text) file or a Microsoft® Access *.mdb* file. For more information, see Exporting Point Data (page 505).

# Drawing Sharing Command Reference

You can use commands to quickly access file and drawing sharing drawing functionality.

# Google Earth Import and Export

# 40

Use AutoCAD Civil to retrieve image and terrain data from Google Earth as well as publish and view your design data in Google Earth.

## About Using Google Earth

Use AutoCAD Civil in conjunction with Google Earth to import image and terrain data and publish and view design data.

■ Import surface images and terrain data from Google Earth to better visualize the future development environment. See Importing a Google Earth Image to AutoCAD Civil (page 1665), Importing Google Earth Terrain Data into a Surface (page 1666), and Importing Google Earth Image and Terrain Data (page 1667).

■ Publish the model space entities from AutoCAD Civil to Google Earth to quickly view your design data in the Earth terrain imagery. See Publishing Civil Data to Google Earth (page 1669).

■ Import the elevation data for the current Google Earth view as a mesh. See Importing Google Earth Elevation Data as a Mesh (page 1668).

■ Attach time-related information to each piece of the model data and then display published model data based on start and end times. See Attaching Time Information to Model Data (page 1670).

**NOTE** You can use the imported Google Earth data for demonstration purposes only. Images imported from Google Earth are low resolution and are not suitable for a land survey. In the same manner, publishing Civil data to Google Earth can only serve as a conceptual planning and design tool.

## Importing a Google Earth Image to AutoCAD Civil

You can import Google Earth images into your AutoCAD Civil drawing.

You can manually specify the image insertion point or you can insert the image using the defined coordinate system in the drawing. Before you start, ensure that no tilting, turning, or rotation have been applied to the image.

**To import a Google Earth image into a Civil project**

1 In Google Earth, fly to a point of interest (see the Google Earth User Guide for more information).

The image that is displayed in the Google Earth 3D Viewer is the source image that will be imported. See the *Google Earth User Guide* for more information.

2 Click Insert tab ➤ Import panel ➤ Google Earth drop-down ➤ Google Earth Image  .

3 Follow the instructions at the command prompt and, depending on whether your drawing has a coordinate system defined (see Specifying Units and Zone Settings (page 63)), do one of the following:

■ Choose to locate the image using the defined coordinate system or manually identify the image location.

■ Manually specify the image insertion point and define image rotation angle by entering the corresponding values or clicking in the drawing workspace.

**NOTE** If a map projection coordinate system is defined, AutoCAD Civil can automatically place the image or terrain data in the proper location in the drawing.

The image is displayed in the drawing as a new object. The image file name is generated and the image is saved in JPEG format in the same folder as the current drawing file. You can use the imported image for adding design objects and data.

**NOTE** The imported image is displayed as grayscale in the application.

## Importing Google Earth Terrain Data into a Surface

Create a AutoCAD Civil surface that represents a specific location on the surface of the Earth by importing terrain data from a Google Earth image.

You can insert the surface using the defined coordinate system or by selecting the previously imported image. Before you start, ensure that no tilting, turning, or rotation have been applied to the image.

**To create a surface using the image terrain data from Google Earth**

1 In Google Earth, fly to a point of interest (see the *Google Earth User Guide* for more information). The image that is displayed in the Google Earth 3D Viewer is the source image whose terrain data will be imported.

2 Click Home tab ➤ Create Ground Data panel ➤ Surfaces drop-down ➤ Create Surface From Google Earth  .

3 Follow instructions in the command prompt and, depending on whether your drawing has a coordinate system defined (see Specifying Units and Zone Settings (page 63)), do one of the following:

■ Choose to locate the surface using the defined coordinate system or by selecting the previously imported image.

■ Locate the surface using the previously imported image.

---

**NOTE** If a map projection coordinate system is defined, AutoCAD Civil can automatically place the image or terrain data in the proper location in the drawing.

---

4 In the Create Surface dialog box, follow the steps for creating a TIN surface. See Creating a TIN Surface (page 601).

A surface is created. It is displayed in AutoCAD Civil drawing and the Prospector tab. The location of the surface points is based on the closest values obtained from the transformation of the Google Earth geographical coordinates to the linear coordinates of the drawing.

Menu

File ➤ Import ➤ Import Google Earth Surface

Command Line

ImportGESurface

## Importing Google Earth Image and Terrain Data

You can import Google Earth images and create a AutoCAD Civil surface based on the terrain data from the image location in one step. The location of the surface points is based on the closest values obtained from the transformation of the Google Earth geographical coordinates to the linear coordinates of the drawing.

The image that is displayed in the Google Earth 3D Viewer is the source image whose terrain data will be imported. Before you start, ensure that no tilting, turning, or rotation have been applied to the image.

**To create a surface and import an image using the Google Earth data**

1 In Google Earth, fly to a point of interest (see the *Google Earth User Guide* for more information).

2 Click Insert tab ➤ Import panel ➤ Google Earth drop-down ➤ Google Earth Image And Surface  .

3 Follow the instructions at the command prompt and, depending on whether your drawing has a coordinate system defined (see Specifying Units and Zone Settings (page 63)), do one of the following:

■ Choose to locate the image and surface using the defined coordinate system or manually identify the image location.

■ Manually identify the image and surface location and orientation.

**Quick Reference**

Ribbon

File ➤ Import ➤ Import Google Earth Image And Surface

Command Line

ImportGEData

# Importing Google Earth Elevation Data as a Mesh

You can import the elevation data for the current Google Earth view as a polygon mesh.

The image that is displayed in the Google Earth 3D Viewer is the source image whose elevation data is imported as a polygon mesh.

Before you start, ensure that no tilting, turning, or rotation have been applied to the source image. For best results, zoom in the displayed view, so that surface terrain details are visible.

**To import a Google Earth mesh**

---

**IMPORTANT** Before importing Google Earth elevation data, maximize the Google Earth application window.

---

1 In Google Earth, fly to a point of interest (see the *Google Earth User Guide* for more information).

2 In AutoCAD Civil, clickInsert tab ➤ Import panel ➤ Google Earth drop-down ➤ Google Earth Image And Surface  .

3 In the drawing, specify the insertion point and rotation angle to orient the image. The mesh is imported into the drawing.

---

**NOTE** If a map projection coordinate system is defined, AutoCAD Civil can automatically place the image or terrain data in the proper location in the drawing.

---

AutoCAD Civil creates a render material, using the displayed Google Earth 3D Viewer image. This render material is associates with the current drawing and assigned to the created mesh.

The image captured from the Google Earth view is saved in the same folder as the current drawing. The image filename inherits the first three letters from the drawing file name.

4 Optionally, to view the image draped on the mesh, select Realistic from the Type list in the Material Editor of the Materials window. For more information, see Object Rendering (page 1577) and Draping Images On Surfaces (page 695).

When importing the Google Earth elevation data to a AutoCAD Civil drawing, note the following:

■ When you place the mesh into the drawing, you can use the AutoCAD MOVE and ROTATE commands to refine the position of the mesh relative to your model. Do not adjust the position of your model. Rather, adjust the position of the mesh relative to your model.

■ The dimensions of the mesh are defined by the extent of longitude and latitude that the mesh covers in Google Earth, and transformation of these extents to the linear units of the drawing.

■ The mesh size is fixed at 32 rows by 32 columns.

■ The material created in the drawing is named using the first three letters of the drawing file, followed by several random numbers.

# Publishing Civil Data to Google Earth

Use the Google Earth publishing wizard to export the 3D design data from AutoCAD Civil to Google Earth for quick visualization of the model within the context of the Earth surface imagery.

After you prepare your AutoCAD Civil drawing data, run the Publish to Google Earth command and follow the steps in the publishing wizard.

**To publish 3D design data to Google Earth**

1   Click Output tab ➤ Publish panel ➤ Publish To Google Earth 🌐 .

2   On the Describe page, specify information about the published drawing. See the Describe page of the wizard (page 1869).

3   On the Items page, specify the model space entities that you want to publish. See the Items page of the wizard (page 1869).

   **NOTE** When there are render materials attached to model space entities in AutoCAD Civil, you can publish the materials with the entities. If timespan information is attached to model space entities, this information is not published to Google Earth when you select to publish render materials. See Attaching Time Information to Model Data (page 1670).

4   On the Geo-Reference page, use the controls to transform the linear coordinates of the drawing to geographic coordinates used in Google Earth. See the Geo-Reference page of the wizard (page 1870).

5   On the Nudge page, fine-tune the location of the created model. See the Nudge page of the wizard (page 1871).

6   On the File page, specify the name and location for your published file. See the File page of the wizard (page 1872).

7   Click Publish and view the status of the publishing operation.

8   After the operation is finished, click View to view the published model in Google Earth.

   **NOTE** If Google Earth is not running, it is launched and the published model is displayed in the Google Earth 3D Viewer.

The resulting .kml or .kmz file is stored in the location that you specified. You can share the published file with remote project participants, who can view it using Google Earth.

**NOTE** You can control the appearance of the published data using the Google Earth controls. For more information, see the Google Earth User Guide.

### Quick Reference

File ➤ Publish To Google Earth

Command Line

PublishKML

PublishKMZ

Dialog Boxes

# Attaching Time Information to Model Data

The GETime command enables you to attach the timespan information to civil object entities. When you import civil model data that contains the timespan information to Google Earth, you can view the information sequentially or as an animation.

You can attach time-related information to each piece of the model data and then display these data based on start and end times (timespan). This command is useful when presenting project development over time.

In Google Earth, you can use the Time slider in Google Earth to control the display of the model data. You can, for example, redefine the time range or move the time range to a different point on a timeline. For more information on Google Earth timeline playback controls in the 3D Viewer, see "Viewing a Timeline" in the *Google Earth User Guide*.

Before you assign a timespan to a civil model, decide on the best way to associate time information with the various entities. For example, you can assign a timespan to each stage of a land development project from modeling a subdivision layout to grading work, or building a road. Alternatively, you can show the progress of each individual stage separately.

**To attach time information to an object**

**NOTE** If you plan to publish your model to Google Earth in the same session, ensure that Google Earth is running.

1   In the drawing, do one of the following:

■   Select an object. Click Surface tab ➤ General Tools panel ➤ Google Earth Timespan 🕒 .

■   At the command line, enter GETime.

**2** Select an object to assign timespan information and press Enter.

**3** In the Timespan for Google Earth dialog box (page 1873), specify the start and end dates by selecting them from the calendar. Click OK.

**4** Repeat steps 2 to 3 to assign timespan information to any other objects.

---

**TIP** Hover over an object to see a tooltip with timespan information attached to the model space entity.

---

**5** When finished, publish the model to Google Earth. See Publishing Civil Data to Google Earth (page 1669).

You can view the published model in the Google Earth 3D Viewer and adjust the necessary parameters using the timeline controls. See "Viewing a Timeline" in the *Google Earth User Guide*.

When you attach timespan information to Civil models, note the following:

■ If you do not attach the start-time information to an object entity, Google Earth starts the playback from the beginning of the timeline.

■ If you do not attach the end-time information to an object entity, Google Earth starts the playback from the start-time point and continues up to the end of the timeline.

■ An object entity without any timespan information attached is displayed in Google Earth constantly.

■ When publishing an object to Google Earth, you can not attach time information to this object and associate a render material with it at the same time.

Dialog Box

Timespan for Google Earth (page 1873)

# Google Earth Import and Export Command Reference

You can use commands to quickly access Google Earth import and export functionality.

The following table lists the AutoCAD Civil commands related to import and export operations with Google Earth and briefly describes their functionality.

| Command | Description |
| --- | --- |
| GETime | Attaches the timespan information to civil object entities (page 1670) |
| ImportGEData | Imports Google Earth image and terrain data into a created TIN surface (page 1667) |
| ImportGEImage | Imports a Google Earth Image into a drawing (page 1665) |

| Command | Description |
| --- | --- |
| ImportGEMesh | Imports elevation data of the current Google Earth view into AutoCAD Civil as a mesh (page 1668) |
| ImportGESurface | Imports Google Earth terrain data into a created TIN surface (page 1666) |
| PublishKML | Publishes Civil design data to Google Earth in the KML (uncompressed) format (page 1669) |
| PublishKMZ | Publishes Civil design data to Google Earth in the KMZ (compressed) format (page 1669) |

# LandXML Import and Export

# 41

Use the AutoCAD Civil LandXML import and export commands to import and export drawing data in LandXML format.

See Understanding LandXML Import and Export (page 1673) for a list of objects that are supported in AutoCAD Civil 2010.

The LandXML import and export functionality is based on the LandXML schema.

AutoCAD Civil supports the following LandXML schema versions:

- LandXML-1.0

- LandXML-1.1

- LandXML-1.2

For more information about the LandXML schema, go to *www.landxml.org*.

## Understanding LandXML Import and Export

LandXML provides a non-proprietary data standard that is driven by an industry consortium of partners.

Use LandXML to transfer data to another drawing or to another application that supports imported XML. For example, you can use LandXML to transfer surfaces between drawings.

Many AutoCAD Civil objects are supported for LandXML import and export. See Supported LandXML Data for Drawing Import and Export (page 1674)for a list of supported objects.

In addition, Survey database data can be imported and exported. For more information, see Importing Survey XML Data.

By transforming AutoCAD Civil drawing data to LandXML, you can:

- **Exchange data**. Import LandXML data into other software applications. The data can then be modified and delivered to customers and agencies in the required formats.

- **Transfer or archive data**. Transfer data to another AutoCAD Civil drawing. Also, you can archive data in a non-proprietary format.

- **Convert units**. Export data using imperial measurements. Then, import it using metric to scale and convert values.

■ **Translate/rotate coordinates**. Globally adjust the elevations of data.

# Supported LandXML Data for Drawing Import and Export

LandXML supports AutoCAD Civil drawing data for import and export.

### General Data Handling

All coordinate locations are always treated as Northing, Easting, Elevation (or Y,X,Z).

All station values are treated as the actual measured distance along the alignment or geometry. Station equations are always imported or exported (if they are defined) with alignment data. However, they are not applied to any geometric station locations in the data; they are used only for display and reporting purposes.

Point references to pointType derived locations <CgPoint pntRef="100"/> are supported. The supported references include: CgPoint, Start, Center, End, Monument, and CrossSectPnt elements. For more information, see .

### LandXML Elements Supported for Drawing Import

| LandXML Element Supported | Notes |
| --- | --- |
| Units | |
| Application | |
| Author | |
| CoordinateSystem | Uses Map Zone name / European Petroleum Survey Group (EPSG) name |
| **CgPoints** | Supports multiple elements. If <CgPoints> is named, a corresponding point group is created and COGO points are added. |
| CgPoint | Imports a COGO point and uses name and desc or code attributes. Number is auto-assigned if name is alpha-numeric, but name is maintained. |
| **Alignments** | |
| CoordGeom | Lines, curves, spirals, and irregular lines. |
| AlignPI | |
| StaEq | |
| Superelevation | |
| DesignSpeeds | |

| LandXML Element Supported | Notes |
|---|---|
| Profiles | Finished ground, design profiles created using imported lines (PVIs), circular vertical curves, parabolic, symmetric, and asymmetric vertical curves. |
| ProfAlign | All elements supported |
| ProfSurf | PVI, pointlist data for a sampled ground surface |
| CrossSects | |
| CrossSectSurf | As sample lines in sample line group associated with alignment |
| DesignCrossSectSurf | As subassembly |
| **Parcels** | Creates parcels from data |
| CoordGeom | All elements supported |
| **Monuments** | Creates COGO points in a monuments points group |
| **Surfaces** | |
| SourceData | |
| Breaklines | Imported as 3D polylines on layer "<surface-name>_Breaklines" |
| Contours | Imported as 3D polylines on layer "<surface-name>_Contours" |
| DataPnts | Imported as COGO point group named "<surfa-cename>_DataPoints" on layer "<surface-name>_DataPoints" |
| Definition | |
| TIN | Option to import faces, then either update trian-gulation or maintain the triangulation in the file. Supports face edge visibility and face neighbor optimization attributes. |
| GRID | |
| **Survey** | |
| ReducedObservations | Creates COGO points in an observations point group. |

| LandXML Element Supported | Notes |
| --- | --- |
| | **IMPORTANT** Using the Import LandXML command from the File menu does not import survey data into the survey database. For more information, see Importing Survey XML Data. |
| SurveyMonuments | Creates COGO points in a monuments point group |
| **PlanFeatures** | |
| CoordGeom | Imported as 3D polylines to current layer |
| **PipeNetworks** | Each <Pipe Network> is imported as a AutoCAD Civil pipe network |
| Pipe | Supports curved pipe |
| Units.diameterUnit | |
| Structs | |
| Units.diameterUnit | |
| PipeFlow | |
| StructFlow | |

**Supported LandXML Elements for Drawing Export**

| LandXML Element Supported | Notes |
| --- | --- |
| Units | Always exported |
| Application | Always exported |
| Author | |
| CoordinateSystem | Uses Map Zone name / European Petroleum Survey Group (EPSG) name |
| **CgPoints** | Point group exports as <CgPoints> with matching name and all points export. If an AutoCAD Civil point has a point name, the name is exported to the LandXML point name attribute. Otherwise, the point number is exported to the LandXML point name attribute. |
| **Alignments** | |
| CoordGeom | As lines, curves, and spirals. |
| AlignPI | |

| LandXML Element Supported | Notes |
| --- | --- |
| StaEq | |
| Superelevation | |
| DesignSpeeds | |
| Profiles | |
| ProfAlign | Design profiles with lines, circular vertical curves, parabolic, symmetric, and asymmetric vertical curves. |
| ProfSurf | |
| CrossSects | |
| CrossSectSurf | Sample lines exported as CrossSectSurfs |
| DesignCrossSectSurf | Assemblies exported as DesignCrossSectSurfs |
| **Parcels** | |
| CoordGeom | As lines, curves, and spirals. |
| **Surfaces** | TIN, GRID, and volume surfaces exported. |
| SourceData | |
| Breaklines | |
| Contours | |
| DataPnts | |
| Definition | |
| TIN | |
| GRID | |
| **Roadways** | Corridors exported as <Roadways> with references to <Alignments> with Profiles and Cross Sections (both sampled ground and design sections) and to one or more reference surfaces. |
| **PipeNetworks** | |
| Pipes | |
| Units.diameterUnit | |
| Structs | |

| LandXML Element Supported | Notes |
|---|---|
| Units.diameterUnit | |
| PipeFlow | |
| StructFlow | |

## LandXML and Sites

In an AutoCAD Civil drawing, a site is used to collect or group sub-collections, such as parcels, alignments, and gradings, by a topology that they share.

When objects that are grouped under the Sites collection are exported to a LandXML file, the site name is exported with them.

When objects are imported from a LandXML file into the drawing, two site pickers are displayed:

■ Alignments Site allows you to specify the site on which the alignments will reside. The default selection is <none>, which places the alignments in the top-level Alignments collection and prevents them from interacting with parcels.

■ Parcels Site allows you to specify the site on which the parcels will reside. If no sites exist in the drawing, the parcels are placed on the default site (Site 1). If the LandXML file has a site name for its features, then that site name is created in the drawing and the parcels are assigned to it.

For more information about sites, see Understanding Sites (page 719).

## Handling Duplicate LandXML Data on Import

When objects in the drawing have identical names to objects in a LandXML file, the imported data can be skipped, renamed upon import, or it can overwrite the existing data.

You can specify your preference for handling duplicate data under Conflict Resolution Settings on the Import tab of the LandXML Settings dialog box (page 1978).

# Viewing and Editing LandXML Drawing Settings

You can view and edit LandXML settings for the entire drawing.

These settings control how data is converted between AutoCAD Civil and a LandXML file, including coordinate translation and rotation, and description information.

In the Toolspace, on the Settings tab, right-click the drawing collection, then, click Edit LandXML Settings. Use the LandXML Settings (page 1978) dialog box, to view and edit all of the LandXML settings for the drawing.

For more information about using the Toolspace and the Settings tab, see The Toolspace Window (page 80).

## Viewing and Editing the LandXML Import Settings

Control how LandXML data is inserted into the drawing when the file is imported.

**To view and edit LandXML import settings**

1 In Toolspace, on the Settings tab, right-click the <drawing name> collection ➤ Edit LandXML Settings.

2 In the LandXML Settings dialog box, click Import tab (page 1978) and modify the settings.

**3**  Click OK.

The settings are saved as the default settings for the drawing.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click <drawing name> ➤ Edit LandXML Settings

Dialog Box

LandXML Settings (page 1978)

## Unit Conversion for LandXML Data

AutoCAD Civil uses conversion factors if the LandXML file you are importing has different units from the current drawing.

You can import LandXML files that use feet or meters.

When imported, the LandXML files are converted to the units of the current drawing. In AutoCAD Civil, the default drawing units can be meters, International Feet, or U.S. Survey Feet. For more information, see Specifying Units and Zone Settings (page 63).

**NOTE** Previously, it was required that you specify International or US Survey Foot in the LandXML settings. This specification is now done in the drawing settings.

**NOTE** Unit conversion is not applied to descriptive LandXML attributes that may contain numeric values. For example, if you are importing a point with the description "12 oak" into a metric project, it will not be changed to "305mm oak."

## Translating and Rotating LandXML Data

Translate imported coordinate data by specifying translation and rotation settings. Use the Import tab of the LandXML Settings dialog box to set the values.

■ **Base point values**. The base point coordinates in the drawing are used to translate and rotate all imported values. These coordinates are in the drawing units.

■ **Translate coordinate values**. The coordinate values are used to translate data from the base point. These coordinates are in the drawing units.

**NOTE** In certain circumstances, you can assign the same values to both the translated coordinates and the base point coordinates. For example, the values would be the same if you want to rotate the coordinates without translating them.

For example, the following formula is used to translate the imported elevation values:

(Translation Coordinate Elevation - Base Point Elevation) + LandXML Elevation = Imported elevation value

Therefore, if the LandXML file elevation is 90 feet, the base point elevation is 0.000 feet, and the translate coordinate elevation is 10.000 feet, the formula is:

(10.000 - 0.000) + 90 = 100

■ **Rotation angle and direction**. The angle and direction, measured about the base point, about which the data is rotated.

## Viewing and Editing the LandXML Export Settings

Control how data in AutoCAD Civil is exported to a file in LandXML format.

**To view or edit LandXML export settings**

1   In Toolspace, on the Settings tab, right-click <drawing name> ➤ Edit LandXML Settings.

2   In the LandXML Settings dialog box, click the Export tab (page 1981) and modify the settings.

For more information, see Point Reference Export Options (page 1680) and Point Description and Code Matching (page 1680).

3   Click OK.

The settings are saved as the default settings for the drawing.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: Right-click <drawing name> ➤ Edit LandXML Settings

Dialog Box

LandXML Settings (page 1981)

## Point Reference Export Options

When selecting the data to export, you can choose to export point references. Set the Export Point References property on the Export tab (page 1981) of the LandXML Settings dialog box to On.

When you turn this option on, AutoCAD Civil creates COGO point references, where possible, for the parcel, alignment, and surface geometry. This means that, if the geometry of parcels, alignments, and surfaces in the drawing match COGO point coordinates within a specified tolerance, the object coordinates are exported to the LandXML file as references to those COGO points.

Point references substitute a known point name instead of using northing and easting coordinates. For example, without a point reference, the start point of a line element is written as follows:

```
<Start>5447.73530 4525.60643</Start>
```

With a point reference, it is written as follows:

```
<Start pntRef="371"></Start>
```

It is also valid for a coordinate geometry element to have a mix of pntRef and coordinate values as shown in the following example:

```
<Line> <Start pntRef="250" /> <End>5632.87775298 3944.16966215</End> </Line>
```

This situation could occur for the endpoint if a COGO point does not exist within the specified tolerance.

## Point Description and Code Matching

Match the AutoCAD Civil description information with LandXML attributes. Use the Code Attribute and Desc Attribute property groups on the Export tab of the LandXML Settings dialog box.

You can either disable or match the 'code' attribute in LandXML to a point's description:

■   **Disabled**: Does not export a point description to the 'code' attribute.

- **Raw Description**: Exports a point raw description to the 'code' attribute.

- **Full Description**: Exports a point full description to the 'code' attribute.

---

**NOTE** Typically, you would export the raw description to the 'code' attribute.

---

You can either disable or match the 'desc' attribute in the LandXML to a point's description:

- **Disabled**: Does not exports a point description to the 'desc' attribute.

- **Raw Description**: Exports a point raw description to the 'desc' attribute.

- **Full Description**: Exports a point full description to the 'desc' attribute.

---

**NOTE** Typically, you would export the full description to the 'desc' attribute.

---

You can also specify whether to export the full description if it is the same as the raw description. For example, if the raw and full descriptions are the same, then only one value is exported. This would occur when points do not have defined description keys.

# Importing LandXML Drawing Data

Import LandXML data into the current AutoCAD Civil drawing.

Importing LandXML data into AutoCAD Civil is a two-step process:

1. Specify the import settings that prepare the data for import. For more information, see Viewing and Editing LandXML Drawing Settings (page 1678).

2. Select the files and the specific data in the file to import.

The LandXML import functionality automatically handles the conversion between the units specified in the LandXML file and the current drawing units.

---

**NOTE** LandXML does not transform coordinate systems automatically. No specific coordinate system transformation is applied other than what is specified by the translation and rotation settings (page 1679).

---

**To import LandXML data**

1. Click Insert tab ➤ Import panel ➤ LandXML 🗃 .

2. In the Import LandXML dialog box, select or browse to the LandXML (*.xml*) file you want to import. Click Open.

3. In the Import LandXML dialog box (page 1977), select sites for the alignments and parcels. See LandXML and Sites (page 1678) for more information.

4. The data tree displays each of the major data collections in the LandXML file. Use the data tree to:
   - Navigate a data collection and view its subcomponents.

   - Expand the collections. Select or clear the check boxes to filter the data types that you want to import into the drawing. By default, all data components are selected for import.

---

**NOTE** The check boxes have a tri-state display. If only some objects are selected under a collection, the check box is shaded ☑ . If all the items are selected, the check box is selected ☑ . If all the items below the collection are cleared, the check box for the collection is cleared ☐ .

---

**5** Click OK to import the LandXML file or click Browse to select another LandXML file.

After you click OK, the data is imported into the drawing. The data components are added to the drawing's applicable data collections in the Prospector tree.

**NOTE** As each object is imported, the Event Viewer Vista (page 2455) dialog box can display the status of each operation. For more information, see The Event Viewer Vista (page 1626).

Dialog Box

Import LandXML (page 1977)

# Exporting LandXML Drawing Data

Export LandXML drawing data from AutoCAD Civil.

You can select the Export LandXML command from the File menu, or you can right-click an object collection in the Prospector tree and select the command.

When you export from the Prospector tree, the Export To LandXML dialog box contains a pre-defined selection set of that collection's data. When you export from the File menu, all drawing data is selected by default, and you can adjust the selection by clearing check boxes. You can alternately specify the objects to export by selecting them from the drawing.

**To export LandXML data**

**1** Click Output tab ➤ Export panel ➤ Export To LandXML .

The Export To LandXML (page 1983) dialog box, which contains a data tree, is displayed. In the tree, each of the major data collections is available for export to the LandXML file.

**2** Do one of the following:

- Select or clear the check boxes to filter the data types that you want to export to the LandXML file. Then click OK.

  **NOTE** The check boxes have a tri-state display. If only some objects are selected under a collection, the check box is shaded . If all the items are selected, the check box is selected . If all the items below the collection are cleared, the check box for the collection is cleared .

- Select data from the drawing by clicking and selecting the objects in the drawing. Press *Enter* after you finished selecting the objects.

**NOTE** When you select one point in a point group, the entire point group is selected. If the point belongs to more than one point group, the point group with the highest display order is selected. For more information, see Changing the Point Group Display Order (page 526).

**3** Specify the LandXML schema version.

**4** In the Export To LandXML dialog box, enter the name of the LandXML (*.xml*) file you want to export and specify the location. Click Save.

# Importing Architectural Data

# 42

Use the Import Building Site command to import architectural model data from Autodesk Revit Architecture to AutoCAD Civil in a collaborative design project.

By implementing the seamless data exchange between Autodesk Revit Architecture and AutoCAD Civil, a site design team can

- Finalize the site plans before the architectural design has been completed.

- Obtain enough information to start preparing the site for construction.

- Reduce the communication cycle between architectural and civil engineering teams.

🔊 Importing Architectural Data Workflow

## Publishing a Design Package File

Use Autodesk Revit Architecture to prepare and publish an architectural model package file.

An architect prepares the architectural model in Autodesk Revit Architecture, applies the corresponding templates, visibility settings and filters, and then publishes the model to the design package file (.adsk). The imported model represents a gross area footprint of the building, with property and utility connection points.

The design package file serves as a medium for sharing data between Autodesk Revit Architecture and AutoCAD Civil and contains the following elements:

- An image of a building footprint

- Data for the building footprint (for example, area and perimeter)

- Images of building model categories (doors, floors, roofs) visible in specific views

- Data for the building model categories (for example, slope and area for the Roof model category)

- An image of a site model

- Base point coordinates data (Easting, Northing, and elevation)

- Property line graphics

- Project information data (for example, building type, occupancy, and total gross building area)
- Package file metadata for workflow type, OPC, and utilities

The following high-level procedure is performed by an architect in Autodesk Revit Architecture to prepare the architectural model for sharing with AutoCAD Civil.

**To publish a design package file in Autodesk Revit Architecture**

- Prepare and simplify the file. The user applies a Civil Engineering View template and related visibility settings and filters.
- Launch the Export Module and specify export settings. The user specifies a footprint level, location, base point, and the number of building model elements to export.
- Save the file. The user specifies the file location and file name.
- View the Export Building Site report that lists a summary of the output contents.

For details, see Exporting Building Sites in the *Autodesk Revit Architecture 2010 User's Guide*.

# Preparing for Importing a Design Package File

Close interaction of architects and civil engineers is important when sharing data between Autodesk Revit Architecture and AutoCAD Civil.

The following is a summary of issues that you should be aware of and steps that you can perform to facilitate the collaboration effort:

- When preparing a design package file for export, the architect can create site utilities with host connectors that are functional in AutoCAD Civil. You should make the architect aware of the utilities that are relevant to the civil project beforehand, so they are exported with the design package file. If the required utilities are not supported in Revit Architecture, the architect would be able to notify you. If you prefer to set up the utility connections yourself, ask the architect to omit the Utilities parameter in the export settings.
- Before finalizing the building site model export, the architect may contact you about the site survey point coordinates, so they can be exported with the model file.
- The architect should apply as much model simplification settings as possible. You should communicate to the architect your minimum requirements regarding the design package file content.
- If the import operation is slow, you can request the architect to reexport the model with modified settings to reduce file size.
- The Export Building Site report is saved with the ADSK building site model file. You can use the report to compare the content of the original file with the imported file.
- Establish a procedure when every time the source design package file is modified, the architect notifies you immediately, so you can update the building site object in your drawing.

# Using the Wizard to Import a Building Site Object

Use the Import Building Site wizard to bring the architectural model, created in Autodesk Revit Architecture, into AutoCAD Civil, confirm and compare the building site units the Civil drawing units, and specify the object insertion point.

**To import a building site object**

1   Click Insert tab ➤ Import panel ➤  ➤ Import Building Site  .

2   On the Select File page of the Import Building Site wizard, click  and select the published ADSK file to import.

   The model image appears in the Preview window. The  marker shows the base point specified in the building site object.

3   Click  to select or modify a template for the building site object name.

4   Optionally, use the ViewCube to manipulate the object in the Preview window. See Overview of ViewCube in the *AutoCAD User's Guide*.

5   Click Next.

   **NOTE** You can click Finish at any time to close the wizard and finish the import.

6   On the Confirm Units page, compare the units used in the building site object, as defined in the ADSK file, with the units used in the current AutoCAD Civil session. All the controls on this page are read-only. Use them for reference information.

7   Click Next.

8   On the Display Properties page, click  to specify the object layer (page 1985).

9   Optionally, click  to edit the default building site style. See Editing a Building Site Style (page 1688).

10   Click Next.

11   On the Insertion Point page, confirm and modify the coordinates and rotation angle of the building site object base point or click Specify In Drawing to orient the model in the drawing manually.

12   Optionally, click Preview to insert the building site object into the drawing as a test.

13   Do one of the following:
   ■   If you are in preview mode, press *Esc* to return to the Import Building Site wizard and continue fine-tuning the base point location.

   ■   Press *Enter* to close the Import Building Site wizard and leave the building site object in the drawing.

14   Click Finish.

Ribbon

Click Insert tab ➤ Import panel ➤  ➤ Import Building Site  .

Command Line

ImportBuildingSite

Dialog Box

Import Building Site wizard (page 1794)

# Creating a Building Site Style

Use the building site style to determine the display properties of the building site object components, such as building footprint, property lines, utilities, site model, and building model.

Use the Toolspace Settings tree to create a building site style.

**To create a building site style**

1   In Toolspace, on the Settings tab, right-click the Building Site Styles collection and click New.

2   On the tabs of the Building Site Style (page 1796) dialog box, enter the required data or specify the settings.

3   Click OK.

## Quick Reference

Toolspace Shortcut Menu

  Settings tab: Building Site ➤ right-click Building Site Style ➤ Edit

Dialog Box

  Building Site Style (page 1796)

# Editing a Building Site Style

Edit the building site style that determines the display properties of the building site object components, such as building footprint, property lines, utilities, site model, and building model.

Use the Toolspace Settings tree to edit a building site style.

**To edit a building site style**

1   In Toolspace, on the Settings tab, right-click the name of the building site style that you want to edit and click Edit.

2   In the Building Site Style (page 1796) dialog box, change the properties of the building site style.

3   Click Apply and then OK.

## Quick Reference

  EditBuildingSiteStyle

Dialog Box

  Building Site Style (page 1796)

# Modifying a Building Site Object in the Drawing

Use the EditBuildingSite command to edit the properties of the building site object in the drawing.

**To edit the building site object properties**

1   In Toolspace, on the Prospector tab, right-click a Building Site item and select Building Site Properties.

2   In the Building Site Properties (page 1798) dialog box, modify the name of the building site object, enter or edit the description, and modify the style.

3   Click Apply and than OK.

## Quick Reference

Toolspace Shortcut Menu

Prospector tab: Building Site ➤ right-click <building site name> ➤ Building Site Properties

Command Line

EditBuildingSiteStyle

Dialog Box

Building Site Properties (page 1798)

# Updating a Building Site Object Definition

Use the UpdateBuildingSite command to update the building site object that was imported into the drawing.

You use this command if the source architectural model has changed and a new ADSK package file was

posted in the shared location. When changes are made to the package file, the out-of-date icon   displays next to a building site item in the Prospector tree. You can update the building site object references without reimporting the object into the drawing.

**To update a building site definition**

1   In Toolspace, on the Prospector tab, right-click a Building Site item and select Update Building Site Definition.

2   In the Select Autodesk Exchange File dialog box, select the updated ADSK file.

3   Click Open.

The definition of the imported building site object is updated and all its references are redefined with new data.

## Quick Reference

Toolspace Shortcut Menu

Command Line

UpdateBuildingSite

# Command Reference

You can use commands to quickly access the functionality of the Building Site object.

The following table lists the AutoCAD Civil commands that relate to editing, importing, and updating the Building Site object, and briefly describes their functionality:

| Command | Description |
| --- | --- |
| EditBuildingSite | Opens the Building Site Properties dialog box, where you can modify the properties of the building site reference object (page 1688) |
| EditBuildingSiteStyle | Opens the Building Site Style dialog box where, you can edit the building site style (page 1688) |
| ImportBuildingSite | Imports a building site object into a Civil drawing (page 1686) |
| UpdateBuildingSite | Updates a building site object definition when the original building site object data were changed (page 1689) |

# Plan Production Tools

# 43

Use AutoCAD Civil plan production tools to quickly create construction documents from drawings.

## Understanding Plan Production Tools

AutoCAD Civil plan production tools automate the process of creating construction documents from your designs.

Use the plan production tools to quickly create sheets that automatically display sections of alignments and profiles in your plans.

Instead of having to manually create viewports along an alignment, and manually recreate sheets each time your data changes, you can create view frame groups that automatically capture predefined areas along an alignment. Select an alignment in your drawing and in just a few minutes you can create sheets that automatically display the desired data.

The plan production tools include the following components:

■ **Plan Production commands**. You can access the plan production commands from the Output tab and Plan Production contextual tab on the ribbon. The Plan Production contextual tab is displayed when you select a view frame or a match line in the drawing.

■ ⬚ **Create View Frames Wizard**. Start the process of using the plan production tools by using this wizard to define a group of view frames along an alignment. For information, see Creating View Frames (page 1703).

■ ⬚ **View Frame Group**. The view frame group object helps you manage a single group of view frames that are displaying consecutive station ranges along the same alignment. You can set many options at the view frame group level, such as styles and labeling. View frame group objects are displayed in the Prospector tree, and you can control their default command settings in the Settings tree. For information, see The View Frame Group Object (page 1694).

■ ⬚ **View Frames**. View frames are rectangular-shaped regions along an alignment that define an area that will be displayed in a sheet. The view frame size, shape, and scale comes from a designated viewport that exists on the layout tab of a specified template. After view frames are created, the properties of the view frame objects are saved in the currently open drawing. The view frame objects are displayed in the drawing and in the Prospector tree, and you can control their default style and labeling in the Settings tree. For information, see The View Frame Object (page 1695).

- ▣ **Match Lines**. In the AutoCAD Civil plan production features, a match line is a straight line that indicate locations in a view frame group where one view frame intersects or matches up with another view frame. Match lines are only displayed in paper space and only in plan view. They are designed to visually indicate the locations (start and end stations) along an alignment where each view frame begins and ends. Match lines have their own object style and they typically include labels that can identify both the previous and next sheet (view frame) along an alignment. You have the option to include a left side match line label, a right side match line label, both, or none, and you can choose where along the match line you want the label to be displayed (top, middle, end of match line). Like view frame objects, match line objects are also displayed in the Prospector tree, and you can control their default style and labeling in the Settings tree. For information, see The Match Line Object (page 1696).

- ▣ **Create Sheets Wizard**. After you have used the Create View Frames wizard, the next step is to use the Create Sheets wizard to quickly create your sheets. For information, see Creating Sheets (page 1719).

After you have created view frames and sheets, you can then use the Sheet Set Manager to organize, publish, share, and manage sheet sets. For information, see "Work with Sheets in a Sheet Set" in the AutoCAD Help.

# Prerequisites for Using Plan Production Tools

A few prerequisites must be in place before you can use the plan production tools.

You can use the plan production tools if you have a drawing that contains an alignment, and if you have access to a template that contains certain types of preconfigured viewports.

Because there are three different categories or types of sheets that you may want to create (plan and profile, plan only, or profile only), the prerequisites are slightly different depending on the type of sheets you want to create.

The simplest way to get started using the plan production tools is to create "plan only" sheets. As long as the current drawing contains an alignment, and you can access the Plan Only template supplied with AutoCAD Civil (which is named *Civil 3D (Imperial) Plan only.dwt*), you can successfully use both wizards. If the current drawing does not contain an alignment, or if you do not have access to the correct type of template, you will not be able use the Create View Frames wizard.

The following table summarizes the prerequisites for using plan production tools:

| Sheet type | Prerequisites for using plan production tools |
|---|---|
| Plan Only | ■ The current drawing must contain an alignment.<br><br>■ You must be able to access a template that contains a viewport with a Viewport Type defined as Plan, such as the *Civil 3D (Imperial) Plan Only.dwt* template located in the Template\Plan Production folder. |
| Profile Only | ■ The current drawing must contain an alignment and a profile.<br><br>■ You must be able to access a template that contains a viewport with a Viewport Type defined as Profile, such as the *Civil 3D (Imperial) Profile Only.dwt* template located in the Template\Plan Production folder. |
| Plan and Profile | ■ The current drawing must contain an alignment and a profile. |

| Sheet type | Prerequisites for using plan production tools |
|---|---|
| | ■ You must be able to access a template that contains a viewport with a Viewport Type defined as Plan, and a viewport with a Viewport Type defined as Profile, such as the *Civil 3D (Imperial) Plan and Profile.dwt* template located in the Template\Plan Production folder. |

**NOTE** When you install AutoCAD Civil, the sample plan production templates are installed to the following location by default: *C:\Documents and Settings\<user name>\Local Settings\Application Data\Autodesk\Civil2010\enu\Template\Plan Production*.

For more information about setting the Viewport Type in a template, see Configuring Viewports for Plan Production (page 1700).

For step-by-step information about how to use the wizards, see Creating View Frames (page 1703) and Creating Sheets (page 1719).

# Plan Production Tools Object Styles and Display

Object styles control how plan production tool objects (view frames and match lines) are displayed.

The following illustration shows the view frame and match lines collections in the Settings tree:

The following table describes the display styles available for the plan production tools components:

| Plan Production Tool Object | Display and labeling styles available |
|---|---|
| View Frames | View frame style and view frame label style |
| Match Lines | Match line style and match line label style |
| View Frame Group | View frame groups are non-graphical objects that manage a collection of view frames and match lines. At the view frame group level, you can set the display and label style defaults for view frames and match lines. |

For more information about styles, see Object Styles (page 53), View Frame Style dialog box (page 2098) and Match Line Style dialog box (page 2099).

For more information about labeling for view frames and match lines, see Labeling View Frames (page 1713), and Labeling Match Lines (page 1718).

Before creating view frames and view frame groups, you should be familiar with creating and managing styles (page 53).

The top-level plan production tool object, the view frame group object, has command-level settings that can be configured from the Settings tree. For general information about command settings, see command settings (page 97).

**See also:**

■  Edit Feature Settings - View Frame Group Dialog Box (page 2081)

■  Edit Feature Settings - View Frame Dialog Box (page 2084)

■  Edit Feature Settings - Match Line Dialog Box (page 2084)

# The View Frame Group Object

View frame groups persist in an AutoCAD drawing as objects with the name AeccViewFrameGroup.

A view frame group object manages a group of view frames that are created while using the Create View Frames wizard. When you use the Create View Frames wizard, you are prompted to enter a name and other object creation criteria for a view frame group. Each view frame group manages the view frames and match lines for a single alignment.

**See also:**

■  Understanding Objects and Styles (page 51)

# View Frame Groups Collection (Prospector Tab)

Use the View Frame Groups collection in the Prospector tree to access the view frame groups in a drawing or a project.

After View frame group objects are created, they are displayed in the View Frame Groups collection in the Prospector tree.

When you expand a view frame group in Prospector, you can see the view frames and match lines associated with it. Expand the View Frames or Match Lines collections to view the names of the view frames or match lines in that group. Selecting an individual view frame or match line in Prospector displays a tabular list of the view frame and match line data in the Prospector list view. For more information, see The Toolspace Item View (page 82).

# View Frame Group Collection (Settings Tab)

Use the View Frame Group collection in the Settings tree to manage view frame group settings and command settings.

Right-click the View Frame Group collection to do the following:

■  Edit the view frame group feature settings.

■  Edit the view frame group label style default settings.

■ Refresh the display of the settings tree.

For more information, see "The Object Collection (Settings Tree)".

Expand the View Frame Group collection to display and edit the default styles and command settings that are available for view frame groups.

| For information about... | See... |
|---|---|
| View frame group settings | Edit Feature Settings - View Frame Group Dialog Box (page 2081) |
| View frame group styles | Plan Production Tools Object Styles and Display (page 1693) |

# The View Frame Object

View frames persist in an AutoCAD drawing as objects with the name AeccViewFrame.

View frame objects are created automatically when you use the Create View Frames wizard. View frames are always associated with a parent view frame group object.

View frames are created based on an alignment in the drawing, and on a designated plan view or profile view viewport in a template. When you choose to create sheets that will contain profile view data in addition to plan view data, you must also have a profile in the drawing. The properties of the view frame are saved in the drawing in which you create the view frame.

Most of the view frame object information is derived from the viewport information specified in the template. For example, the view frames you create get their size and scale from the viewport in the template. Similarly, the sheet layout is also derived from the referenced template.

An important concept to understand is that the viewports in the referenced template must have a property called Viewport Type set to either plan or profile, depending on the type of data you want that viewport to display. For more information, see Configuring Viewports for Plan Production (page 1700).

**See also:**

■ Understanding Objects and Styles (page 51)

# View Frame Styles and Display

How view frames are displayed is controlled by a view frame style, a view frame label style, and choices made on the Create View Frames wizard.

**View Frame Style**

The view frame style controls the appearance of the view frame. You can set typical style characteristics, such as visibility, layer, color, linetype, linetype scale, and lineweight.

View frames have only one display component, the border, which is visible only in plan view.

For more information, see View Frame Style Dialog Box (page 2098) or Object Styles (page 53)

**View Frame Label Style and Location**

You can specify a label style and a location for the label that will be displayed on each view frame. Set the defaults for this view frame label behavior using the View Frame Group Settings dialog box.

You can choose from a variety of locations around the view frame to place the view frame label. For example, you can choose to place view frame labels at the top left, top center, middle right, and so on. You make this choice in the Create View Frames wizard. You can change this location later, after it has been created by right-clicking the label and selecting Edit Label. For more information, see Labeling View Frames (page 1713).

## View Frames Collection (Prospector Tab)

Use the View Frame Groups collection in the Prospector tree to access the view frames in a drawing or a project. As view frame objects are created, they are displayed in the View Frame Groups collection.

Expand the View Frame Groups collection, and then expand a view frame group object beneath it to view the names of the view frames associated with a view frame group. To display a tabular list of the view frames in the Prospector list view, select a view frame in the Prospector tree. For more information, see The Toolspace Item View (page 82).

## View Frame Collection (Settings Tab)

Use the View Frame collection in the Settings tree to manage view frame feature settings, styles, and command settings.

Right-click the View Frame collection to do the following:

■ Edit the view frame feature settings.

■ Edit the view frame label style default settings.

■ Refresh the display of the settings tree.

For more information about the contents of this shortcut menu, see "The Object Collection (Settings Tree)".

Expand the View Frame collection to display and edit the styles that are available for view frames.

| For information about... | See... |
|---|---|
| View frame settings | Edit Feature Settings - View Frame Dialog Box (page 2084) |
| View frame styles | Plan Production Tools Object Styles and Display (page 1693) |

## The Match Line Object

Match lines persist in an AutoCAD drawing as objects with the name AeccMatchLine.

If you selected the Insert Match Lines check box on the Match Lines page of the Create View Frames wizard, a match line is created at each view frame intersection. The first and last view frames in a group have only one match line. For plan only sheets, you have the option to not insert match lines on the view frames. To do this, simply remove the check mark from this check box on the Create View Frames wizard.

NOTE Match lines will always be inserted in profile views. Therefore, when creating plan and profile or profile only sheets, match lines will always be inserted, and the Insert Match Lines check box is selected but unavailable (you cannot remove the check mark). If you are creating plan only sheets, you can remove the check mark from the box and match lines will not be inserted in the resulting plan views.

Properties of match lines, such as where they are positioned on the alignment, a match line style, and a match line label style, can be specified on the Match Lines page of the Create View Frames wizard. You can set defaults for their styles using the Match Line settings available on the Settings tab in Toolspace.

Match lines have a match line mask area on the outside of each match line. This lets you mask data outside of the match lines. You can set hatch pattern options for this area using the Match Line Style dialog box.

Match lines and the match line mask area are displayed only in plan views, not in profile views. The match line mask area exists only in paper space.

**See also:**

- Editing the Match Line Mask Area (page 1715)
- Understanding Objects and Styles (page 51)

## Match Lines Styles and Display

How match lines are displayed is controlled by a match line style, a match line label style, and choices made on the Match Lines page of the Create View Frames wizard.

**Match Line Style**

Use the match line style to control the appearance of the match line. You can set typical style characteristics, such as visibility, layer, color, linetype, linetype scale, and lineweight. For more information, see Match Line Style Dialog Box (page 2099) or Object Styles (page 53).

**Match Line Mask Area**

Use the match line mask area to hide or mask the area that exists between the outside of a match line and the inside border or boundary of the view frame. This component exists only in plan views, not profile views, and only in paper space. The following illustration shows an example of the two match line mask areas in gray, on the left and right sides of a plan view viewport:

The Display tab of the Match Line Style dialog box includes an option to specify a hatch pattern for this match line mask area. Use this option to help you make your construction documents look better by masking the drawing data that exists outside of the match lines. See Editing the Match Line Mask Area (page 1715) for more information.

Match line labels are displayed on top of the match line mask area, and are therefore visible over it.

**Match Line Label Style and Location**

You can specify a label style for the label that will be displayed on the left side of a match line or on the right side of a match line. Since each individual match line is displayed in two sheets, it's convenient to have the ability to set label styles differently for the label that will be displayed on the left side of the match line, and another label style for the label that will be displayed on the right side of the match line.

Also, you can display only one match line label (on the left or on the right side of the match line) by simply turning off the visibility of one match line label.

You can choose to place the left and right side match line labels at the start, end, or middle of the match line, or where the alignment intersects the match line. For more information, see Labeling Match Lines (page 1718).

Set the defaults for this match line label behavior using the View Frame Group Settings dialog box.

# Match Lines Collection (Prospector Tab)

Use the View Frame Groups collection in the Prospector tree to access the match lines in a drawing or a project.

As match lines objects are created, they are displayed in the parent View Frame Groups collection they are associated with. Expand the View Frame Group collection, and then expand a view frame group object beneath it to view the names of the match lines associated with a view frame group. To display a tabular list of the match lines in the Prospector list view, select a match line in the Prospector tree. For more information, see The Toolspace Item View (page 82).

# Match Line Collection (Settings Tab)

Use the Match Line collection in the Settings tree to manage match line settings, styles, and command settings.

Expand the View Frame collection to display and edit the styles that are available for match lines.

Right-click the Match Line collection to do the following:

■ Edit the match line feature settings.

■ Edit the match line label style default settings.

■ Refresh the display of the settings tree.

For more information about the contents of this shortcut menu, see "The Object Collection (Settings Tree)".

| For information about... | See... |
| --- | --- |
| Match line settings | Edit Feature Settings - Match Line Dialog Box (page 2084) |
| Match line styles | Plan Production Tools Object Styles and Display (page 1693) |

# Labeling Plan Production Tool Components

By default, view frames and match lines contain standard object labels.

If you want view frames and match lines to be displayed without labels, you can delete the labels or turn off the visibility of the label.

The View Frame Group page of the Create View Frames wizard contains the option for setting the view frame labels, and the Match Lines page contains the option for setting match line labels.

In the drawing, there are no labels for view frame group objects. However, since the view frame group object is the parent object for view frames, you can set label defaults for view frames using by View Frame Group collection in the Toolspace Settings tree. Right-click View Frame Group in the Settings tree, and click Edit Label Style Defaults on the shortcut menu. The Edit Label Style Defaults - View Frame dialog box is displayed. For more information, see Edit Label Style Defaults Dialog Box (Feature Level) (page 1941).

On the Toolspace Settings tab, in the View Frame ➤ Label Style collection, set up label styles to use for view frames. Do the same for match lines using the Match Line ➤ Label Style collection.

■ Labeling View Frames (page 1713)

■ Labeling Match Lines (page 1718)

# Preparing for Plan Production

Set up your drawing templates with useful viewports, along with standard styles and settings for plan production objects (view frame groups, view frames, and match lines).

Setting up templates helps you work efficiently and ensures that final drawings conform to office standards.

When you use the plan production tools, you can use predefined templates that are specifically configured for use with plan production features. These templates are located in the Templates folder.

You can also use your own custom templates or existing AutoCAD Civil templates. If you choose to use templates other than the ones located in the Plan Production folder, an important prerequisite is that you first set the viewport types for plan view or profile view. This is explained in detail in Configuring Viewports for Plan Production (page 1700).

NOTE Only templates that contain viewports that have been specially configured with a Viewport Type of either "Plan" or "Profile" can be used with the plan production tools.

In addition to setting the viewport type, you may also want to adjust the size, scale, and other viewport settings for the templates you will use for plan production.

Following is a summary of the tasks you may need to perform on your templates before using the plan production tools:

■ Ensure that the Viewport Type property is set to either Plan or Profile.

■ Adjust viewport settings, such as size, scale, and so on.

■ Insert a north arrow block in the plan view viewport in the template (paper space).

NOTE When AutoCAD Civil is installed, templates that come with the product are installed to the following location by default: *C:\Documents and Settings \ <User Name >\Local Settings\Application Data\Autodesk\Civil2010\enu\Template.* The templates that are preconfigured with viewport types for plan view and profile view are located in: *C:\Documents and Settings \ <user name >\Local Settings\Application Data\Autodesk\Civil2010\enu\Template\Plan Production.*

**To prepare drawing templates for using the plan production tools**

1 Open a new drawing or template.

2 Select the default settings for the template.

For example, you may want to set the default object styles and label styles for all objects, and in particular for the new plan production objects (view frame groups, view frames, and match lines).

| For information about ... | See this Help topic |
| --- | --- |
| General AutoCAD Civil object styles | Object Styles (page 53) |
| General AutoCAD Civil label styles | Defining Label Settings (page 1475) |
| Plan production tool object styles and labels | Editing Plan Production Tool Settings (page 1701) |

**3** Configure viewport settings.

You'll want to configure your viewports as desired and capture this in the template(s). For example, you may want to adjust the size, scale, rotation, or other viewport settings. Also, you must make sure the Viewport Type for each viewport is set to Plan or Profile. If you use the AutoCAD Civil plan production templates provided in the Templates\Plan Production folder, the Viewport Types are already configured. However, if you use your own custom templates, or templates from previous AutoCAD Civil versions, you must set this property on the viewports. See Configuring Viewports for Plan Production (page 1700) for more information.

**4** Optionally, you may want to insert a north arrow block in the desired location in the layout.

**5** It is recommended that you lock the viewport(s).

**6** Save the drawing as a template (*.dwt*).

# Configuring Viewports for Plan Production

Before using custom templates for plan production, you must set the viewport type to either Plan or Profile.

By default, most of the templates provided with AutoCAD Civil have the Viewport Type property set to Undefined. However, the plan production templates that are located in the Template folder have viewports that are already configured to the appropriate viewport type: plan or profile.

The plan production templates that contain preconfigured Viewport Types are named:

*Civil 3D (Imperial) Plan and Profile.dwt*

*Civil 3D (Imperial) Plan Only.dwt*

*Civil 3D (Imperial) Profile Only.dwt*

If you want to use custom templates with the plan production features, you must set the Viewport Type to Plan or Profile, depending on the type of viewport you want.

If you use the predefined Plan Production templates located in the Template\Plan Production folder, the Viewport Types are already appropriately set.

While you are using the Create View Frames wizard, if you try to select a template that does not have appropriately defined viewports for the sheet type you select in the wizard (plan only, profile only, or plan and profile), AutoCAD Civil detects this and displays a message indicating that layouts containing the necessary viewports for the sheet type were not found.

**NOTE** When AutoCAD Civil is installed, templates that come with the product are installed to the following location by default: *C:\Documents and Settings \ <User Name >\Local Settings\Application Data\Autodesk\Civil2010\enu\Template\Plan Production\*.

**To set the Viewport Type for use with the plan production features**

**1** Open a drawing template.

**2** Make sure you are on a layout tab in paper space.

**3** Select the viewport that you want to display *plan* view data, right-click on it and then click Properties. The Properties palette is displayed.

> **NOTE** You can also display the Properties palette using one of the following methods:
>
> ■ Click the ⊞ Properties button on the Home tab of the ribbon.
>
> ■ Press Ctrl + 1.
>
> ■ At the command line, enter Properties.

**4** Scroll down to the Viewport section at the bottom of the Properties palette. Set the Viewport Type to Plan.

**5** Now right-click the viewport that you want to display *profile* view data, and set the Viewport Type to Profile.

**6** Save the template as *.dwt*.

# Editing Plan Production Tool Settings

Use view frame group settings to specify the default behavior for plan production tool commands.

Settings are handled in a standard way throughout AutoCAD Civil. You access settings using the Toolspace Settings tree. You can control settings at three levels: the drawing level, the object collection (feature) level, and the command level. For more information, see Understanding Settings (page 61).

Use the Settings tree View Frame Group collection shortcut menu to establish defaults for all plan production tool commands. You can change plan production tool-specific settings at this level, or override the drawing ambient settings.

Use the Commands collection in the View Frame Group collection to change plan production tool settings for a specific command.

> **NOTE** Overrides to the drawing ambient settings at the View Frame Group collection level and the Commands collection level affect only the specified level. The drawing level settings are not changed.

The topics in this section describe only those settings that affect plan production tool-related commands. They do not apply to the drawing ambient settings that you can change at the View Frame Group collection level and the View Frame Group command level, even though those settings are displayed in the Edit Feature Settings - View Frame Group dialog box. For more information about the drawing ambient settings, see Specifying Ambient Settings (page 68).

# Changing Plan Production Tool Creation Settings

Use the plan production tool creation and naming settings in the View Frame Group Settings (page 2081) dialog box to change plan production tool settings before you create view frames or sheets.

For example, before using the Create View Frames wizard, you should specify the default choices you want to use for plan production object names (object name format) and label styles. This will set your defaults for plan production objects (view frame groups, view frames, and match lines).

If a closed lock appears in the Lock column for a property, the property is locked at a higher level of the Settings tree. It cannot be changed at this level.

If you change a property value, a check mark is placed in the Override column. This override is also noted in the property table for related objects higher up the Settings tree, where an arrow is displayed in the Child Override column.

**To change plan production tool creation settings**

1 Do one of the following:

- **To edit settings for all plan production tool commands**: In Toolspace, on the Settings tab, right-click the View Frame Group collection. Click Edit Feature Settings. Do the same for the View Frame and Match Line collections on the Settings tab.

- **To edit settings for a specific command**: In Toolspace, on the Settings tab, expand the View Frame Group collection. Expand the Commands collection. Right-click the name of a command and click Edit Command Settings. For example, right-click the CreateSheets command and click Edit Command Settings.

The Edit Feature Settings (page 2081) dialog box is displayed.

2 To specify the default sheet creation and view frame creation options, right-click either the CreateSheets or CreateViewFrames commands and click Edit Command Settings.

3 To edit the default naming format for plan production tool objects (such as view frame groups, view frames, and match lines), expand the Default Name Format property group. Edit the Name Template settings for each item.

4 Click Apply.

Edit Feature Settings (View Frame) (page 2084)
Edit Feature Settings (Match Line) (page 2084)

# Changing Plan Production Tools Default Style Settings

Use the view frame group settings to specify default styles and labels for view frame and match line creation.

The default styles specified in these settings are used to establish the default settings for the styles in the Create View Frame wizard, the View Frame Group Properties dialog box, the View Frame Properties dialog box, and the Match Line Properties dialog box.

**To change the plan production tool objects style and label settings**

1  In Toolspace, on the Settings tab, right-click the View Frame Groups collection. Click Edit Feature Settings to open the View Frame Group Settings (page 2081) dialog box.

2  Expand the Default Styles property group.

3  To specify default styles for plan production tool objects (view frames and match lines), click the corresponding field. Click [...] to open the Select Style dialog box.

4  To specify a default view frame or match line style, click View Frame Style or Match Line Style. Click [...] to open the Select Style dialog box.

5  To specify a default style for view frame or match line labels, click the corresponding field. Click [...] to open the Select Label Style dialog box.

6  To specify a default location for view frame or match line labels, click the corresponding field and select a location in the drop-down list.

7  Click Apply.

Toolspace Shortcut Menu

  Settings tab: right-click View Frame Group collection  ➤  Edit Feature Settings

Dialog Box

  View Frame Group Settings (page 2081)

# Creating View Frames

Use the Create View Frames wizard to quickly create view frames along an alignment.

You create view frames automatically by using the Create View Frames wizard. Start the wizard in any of the following ways:

■  Click Output tab ➤ Plan Production panel ➤ Create View Frames  .

■  In the Prospector tree, right-click View Frame Groups  ➤  Create View Frames.

■  At the command line, enter CreateViewFrames.

The view frames that are created represent rectangular areas along the alignment that will be displayed on plan/profile or plan-only sheets.

Before you create view frames, the desired alignment must already exist in your drawing. Depending on the type of sheets you want to produce (plan and profile or profile only), you may also need to have a profile already created. If you are creating a plan only view frame (or sheet set), then you do not need to have a profile in the drawing. For information, see Preparing for Plan Production (page 1699).

You can also insert a new view frame into an existing view frame group. For information, see Inserting View Frames (page 1714).

**To create view frames**

1  Do one of the following:

   ■ Click Output tab ➤ Plan Production panel ➤ Create View Frames 📇 .

   ■ In the Toolspace Prospector tree, right-click the View Frame Groups collection and click Create View Frames.

   The Create View Frames wizard is displayed.

   ---
   **NOTE** On any page of this wizard, you can click Create View Frames to create the view frames using the default choices on the wizard pages. If a criteria is needed that has not been supplied, then the Create View Frames button is unavailable (grayed out). You can also click the links on the left side of the wizard to go directly to a wizard page.

   ---

2  In the Alignments page (page 2084), select an alignment.

3  In the Station Range section, choose one of the following:
   ■ Automatic: Selects the entire alignment. So the start station is the start station of the alignment, and the end station is the end station of the alignment.

   ■ User Specified: When this is selected, you may enter a value or click 🖱 to specify a start and end location (stations) along the alignment in the drawing area.

4  Click Next to display the Sheets page.

**5** In the Sheets page (page 2085), in the Sheet Settings section, under Choose The Sheet Type You Want To Generate, select one of the following:

| Option | Result (Conceptual Image) |
|---|---|
| Plan And Profile | <br><br>The sheets that will be created will contain plan views and profile views. |
| Plan Only | <br><br>The sheets that will be created will contain plan views only (no profile views). |
| Profile Only | <br><br>The sheets that will be created will contain profile views only (no plan views). |

In the Template For Plan And Profile Sheet field, click ⁝⁝⁝ to open the Select Layout As Sheet Template dialog box and browse to the template to use for the sheets that will be created. The template you select must have viewports defined as plan and/or profile, depending on the sheet type selected in this dialog box (Plan And Profile, Plan Only, or Profile Only).

**6** Click OK in the Select Layout As Sheet Template dialog box.

**NOTE** If you select a template that does not have appropriately defined viewports for the sheet type you select (Plan Only, Profile Only, or Plan and Profile), AutoCAD Civil detects this and displays a warning message. For more information see, Configuring Viewports for Plan Production (page 1700).

**7** In the View Frame Placement section, select one of the following or accept the default:

| Option | Result (Conceptual Image) |
|---|---|
| Along Alignment | \nThe view frames will be aligned along the alignment. Typically, this is the preferred method for making the most efficient use of paper when plotting. |
| Rotate To North | \nThe view frames will be rotated according to the north arrow orientation of the drawing. |

**8** Optionally, you may select the check box next to the Set The First View Frame Before The Start Of The Alignment option, and then enter a value in the value field.

This sets the distance before the start station of the alignment that the first view frame is placed. Entering a distance here provides the specified amount of space before the selected alignment start so that the alignment start does not coincide with the edge of the viewport. If this check box is not selected, then this field is ignored, and the first view frame may be placed at the start of the alignment. Often the view frame start will be as desired without altering this option.

**9** Click Next to display the View Frame Group page.

**10** On the View Frame Group page (page 2086), specify a name, and optionally, a description of the view frame group object that will be created using this wizard.

**11** On the View Frame section, specify a layer, name, style, and label style for the view frames.

**12** In the Label Location field, choose the desired location to place the view frame labels. For example, choosing Top Left places the view frame labels at the top left side of the view frame.

**13** Click Next to display the Match Lines page.

**14** On the Match Lines page (page 2087), if you chose Plan Only, you can choose to insert match lines on the view frames by selecting the check box next to Insert Match Lines. Match lines are only displayed in model space and in plan views. They are not displayed in profile views.

---

**NOTE** If you do not want match lines included on the plan only view frames, clear the check mark from this option. This disables the options on this page. If you selected to create plan and profile or profile only sheets, this check box is automatically selected, and you cannot edit it (not available, grayed out).

---

**15** In the Positioning section, you may select one or both of the following options, and enter desired values in the text fields. Both these options let you adjust where match lines are placed, and how they may be moved after creation, so that they do not obstruct important drawing data.

- Snap Station Value Down To The Nearest: When this check box is not selected (cleared), match line positioning on the view frame is determined by using a rounding value based on derived stations. When this check box is selected, the match lines are positioned on the view frames based on the rounding calculation value entered. The rounding calculation always rounds down. For example, if the calculated station for a match line is 48+37.69, then a rounding of 100 would place the match line on 48+00.

| When Snap Station Value Down To The Nearest is set to ... | the station will round to |
|---|---|
| 100 | 18+00 |
| 50 | 18+50 |
| 10 | 18+60 |
| 1 | 18+65 |
| 27+45.3 to 50 | 27+00 to the next lowest multiple of 50 |

  **NOTE** This option will not accept values that cause the match lines to be placed in undesirable locations, such as before the previous match line or before the beginning of the alignment. If a rounding calculation would result in the match line being placed in an undesirable location, then the rounding calculation is ignored and the match lines are placed at calculated station.

- Allow Additional Distance For Repositioning (Increases View Overlap): Because the location of match lines is calculated automatically, it is possible that after you might need to move the match line slightly. For example, in some cases match lines or match line labels may be obscuring data of interest. You can use this option to increase the margin by which you can move (reposition) match lines. Using this option will have a side-effect of increasing the overlap area of view frames. When this check box is selected, you can move the match lines in plan view by the distance specified with this option. This ensures that the match line remains within (between) the intersection of the two neighboring view frames. You should enable this option if you want to be able to move the match lines by a certain distance. Note that having this option enabled is useful if you need to force an overlap of view frames when, on a straight line alignment, adjacent edges or sides of two view frames are at the same location, thereby not allowing enough room for labels.

**16** In the Match Line section, specify a layer, name, and style for the match lines that will be created.

**17** In the Labels section, specify the labeling criteria for the match line labels, including location.

**18** Click Next to display the Profile Views page.

  **NOTE** The Profile Views page is not available (grayed out) if a sheet type of Plan Only was chosen on the Sheet Set page of this wizard.

**19** On the Profile Views page (page 2089), verify that an appropriate profile view style and band set have been selected. If desired, you may select a different profile view style and band set.

  **NOTE** It is important to understand that the profile view style and band set for the profile view cannot be changed later when you are using the Create Sheets wizard to create sheets. For more information, see Understanding Profile View Options (page 1724).

**20**   Click Create View Frames to create the view frames.

When the wizard has completed creating the view frames, you will notice the following:

- The view frames and match lines are created in the drawing.

- In the Prospector tree, the following objects are created: one view frame group, one or more view frames in a view frames collection, one or more match lines in a match lines collection.

**NOTE** If the Insert Match Lines check box on the Match Lines page was not selected (cleared), then match lines are not created.

Now that the view frames are created, you may want to adjust the location or labels of the view frames and match lines. See Moving View Frames (page 1711) or Moving Match Lines (page 1716) for more information.

After you are satisfied with how your view frames and match lines are positioned, the next step is to create the sheets using the Create Sheets wizard. See Creating Sheets (page 1719) for step-by-step information.

### Quick Reference

Ribbon

  General menu ➤ Plan Production Tools ➤ Create View Frames

Toolspace Right-Click Menu

  Prospector tab: right-click View Frame Groups collection ➤ Create View Frames

Command Line

  CreateViewFrames

Dialog Box

  Create View Frames Wizard (page 2084)

# Using View Frame Groups

Create view frame groups using the Create View Frames wizard.

After view frame groups are created, you can edit certain properties of the view frame group, or delete it. Although you can move view frames and match lines within a view frame group, view frame groups themselves are not designed to be moved as an entity.

You can delete individual view frames within a view frame group. You can also delete the entire view frame group. Deleting the entire view frame group object automatically deletes all the view frames and match lines associated with it.

**NOTE** View frame groups are not dynamically associated with the sheet files that are created from them. Updating a view frame group, moving match lines, or moving view frames will not affect the sheet files. The same is true with the sheet files created from the view frame groups. Updating the sheet files has no impact on the view frame groups.

After a view frame group is created, you can delete the alignment from which it was created, if you need to. Labeling functionality, such as the ability to display the sheet number in labels in the view frames, is still maintained even if the original alignment from which the view frame group was created is deleted.

# Creating View Frame Groups

Use the Create View Frames wizard to create view frame groups.

On the third page of the Create View Frames wizard—the View Frame Group page—you specify the object creation criteria for the view frame group object. For example, you enter a name for the view frame group object, and you can select the layer for the view frames. For more information see, View Frame Group page (page 2086) of the Create View Frames wizard.

Note that you can also create a reference to an existing view frame group data shortcut. For more information, see Creating a View Frame Group Reference (page 1709).

You can also insert a new view frame in to an existing view frame group. See Inserting View Frames (page 1714) for more information.

# Creating a View Frame Group Reference

You can create a reference to an existing view frame group in a data shortcut (page 2472) or a Vault project.

The view frame group reference is a lightweight read-only copy of the original. By means of data references, you can reuse a view frame group among several drawings to create consistency in the plan production sheets. Before you create the view frame group reference, it must exist in the current project collection on the Toolspace Prospector tab.

Before you create a view frame group reference, you must first create a reference to the related alignment.

**See also:**

■  Creating Data Shortcuts (page 131)

■  Vault: Checking a Drawing in to a Project (page 158)

**To create a reference to a data shortcut view frame group**

1  In Toolspace, on the Prospector tab, ensure that the correct project folder is identified on the Data Shortcuts node.

2  Expand the Data Shortcuts ➤ View Frame Groups collection, right-click the desired group, and then click Create Reference.

   The Create View Frame Groups Reference dialog box is displayed, in which you can optionally change properties of the reference view frame group, as described in the following steps.

3  In the Create View Frame Group Reference dialog box, to change the source of the reference, select the source in the Source View Frame Group list.

4  Enter a unique name for the view frame group and optionally, a description.

5  For the view frames and match lines included in this view frame group, you can specify a style, label style, and layer, or accept the defaults.

6  Click OK to create the view frame group reference.

   In the Prospector tree, the view frame group reference is displayed under the View Frame Groups collection with a  next to it.

**To create a reference to a view frame group in a Vault project**

1  In Toolspace, on the Prospector tab, in Master View, expand the Projects ➤ <project name> ➤ View Frame Groups collection, right-click the desired view frame group, and then click Create Reference.

The Create Surface Reference dialog box is displayed, in which you can optionally change properties of the reference group, as described in the following steps.

2   In the Create View Frame Group Reference dialog box, to change the source of the reference, select the source in the Source View Frame Group list.

3   Enter a unique name for the view frame group and optionally, a description.

4   For the view frames and match lines included in this view frame group, you can specify a style, label style, and layer, or accept the defaults.

5   Click OK to create the view frame group reference.

In the Prospector tree, the view frame group reference is displayed under the View Frame Groups collection with a  next to it.

Dialog Box

Create View Frame Group Reference (page 2203)

## Editing View Frame Groups

You can edit certain properties of a view frame group, or add a new view frame to a view frame group.

For example, you can change a view frame group's object name, description, or the style of the view frames and match lines, as well as the layers on which they are displayed. For more information, see the View Frame Group Properties dialog box (page 2095).

For information on adding a view frame to a view frame group, see Inserting View Frames (page 1714).

The following restrictions apply to editing view frame groups:

■   Although you can move view frames and match lines within a view frame group, view frame groups themselves are not designed to be moved as an entity.

■   You can delete an entire view frame group, which deletes all view frames, match lines, and labels associated with the group.

■   You can delete individual view frames or match lines within a view frame group.

## Deleting View Frame Groups

Deleting a view frame group also deletes all view frames, match lines, and labels associated with that view frame group.

Any sheets or sheet sets that have already been created from that view frame group are not affected.

If you explode one or more view frames or match lines, all view frames and match lines in that view frame group are exploded, and the following objects are deleted: view frames, match lines, and the view frame group.

**To delete a view frame group**

1 Click a view frame in the group. Click Plan Production tab ➤ Modify View Frame panel ➤ ▼ ➤ Delete Group ▣ .

2 The view frame group, and all view frame and match line objects belonging to it, are removed from the View Frame Groups collection on the Prospector tab. The view frames and match lines are automatically removed from the drawing.

## Quick Reference

Ribbon

Click a view frame in the group. Click Plan Production tab ➤ Modify View Frame panel ➤ ▼ ➤ Delete Group ▣

Toolspace Right-Click Menu

Command Line

DeleteViewFrameGroup

# Editing View Frames

You may want to edit view frame styles, view frame label styles, or edit, move or delete view frames or their labels.

Like other AutoCAD Civil objects, you can edit certain properties of a view frame. For example, you can change a view frame's object name, description, object style, or the layer on which it is displayed.

View frame objects are displayed in the Prospector tree, and you can control their default style and labeling from the View Frame collection in the Settings tree. For more information, see the View Frame Properties dialog box (page 2093).

View frames can include a label that displays the information you want. For example, you may want your view frame labels to identify the area along the alignment it is displaying, or reference more specific data from that area.

You can move or rotate a view frame, but you cannot resize it. You can also insert or delete view frames within a view frame group.

# Moving View Frames

After view frames are created, they can be moved or rotated using grips.

The center, slider, and rotation grips on the view frame enable you to move or rotate it.

Although you can move or rotate view frames, you cannot change the size of a view frame. This is because the view frame's size is based on the size of the viewport it references in the associated template.

You will notice that when you move a view frame, the view frame stays attached to the alignment it is associated with. If a view frame is moved off the alignment, and you want to reattach it to the alignment,

be certain that OSNAPS are turned on, and you can drag the center grip towards the alignment. When you move a view frame that has a view frame label on it, the label moves with the view frame.

Moving a view frame does not move any match lines associated with that view frame. When moving a view frame, the match lines associated with the view frame stay positioned where they intersect the alignment, and do not move.

If you need to move view frames *after* sheets have been created, instead of moving the view frames, you should make these changes to the sheet by editing the viewport. If you move view frames after sheets have been created, these changes will not be reflected in any sheets that have already been created from the view frames. In order to see those changes reflected in the sheets, you will have to recreate the sheets.

If the alignment associated with a view frame has been deleted, the view frame remains, but the slider grip is no longer displayed, and the view frame can be moved in any direction.

Also, if the view frame is set to align with a north arrow block in the drawing, the rotation grip is not displayed.

For more information about grips, see "Using Grips to Edit Objects" in the AutoCAD Help.

**To move or rotate view frames using grips**

1  In either model space, click the view frame you want to move or rotate.

2  Click one of the following grips on the view frame:

   ■  ▢ Center grip: Moves the view frame freely in any direction.

   ■  ◇ Slider grip: Moves the view frame forward or backward along the alignment. If the view frame is moved off the alignment, the offset to the alignment is maintained. If the view frame remains parallel to the tangent to the alignment, the grips stay on alignment.

   ■  ● Rotation grip: Rotates the view frame about the center of the view frame.

   **NOTE** If the view frame is set to align with a north arrow block in the drawing, the rotation grip is not displayed (not available).

3  Drag the grip to move or rotate the view frame.

# Deleting View Frames

You can delete a view frames in a view frame group, or delete the entire view frame group.

You can delete a view frame in a view frame group. Or you can delete all view frames within a view frame group by deleting the entire view frame group in Prospector. Deleting a view frame group deletes all view frames and match lines within a view frame group, in addition to deleting the view frame group object as well.

When you delete a view frame group, any sheets and/or sheet sets that may have already been created by the view frame group are not affected.

If you explode one or more view frames or match lines, all view frames and match lines in that view frame group are exploded, and the following objects are deleted: view frames, match lines, view frame group.

**NOTE** When two view frames share a common match line, and you delete one of the view frames, the shared match line is not removed.

For more information, see Deleting View Frame Groups (page 1710).

**To delete a single view frame**

■ In the Prospector tree, expand the desired View Frame Group object, then right-click a view frame and click Delete.
The view frame and its associated match line object(s) are removed from the View Frames and Match Lines collections in the Prospector tree, and in the drawing.

**NOTE** When two view frames share a common match line, and you delete one of the view frames, the shared match line is not removed.

# Labeling View Frames

You can include or omit labels on view frames, specify their location, and you can design and specify view frame label styles that suit your needs.

Use the View Frame Group page in the Create View Frames wizard to select a label style and label location for view frames in a view frame group.

If you do not want labels on a view frame, you can turn off the visibility of the labels in the label style.

Use the Label Location options on the View Frame Group page in the Create View Frames wizard to select where the view frame labels will be placed. For example, selecting Top Left places the view frame label at the top left corner of the view frame.

You can delete view frame labels. Selecting any view frame label automatically selects all view frame labels associated with that view frame group. You can delete all view frame labels in a view frame group by selecting them and pressing the Delete key. To delete individual labels, Ctrl-click on a label to select it and press Delete.

In the View Frame collection in the Toolspace Settings tree, you can create and edit view frame label styles. See Creating and Editing Label Styles (page 1477) for more information.

**To edit view frame label styles**

1 In the Settings tree, expand the View Frame collection, and then expand the Label Styles collection.

2 Double-click the Standard label style.

3 Use the Label Style Composer to edit the default Standard view frame label style, or create your own custom label style for view frames.

**To edit existing view frame labels**

1 In the drawing, do one of the following:

■ to select all view frame labels in a view frame group, click on any view frame label

■ to select a single view frame label, use Ctrl + left-click on a view frame label

2 Right-click and select Edit Labels on the right-click shortcut menu.

3 Use the Edit View Frame Labels dialog box to select a different label style, create a new label style, edit the existing label style, or change the label location.

**To reset view frame labels**

1 In the drawing, do one of the following:

■ to select all view frame labels in a view frame group, click on any view frame label

■ to select a single view frame label, use Ctrl + left-click on a view frame label

**2** Right-click and select Reset Labels on the right-click shortcut menu.

### Quick Reference

Toolspace Shortcut Menu

Settings tab: View Frame ➤ Label Styles

Dialog Box

Label Style Composer Dialog Box (page 1942)

# Inserting View Frames

You can insert a new view frame into a view frame group.

In most cases, the new view frame is inserted before the selected view frame.

You can insert a new view frame by

■ right-clicking on a view frame and clicking Insert View Frame

■ entering the InsertViewFrame command and specifying an insertion point in the drawing

Each of these methods is described below.

### Right-clicking on a View Frame and Clicking Insert View Frame

When you insert a new view frame by right-clicking on an existing view frame and clicking Insert View Frame, or if you use the InsertViewFrame command and select an existing view frame, the new view frame is inserted as follows:

■ If there is no gap (blank space) between the selected view frame and its previous view frame, the new view frame is inserted before the selected view frame (towards the beginning of the alignment).

■ If there is a gap (blank space) between the selected view frame and its previous view frame, the new view frame is inserted by finding the center (at the alignment) of the two match lines, and inserting the new view frame centered on this point. If the selected view frame is the first view frame in the view frame group, and therefore, has no left match line, a new left match line is created.

**Specifying an Insertion Point in Drawing**

When you insert a new view frame by using the InsertViewFrame command and you enter S to specify an insertion location, the following rules are used:

■ If the selected point is a valid location for a view frame, the new view frame is inserted, centered in the selected point.

■ If the selected point is not a valid location for a view frame, a message indicates that the location is not valid for view frame insertion, and the new view frame is not inserted.

A valid location is some other point along the alignment, or close to the alignment.

**To insert a view frame into a view frame group**

➤ Do one of the following:

■ In the drawing area, right-click on a view frame and click  Insert View Frame.

■ At the command line, enter InsertViewFrame, and then click on a view frame, or select an insertion point in the drawing area.

The new view frame is inserted.

## Quick Reference

Drawing Area Shortcut Menu

Right-click <view frame object> ➤ Insert View Frame

Command Line

InsertViewFrame

# Editing Match Lines

You can edit match line styles, match line label styles, or edit, move or hide match lines or their labels.

Like other AutoCAD Civil objects, you can edit certain properties of a match line. For example, you can change a match line's object name, description, object style, or the layer on which it is displayed. Match line objects are displayed in the Prospector tree, and you can control their default style and labeling in the Match Line collection in the Settings tree. For more information, see the Match Line Properties dialog box (page 2094).

Match lines can include a label containing information that you want. For example, you may want your match line labels to identify the previous and next sheet (view frame).

You can edit a match line length using grips, or move match lines. Use the options on the Match Lines page of the Create View Frames wizard to control how match lines are positioned on alignments, and by how much distance match lines can be repositioned (moved) after you create them.

The only way match lines can be deleted is to delete the view frame, or the view frame group, it belongs to. Use the match line style to hide the visibility of match lines if you do not want them to display. For more information, see Deleting Match Lines (page 1717).

# Editing the Match Line Mask Area

The Match Line Style (page 2099) dialog box contains options for setting a hatch pattern in the mask area.

The mask is displayed in paper space in the area between the outside of a match line and the inside boundary of the view frame, indicated by the dark shaded areas in the following illustration:

The match line mask area is the area that exists between the outside of a match line and the inside border or boundary of the view frame. On the Display tab of the Match Line Style dialog box, there is an option to set the hatch pattern for this match line mask area.

Match line labels are displayed on top of the match line mask area, and are therefore visible over it.

**To edit the match line mask area**

1   In the Settings tree, expand the Match Line collection, and then expand the Match Line Style collection.

2   Double-click a match line style to open the Match Line Style dialog box.

3   Click the Display tab.

4   Select a View Direction (2D or 3D). You can set different hatch patterns for 2D and 3D.

5   In the Component Hatch Display section at the bottom, click the current value for Pattern. The Hatch Pattern dialog box is displayed.

6   Select a hatch type from the list. Optionally, you may browse to another hatch pattern palette. For more information about hatch patterns, see "Overview of Hatch Patterns and Fill" in the AutoCAD Help.

7   Click OK in the Hatch Pattern dialog box.

8   Optionally, you may specify Angle and/or Scale.

9   Click either Apply or OK on the Display tab of the Match Line Style dialog box.

# Moving Match Lines

You can move match lines in plan view if you have enabled the match line repositioning option during view frame creation.

The following match line positioning options are displayed on the Match Lines page in the Create View Frames wizard:

■   Snap Station Value Down To The Nearest

■   Allow Additional Distance For Repositioning (Increases View Overlap)

**Snap Station Value Down to the Nearest**

When the Snap Station Value Down To The Nearest check box is selected, match line positioning is determined by using the value entered in the Distance field, which is in drawing units.

The rounding calculation always rounds down. The following table lists examples of this calculation based on the value entered.

| When Snap Station Value Down To The Nearest is set to ... | The station rounds to |
| --- | --- |
| 100 | 18+00 |
| 50 | 18+50 |
| 10 | 18+60 |
| 1 | 18+65 |
| 27+45.3 to 50 | 27+00 to the next lowest multiple of 50 |

**NOTE** This option will not accept values that cause the match lines to be placed in undesirable locations, such as before the previous match line or before the beginning of the alignment. If a rounding calculation would result in the match line being placed in an undesirable location, then the rounding calculation is ignored and the match lines are placed at calculated station.

When this check box is not selected (cleared), match line positioning on the view frame is determined by using a rounding value based on derived stations.

**Allow Additional Distance For Repositioning (Increases View Overlap)**

When this check box is selected, you can move match lines within a specified limit. Enabling this option can also be used to force an overlap of frames in plan sheets only when, on a straight line alignment for example, adjacent edges of two view frames might be coincident, and therefore not provide enough room on either side of the match line for labeling and notes.

Note that the value entered here is the total distance that is removed from the calculated distance between match lines. It will allow for match lines to be moved apart to the total calculated distance. However, AutoCAD Civil will not allow you to enter a distance that is greater than the view frame width.

**To move match lines**

1 In either model space or paper space, click the match line you want to move.

2 Click one of the following grips on the match line:

- **Center grip**: Moves the match line freely in any direction.

- **Slider grip**: Moves the match line forward or backward along the alignment.

- **Rotation grip**: Rotates the match line about the center of the match line.

3 Drag the grip to move or rotate the view frame.

# Deleting Match Lines

Match lines are deleted automatically when you delete a view frame or view frame group.

After match lines are created, the only way to delete them is to delete the view frame, or view frame group object they belong to. For more information, see Deleting View Frames (page 1712) or Deleting View Frame Groups (page 1710).

If you explode one or more match lines or view frames, all match lines and view frames in that view frame group are exploded, and the following objects are deleted: match lines, view frames, view frame group.

You can delete match line labels. Selecting any match line label automatically selects all match line labels in that view frame group. To delete them individually, select them by using Ctrl + click, and then press the Delete key.

If you do not want match lines to display, change the display style so that the match line component's visibility is turned off. For more information, see Match Lines Styles and Display (page 1697).

## Labeling Match Lines

You can insert or omit labels on match lines, specify label location, and design and specify match line label styles that suit your needs.

Use the Match Lines page of the Create View Frames wizard to select a label style and label location for the left and right side match lines.

If you do not want labels to be displayed on match lines, turn off their visibility using the match line label style.

Use the Left Label Location and the Right Label Location options on the Match Lines page in the Create View Frames wizard to select where the match line labels will be placed. Select from the following locations:

- **Start**: Places the match line label at the start of the match line, near the top of the view frame.

- **End**: Places the match line label at the end of the match line, near the bottom of the view frame.

- **Middle**: Places the match line label at the middle of the match line.

- **Alignment Intersection**: Places the match line label where the alignment intersects the match line.

In the Match Line collection in the Toolspace Settings tree, you can create and edit match line label styles. For the match line text component, by default you can select from the following properties to add to a match line label:

- Match Line Name

- Match Line Number

- View Frame Group Alignment Name

- View Frame Group Name

- Match Line Station Value

- Match Line Raw Station Value

- Previous Sheet Number

- Next Sheet Number

**NOTE** If you use the Previous Sheet Number or the Next Sheet Number properties in your match line labels, this information displays as "####" in the match line label until the sheets are generated. After the sheets are generated, the match line label is populated with appropriate sheet number information.

See Creating and Editing Label Styles (page 1477) for more information.

**To edit match line label styles**

1 In the Settings tree, expand the Match Line collection, and then expand the Label Styles collection.

2 Expand the Match Line Left collection. Double-click the Standard label style.

3 Use the Label Style Composer to edit the default Standard match line label style, or create your own custom label style for the left side match line.

4 Repeat step 3 for the right side match line label.

**To edit existing match line labels**

1 In the drawing, do one of the following:

- to select all match line labels in a view frame group, click on any match line label

- to select a single match line label, press and hold the Ctrl key while clicking on a match line label

2 Right-click and select Edit Labels on the right-click shortcut menu.

3 Do one of the following:

- use the Edit Match Line Group Labels dialog box to edit labels for all match lines in the view frame group

- use the Edit Match Line Label dialog box to edit a single match line label

You can select a different label style, create a new label style, edit the existing label style, or change the label location for the selected match lines.

**To reset match line labels**

1 In the drawing, do one of the following:

- to select all match line labels in a view frame group, click on any match line label

- to select a single match line label, press and hold the Ctrl key while clicking on a match line label

2 Right-click and select Reset Labels on the right-click shortcut menu.

# Creating Sheets

Use the Create Sheets wizard to quickly create sheets for construction documents (plans).

After you have used the Create View Frames wizard to create view frames, you can create sheets automatically using the Create Sheets wizard.

You can specify whether the sheets are created in the current drawing or in one or more new drawings.

**NOTE** If you choose to create sheets that display profile views, the profile views will be created and placed in the drawing automatically in model space in the file containing the sheets.

Before you can use the Create Sheets wizard, in the drawing you must have already created a view frame group using the Create View Frames wizard.

It is important to note that the profile view style and band set that were used during the Create View Frames wizard are used to calculate the placement of view frames. These styles cannot be changed later for the view frame group.

**To create sheets**

1 Do one of the following:

■ Click Output tab ➤ Plan Production panel ➤ Create Sheets 📑 .

■ In the Prospector tree, expand the View Frames Groups collection, right-click a View Frame Group ➤ Create Sheets.

■ At the command line, enter CreateSheets.

**NOTE** On any page of this wizard, you can click Create Sheets to create the sheets using the default choices on the wizard pages. If a criteria that is needed that has not been supplied, then the Create Sheets button is not available (grayed out). You can also click the links on the left side of the wizard to go directly to a wizard page.

2 On the View Frame Group And Layouts page (page 2089), select a view frame group from the list.

**NOTE** As a reminder, the sheet type that was selected for this view frame group is displayed beneath the View Frame Group list.

3 For View Frame Range, all view frames are selected for processing by default, but you can choose a single view frame, or multiple view frames from the group by clicking Selection and then clicking the Choose View Frames ... button.

4 In the Layout Creation section, choose how the layouts will be created. A conceptual image on the right side of the wizard page provides an indication of the result.

| Option | Description |
| --- | --- |
| Number Of Layouts Per New Drawing (1) | This option may be an appropriate choice if you plan to have several people working |

| Option | Description |
|---|---|
| | on individual sheets. When this option is selected, and you enter 1 for the value, one new layout (sheet) is created in each new drawing. The total number of sheets and drawings depends on the length of the alignment selected and other criteria, such as the size of the viewports in the referenced template. |
| Number Of Layouts Per New Drawing (>1) | If you choose this option and enter a value greater than 1 (3, for example), then 3 new layouts are created in each new drawing. The total number of sheets and drawings depends on the length of the alignment selected and other criteria, such as the size of the viewports in the referenced template. |
| All Layouts In One New Drawing | This option may be an appropriate choice if having each individual layout in a separate drawing is not necessary for you, and if you have less than 10 sheets. You may place all the layouts in one newly created drawing. The total number of sheets depends on the length of the alignment selected and other criteria, such as the size of the viewports in the referenced template. For optimal results, it is recommended that you create no more than 10 sheets per drawing. Therefore, this option may not be the best choice if you have more than 10 sheets. |
| All Layouts In The Current Drawing | If you are generating less than 10 sheets, you may want to generate the layouts in the current drawing. The total number of sheets depends on the length of the alignment selected and other criteria, such as the size of the viewports in the referenced template. |

**NOTE** For optimal results, it is recommended that you create no more than 10 sheets per drawing. Therefore, this option may not be the best choice if you have more than 10 sheets.

5 Specify a name for the layouts or accept the default naming template.

6 Optionally, you can use the Choose The North Arrow Block To Align In Layouts option to automatically align a north arrow block in the sheet(s). Any blocks that exist in the referenced template (*.dwt*) are

displayed in the drop-down list. If no blocks exist in the referenced template, the list displays None. If you select a block from this list, that block will be aligned to the north on the sheet(s).

**7** Click Next to display the Sheet Set page.

**8** On the Sheet Set page (page 2090), do one of the following:

■ If you want to manage the sheets using the Autodesk Vault project management features, and you are already logged in to the desired vault, the Add Files To Vault is automatically selected.

■ If you want to manage the sheets using the Autodesk Vault project management features, and you are not logged in to the desired vault, click Log In To Vault ..., log in to the desired project, and then return to the Sheet Set page and click Add Files To Vault.

■ If you do not want to manage the sheets using the Autodesk Vault project management features, make sure the Add Files To Vault check box is not selected (cleared).

**NOTE** If you choose to manage sheets using the Autodesk Vault project management features, the sheet set file (.*dst*), and the sheet files (.*dwg),* will be added to the vault project you selected. If Autodesk Vault is not currently installed on the machine you are using, these options are not available (grayed out and not available for edit).

**9** In the Sheet Set section, select either New Sheet Set or Add To Existing Sheet Set.

**10** In the Sheet Set File (.DST) Storage Location field, specify a location where the sheet set file (.*dst*) will be stored. If you selected Add To Existing Sheet Set, this field displays the path of the sheet set file for the sheet set selected in the Add To Existing Sheet Set field. If you want to use the Sheet Set Manager later to manage this sheet set, you will need to know this location and filename.

**11** In the Sheets section, specify a storage location and name for the sheet file(s) that will be created during this wizard session. If you have chosen to save all sheets in the current drawing (the All Layouts In The Current Drawing choice on the Create Sheets wizard View Frame Group and Layouts page), these fields are not available (read only, grayed out).

■ Sheet Files Storage Location: Specifies the location where the sheet files created during this session will be located. Click ⬚ to select a location. If you are logged in to a project in Vault, by default this path displays the root folder for the project. If you are not logged in to a project in Vault, by default this path is set to the directory containing the working (current) drawing.

■ Sheet File Name: Specifies the name of the sheet file(s) that will be created.

**12** Click Next to display the next page in the wizard sequence. If the view frames do not include any profile views, then the Profile Views page of the Create Sheets wizard is not available, and the Data References page is displayed next.

**13** On the Profile Views page (page 2091), you can specify additional settings for profile views. Note that the profile view style and the band set that were selected during view frame creation cannot be changed at this stage; however, the current profile view style and band set that will be used are displayed as read-only on this page. Only additional settings relating to profile views (Other Profile View Options) can be changed at this part of the process. For more information, see Understanding Profile View Options (page 1724).

**NOTE** If you need to change these profile view or band set style settings, you must cancel out of the Create Sheets wizard and recreate the view frames, using the updated style choices for the profile views and/or the band sets.

**14** In the Other Profile View Options section, you can get other settings from an existing profile view, or you can choose settings by launching the Profile View wizard at this point (from this page of the Create Sheets wizard). If you choose to launch the Profile View wizard from the Create Sheets wizard, you will

be returned to the Profile Views page of the Create Sheets wizard when you are finished selecting profile view options.

**15** If you are creating plan and profile sheets, you can choose how to align the data that is displayed in the plan and profile views using the Align Views options. If you are creating plan only or profile only sheets, these options are not available. These options are useful on projects that require the data displayed in sheets to be aligned according to certain project requirements (such as aligned left, center, or right).

- Align Profile And Plan View At Start: When this option is selected, the left side (start station) match line in the plan view aligns with the left side (start) of the profile view.

- Align Profile And Plan View At Center: When this option is selected, the center of the plan view aligns with the center point of the profile view.

- Align Profile And Plan View At End: When this option is selected, the right side (end station) match line in the plan view aligns with the right side (end) of the profile view.

**16** Click Next to display the Data References page.

> **NOTE** The Data References page is not available if you chose All Layouts In The Current Drawing in the Layout Creation section of the View Frame Group and Layout page.

**17** On the Data References page (page 2092), you can select or omit the data you want to be included in your sheets. Select the check box next to the data references you want displayed in the sheets. Some references cannot be removed from the selection, such as the alignment and profile associated with these sheets. If you are including pipe networks in the destination drawing(s), you may want to check the Copy Pipe Network Labels To Destination Drawings to also copy the labels associated with any selected pipe networks.

**18** Click Create Sheets to create the sheets.

**19** If you selected to create sheets containing profile views, you are prompted to select an insertion point in model space to create the profile views. Click a location in the drawing (model space) to insert the profile views.

You will only see profile views in the current drawing if you selected the All Layouts in the Current Drawing option in the Layout Creation section of the View Frame Group and Layout page.

Depending on your Event Manager settings, Event Manager messages may inform you of the location of the sheet sets, as well as the number of layouts created.

Once the sheets are created, the Sheet Set Manager automatically displays, showing the newly created sheets in a sheet set. For more information about the Sheet Set Manager, see the Sheet Set Manager Help topics in the AutoCAD Help.

Dialog Box

# Understanding Profile View Options

When using the plan production wizards, it is important to understand how profile view options affect the data displayed in profile views.

Sizing of the profile view in the viewport requires information from the profile view style and band set. Together these items determine the extents of the data that will be presented in the viewport. Because the profile view style and the band set determine the extent of the data presented in the view port, these items must be configured as desired before starting the Create View Frames wizard, and then selected at the time that the view frames are created (when using the Create View Frames wizard).

There are other profile view settings, however, that can be specified during the creation of the profile view, or rather, while using the Create Sheets wizard. These settings include split profile view options, profile display options, pipe network display options, and data band information.

Changing these settings is not required until the profile views are actually created. These profile view settings can be specified in one of two ways on the Profile Views page of the Create Sheets wizard. These two different methods of changing profile view information during view are described in the following table.

| Method of changing profile view information | Description |
| --- | --- |
| Selecting an existing profile view | Selecting an existing profile view **does not override** the profile view style and band set information used when the view frames were created. |
| Using the Create Multiple Profile View wizard | Using this option will allow you to step through the Create Multiple Profile View wizard with several values pre-populated (some of which cannot be changed, such as style, station range, etc.).<br>The options that will either be extracted from the selected profile view, or gathered from the Create Multiple Profile View wizard, and subsequently used in creating profile views for sheets include:<br>■ split profile view options<br>■ profile display options<br>■ pipe network display options<br>■ data band (band set) information |

If desired, you can select an existing profile view when you are using the Create View Frames wizard, and then, when you are using the Create Sheets wizard, you can modify that profile view using the Multiple Profile View wizard.

# Using Vault with Plan Production Tools

This section describes how to use Autodesk Vault with plan production tools.

You may want to manage the objects and files that are both consumed (used) by and created from the plan production tools with Autodesk Vault. If you choose to do so, you will be using an efficient mechanism for maintaining your organization's standards for plan set drawing templates.

If you choose to use Autodesk Vault with the plan production features, the following files associated with plan production will be added to the selected project in Autodesk Vault:

■ sheet set data file (*.dst*),

■ the current drawing (*.dwg*)

If you are saving sheets to the current drawing file, and the current drawing file is already in the vault, that drawing file cannot be checked in to vault automatically. This must be done by you.

The Add To Autodesk Vault check box is not available for editing (grayed out) when sheets are being saved to the current file. In other words, when All Layouts In The Current Drawing is selected on the View Frame Group And Layouts page in the Create Sheets wizard, the Add To Autodesk Vault option is also not available (grayed out).

# Using Data References with Plan Production Tools

You can use data references with plan production tools.

When using the Create Sheets wizard, you can select the objects in the drawing that you want to include or exclude from the resulting sheets.

To do this, use the Data References page in the Create Sheets wizard, where you can select the objects that you want to be referenced in the sheets. You can select the following object types:

■ surfaces

■ alignments

■ profiles

■ pipe networks

When you select an object by placing a check mark next to it, a data reference (data shortcut) to that object is created in the sheet. This provides a way for you to include or exclude certain objects from the sheets.

Including data references in your sheets instead the actual data ensures that the geometry of the source data can be modified only in the source drawing, not in the resulting sheet drawing. However, display styles and labels for the reference object can be modified in the sheet drawing.

Another benefit of using data references is that if the source data objects change, the information displayed in the sheets dynamically updates.

For more information, see Using Data Shortcuts (page 127).

# Plan Production Tools Command Reference

You can use commands to quickly access plan production tools.

The following table lists the plan production tool AutoCAD Civil commands and briefly describes their functionality.

| Command | Description |
| --- | --- |
| CreateSheets | Displays the Create Sheets wizard for creating sheets. (page 1719) |
| CreateViewFrames | Displays the Create View Frames wizard for creating view frames. (page 1703) |

| Command | Description |
| --- | --- |
| DeleteViewFrameGroup | Deletes the selected view frame group (page 1710) |
| EditMatchLineProperties | Specifies the match line style, name, and description (page 2094) |
| EditMatchLineStyle | Controls the display of match lines and the hatch pattern of the match line mask (page 1715) |
| EditViewFrameGroupProperties | Specifies view frame and match line styles, names, and descriptions for the entire view frame group (page 2095) |
| EditViewFrameLabels | Edits view frame label style and location (page 1713) |
| EditViewFrameProperties | Specifies the view frame name, description, and style (page 2093) |
| EditViewFrameStyle | Controls the view frame border visibility and color (page 1695) |
| InsertViewFrame | Inserts a new view frame into a view frame group (page 1714) |

# Command Reference

# 44

AutoCAD Civil adds its own unique civil engineering and surveying commands to the AutoCAD command set.

This section provides information about the commands in AutoCAD Civil.

For information about AutoCAD commands, see the *AutoCAD Command Reference*.

## Accessing Commands

You can access many AutoCAD Civil commands using more than one method.

In Help, click the Quick Reference tab on a tabbed help topic to display a table providing the methods available for accessing a specific command. Not all methods are available for all commands. Where applicable, the following information is available on the Quick Reference tab:

| | |
|---|---|
| **Ribbon** | Describes how to access the command from the ribbon. |
| **Menu** | Describes how to access the command from the cascading menu. |
| **Toolspace Shortcut Menu** | Describes how to access the command from Toolspace by right-clicking an object in the Prospector or Settings tree. |
| **Object Shortcut Menu** | Describes how to access the command from a drawing by right-clicking the applicable object. |
| **Command Line** | Describes how to access the command from the command line. |
| **Toolbar** | Shows the toolbar icon to click or describes how to access the command from a toolbar. |
| **Dialog Box** | Provides a link to the dialog box that is opened by the command. |

# Command Listing

Use the links in this section to access Help topics that describe the commands that are available at the command line in AutoCAD Civil.

| Feature | Command Summary |
|---|---|
| Alignments | Alignment Command Reference (page 1016) |
| Assemblies and Subassemblies | Assembly and Subassembly Command Reference (page 1421) |
| Corridors | Corridor Command Reference (page 1375) |
| Drawings | Drawing Command Reference (page 124) |
| Drawing and Data Sharing | Drawing Sharing Command Reference (page 1663) |
| Google Earth Import/Export | Google Earth Import and Export Command Reference (page 1671) |
| Grading | Grading Command Reference (page 804) |
| Intersections | Intersection Command Reference (page 1460) |
| LandXML | LandXML Command Reference (page 1683) |
| Lines/Curves | Lines and Curves Command Reference (page 597) |
| Materials Analysis | Material Analysis Command Reference (page 1180) |
| Parcels | Parcels Command Reference (page 853) |
| Pipes | Pipe Network Command Reference (page 1284) |
| Plan Production | Plan Production Tools Command Reference (page 1725) |
| Points | Point Command Reference (page 516) |
| Profile Views | Profile View Command Reference (page 1121) |
| Profiles | Profile Command Reference (page 1121) |
| Project Management | Project Management Command Reference (page 182) |
| Sections | Sections Command Reference (page 1158) |
| Sites | Sites Command Reference (page 728) |
| Surfaces | Surfaces Command Reference (page 715) |
| Survey | Survey Command Reference (page 391) |
| Utilities | Utilities Command Reference (page 1651) |
| Transparent commands | Transparent Command Reference (page 1600) |

| Feature | Command Summary |
|---|---|
| User Interface | User Interface Command Reference (page 107) |

# AutoCAD Commands and AutoCAD Civil Objects

The following topic provides information about AutoCAD command operations on certain AutoCAD Civil objects and the results.

All AutoCAD Civil objects support the AutoCAD List, Explode, and Erase commands.

**NOTE** Exploding an object results in an unnamed AutoCAD block. Exploding again results in a base AutoCAD entity.

Most AutoCAD Civil objects support other commands to some degree. These commands include Copy, Move, Mirror, Offset, Scale, Block/wBlock, Rotate, Trim and Extend.

**NOTE** You can get the "Copy" behavior by using the Home tab ➤ Modify panel ➤ Copy ⬚ command on the ribbon, or by entering COPY at the command line or by using the Basic Modify Tools ➤ Copy command on the shortcut menu. You can get the "Block/Wblock" behavior by using the Clipboard ➤ Copy or Clipboard ➤ Copy With Base Point commands on the shortcut menu, pressing Ctrl + C, or entering WBLOCK at the command line.

## Supported AutoCAD Command Notes

Surface
If the surface is erased or exploded, profiles and sections that reference that surface become static.
Mirror will create a copy but will not honor the mirror settings.
Point groups used in the surface definition are included as part of the Wblock.

Point
When Wblocking and Inserting points, or copying points, a dialog box is displayed to resolve number conflicts.

**Table**
Wblocking a table also copies the required geometry. For example, the points are copied along with the point table.

Alignment
Exploding or erasing an alignment explodes or erases all objects that are dependent on the alignment (such as profiles, profile views, sample lines, sections, and section views).
Copying the alignment will create an alignment with a new name in the same site. All dependent objects will be copied and included with the new alignment.
Wblock/Insert will copy the alignment and all dependent objects into a new site.

Parcel (select parcel label)
When copying or Wblocking a parcel, the dependent parcel segments are included. If the objects are inserted into the same drawing, a new site is created.
Only the parcel labels can be moved.

Parcel Segment Lines
Wblocking/Inserting the parcel segment lines creates segment lines in a new site.

Grading

There are two distinct copy operations which can be done on a grading object. Copying the footprint feature line or individual target line creates a new feature line in a new site. Copying the entire grading object copies the footprint, target, and criteria.

The footprint can be moved. The target line cannot be moved.

If the grading criteria references a surface, the surface will be included in a Wblock/Insert operation.

Profile

Erasing a profile or section erases it from all profile or section views.

Profiles and sections can only be moved vertically within a view.

Profile View

If the profile or profile view is Wblocked, all objects required for the profile or profile view (such as the surface, alignment, profile, sample lines, and sections) are copied. If the objects are copied into the same drawing, a new site is created.

Sample Line

You cannot copy or move a Sample Line

Section

Erasing a profile or section erases it from all profile or section views.

Profiles and sections can only be moved vertically within a view.

If the sample line, section, or section view is Wblocked, all objects that are required for the sample line, section, or section view (such as the surface, alignment, sections, and sample lines) are copied. If the objects are copied into the same drawing, a new site is created.

Assembly

The names of assemblies and subassemblies are incremented when copied. Copying an assembly copies the assembly and all dependent subassemblies.

Mirror will create a copy but will not honor the mirror settings.

Corridor

Copying or Wblocking a corridor copies all of the dependent data such as assemblies, alignments, and surfaces.

Pipe Network

Network Objects are not accessible through Object Enabler environment.

Pipe

Copying a network part profile will create a copy of the parent network part (pipe or structure).

Structure

Copying, mirroring, arraying, and offsetting pipes and structures updates the references of any connected parts.

Copied pipes and structures will be in the same network.

Moving or rotating a structure causes any connected parts to move with it. (the connections are maintained).

Moving or rotating a pipe breaks the connection to any connected parts.

Scaling a pipe or structure affects position but does not affect size.

Wblocking pipes and structures copies all dependent objects.

**Survey Network**

Using the copy command on a survey network creates feature lines. The move command disassociates the figure from the model.

**Survey Figure**

Using the offset command on a survey figure generates a feature line object, not a survey figure.

The move commands dissassociates the figure from the model.

**Mass Haul Line**

Using the explode command keeps the layer and display settings.

With the Extend command, the object can be selected as an edge to extend to, but cannot be selected to extend

With the Trim command, the object can be selected as a trim edge, but cannot be trimmed

If the mass hauls is Wblocked, all objects that are required for it will be copied. Wblock/Insert is used when the user keys in ^C and ^V.

**Mass Haul View**

Views are automatically named according to "Existing Name" (#), where # is an increment. If a conflict is found, the next counter will be used.

The copy command or right-click "Copy Selection" will create a copy of the View with a name of "Existing Name" (#), where # is an increment.

The explode command will keep the layer and display settings. Exploding the View will not explode the haul line.

The mirror command is successful on a View, but it will not honor the mirror settings. You will get an additional copy of the Profile View.

If the View is Wblocked, all objects that are required for the View will be copied. Wblock/Insert is used when the user keys in ^C and ^V

**Civil Projection in Profile View and Section View**

Erase will remove from view but should not remove plan object.

Explode will keep the layer and display settings.

**AutoCAD Projection in Profile View and Section View**

Erase will remove from view but should not remove plan object.

Explode will keep the layer and display settings.

**Intersection**

Explode will keep the layer and display settings.

**Building Site**

Explode will keep the layer and display settings.

# Dialog Box Reference

# Alignment Dialog Boxes

# 45

The following topics provide information about the Alignment dialog boxes.

## Alignment Entities Vista

Use this vista to view and edit entities that are part of the solved alignment geometry.

Use the Alignment Entities window to navigate through all solved alignment entities. You can select an entity in the Alignment Entities window and then edit it in the Alignment Layout Parameters window. Attributes in the Alignment Entities window are automatically updated as you edit the alignment.

You can filter the display to show a selected range of entities along an alignment. See Selecting Alignment Entities (page 989) for more information.

The Alignment Entities vista is like a spreadsheet. Each row represents an alignment entity and each column represents an attribute for that entity. You can resize, move, and copy columns.

The first column (No.) is always displayed. It does not move when you use the scroll bar.

**NOTE** Two column configurations are available: default and criteria-based design. To switch between the configurations, or to create your own configuration, right-click a column heading, and click Customize Columns.

This window remains open when you grip edit the alignment or enter another command. The window closes when you either delete the currently selected alignment, click the X button, or click ▣ on the Alignment Layout Toolbar (page 1747).

No.
Specifies the entity number in the order of selection. This variable changes as entities are selected and deselected.

A ⚠ warning symbol is displayed in this cell if the sub-entity violates the specified design criteria (page 866).

Number
Specifies the entity number in the order in which it appears along the alignment. This value changes as alignment entities ahead of it are created or deleted. This column cannot be hidden or deleted.

Curve Group Index
Specifies the curve group description.

**Curve Group Sub-Entity Index**

Specifies the curve group sub-entity description.

**Type**

Specifies either line, curve, or spiral as the entity type.

**Length**

Specifies the length of the entity.

A ⚠ warning symbol is displayed in this cell if the sub-entity length value is not greater than or equal to the value in the Minimum Length cell.

**Direction**

Specifies the direction of the entity.

**Minimum Length**

Specifies the minimum transition length defined in the design criteria file (page 2472) for the current design speed.

**Radius**

Specifies the radius of the curve.

A ⚠ warning symbol is displayed in this cell if the sub-entity radius value is not greater than or equal to the value in the Minimum Radius cell.

**Minimum Radius**

Specifies the minimum radius value defined in the design criteria file (page 2472) for the current design speed.

**A**

Specifies the A value.

**Constraint1**

Specifies the constraint of the entity: either fixed, free, or floating.

**Constraint2**

Specifies the number of points in the constraint of the tangent.
If the entity was created by best fit, [...] appears to the right of the Best Fit entry. If the entity has been

edited since it was created from best fit regression data, ▽ appears. Click [...] to open the Regression Data vista (page 1990) and review the regression points and synchronize the entity to the regression data.

**Bearing**

Specifies the direction of the entity.

**Start Station**

Specifies the starting station for the entity.

**End Station**

Specifies the ending station for the entity.

**Start Point**

Specifies the coordinates for the starting point of the entity.

**End Point**

Specifies the coordinates for the end point of the entity.

**Pass Through Point1**

Specifies the point coordinates for the first pass-through point of an alignment entity.

**Pass Through Point2**

Specifies the point coordinates for the second pass-through point of an alignment entity.

**Pass Through Point3**

Specifies the direction of the third user-specified pass-through point on a curve entity.

**Spiral Type**

Specifies the spiral type.

**Incurve**

Specifies whether the curve is incoming or outgoing.

**Compound**

Displays True when a spiral has a curve at each end.

**Radius In**

Specifies the incoming curve radius.

**Radius Out**

Specifies the outgoing curve radius.

**Total X**

Specifies the tangent distance between the beginning point of the incoming spiral (TS) and the endpoint of the spiral and beginning point of the circular curve.

**Total Y**

Specifies the perpendicular offset distance between the beginning point of the circular curve (SC) and the incoming tangent.

**Short Tangent**

Specifies the distance from the spiral point of the horizontal tangent intersection (SPI) to the end of the spiral (SPI).

**Long Tangent**

Specifies the distance from the beginning of the spiral (TS) to the spiral point of horizontal tangent intersection (SPI).

**P**

Specifies the offset distance from the incoming tangent to the beginning point (PC) of the shifted circular curve.

**K**

Specifies the abscissa between the beginning point of the spiral (TS) and the beginning point of the shifted circular curve.

**Spiral Definition**

Specifies the spiral definition.

**SPI Station**

Specifies the station value of the SPI. Adds the tangential distance from the beginning of the Spiral (TS) to the SPI to the station value of the TS.

**SPI Northing**

Specifies the XY coordinates of the spiral point of horizontal tangent intersection.

**SPI Easting**

Specifies the XY coordinates of the spiral point of horizontal tangent intersection.

**SPI Included Angle**

Specifies the angle representing the difference in direction of the incoming tangent and the outgoing tangent of the spiral.

**Radial Point Northing**

Specifies the coordinates of the spiral northing.

**Radial Point Easting**

Specifies the coordinates of the spiral easting.

**Center Point**

Specifies the coordinate of the center point of a circular curve.

**Direction At Through Point1**

Specifies the XY coordinates of the first user-specified pass-through point.

**Direction At Through Point2**

Specifies the XY coordinates of the second user-specified pass-through point.

**Greater than 180 Degrees**

- Displays True if the curve angle is defined as greater than 180 degrees.

- Displays False if the curve angle is defined as less than 180 degrees.

**Compound**

Displays True when the spiral has a curve at each end.

**Delta Angle**

Specifies the angular difference in the direction of the incoming and out going tangents.

**External Tangent**

Specifies the distance from the beginning of the curve (PC) to the PI or from the PI to the end of the curve (PT).

**Chord Direction**

Specifies the bearing along the line joining the beginning of the curve (PC) and the end of the curve (PT).

**External Secant**

Specifies the radial difference from the PI to the midpoint of the curve.

**PI Included Angle**

Specifies the included angle between the incoming and outgoing tangents of the curve.

**Chord Length**

Displays the chord length of the circular curve.
Specifies the distance along the line joining the beginning of the curve (PC) and the end of the curve (PT).

**Mid-Ordinate**

Specifies the distance from the midpoint of the curve, perpendicular to the midpoint of the chord.

**PI Station**

Specifies the station value of the PI by adding the PC to the PI tangent length to the station value at the beginning of the curve (PC).

**Design Speed**

Specifies the design speed for each sub-entity.

Minimum Radius Table

Specifies the minimum radius table for each sub-entity. The Minimum Radius Table is defined in the design criteria file (page 2472).

A ⚠ warning symbol is displayed in this cell if the sub-entity radius value is not greater than or equal to the value in the Minimum Radius cell.

Transition Length Table

Specifies the minimum transition length table for each sub-entity. The Transition Length Table is defined in the design criteria file (page 2472).

A ⚠ warning symbol is displayed in this cell if the sub-entity length value is not greater than or equal to the value in the Minimum Length cell.

Attainment Method

Specifies the superelevation attainment method for each sub-entity. The Attainment Method is defined in the design criteria file (page 2472).

**Related procedures:**

■ Criteria-Based Alignment Design (page 866)

■ Selecting Alignment Entities (page 989)

■ Editing Alignment Entity Layout Parameters (page 994)

# Alignment Geometry Points Dialog Box

Use this dialog box to specify the alignment geometry points that you want to label.

## Select Geometry Points To Label

☑ Select All

Selects all check boxes in the Label column.

☐ Deselect All

Clears all check boxes in the Label column.

Geometry Points Column

Identifies the available geometric details.

**NOTE** The Abbreviations (page 1855) tab in the Drawing Settings dialog box also lists these geometry points.

Label Column

Specifies whether to label a geometry point.

**Related procedures:**

■ Using Label Sets (page 973)

# Alignment Labels Dialog Box

Use this dialog box either to create and save label sets or to import an existing label set.

**Type**

Specifies the type of label, which is related to elements in the alignment that can be labeled. After you select a label type, you assign a style. Select one or more label types to include in the label set:

- Major station

- Minor station

- Geometry points

- Station equations

- Design speeds

- Profile Geometry Points

- Superelevation Critical Points

**NOTE** You can add a label type multiple times in a label set. For example you could add geometry points twice and then apply a style to the first entry of geometry points at specified starting and ending stations. Then, in the second entry for geometry points, you could specify another style and the starting and ending stations where you want to apply that style.

**<Label Type> Style List**

Lists the styles available for the specified label type. Select a style from the list.

**Style Selection**

Specifies the style options. Create a new style, copy or edit the current style selection, or pick a style from the drawing.

**Style Detail**

Opens the Style Detail dialog box. Preview the style and creation information.

**Add>>**

Adds the selected element and style to the label set.

**NOTE** You must first select major stations in order to add minor stations.

Deletes the selected element in the label set.

**Reset**

Resets manual or grip edits that may have been made to any labels.

**Type**

Displays the label types added from the Type list.

**Style**

Displays the label style selected and added from the Style list. Click to change the style.

**Increment**

Displays the increment at which the label is displayed. To change the default value, click in the cell, and enter a new value.

**NOTE** Increment does not apply to all label types.

**Start Station**

Displays the starting station at which the label is displayed. By default, the start station is at the beginning of the alignment. To change the default display, clear the check box and enter a new value.

**End Station**

Displays the ending station at which the label is displayed. By default, the end station is at the end of the alignment. To change the default display, clear the check box and enter a new value.

**Geometry Points To Label**

Specifies the geometry points to label for the Geometry Points, Profile Geometry Points, and Superelevation Critical Points label types. You can label a selection of geometry points in a label type using a selected style. You can then add another instance of the same label type, which can label a second selection of

geometry points using a different style. Click [...] to select the geometry points to label.

**Profile**

For Profile Geometry Points label types, specifies which profile's geometry points are labeled on the

alignment [...] to change the profile.

**Station Index Increment**

When a station label style is in Station Index Format, this is the base value used to format the station labels.

For example, when station labels are displayed at 20-meter increments using the default Station Format, they are formatted as 0+00, 0+20, 0+40, 0+60, etc. If the same labels used the Station Index Format, with the Station index Increment set to 10, the labels would be formatted as 0+0, 2+0, 4+0, 6+0, etc. Changing the Station Index Increment to 20 would format the labels as 0+0, 1+0, 2+0, 3+0, etc.

**Import Label Set**

Opens the Select Style Set dialog box. Select a previously saved label set style and use it on the current alignment. Importing a label set overwrites the existing setting on the Labels tab.

**Save Label Set**

Opens the Label Set Dialog Box (page 1771). Configure the name and other settings for the current label set. This set is saved on the Toolspace Settings tab.

**Related procedures:**

■  Using Alignment Label Sets (page 973)

# Alignment Layout Parameters Window

Use this window to display and edit many attributes of any given single sub-entity within an alignment.

You can use the Alignment Layout Parameters window to change individual lines, curves, and spirals in the alignment. Use this window along with the Alignment Entities vista, which displays all of the sub-entities that make up a given alignment.

You can edit available parameters. You cannot edit parameters that are unavailable (shaded).

If the alignment uses design criteria, then the Alignment Layout Parameters window contains up to three

panels that can be collapsed by clicking ⌃ . If design criteria has not been associated with the alignment, then only the Layout Parameters panel is available.

You cannot dock the Alignment Layout Parameters window, but you can pin or resize it.

This window stays open when you grip edit the alignment or enter another command. The window closes when you either delete the currently selected alignment, click the X button in the upper right-hand corner of the window, or click  on the Alignment Layout Tools toolbar (page 1747).

**Design Speed**

Specifies the design speed of the current sub-entity.

---

**NOTE** If multiple speeds are assigned to a sub-entity, then the highest speed is used to look up constraint values from the design criteria file and to validate the design checks. This ensures the safest design for that sub-entity.

---

### Design Criteria Panel

The following parameters are displayed only if design criteria has been associated with the alignment.

Use the Design Criteria panel to apply design criteria that is different from the default values that have been set for the alignment. To change a criterion value, click the Value cell in the appropriate row.

A  warning symbol in the Property column indicates that the sub-entity design violates the criteria set in the design criteria file. You can find and correct the specific parameter that has been violated by examining the Layout Parameters panel.

Minimum Radius Table

Defines the minimum radii for a given road type and design speed.

Transition Length Table

A table of values in the Superelevation Attainment Method formulas. You can use the table to calculate the distances between the critical superelevation transition points for different types of roadways as a function of curve radius and design speed.

Attainment Method

Specifies how superelevation is applied, and the method (crowned or planar) that is used to calculate superelevation transition stations for different types of roadways.

### Layout Parameters

Use this panel to examine and change the general layout parameters of the selected sub-entity.

Click  Show More to expand the number of parameters that appears in the window. The default, collapsed view displays editable and other important parameters. Use the horizontal and vertical scroll bars when the list is longer or wider than the window.

When a design criteria file has been associated with an alignment, the Constraints column displays the value to which a given parameter is limited. The selected design criteria file defines the constrained values. When a parameter value violates the range displayed in the Constraints column, a  warning symbol appears next to the parameter name.

---

**NOTE** The constraint definition for each alignment entity determines the parameters that are displayed in the Layout Parameters panel.

---

### Line

Entity

Specifies a number for the Line, in the order of creation.

Curve Group Index

Specifies the curve group description.

Curve Group Sub-Entity Index
Specifies the curve group sub-entity description.

Type
Specifies either Line, Curve, or Spiral as the sub-entity type.

Constraint1
Specifies either Fixed, Free, or Floating as the general constraint type.

Constraint2
Specifies a detailed description of the entity constraints.

Length
Specifies the Line length.

> **NOTE** You can edit the length of a floating line that is attached to the end of an entity.

Bearing
Specifies the direction of the line.

Start Station
Specifies the starting station of the line for the solved portions of the alignment.

End Station
Specifies the end station of the Line for the solved portions of the alignment.

Start Point
Specifies the XY coordinates for the start point of the Line.

End Point
Specifies the XY coordinates for the endpoint of the Line.

Pass Through Point1
Specifies the XY coordinates of the first user-specified pass-through point.

Pass Through Point2
Specifies the XY coordinates of the second user-specified pass-through point.

## Curve (independent or in SCS)

Entity
Specifies the curve number relative to the order of creation.

Curve Group Index
Specifies the curve group description.

Curve Group Sub-Entity Index
Specifies the curve group sub-entity description.

Type
Specifies Curve as the entity type.

Constraint1
Specifies either Fixed, Free, or Floating as the general constraint type.

Constraint2
Specifies a detailed description of the entity constraints.

Radius
Specifies the radius of the curve entity.

**Length**

Specifies the length of the curve entity.

**Pass Through Point1**

Specifies the XY coordinates of the first user-specified pass-through point.

**Pass Through Point2**

Specifies the XY coordinates of the second user-specified pass-through point.

**Pass Through Point3**

Specifies the XY coordinates of the third user-specified pass-through point.

**Center Point**

Specifies the XY coordinates of the center point.

**Start Station**

Specifies the starting station of the curve for the solved portion of the alignment. Unsolved curves do not display a Start Station.

**Start Point**

Specifies the XY coordinates of the start point of the curve.

**End Station**

Specifies the end station of the curve for solved portions of the alignment. Unsolved curves do not display an end station.

**End Point**

Specifies the XY coordinates of the endpoint of the curve.

**Direction At Through Point 1**

Specifies the XY coordinates of the first user-specified pass-through point.

**Direction At Through Point 2**

Specifies the XY coordinates of the second user-specified pass-through point.

**Greater Than 180 Degrees**

- Displays True if the curve angle is defined as greater than 180 degrees.

- Displays False if the curve angle is defined as less than 180 degrees.

**Compound**

- Displays True if the curve is defined as compound to the curve before it.

- Displays False if the curve is defined in the reverse direction to the curve before it.

**Delta Angle**

Specifies the included angle of the solved portion of the curve.

**External Tangent**

Specifies the distance from either the beginning of the curve (PC) to the point of intersection (PI), or from the PI to the end of the curve (PT).

**Chord Direction**

Specifies the bearing along the line joining the beginning of the curve (PC) and the end of the curve (PT).

**External Secant**

Specifies the radial difference from the PI to the midpoint of the curve.

PI Included Angle

Specifies the included angle between the incoming and outgoing tangents of the curve.

Chord Length

Specifies the distance along the line joining the beginning of the curve (PC) and the end of the curve (PT).

Mid-Ordinate

Specifies the distance from the midpoint of the curve, perpendicular to the midpoint of the chord.

PI Station

Specifies the station value of the PI by adding the PC to the PI tangent length to the station value at the beginning of the curve (PC).

## Spiral

Entity

Specifies the spiral number relative to the order of creation.

Curve Group Index

Specifies the curve group description.

Curve Group Sub-Entity Index

Specifies the curve group sub-entity description.

Type

Specifies Spiral as the entity type.

Constraint1

Specifies the spiral as either Fixed or Free.

Constraint2

- Specifies the Spiral In, Radius, and Spiral Out for free spirals that are part of a Spiral-Curve-Spiral group.

- Specifies the start point, direction, radius, and length for fixed spirals.

Spiral Type

Displays True when the spiral has a curve at both ends.

Start Station

Specifies the Start Station at the beginning of the spiral.

Start Point

Specifies the XY coordinates of the Start Point of the spiral.

End Station

Specifies the end station for the solved spiral portions of the alignment. Unsolved portions do not display an end station.

End Point

Specifies the XY coordinates of the End Point of the spiral.

Incurve

Specifies the incoming curve radius.

Length

Specifies the length of the Spiral.

A

Specifies the A value.

Compound

- Displays True if the curve is defined as compound to the curve before it.

- Displays False if the curve is defined in the reverse direction to the curve before it.

Radius In

Specifies the incoming curve radius.

Radius Out

Specifies the outgoing curve radius.

Total X

Specifies the tangent distance between the beginning point of the incoming spiral (TS) and the endpoint of the spiral and beginning point of the circular curve.

Total Y

Specifies the perpendicular offset distance between the beginning point of the circular curve (SC) and the incoming tangent.

Short Tangent

Specifies the distance from the spiral point of the horizontal tangent intersection (SPI) to the end of the spiral (SPI).

Long Tangent

Specifies the distance from the beginning of the spiral (TS) to the spiral point of horizontal tangent intersection (SPI).

P

Specifies the offset distance from the incoming tangent to the beginning point (PC) of the shifted circular curve.

K

Specifies the abscissa between the beginning point of the spiral (TS) and the beginning point of the shifted circular curve.

Spiral Definition

Specifies the spiral definition.

PI Included Angle

Specifies the included angle between the incoming and outgoing tangents of the curve.

SPI Station

Specifies the station value of the SPI. Adds the tangential distance from the beginning of the Spiral (TS) to the SPI to the station value of the TS.

SPI Northing

Specifies the XY coordinates of the spiral point of horizontal tangent intersection.

SPI Easting

Specifies the XY coordinates of the spiral point of horizontal tangent intersection.

SPI Included Angle

Specifies the angle representing the difference in direction of the incoming tangent and the outgoing tangent of the spiral.

Radial Point Northing

Specifies the coordinates of the spiral northing.

Radial Point Easting

Specifies the coordinates of the spiral easting.

**Design Checks**

The Design Checks panel displays the name and contents of the design check set that is associated with the alignment.

When the sub-entity design violates a design check, a ⚠ warning symbol appears next to the affected design check.

**NOTE** The Design Checks panel is available only for alignments that use a design check set.

**Related procedures:**

■ Editing Alignment Entity Layout Parameters (page 994)

■ Criteria-Based Alignment Design (page 866)

# Alignment Layout Tools

Use this toolbar to draw simple tangent-tangent lines, create constraint-based alignment geometry, and edit an alignment.

The name of the currently selected alignment is displayed at the top of the toolbar. When you click an icon, the current command is displayed at the bottom of the toolbar. The toolbar remains open when you grip edit the alignment or enter another command. The toolbar closes when you either delete the currently selected alignment or click the X button in the upper-right corner of the toolbar.

Tangent-Tangent (No Curves)

Adds a series of fixed tangents between specified points.

Tangent-Tangent (With Curves)

Adds a series of fixed tangents between specified points, with free curves automatically added at the points of intersection.

Curve And Spiral Settings

Specifies the curve parameters to use with the Tangent-Tangent With Curves command.

Insert PI

Breaks a fixed line into two adjacent fixed lines by creating a point of intersection (PI) at a point that you specify.

Delete PI

Creates a single tangent from two adjacent tangents by removing their point of intersection (PI).

Break Apart PI

Separates the point of intersection (PI) where the endpoints of two fixed or floating tangents meet.

**Convert AutoCAD Line And Arc**

Creates a fixed two-point line or three-point curve alignment entity from an AutoCAD object.
An alignment sub-entity that has been converted from an AutoCAD entity may be added as a solved portion of the alignment geometry in either of two ways:

■ Before the AutoCAD entity is converted, it must be attached to an unattached end point of another solved sub-entity in the alignment.

■ After the AutoCAD entity has been converted, it may be joined to the solved alignment geometry using the alignment layout tools.

**Reverse Sub-entity Direction**

Reverses the direction of a fixed, unconnected line or curve sub-entity.

**Delete Sub-Entity**

Deletes a specified alignment sub-entity.

**Edit Best Fit Data For All Entities**

Displays a table of data that contains the original regression data for all alignment sub-entities that were created by best fit.

**Pick Sub-entity**

Displays a selected sub-entity's parameters for editing.

**Alignment Layout Parameters**

Displays a vertical table of numeric data about a single, selected alignment sub-entity.

**Alignment Entities**

Displays a horizontal table of numeric data about multiple, selected alignment subentities.

**Undo**

Reverses the last AutoCAD Civil or AutoCAD command.

**Redo**

Reverses the last Undo command. Redo is limited to one operation.

## Line Tools

Add constraint-based fixed, free, or floating lines to an alignment.

**Fixed Line (Two points)**

Adds a fixed line between two specified points.

**Fixed Line (From curve end, length)**

Adds a fixed line to and from the endpoint of an existing curve to another specified point. Tangency is not maintained if either entity is edited.

**Fixed Line - Best Fit**

Adds the most probable fixed line through a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen.

**Floating Line (From curve, through point)**

Adds a floating line from any point on an existing curve entity through a specified point.

**Floating Line (From curve end, length)**

Adds a floating line tangent, with a specified length, to the end of a curve entity. Tangency is maintained to the attached entity end, regardless of how the entity is edited.

**Floating Line - Best Fit**

Adds the most probable floating line from a point on an existing entity through a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen. Tangency is maintained to the attached entity, regardless of how the entity is edited.

**Free Line (Between two curves)**

Adds a free line between two existing curves.

## Curve Tools

Add constraint-based fixed, free, or floating curves to an alignment.

**Fixed Curve (Three points)**

Adds a fixed curve through three points.

**Fixed Curve (Two points and direction at first point)**

Adds a fixed curve that is defined by specified start and end points and a direction at the start point.

**Fixed Curve (Two points and direction at second point)**

Adds a fixed curve that is defined by specified start and end points and a direction at the end point.

**Fixed Curve (Two points and radius)**

Adds a fixed curve that is defined by specified radius, direction, and start and end points.

**Fixed Curve (From entity end, through point)**

Adds a fixed curve from the end of an existing entity to a specified end point.

**Fixed Curve (Center point and radius)**

Adds a full, fixed circle that is defined by a specified center point, direction, and radius.

**Fixed Curve (Center point and through point)**

Adds a full, fixed circle that is defined by a specified center point, direction, and pass-through point.

**Fixed Curve (Through point, direction at point and radius)**

Adds a full, fixed circle that is defined by a specified pass-through point, direction at the pass-through point, curve direction, and radius.

**Fixed Curve - Best Fit**

Adds the most probable fixed curve through a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen.

**Floating Curve (From entity, radius, through point)**

Adds a floating curve, which is defined by a specified radius and angle range, from an existing entity to a specified end point.

**Floating Curve (From entity end, through point)**

Adds a floating curve from the end of an existing entity to a specified pass-through point.

**Floating Curve (From entity, through point, direction at point)**

Adds a floating curve from an existing entity to a specified pass-through point.

**Floating Curve (From entity end, radius, length)**

Adds a floating curve, which is defined by a specified direction, radius, and length, to the end of an existing entity.

**Floating Curve - Best Fit**

Adds the most probable floating curve from an existing entity through a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen. Tangency is maintained to the attached entity, regardless of how the entity is edited.

**Free Curve Fillet (Between two entities, radius)**

Adds a free curve, which is defined by a specified angle range and radius, between two entities.

**Free Curve Fillet (Between two entities, through point)**

Adds a free curve, with a specified pass-through point, between two entities.

**Free Curve - Best Fit**

Adds the most probable free curve between two existing entities, and through a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen. Tangency is maintained to the attached entities, regardless of how the entities are edited.

### Lines with Spiral Tools

**Floating Line with Spiral (From curve, through point)**

Adds a floating spiral-line group, which is defined by a specified pass-through point, to a curve.

**Floating Line with Spiral (From curve end, length)**

Adds a floating spiral-line group, which is defined by the line length, to a curve.

### Curves with Spiral Tools

**Floating Curve with Spiral (From entity end, radius, length)**

Adds a floating spiral-curve group, which is defined by a specified radius and pass-through point, to a line.

**Floating Curve with Spiral (From entity, radius, through point)**

Adds a floating spiral-curve group, which is defined by a specified radius and length, to a curve.

**Floating Reverse Curve with Spirals (From curve, radius, through point)**

Adds a floating reverse spiral-spiral-curve group, which is defined by a specified radius and pass-through point, to a curve.

**Floating Reverse Curve with Spirals (From curve, two points)**

Adds a floating reverse spiral-spiral-curve group, which is defined by two specified pass-through points, to an existing curve.

**Free Spiral-Curve-Spiral (Between two entities)**

Adds a free spiral-curve-spiral group between

- Two tangents, creating a simple spiral.

- A tangent and a curve, creating a compound spiral at one end and a simple spiral at the other end.

- Two curves, creating two compound spirals at each end.

**Free Compound Spiral-Curve-Spiral-Curve-Spiral (Between two tangents)**

Adds a free compound spiral-curve-spiral-curve-spiral group between two tangents. You can specify a zero length for any of the three spirals.

**Free Reverse Spiral-Curve-Spiral-Spiral-Curve-Spiral (Between two tangents)**

Adds a free reverse spiral-curve-spiral-spiral-curve-spiral group between two tangents.

## Spiral Tools

**Fixed Spiral**

Adds a fixed spiral, which is defined by a specified radius and length, to the end of a line or curve.

**Free Spiral (Between two entities)**

Adds a free, compound spiral between two curves with different radii.

**Free Compound Spiral-Spiral (Between two curves)**

Adds a free compound spiral-spiral group between two curves.

**Free Reverse Spiral-Spiral (Between two curves)**

Adds a free reverse spiral-spiral group between two curves.

**Free Compound Spiral-Spiral (Between two tangents)**

Adds a free compound spiral-spiral between two tangents.

**Free Compound Spiral-Line-Spiral (Between two curves, spiral lengths)**

Adds a free compound spiral-line-spiral group, which is defined by specified spiral lengths, between two curves.

**Free Reverse Spiral-Line-Spiral (Between two curves, spiral lengths)**

Adds a free reverse spiral-line-spiral group, which is defined by specified spiral lengths, between two curves.

**Free Compound Spiral-Line-Spiral (Between two curves, line length)**

Adds a free compound spiral-line-spiral group, which is defined by a specified line length, between two curves.

**Free Reverse Spiral-Line-Spiral (Between two curves, line length)**

Adds a free reverse spiral-line-spiral, which is defined by a specified line length, between two curves.

**Related procedures:**

- Adding Lines, Curves, and Spirals to an Alignment (page 898)

# Alignment Properties Dialog Box

Use this dialog box to review or edit many alignment details such as the name, design speeds, label sets, and superelevation.

Some of the tabs on this dialog box are conditional, subject to alignment type. For example, the Curb Return Parameters tab appears only for curb return alignments.

**See also:**

■ Alignment Properties (page 863)

## Information Tab (Alignment Properties Dialog Box)

Use this tab to change the alignment name, description and alignment style information, and to review details, such as when the style was most recently modified.

Name

Specifies the name of the current alignment style.

Description

Specifies an optional description of the current alignment style.

Object Style

Specifies the alignment style. Select other styles from the list.

 Style Selection

Specifies the style options. You can create a style, copy or edit the current style selection, or pick a style from drawing.

 Style Detail

Opens the Style Detail dialog box. Preview the style and creation information.

Type

Specifies the alignment type: Centerline, Offset, Curb Return, or Miscellaneous.

Show Tooltips

Controls whether tooltips are displayed for the object in the drawing (not over toolbar icons).

## Station Control Tab (Alignment Properties Dialog Box)

Use this tab to establish the Station Reference Point and assign station equations along the alignment.

**Reference Point Station**

X

Specifies the X coordinate value for the Station Reference Point. By default, this value corresponds to the starting point on the alignment. Enter a value or pick a point in the drawing.

Y

Specifies the Y coordinate value for the Station Reference Point. By default, this value corresponds to the starting point on the alignment. Enter a value or pick a point in the drawing.

 Pick Reference Point

Specifies the XY coordinates for the Station Reference Point. Pick points in the drawing to specify the coordinates.

Station

Specifies the station at the reference point.

**Station Information**

Start

Displays the beginning station for the first solved entity in the alignment.

End

Displays the ending station for the last solved entity in the alignment.

Length

Displays the length of the alignment as the summation of the length of solved entities along each alignment.

**Station Equations**

Add Station Equation

Specifies the location for a station equation. Click the button and specify the station for the new equation by either picking a station in the drawing or entering a raw station value on the command line.

Delete Station Equation

Deletes the selected station from the drawing. Select the station row that you want to delete and click this button.

Equation

Displays the index number of the equation sorted by raw station location on the alignment.

Raw Station Back

Displays the station value at the location of the Station Equation before any Station Equation values are assigned. If there is only one Station Equation value, then the Raw Station Back and Station Back values match.

Station Back

Displays the station value at the location of the Station Equation value before any Station Equations are assigned. If there is only one Station Equation value, then the Raw Station Back and Station Back values match.

If the alignment contains more than one Station Equation value, then the Station Back value of all Station Equation values, except for the first equation, are relative to the Station Ahead value and the Station Equation value directly before it.

Station Ahead

Specifies the new station values immediately after the Station Equation value.

Increase/Decrease

Specifies whether the stations increase or decrease in value following the Station Equation location.

Comment

Specifies notes or instructions relevant to the station equations. Enter optional comments. These comments can be used in labels for station equations.

## Masking Tab (Alignment Properties Dialog Box)

Use this tab to suppress the display of an alignment and its labels for a range of stations.

Add Masking Region

Click to add a new mask region. You are asked to specify the start and end stations for the region.

 Delete Masking Region

Click to remove a mask region selected in the table.

**Masking Table**

Region

Identifies the mask region along the alignment.

Mask

When selected, the mask is applied; the mask region does not display. When deselected, the mask is removed; the region displays. A deselected mask remains in the table for future use.

Lock to Start

Click to set the start of the first mask region at the start of the alignment.

Start Station

Displays the alignment station at which the mask region begins.

Lock to End

Click to set the end of the last mask region at the end of the alignment.

End Station

Displays the alignment station at which the mask region ends.

Comment

Use this space to add text notes about the mask region.

# Design Criteria Tab (Alignment Properties Dialog Box)

Use this tab to establish the design criteria, including speeds along the length of the alignment.

**Design Speeds**

Alignments can have an unlimited number of design speeds, but they can have only one design speed at any given location.

 Add Design Speed

Specifies the location for a new design speed. Click the icon and pick a point on the alignment or enter a value at the command line to create a design speed.

 Delete Design Speed

Deletes the selected design speed. Select the design speed row and click the button to delete the design speed.

Station

Displays the station location of the design speed.

Design Speed

Specifies the design speed for the location. Click in the cell to enter a new design speed or accept the default.

Comment

Specifies notes or instructions relevant to the design speeds. Enter optional comments. These comments can be used in labels.

**Criteria-Based Design (Unlabled)**

Use the following controls to change the design criteria file, default criteria, or design check set.

### Use Criteria-Based Design

Causes the Use Design Criteria File and Use Design Check Set check boxes to become available. If this check box is cleared, Design Speed is the only design criteria that will be applied to the alignment.

### Use Design Criteria File

Applies the default design criteria file to the alignment and causes the Default Criteria property table to become available. The first design criteria file found in the *C:\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\Data\Corridor Design Standards\<units>* directory is used by default. Click

⊡ to select a different design criteria file.

The Default Criteria table displays the Properties, or table contents, that are defined in the selected design criteria file. Click the Value column to change a criteria table.

For more information, see Design Criteria Files (page 867).

### Use Design Check Set

Applies the default design check set to the alignment. Use the list to select from the available design check sets. You can also use the selector to create a design check set, copy or edit the current design check set, or pick a design check set from another alignment in the drawing.

For more information, see Alignment Design Checks (page 871).

## Profiles Tab (Alignment Properties Dialog Box)

Use this tab to view data about a profile associated with the alignment.

### Name

Specifies the name of the profile.

### Description

Specifies an optional description for the profile.

### Type

Specifies whether the current profile represents the existing ground or a finished grade.

### Surface Name

Displays the name of the surface from which the EG Profile gets elevations.

### Offset

Specifies the offset distance from the centerline of the parent horizontal alignment: either 0 for a centerline profile, a positive number for a right offset, or a negative number for a left offset.

### Update Mode

For existing ground profiles only. Specifies whether the profile updates automatically to reflect changes in surface elevation.

■ Dynamic: The profile automatically updates to reflect changes in the surface elevation or the geometry of the parent horizontal alignment.

■ Static: The profile shows surface elevations at the time of its creation. It does not update to reflect changes that occur later.

### Layer

Specifies the drawing layer on which the profile is placed.

### Style

Specifies the style used by the profile.

Station Start/End

Specifies the first and last station numbers for the profile. The station numbers represent distances along the parent horizontal alignment.

Elevation Minimum/Maximum

Specifies the highest and lowest elevation values that occur along the profile.

## Profile Views Tab (Alignment Properties Dialog Box)

Use this tab to view data about a profile view.

Name

Specifies the name of the profile.

Description

Specifies an optional description for the profile.

Stations Start/End

Specifies the first and last station numbers for the profile. The station numbers represent distances along the parent horizontal alignment.

Style

Specifies the style used by the profile.

Band Style

Specifies the band style used by the profile.

## Superelevation Tab (Alignment Properties Dialog Box)

Use this tab to enter and edit superelevation values and to add or delete transition stations.

### Superelevation Controls

Add A Transition Station

Specifies a transition station in the drawing.

Delete Transition Station

Deletes the selected transition station.

Set Superelevation Properties

Opens the Superelevation Specifications (page 1776) dialog box. Use this dialog box to define the settings and properties used to calculate the superelevation specifications for the alignment.

Hide Inside Lanes And Shoulders

If selected, hides the inside lanes and shoulders.

No.

Displays the entry number.

Superelevation Region

Displays the region number.

Station

Specifies the station of the superelevation transition point. Minimally, include the beginning and ending station of the alignment to enable establishing at least one superelevation zone.

Description

Specifies the type of transition point:

- Begin Alignment

- Begin Full Super

- Begin Normal Crown

- Begin Normal Shoulder

- End Alignment

- End Full Super

- End Normal Crown

- End Normal Shoulder

- Level Crown

- Low Shoulder Match

- Reverse Crown

- Shoulder Breakover

Left Side and Right Side Columns

Specifies the percent slopes for the various shoulder and lane segments.

Smoothing Curve Length

Specifies the length of the smoothing vertical curve at the transition point.

**Related procedures:**

- Adding Superelevation Specifications (page 884)

# Offset Parameters Tab (Alignment Properties Dialog Box)

For a dependent offset alignment, use this tab to set properties of the offset.

## Parent Alignment

Name

Specifies the name of the parent alignment, which controls the offset alignment.

Nominal Offset Value

Specifies the offset distance from the parent alignment.

Start Station – Lock to Start of Parent

Specifies the station of the parent alignment where the offset alignment begins. Enter a station value, or select the checkbox to begin the offset at the start of the parent alignment.

End Station – Lock to End of Parent

Specifies the station of the parent alignment where the offset alignment ends. Enter a station value, or select the checkbox to extend the offset to the end of the parent alignment.

Update Mode

Specifies whether the offset alignment reacts to edits of the parent alignment:

- **Dynamic.** The offset is updated with any changes to the parent alignment.

- ■ **Static**. The offset alignment geometry is preserved, unafffected by changes to the parent alignment.

Lock Mode

For dynamic update mode, specifies how the offset alignment is associated with the geometry of the parent alignment:
- ■ **Geometry Locking.** The start and end of the offset are located in relation to the nearest geometry points on the parent alignment.

- ■ **Station Locking**. The start and end of the offset are locked to the specified start and end stations on the parent alignment.

## Curb Return Parameters Tab (Alignment Properties Dialog Box)

For a curb return alignment, use this tab to review and edit design data.

### Parent Alignment 1

Name

Specifies the alignment that forms the basis of the design at the start of the curb return alignment.

Curb Return End Point Station

Specifies the station value on the parent alignment where the curb return alignment starts.

Curb Return Offset Value

Specifies the offset from the initial attachment point of the start of the curb return alignment, which is typically an offset alignment from the centerline. This field is editable.

### Parent Alignment 2

Name

Specifies the alignment that forms the basis of the design at the end of the curb return alignment.

Curb Return End Point Station

Specifies the station value on the parent alignment where the curb return alignment ends.

Curb Return Offset Value

Specifies the offset from the initial attachment point of the end of the curb return alignment, which is typically an offset alignment from the centerline. This field is editable.

Update Mode

Specifies whether the curb return alignment reacts to edits of the parent alignment or offset. This field is editable.
- ■ Dynamic. The curb return alignment is updated in response to edits of other intersection objects.

- ■ Static. The curb return alignment is at a fixed location, and does not respond to edits of other intersection objects.

Lock Mode

Specifies that the curb return is always geometry locked. The start and end of the curb return offset are located in relation to the nearest geometry points on the parent alignment.

# Alignment Style Dialog Box

Use this dialog box to control the display of each alignment component.

Create different styles to use in the various phases of your project. For example, you can create a first style to use specifically in the design phase that displays lines, curves, and other alignment subcomponents in

different colors. Then, you can create a second style to use for plotting that displays only the solved alignment geometry in one color and linetype.

**See also:**

- [Alignment Styles](#) (page 885)

# Information Tab (Alignment Style Dialog Box)

Use this tab to change the alignment style name and description information, and to review details about the alignment, such as when the style was most recently modified.

For more information, see Information Tab (Style Dialog Box) (page 1801).

# Design Tab (Alignment Style Dialog Box)

Use this tab to specify grip editing behavior. The value you enter increases or decreases the radius of curves to an even increment.

### Grip Edit Behavior

Enable Radius Snap

Specifies whether the cursor snaps to the specified increment when grip editing the radius of a free curve.

Radius Snap Value

Specifies the increment of the radius snap.

**NOTE** The snap value is based on zero. For example, if the current radius is 150.5 and the radius snap value is 10, when you grip edit the alignment to the next highest radius the radius value is 160, not 160.5.

# Markers Tab (Alignment Style Dialog Box)

Use this tab to specify the display and appearance of points on the alignment.

### Alignment Points and Marker Styles

Name

Displays the name of the point on the alignment.

Marker Style

Specifies the style for the point on the alignment. Click to open the Pick Marker Style dialog box where you can select a style or <None>.

### Arrowhead

Type

Specifies the arrowhead style for the alignment direction arrow. Select a style from the list or select User Arrow to select an AutoCAD block.

Size Options

Specifies the method used to determine the size of the arrowhead:

- Use Drawing Scale: Determines size of the arrowhead by multiplying the specified value by the drawing scale. Enter the scale factor.

- Use Fixed Scale: Activates the Fixed Scale options.

- Use Size in Absolute Units: Specifies that the arrowhead size is an absolute value based on the displayed units. Enter the value.

■ Use Size Relative to Screen: Specifies that the size of the arrowhead is a percentage of the drawing screen size. Enter the percentage.

Inches/Meters
Specify value for feet or meters.

Fit Options
Specifies how the arrow is displayed when the profile segment is shorter than the arrowhead. Select Shrink, Omit, or Always Draw.

Fixed Scale
Specifies independent fixed scale values when Size Options is set to Use Fixed Scale. Enter a value for X.

## Display Tab (Alignment Style Dialog Box)

Use this tab to change the display and visibility of alignment object components.

Alignment components include:

**Line**: Solved lines with true tangent lengths that are part of the alignment geometry.

**Curve**: Solved curves that are true curve lengths within the alignment.

**Spiral**: Spiral entities within the alignment geometry.

**Arrow**: Shows the direction of the alignment entities, either solved or unsolved.

**Line Extensions**: Line segments that extend beyond the solved portion of a line to a pass-through point or another constraint.

**Curve Extensions**: Curve segments that extend beyond the solved portion of a curve to a pass-through point or another constraint.

**Warning Symbol**: Markers that identify entities that violate the rules specified in the design criteria file. This component only applies to alignments that use design criteria.

**Pass-Through Points**: Markers that denote the pass-through points that define the geometry of any given entity.

**PI Points**: Markers that denote the pass-through points of two lines only when the pass-through points coincide exactly.

**Station Reference**: Markers that denote the station reference point on the alignment.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Alignment Style Dialog Box)

Use this tab to review all the information about the current alignment style. You can copy and paste this information to the clipboard.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

## Create Alignment From Objects Dialog Box

Use this dialog box to specify the attributes of an alignment, including the name, description, style, and starting station.

Name
Specifies the name of the alignment. Each alignment must have a unique name.

Type

Specifies the alignment type: Centerline, Offset, Curb Return, or Miscellaneous.

Description

Specifies an optional description of the alignment.

Starting Station

Specifies the station value that is assigned to the beginning of the first entity in the alignment.

NOTE Use the Station Control tab in the Alignment Properties dialog box to change the starting station after you create an alignment.

**General Tab**

Site

Specifies a site for the alignment. Select a site from the list, or click  to either create a site or select one from an object in the drawing. The alignment and the object you select in the drawing are associated with the same site.

NOTE The default selection is <None>, which places the alignment in the top-level Alignments collection in Prospector. See Alignment and Site Interaction (page 721) for more information.

Alignment Style List

Displays the current style. Click the arrow to select another alignment style in the drawing.

Style Selection

Specifies the style options. Create a style, copy or edit the current style selection, or pick a style from drawing.

Style Detail

Opens the Style Detail dialog box. Preview the style and creation information.

Alignment Layer Display List

Displays the layer on which the alignment object will be created.

Object Layer

Opens the Object Layer Dialog Box (page 1985), in which you can select or create a layer on which the alignment will be drawn.

Alignment Label Set List

Displays the default alignment label set. You can either accept the default label set, or use the list to select a different one from the drawing.

Label Set Selection

Edits or copies the current label set, or creates a label set. The Style Detail icon previews the current style.

Style Detail

Opens the Style Detail dialog box. Preview the label set and creation information.

**Conversion Options**

Add Curves Between Tangents

Specifies whether to automatically add curves between each tangent.

- Selected: Curves are placed at each tangent-tangent intersection. The radius of the curve is calculated as a percentage of the tangent length and the deflection angle.

■ Cleared: Curves are not added automatically during creation.

---

**NOTE** You can add curves using the Alignment Layout Tools.

---

Erase Existing Entities

Specifies whether the entities you selected when creating the alignment are erased. Select the check box to erase the entities.

### Design Criteria Tab

Starting Design Speed

Specifies the design speed at the alignment starting station. If no other design speeds are applied to the alignment, then the Starting Design Speed is applied to the entire alignment.

Use Criteria-Based Design

Specifies whether design criteria is applied to the alignment. If this check box is cleared, then the Use Design Criteria File and Use Design Check Set options are not available.

Use Design Criteria File

Specifies whether to associate a design criteria file with the alignment. If this check box is cleared, then the design criteria file selector and Default Criteria table are not available.
For more information, see Design Criteria Files (page 867).

Design Criteria File Selector

Specifies the design criteria file to associate with the alignment. The first design criteria file found in the following directory is used by default: *C:\Documents and Settings\All Users\Application*

*Data\Autodesk\Civil2010\enu\Data\Corridor Design Standards\<units>*. Click ![button] to select a different design criteria file.

Default Criteria Table

Displays the standards formulas that are defined in the selected design criteria file. Click the Value column to change a criteria table.

### Use Design Check Set

Use Design Check Set Check Box

Specifies whether to associate a design check set with the alignment. If this check box is cleared, then the Design Check Set list is not available.
For more information, see Alignment Design Check Sets (page 875).

Design Check Set List

Displays the default design check set. You can either accept the default design check set, or use the list to select a different one from the drawing.

![icon] Design Check Set Selection

Edits or copies the current design check set, or creates a design check set.

### Related procedures:

■ Creating an Alignment from Graphic Entities (page 891)

■ Criteria-Based Alignment Design (page 866)

# Create Alignment - Layout Dialog Box

Use this dialog box to enter information about an alignment, such as its name, a description, and the starting station for the alignment. Also, you can use it to select an alignment style, label set style, site, and design criteria.

**Related procedures:**

- Creating an Alignment with the Alignment Layout Tools (page 887)
- Criteria-Based Alignment Design (page 866)

## General Tab (Create Alignment - Layout Dialog Box)

Use this tab to enter basic information about the alignment, including site, style, layer, and label set.

Name

Specifies the name of the alignment. Each alignment must have a unique name.

Description

Specifies an optional description of the alignment.

Starting Station

Specifies the station value that is assigned to the beginning of the first alignment entity created.

**NOTE** Use the Station Control tab in the Alignment Properties dialog box to change the starting station after you create an alignment.

### Site

Specifies a site for the alignment. Select a site from the Site list, or click  to either create a site or select one from an object in the drawing. The alignment and the object you select in the drawing are associated with the same site.

**NOTE** The default selection is <None>, which places the alignment in the top-level Alignments collection in Prospector. See Alignment and Site Interaction (page 721) for more information.

### Alignment Style

Alignment Style List

Displays the current style. Click the arrow to select another alignment style in the drawing.

 Style Selection

Specifies the style options. Create a style, copy or edit the current style selection, or pick a style from drawing.

 Style Detail

Opens the Style Detail dialog box. Preview the style and creation information.

### Alignment Layer

Alignment Layer Display List

Displays the layer on which the alignment object is created.

 Object Layer

Opens the Object Layer Dialog Box (page 1985), in which you can select or create a layer on which the alignment is drawn.

### Alignment Label Set

Alignment Label Set List
　Displays the default alignment label set. You can either accept the default label set, or use the list to select a different one from the drawing.

 Label Set Selection
　Edits or copies the current label set, or creates a label set. The Style Detail icon previews the current style.

 Style Detail
　Opens the Style Detail dialog box. Preview the label set and creation information.

# Design Criteria Tab (Create Alignment - Layout Dialog Box)

Use this tab to specify the design criteria settings, including the design criteria file and design check set.

Name
　Specifies the name of the alignment. Each alignment must have a unique name.

Description
　Specifies an optional description of the alignment.

Starting Station
　Specifies the station value that is assigned to the beginning of the first alignment entity created.

　**NOTE** Use the Station Control tab in the Alignment Properties dialog box to change the starting station after you create an alignment.

### Starting Design Speed

Specifies the design speed at the alignment starting station. If no other design speeds are applied to the alignment, then the Starting Design Speed is applied to the entire alignment.

### Use Criteria-Based Design

Specifies whether design criteria is applied to the alignment. If this check box is cleared, then the Use Design Criteria File and Use Design Check Set options are not available.

### Use Design Criteria File

Use Design Criteria File
　Specifies whether to associate a design criteria file with the alignment. If this check box is cleared, then the design criteria file selector and Default Criteria table are not available.
　For more information, see Design Criteria Files (page 867).

Design Criteria File Selector
　Specifies the design criteria file to associate with the alignment. The first design criteria file found in the *C:\Documents and Settings\All Users\Application Data\Autodesk\Civil2010\enu\Data\Corridor Design Standards\<units>* directory is used by default. Click  to select a different design criteria file.

Default Criteria Table
　Displays the alignment standards formulas that are defined in the selected design criteria file. Click the Value column to change a criteria table.

### Use Design Check Set

Use Design Check Set Check Box
　Specifies whether to associate a design check set with the alignment. If this check box is cleared, then the Design Check Set list is not available.

For more information, see Alignment Design Check Sets (page 875).

Design Check Set List

Displays the default design check set. You can either accept the default design check set, or use the list to select a different one from the drawing.

Design Check Set Selection

Edits or copies the current design check set, or creates a design check set.

# Create Offset Alignments Dialog Box

Use this dialog box to create dependent offset alignments from an existing alignment.

You can create multiple offsets in a single operation, including a different number on each side of the parent alignment. The offset distance can be different on each side of the parent alignment.

Alignment to Offset From

Specifies the name of the parent alignment.

Offsets Name Template

Specifies the format of the alignment name. If you want to change this format, click the button to open the Name Template Dialog Box (page 1806).

Station Range

Specifies the start and end stations on the parent alignment where the offset alignments will start and end. You can either enter numeric values, or click the buttons and pick locations in the drawing.

No. of Offsets on Left/Right

Specifies the number of offsets to create on each side of the alignment. Left and right sides are determined from a position facing toward the end of the parent alignment.

Incremental Offset on Left/Right

Specifies the offset distance on each side, between each pair of alignment.

**General Tab**

Site

Specifies a site for the alignment. Select a site from the list, or click   to either create a site or select one from an object in the drawing. The alignment and the object you select in the drawing are associated with the same site.

NOTE The default selection is <None>, which places the alignment in the top-level Alignments collection in Prospector. See Alignment and Site Interaction (page 721) for more information.

Alignment Style List

Displays the current style. Click the arrow to select another alignment style in the drawing.

Style Selection

Specifies the style options. Create a style, copy or edit the current style selection, or pick a style from drawing.

Style Detail

Opens the Style Detail dialog box. Preview the style and creation information.

Alignment Layer Display List

Displays the layer on which the alignment object will be created.

 Object Layer

Opens the Object Layer Dialog Box (page 1985), in which you can select or create a layer on which to draw the alignment.

**Alignment Label Set List**

Displays the default alignment label set. You can either accept the default label set, or use the list to select a different one from the drawing.

 Label Set Selection

Edits or copies the current label set, or creates a label set. The Style Detail icon previews the current style.

 Style Detail

Opens the Style Detail dialog box. Preview the label set and creation information.

**Design Criteria Tab**

**Starting Design Speed**

Specifies the design speed at the alignment starting station. If no other design speeds are applied to the alignment, then the Starting Design Speed is applied to the entire alignment.

**Use Criteria-Based Design**

Specifies whether design criteria is applied to the alignment. If this check box is cleared, then the Use Design Criteria File and Use Design Check Set options are not available.

**Use Design Criteria File**

Specifies whether to associate a design criteria file with the alignment. If this check box is cleared, then the design criteria file selector and Default Criteria table are not available.
For more information, see Design Criteria Files (page 867).

**Design Criteria File Selector**

Specifies the design criteria file to associate with the alignment. The first design criteria file found in the following directory is used by default: *C:\Documents and Settings\All Users\Application*

*Data\Autodesk\Civil2010\enu\Data\Corridor Design Standards\<units>*. Click  to select a different design criteria file.

**Default Criteria Table**

Displays the standards formulas that are defined in the selected design criteria file. Click the Value column to change a criteria table.

**Use Design Check Set**

**Use Design Check Set Check Box**

Specifies whether to associate a design check set with the alignment. If this check box is cleared, then the Design Check Set list is not available.
For more information, see Alignment Design Check Sets (page 875).

**Design Check Set List**

Displays the default design check set. You can either accept the default design check set, or use the list to select a different one from the drawing.

 Design Check Set Selection

Edits or copies the current design check set, or creates a design check set.

**Related procedures:**

■ Creating Offset Alignments (page 895)

# Curve and Spiral Settings Dialog Box

Use this dialog box to enter the curve settings you want to use when creating alignments or parcels using the Tangent-Tangent (With Curves) command and to specify the spiral defaults.

While you can select various combinations of Spiral In, Curve, and Spiral Out, the A value of the spirals is controlled by the radius of the curve. The length of the spirals is controlled by changing the A Value.

**NOTE** If the alignment has design criteria applied to it, the default values specified in the Curve and Spiral Settings dialog box will not be used. Instead, the minimum values in the specified design criteria file will be applied. For more information, see Creating an Alignment with the Alignment Layout Tools (page 887).

For more information on spirals and spiral formulas, see Spiral Definitions (page 939).

Type

Specifies the spiral type.

**NOTE** The spiral type you specify is used in all spiral commands on the Alignment Layout Tools toolbar.

Spiral In

Specifies whether your design includes a spiral either before a curve or before a Spiral Out.

Length

Specifies the length for the Spiral In.

A Value

Specifies the A value for the Spiral In.

Curve

Specifies how a curve is inserted: either with or without the Spiral In, with or without the Spiral Out or by itself.

Radius

Specifies a radius value. This value applies to curves and spirals. If you change the curve radius, the A value also changes.

Spiral Out

Specifies whether your design includes a Spiral Out.

Length

Specifies the length for the Spiral Out.

A Value

Specifies the A value for the Spiral Out.

# Edit Feature Settings - Alignment Dialog Box

Use this dialog box to view and change alignment-related settings.

This topic documents settings in all alignment-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

■ Drawing-level ambient settings are identified by the [icon] drawing icon.

- Alignment feature settings are listed near the top of this dialog box, after the General property group, and are identified by the ⇥ alignment icon.

- Alignment command settings are identified by the ⊞ command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

These settings establish the default styles assigned to alignments and alignment-related labels.

## ⇥ Default Styles

Use these settings to specify the default styles for new alignments.

Alignment Style

  Specifies the default alignment style. Click in the Value column, and click ⋯ to select a style in the Alignment Style dialog box.

Alignment Label Set

  Specifies the default alignment label set. Click a cell in the Value column, and click ⋯ to select the label set in the Alignment Label Set dialog box.

Marker Style

  Specifies the display and appearance of points on the alignment. Click in the Value column, and click ⋯ to select a style in the Marker Style dialog box.

Line Label Style

  Specifies the default line label style. Click in the Value column, and click ⋯ to select a style in the Line Label Style dialog box.

Curve Label Style

  Specifies the default curve label style. Click in the Value column, and click ⋯ to select a style in the Curve Label Style dialog box.

Spiral Label Style

  Specifies the default spiral label style. Click in the Value column, and click ⋯ to select a style in the Spiral Label Style dialog box.

Station Offset Label Style

  Specifies the default station offset label style. Click in the Value column, and click ⋯ to select a style in the Station Offset Label Style dialog box.

Tangent Intersect Label Style

  Specifies the default tangent intersection label style. Click in the Value column, and click ⋯ to select a style in the Tangent Intersect Label Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

### ⇥ Default Name Format

Use these settings to specify the default name formats for new alignments. Click in the Value column, and click ⬚ to make changes in the .

### ⇥ Station Indexing

Use this setting to specify the default station increment.

Default Station Index Increment
> Specifies the default value for station increments.

### ⇥ Superelevation Options

Use these settings to to specify defaults for calculating superelevation specifications.

Corridor Type
> Specifies the type of roadway as Undivided (single carriage way) or Divided (dual carriage way).

Cross Section Shape
> CrownedSpecifies the cross sectional shape of the roadway as Planar or :
>
> - Planar: There is no change in slope between the travel lanes.
>
> - Crowned: When no superelevation is applied, travel lanes slope downward in opposite directions from a common crown point.

Highside Location (For Planar Roads)
> Specifies the default Highside Location for planar roads.
>
> - Left Edge: Specifies that the high side of the roadway is on the left edge on tangent (unsuperelevated) sections when the corridor type is Undivided and the Cross Section Shape is planar.
>
> - Level: The roadway is level (0% slope) on tangent sections.
>
> - Right Edge: Specifies that the high side of the roadway is on the right edge on tangent (unsuperelevated) sections, when the corridor type is Undivided and the Cross Section Shape is planar.

Nominal Width - Pivot To Edge
> Specifies the typical width of the roadway from the superelevation pivot point to the outer edge-of-traveled way. Some superelevation attainment methods require that you specify this value to calculate the length of the superelevation transition. Enter a width in the Value column or click ⬚ and select a distance in the drawing area.

Normal Lane Slope (%)
> Specifies the % slope of the roadway lanes on tangent (unsuperelevated) tangents. Typical values are -15% to -2.5% for the slope used for roadway lanes when no superelevation is applied.

Normal Shoulder Slope (%)
> Specifies the % slope value of the roadway shoulders. This value is only required if either of the shoulder superelevation methods is not set to Default. Default value for a normal shoulder slope is -5%.

Station Rounding Option
> Specifies the number of positions for station rounding. Click the Value cell and choose one of the following from the list:
>
> - None: leaves stations as they are specified in the table
>
> - 0.1: rounds to the nearest tenth value of the station
>
> - 1: rounds up to nearest full station value

- 5: rounds up to nearest fifth meter or foot

- 10: rounds up to nearest tenth meter or foot

**NOTE** The following options for Outside Shoulder Superelevation Method and Inside Shoulder Superelevation Method are only available if the Cross Section Shape is Crowned. These options are not available for Planar roads.

Outside Shoulder Superelevation Method
Specifies the method that is applied to the outside shoulder during superelevation:

- Default Slopes: Default slopes are retained and shoulders are not superelevated.

- Match Lane Slopes: Shoulder slopes match the slopes applied to the adjacent traveled ways through out the superelevation process.

- Breakover Removal: Shoulders on the outside edge of the curve are adjusted upward to match the Normal Lane Slope (%) before the lane begins to superelevate. The high-side shoulder slope matches the high-side lane slope throughout the superelevation process, and it then rotates downward back to the Normal Shoulder Slope (%) value when the lanes are back to the unsuperelevated condition.

Inside Shoulder Superelevation Method
Specifies the method that is applied to the inside shoulder during superelevation:

- Default Slopes: Default slopes are retained and shoulders are not superelevated.

- Match Lane Slopes: Shoulder slopes match the slopes applied to the adjacent traveled ways through out the superelevation process.

- Breakover Removal: Shoulders on the outside edge of the curve are adjusted upward to match the Normal Lane Slope (%) before the lane begins to superelevate. The high-side shoulder slope matches the high-side lane slope throughout the superelevation process, and it then rotates downward back to the Normal Shoulder Slope (%) value when the lanes are back to the unsuperelevated condition.

## Criteria-Based Design Options

Use these settings to specify defaults for creating an alignment using design criteria.

Default Design Speed

Specifies the default alignment design speed. Enter a speed in the Value column or click and select a design speed in the drawing area.

Criteria-Based Design Option
Specifies whether alignments use design criteria by default. If this option is set to False, the remaining Criteria-Based Design Options are not available.

**NOTE** If the Criteria-Based Design Option is set to False, then the remaining Criteria-Based Design Options are not available.

Use Design Criteria File Option
Specifies whether to use a design criteria file by default. If this option is set to True, then the first XML file found in the *<install directory>\Data\Corridor Design Standards\<units>* directory is used by default.

Use Design Checks Option
Specifies whether to use a design check set by default.

Default Design Check Set

Specifies the default design check set. Click in the Value column, and click to select a set in the Default Design Check Set dialog box.

Design Speed Lookup Method

Specifies the table lookup rule in cases where the actual design speed does not exactly match the speed specified in the design criteria tables:

- Interpolate: Table values are interpolated to the given speed.

- Use Nearest Higher Speed: Uses the table values that correspond to the next highest design speed found in the table. (Conservative rule)

- Round To Nearest Speed: Uses the table values corresponding to the nearest speed, either higher or lower.

Radius Lookup Method

Specifies the table lookup rule in cases where the actual radius does not exactly match the speed specified in the design criteria tables:

- Interpolate: Interpolates table values for the curve group radius.

- Use Nearest Lowest Radius: Uses table values corresponding to the next lowest radius found in the table.(Conservative rule)

- Round To Nearest Radius: Uses table values corresponding to the nearest radius value found in the table.

**Related procedures:**

- Alignment Settings (page 860)

# Label Set Dialog Box

Use this dialog box to view or edit the properties of label sets, such as the label set name and included labels.

**See also:**

- Using Alignment Label Sets (page 973)

# Information Tab (Label Set Dialog Box)

Use this tab to edit primary information about a label set.

Name

Specifies the name of the label set.

Description

Specifies an optional description of the label set.

Created By

Displays the AutoCAD login name of the person who created the label set.

Date Created

Displays the date and time the label set was created.

Last Modified By

Displays the AutoCAD login name of the person who last modified the label set.

Date Modified

Displays the date and time the label set was last modified.

# Labels Tab (Label Set Dialog Box)

Use this tab to specify which labels are included in the set.

Type

Specifies the type of label to be configured and added to the label set.

**NOTE** Labels sets for superimposed profiles have only major stations and minor stations label types.

<Label Type> Label Style List

Specifies the style for the labels. Use the buttons to create or edit a label style.

 Style Selection

Specifies the style options. Create a style, copy or edit the current style selection, or pick a style from drawing.

 Style Detail

Opens the Style Detail dialog box. Preview the style and creation information.

Add>>

Adds the specified label style to the label set.

✖

Deletes a label style from the label set.

**List of Selected Styles (Unlabeled)**

When you add a label style to a set, it is inserted into the list in the lower part of the dialog box. Use this area to define properties for the label styles and to change the selected label styles.

Type Column

Displays the label types in the current label set.

Style Column

Specifies the label style to include in the set. Click  to open the Pick Label Style dialog box.

Increment Column

Specifies the increment at which to insert major and minor station labels. Click the cell to edit the value.

**NOTE** This setting is available for station labels only.

Geometry Points To Label Column

Specifies the geometry points to label for the Geometry Points, Profile Geometry Points, and Superelevation Critical Points label types. You can label a selection of geometry points in a label type using a selected style. You can then add another instance of the same label type, which can label a second selection of geometry points using a different style. Click  to select the geometry points to label.

**Profile Label Properties**

When you add a profile label style to a label set, you can specify property values that are unique to profile label sets:

Dim Anchor Opt

Specifies the location of the anchor used to position dimension lines for certain profile view labels, such as vertical curve labels.

- **Distance Above**: Moves the dimension line anchor up the distance specified in the Dim Anchor Val field.

- **Fixed Elevation**: Places the dimension line anchor at a fixed elevation on a profile view. Specify the elevation in the Dim Anchor Val field.

- **Distance Below**: Moves the dimension line anchor down the distance specified in the Dim Anchor Val field.

Dim Anchor Val

Specifies the dimension line anchor value to apply using the Dim Anchor Opt.

Weeding

Specifies a label exclusion distance for grade break labels only. Use this setting to remove overlapping labels, making it easier to read the remaining labels. If another grade break occurs within the specified distance, it is not labeled.

**NOTE** This setting is available for Grade Break labels only.

**Related procedures:**

- [Creating a Label Set](#) (page 1547)

# Offset Parameters Dialog Box

Use this dialog box to edit the specifications of an offset alignment or widening.

Alignment Name

Identifies the alignment for which parameters are displayed.

Nominal Offset

Specifies the current offset distance for regions of the alignment that are not widened. You can edit this value.

Add a Widening button

Click to add a new widening, and then specify the parameters.

**✖** Delete Region

Click to delete the active region

**⊟▼** Expand All Categories

Click to show all levels of the parameter tree.

**⊟▲** Collapse All Categories

Click to hide all sublevels of the parameter tree, showing only the region and transition headings.

**Parameter Table**

When you click the name of a region in this table, the region is highlighted in the drawing.

Region Type

Nominal or Specific. A nominal region is generally placed before or after a widening, and the length is not critical to the widening design. A specific region is part of a widening, and has a specific length.

Start/End Station

Edit numeric values in the table, or click ![icon] and click a station value in the drawing.

Region Length

Edit the numeric value in the table, or click ![icon] and click two points in the drawing to specify a length. Changes to this value also change the end station value for the region.

Offset

Edit the numeric value in the table, or click ![icon] and click two points in the drawing to specify an offset distance.

Transition Type

Choose from one of four types:

**Linear transition**

**Curve-Line-Curve transition**

**Curve-Curve-Reverse Curve transition**

**Curve- Reverse Curve transition**

Taper Input Type

For transitions, specifies how the offset is designed: either By Length (longitudinal) or By Taper Ratio (offset: station distance).

# Profile Geometry Points Dialog Box

Use this dialog box to specify the profile geometry points that you want to label.

### Select Profile

Lists the profiles that are available for selection. Click  to select a profile from the drawing.

### Description

Displays the description of the selected profile. A profile description is set in the profile properties.

### Select Geometry Points To Label

 Select All

Selects all check boxes in the Label column.

 Deselect All

Clears all check boxes in the Label column.

Profile Geometry Points Column

Identifies the available geometric details.

**NOTE** The Abbreviations (page 1855) tab in the Drawing Settings dialog box also lists these geometry points.

Label Column

Specifies whether to label a geometry point.

### Related procedures:

■  Using Label Sets (page 973)

# Superelevation Critical Points Dialog Box

Use this dialog box to specify the superelevation critical points that you want to label.

### Select Superelevation Points To Label

 Select All

Selects all check boxes in the Label column.

 Deselect All

Clears all check boxes in the Label column.

Superelevation Points Column

Identifies the available geometric details.

**NOTE** The Abbreviations (page 1855) tab in the Drawing Settings dialog box also lists these geometry points.

Label Column

Specifies whether to label a geometry point.

**Related procedures:**

■ Using Label Sets (page 973)

# Superelevation Specification Dialog Box

Use this dialog box to edit Design Rules and Default Options for each Superelevation Region.

The settings in this dialog box are used to calculate the superelevation specifications for the alignment. The Properties pane displays a Superelevation Region for each curve group in the alignment. Each region has design rules and default options. When you click OK the dialog box closes and any existing entries on the Superelevation tab are overwritten.

---

**WARNING** If the horizontal geometry violates minimum standards in the look-up tables, for example, if the radius of the curve is too small for the design speed, the Event Viewer posts a warning. It is highly recommended that you set the Show Event Viewer setting to Yes in the General section of the Edit Feature Settings - Alignment Dialog Box (page 1767) dialog box.

---

### Design Rules

In this section you specify the tables to use for superelevation rate, transition length, and attainment method.

Curve Start Station

Displays the station of the beginning curve group. This value is derived from the alignment geometry.

Curve End Station

Displays the station at the end of the curve group. This value is derived from the alignment geometry.

Design Speed

Displays the design speed for the curve group. This value is derived from the Design Criteria tab of the Alignment Properties. If the curve group has two or more design speeds, the highest design speed is displayed.

Design Criteria File Name

Specifies the name of the design criteria file. This file defines minimum radius tables, superelevation attainment methods and formulae, superelevation rates and transition lengths for various roadway types and design speeds. Click in the cell to browse to the location of the design criteria file.

Superelevation Rate Table

Specifies the name of the superelevation rate table used to determine the maximum superelevation rate for the curve group. Click the arrow to display a list of the superelevation rate tables associated with the specified design criteria file.

Transition Length Table

Specifies the name of the superelevation transition length table used to calculate the transition stations for the curve group. Click the arrow to display a list of the transition length tables associated with the specified superelevation rate table.

Attainment Method

Specifies the name of the superelevation attainment method for the curve group. Click the arrow to display a list of the attainment methods associated with the specified design criteria file.

### Default Options

In this section, you specify the general settings used to calculate superelevation specifications.

**Corridor Type**

Specifies the type of roadway as Undivided (single carriage way) or Divided (dual carriage way).

**Cross Section Shape**

Specifies the cross sectional shape of the roadway as Planar or Crowned:

- Planar: There is no change in slope between the travel lanes.

- Crowned: When no superelevation is applied, travel lanes slope downward in opposite directions from a common crown point.

**Highside Location**

Specifies the default Highside Location for planar roads.

- Left Edge: Specifies that the high side of the roadway is on the left edge on tangent (unsuperelevated) sections when the corridor type is Undivided and the Cross Section Shape is planar.

- Level: The roadway is level (0% slope) on tangent sections.

- Right Edge: Specifies that the high side of the roadway is on the right edge on tangent (unsuperelevated) sections, when the corridor type is Undivided and the Cross Section Shape is planar.

**Nominal Width - Pivot To Edge**

Specifies the typical width of the roadway from the superelevation pivot point to the outer edge-of-traveled way. Some superelevation attainment methods require that you specify this value in order to calculate the length of the superelevation transition.

**Normal Lane Slope (%)**

Specifies the % slope of the roadway lanes on tangent (unsuperelevated) tangents. Typical values are -15% to -2.5%. for the slope used for roadway lanes when no superelevation is applied.

**Normal Shoulder Slope (%)**

Specifies the % slope value of the roadway shoulders. This value is only required if the Shoulder Method selection is not set to None. Default value for a normal shoulder slope is -5%.

**Station Rounding Option**

Specifies the number of positions for station rounding. Click the Value cell and choose one of the following from the list:

- None: Leaves stations as they are specified by table

- 0.1: Rounds to the nearest tenth value of the station

- 1: Rounds to nearest full station value

- 5: Rounds to nearest 5th meter or feet

- 10: Rounds to nearest 10th meter or feet

**Design Speed Lookup Method**

Specifies the superelevation table lookup rule in cases where the actual design speed does not exactly match the speed specified in the table:

- Interpolate: Table values are interpolated to the given speed.

- Use Nearest Higher Speed: Uses the table values that correspond to the next highest design speed found in the table. (Conservative rule)

- Round To Nearest Speed: Uses the table values corresponding to the nearest speed, either higher or lower.

Radius Lookup Method

Specifies the superelevation table lookup rule in cases where the actual curve group radius does not exactly match the values specified in the table:

■ Interpolate: Interpolates table values for the curve group radius.

■ Use Nearest Lowest Radius: Uses table values corresponding to the next lowest radius found in the table.(Conservative rule)

■ Round To Nearest Radius: Uses table values corresponding to the nearest radius value found in the table.

**NOTE** The following options for Outside Shoulder Superelevation Method and Inside Shoulder Superelevation Method are only available if the Cross Sections Shape is Crowned. These options are not available for Planar roads.

Outside Shoulder Superelevation Method

Specifies the method that is applied to the outside shoulder during superelevation:

■ Default Slopes: Default slopes are retained and shoulders are not superelevated.

■ Match Lane Slopes: Shoulder slopes match the slopes applied to the adjacent traveled ways through out the superelevation process.

■ Breakover Removal: Shoulders on the outside edge of the curve are adjusted upward to match the Normal Lane Slope (%) before the lane begins to superelevate. The high-side shoulder slope matches the high-side lane slope throughout the superelevation process, and it then rotates downward back to the Normal Shoulder Slope (%) value when the lanes are back to the un-superelevated condition.

Inside Shoulder Superelevation Method

Specifies the method that is applied to the inside shoulder during superelevation:

■ Default Slopes: Default slopes are retained and shoulders are not superelevated.

■ Match Lane Slopes: Shoulder slopes match the slopes applied to the adjacent traveled ways through out the superelevation process.

■ Breakover Removal: Shoulders on the outside edge of the curve are adjusted upward to match the Normal Lane Slope (%) before the lane begins to superelevate. The high-side shoulder slope matches the high-side lane slope throughout the superelevation process, and it then rotates downward back to the Normal Shoulder Slope (%) value when the lanes are back to the unsuperelevated condition.

**Related procedures:**

■ Superelevation (page 877)

# Assemblies and Subassemblies Dialog Boxes

# 46

The following topics provide information about the Assemblies and Subassemblies dialog boxes.

## Assembly Properties Dialog Box

Use this dialog box to edit the properties of an assembly.

## Information Tab (Assembly Properties Dialog Box)

Use this tab to view or edit general information about the assembly.

Name
  Specifies the name of the current assembly.

Description
  Specifies an optional description for the current assembly.

Object Style
  Specifies the style used to display the current assembly. See Select Style Dialog Box (page 1805) or Assembly Style Dialog Box (page 1781) for more information.

Show Tooltips
  Controls whether tooltips are displayed for the object in the drawing (not over toolbar icons).

## Construction Tab (Assembly Properties Dialog Box)

Use this tab to view the organizational structure of the subassemblies and subassembly groups comprising the assembly.

Item
  The left pane tree view displays the organizational structure of the assembly. Subassemblies are displayed in the tree view in the order in which they are processed (top to bottom). This is the same order in which each subassembly was added to the assembly. The tree view also shows how the subassembly groups are

connected to a primary baseline, or to a given offset line. You can delete, move or rename many items in this view using the right-click shortcut menu.

Input Value

When a subassembly is selected in the left pane, this pane lists information on the input parameter values that are used to calculate the size, shape, and geometry of the subassembly.

Value Name

Specifies the name of each input parameter associated with the subassembly.

Default Input Value

Specifies the input parameter value used in the processing for the selected subassembly. To edit this field, double-click in it.

Parameter Reference

Specifies that the output value from another subassembly is used as the input parameter value for the selected subassembly.

- **Use**: The value specified in the Get Value From field is used for the input parameter value instead of the default input parameter value.

- **Get Value From**: Specifies the output value from another subassembly that is used as the input parameter value for the selected subassembly.

Output Value

Lists read-only information about any output parameter values used during processing for the selected subassembly. These output values can be used as input values for other subassemblies. The actual output values are calculated only when the assembly is applied (when the corridor is created).

Value Name

Specifies the name of any output parameters for the selected subassembly.

Output Value

Specifies the value of any output parameters for the selected subassembly.

**Subassembly Help**

When a subassembly is selected in the tree view, click this button to display the Help topic describing the construction, behavior, and other details of the subassembly.

# Codes Tab (Assembly Properties Dialog Box)

Use this tab to edit the display styles for the codes associated with the selected assembly.

Code Set Style

Specifies the current code set style for the assembly. For more information, see Select Style Dialog Box (page 1805).

The properties table contains the following columns:

Name

Displays an expandable tree with a collection for each type of code: Link, Point, and Shape. Expand the collections to display the individual codes. For information about codes, see Understanding Point, Link, and Shape Codes (page 1406).

Description

Displays the description of each code.

Style

Displays the style assigned to each code.

Label Style

Displays the label style assigned to each code or <none> if no label style is assigned.

Render Material

Displays the render material assigned to each code or <none> if no render material is assigned.

Material Area Fill Style

Displays the Material Area Fill style assigned to each code or <none> if no label style is assigned.

# Assembly Style Dialog Box

Use this dialog box to control the display of the assembly in the drawing.

# Information Tab (Assembly Style Dialog Box)

Use this tab to edit the assembly style name and description and to review details, such as when the style was created and most recently used.

For more information, see Information Tab (Style Dialog Box) (page 1801).

# Marker Tab (Assembly Style Dialog Box)

Use this tab to specify the appearance of the assembly components (insertion point, baseline, baseline point, offset, and offset point) in the drawing.

Component

Specifies the assembly component for which you want to specify the appearance.

Use AutoCAD POINT For Marker

Specifies that the assembly component is displayed using the current AutoCAD point symbol, which is specified by the AutoCAD PDMODE and PDSIZE system variables.

Use Vertical LINE For Marker

Specifies that a vertical line is used for the component. Used for baseline and offset components. You can specify the length of the line using the Size field.

## Use Custom Marker

Use Custom Marker

Displays the assembly using the specified symbol.

Custom Marker Style

Specifies the symbol for displaying the marker. Click one of the five symbols to the left to use as a base symbol. Optionally, click the sixth symbol, the seventh symbol, or both, to superimpose them over the base symbol. The specified symbol combination is displayed in the Preview window.

## Use AutoCAD Block Symbol For Marker

Use AutoCAD BLOCK Symbol For Marker

Displays the assembly using a reference to the selected AutoCAD block. The block is scaled using the options specified under Size.

Blocks

Lists block definitions available in the drawing. Do one of the following:

■ Click a block name to select the block to be used for the assembly symbol. The block is displayed in the Preview window.

■ Right-click in the block list window and click Browse to select a block located in another folder.

The specified block is displayed in the Preview window.

**Marker Rotation Angle**

Marker Rotation Angle

Specifies the rotation angle for the symbol. Applies to all three symbol types (AutoCAD Point, Custom Marker, and AutoCAD Block). Enter a value or click ⬚ to specify an angle.

**Size**

Options

Specifies symbol scaling:

■ Use Drawing Scale: Determines size of the marker by multiplying the specified value by the drawing scale. Enter the scale factor.

■ Use Fixed Scale: Activates the Fixed Scale options.

■ Use Size in Absolute Units: Specifies that the marker size is an absolute value based on the displayed units. Enter the value. This is the only setting applicable for the baseline and offset line components.

■ Use Size Relative to Screen: Specifies that the size of the marker is a percentage of the drawing screen size. Enter the percentage.

Fixed Scale

Specifies independent fixed scale values when Options is set to Use Fixed Scale. Enter values for X, Y, or Z.

Orientation reference

Specifies the marker rotation angle:

■ Orient Marker To World Coordinates: Specifies that the maker rotation angle is relative to the world coordinate system.

■ Orient Marker To View: Specifies that the maker rotation angle is relative to the current AutoCAD view direction.

# Display Tab (Assembly Style Dialog Box)

Use this tab to change the display and visibility of assembly object components.

Assembly components include:

■ Insertion Point: Specifies the location in the drawing where the assembly is inserted.

■ Baseline: In layout mode, the symbol that is used to identify the assembly baseline in a drawing.

■ Baseline Point: Specifies the location that is used as the baseline location (point) for the assembly in the drawing.

■ Offset: If the assembly is associated with an offset, specifies the offset value.

■ Offset Point: If the assembly is associated with an offset, specifies the offset location in the drawing.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Assembly Style Dialog Box)

Use this tab to review all the information for the current assembly style. This information can be copied and pasted to the clipboard.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Code Set Style Dialog Box

Use this dialog box to edit the code set style.

# Information Tab (Code Set Style Dialog Box)

Use this tab to edit general information for the code set style.

Name

Specifies the code set style name.

Description

Specifies an optional description of the code set style.

# Codes Tab (Code Set Style Dialog Box)

Use this tab to view or change the style for each point, link, or shape code included in the code set.

Name

Displays an expandable tree with a collection for each type of code: Link, Point, and Shape. Expand the collections to display the individual codes. Right-click a code collection to add a style.

Description

Displays the description of each code.

Style

Displays the style assigned to each code. Click  to select a style in the Pick Style dialog box.

Label Style

Displays the label style assigned to each code or <none> if no label style is assigned. Click  to select a style in the Pick Style dialog box.

Render Material

Displays the render material assigned to each link code or <none> if no render material is assigned. Click

 to select a render material in the Select Render Material dialog box, or click  to select a render material from an object in the drawing. You can only assign render materials to link codes, not point codes or shape codes.

Material Area Fill Style

Displays the Material Area Fill style assigned to each link code or <none> if no label style is assigned. Click

 to select a style in the Pick Style dialog box. You can only assign material area fill style to link codes, not point codes or shape codes.

Feature Line Style

Displays the feature line style assigned to each point code. You can only assign feature line style to point

codes, not to link codes or shape codes. des. Click  to select a style in the Pick Style dialog box.

Import Codes

Adds codes from a selected subassembly, assembly, or corridor to this code set.

**Related procedures:**

- Understanding Point, Link, and Shape Codes (page 1406)
- Adding or Importing Codes to a Code Set Style (page 1415)

# Create Assembly Dialog Box

Use this dialog box to specify the initial parameters for the assembly, including a style and a layer.

Name

Specifies the name of the assembly.

Opens the Name Template (page 1806) dialog box, where you can modify the naming template.

Description

Specifies an optional description of this assembly.

## Assembly Style

Style List

Specifies the assembly style. Select a new style by clicking the drop-down arrow.

Style Selection

Specifies the style options. You can create a new style, copy or edit the current style, or pick a style from the drawing.

Style Detail

Opens the Style Detail dialog box where you can preview the style and creation information.

## Code Set Style

Style List

Specifies the code set style. Select a new style by clicking the drop-down arrow.

Style Selection

Specifies the style options. You can create a new style, or copy or edit the current style.

Style Detail

Opens the Style Detail dialog box where you can preview the style and creation information.

## Assembly Layer

Specifies the name of the layer on which this assembly object will be created. To change the layer, click the Object Layer icon and select a layer.

# Create Subassembly From Polyline Dialog Box

Use this dialog box to specify the initial parameters for a subassembly created from an existing polyline.

Name

Specifies the name of the subassembly.

Opens the Name Template (page 1806) dialog box, where you can modify the naming template.

Description

Specifies an optional description of this subassembly.

### Code Set Style

Style List

Specifies the current code set style. Select a new style by clicking the drop-down arrow.

Style Selection

Specifies the style options. You can create a new style, copy or edit the current style, or pick a style from the drawing.

Style Detail

Opens the Style Detail dialog box where you can preview the style and creation information.

### Subassembly Layer

Displays the name of the layer on which this subassembly object will be created. To change the layer, click the Object Layer icon and select a layer.

### Conversion Options

Mid-Ordinate Distance

If the subassembly object contains curves, all curves will be tessellated (converted into a finite number of segments) using this value to determine the length of the tessellated segments.

Link Creation

Specifies symbol scaling:

- None: Generates no links. Only points will be created at the vertices.

- Single: Creates one link from all the segments created from the object selected. This is provided to make creating shapes simpler. Using the Add Shape right-click command, you only need to perform one action.

- Multiple: Creates a new link for each segment created from the object selected. This is useful for assigning link codes to different parts of the subassembly for creating surfaces and other display characteristics.

### Erase Existing Entities

To retain existing entities, as well as the new subassembly, clear this check box.

# Edit Feature Settings - Assembly Dialog Box

Use this dialog box to view and change assembly-specific settings.

This topic documents settings in all assembly-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

- Drawing-level ambient settings are identified by the  drawing icon.

- Assembly feature settings are listed near the top of this dialog box, after the General property group, and are identified by the  assembly icon.

- Assembly command settings are identified by the  command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

## Default Styles

These settings establish the default styles assigned to assembly components:

Assembly Style

Specifies the default style for assemblies. Click in the Value column. Click in the Value column, and click [...] to select a style in the Assembly Style dialog box.

Code Set Style

Specifies the default code set style. Click in the Value column, and click [...] to select a style in the Code Set Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

### Default Name Format

Use these settings to specify the default name formats for assemblies, assembly offsets, and assembly groups.

Click in the Value column, and click [...] to make changes in the Name Template dialog box (page 1806).

# Edit Feature Settings - Subassembly Dialog Box

Use this dialog box to view and edit subassembly-specific settings.

This topic documents settings in all subassembly-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

- Drawing-level ambient settings are identified by the drawing icon.

- Subassembly feature settings are listed near the top of this dialog box, after the General property group, and are identified by the subassembly icon.

- Subassembly command settings are identified by the command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

## Default Styles

These settings establish the default styles assigned to subassemblies.

Code Set Style

Specifies the default code set style. Click in the Value column, and click [...] to select a style in the Code Set Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

### Subassembly Name Templates

Use these settings to specify the default name formats for subassemblies created from macros and from polylines. Click in the Value column, and click ⊡ to make changes in the Name Template dialog box (page 1806).

### Convert From Polyline

**NOTE** This property group is displayed when you access the settings from the CreateSubFromPline command.

Use these settings to specify the default behavior for creating subassemblies from polylines.

Mid-ordinate Distance
Specifies mid-ordinate distance to approximate curvilinear segments. Enter a distance in the Value column or click ⊡ and select a distance in the drawing area.

Link Creation
Specifies the quantity of subassembly links (None, Single, Multiple) created from the polyline(s).

## Import Subassemblies Dialog Box

Use this dialog box to import one or more subassemblies from a package file to a tool palette or catalog.

If you have a package file that contains one or more subassemblies, you can import the subassembly or subassemblies to an AutoCAD Civil tool palette or catalog.

**Related procedures:**

■ Sharing Subassemblies (page 1403)

### Source File

Specifies the name and location of the package file (.pkt) containing one or more subassemblies.

📂

Opens the Select File dialog box where you can navigate to the package file (.pkt) containing the subassembly or subassemblies to be imported.

### Import To

You can import subassemblies to a tool palette, to a catalog, or to both locations at the same time.

Tool Palette
When this option is selected, the subassemblies will be imported to the selected tool palette. Select a tool palette by clicking the drop-down arrow. The name of the currently open tool palette is displayed (selected) by default.

Catalog Library/My Imported Tools
When this option is selected, the subassembly or subassemblies contained in the package file will be imported to the My Imported Tools catalog in the catalog library. If the My Imported Tools catalog does not exist, it will be automatically created.

## Link Style Dialog Box

This dialog box defines a link style, which controls the way a subassembly link component is displayed in a drawing.

## Information Tab (Link Style Dialog Box)

Use this tab to change the link style name and description information and to review details, such as when the style was most recently modified

For more information, see .

## Display Tab (Link Style Dialog Box)

Use this tab to change the display and visibility of the link component.

For more information, see .

## Summary Tab (Link Style Dialog Box)

Use this tab to display information about a particular link style. This information can be copied and pasted to the clipboard.

For more information, see .

# Marker Style Dialog Box

This dialog box defines a marker style, which controls the way a subassembly marker (point) component is displayed in a drawing.

## Information Tab (Marker Style Dialog Box)

Use this tab to edit the marker style name and description and to review details, such as when the style was most recently modified.

For more information, see .

## Marker Tab (Marker Style Dialog Box)

Use this tab to specify the appearance of the marker symbol in the drawing.

### Use AutoCAD Point For Marker

Use AutoCAD Point For Marker

> Displays the marker using the current AutoCAD point symbol, which is specified by the AutoCAD PDMODE and PDSIZE system variables.

### Use Custom Marker

Use Custom Marker

> Displays the marker using the specified symbol.

Custom Marker Style

> Specifies the symbol for displaying the marker. Click one of the five symbols on the left to use as a base symbol. Optionally, click the sixth symbol, the seventh symbol, or both, to superimpose them over the base symbol. The specified symbol combination is displayed in the Preview window.

### Use AutoCAD Block Symbol For Marker

Use AutoCAD Block Symbol For Marker

> Displays the marker using a reference to the selected AutoCAD block. The block is scaled using the options specified under Size.

### Blocks list

Lists block definitions available in the drawing. Do one of the following:

- Click a block name to select the block to use for the point symbol. The block is displayed in the Preview window.

- Right-click in the block list window. Click Browse to select a block located in another folder.

The specified block is displayed in the Preview window.

## Marker Rotation Angle

### Marker Rotation Angle

Specifies the rotation angle for the symbol. Applies to all three symbol types (AutoCAD Point, Custom Marker, and AutoCAD Block). Enter a value or click ![cursor] to specify an angle.

### Orientation Reference

Specifies the Marker Rotation Angle:

- World Coordinate System: Specifies that the marker rotation angle is relative to the world coordinate system.

- View: Specifies that the marker rotation angle is relative to the current AutoCAD view direction.

## Size

### Options

Specifies symbol scaling:

- Use Drawing Scale: Determines the size of the marker by multiplying the specified value by the drawing scale. Enter the scale factor.

- Use Fixed Scale: Activates the Fixed Scale commands.

- Use Size in Absolute Units: Specifies that the marker size is an absolute value based on the displayed units. Enter the value.

- Use Size Relative to Screen: The size of the marker is a percentage of the drawing screen size. Enter the percentage.

### Fixed Scale

Specifies independent fixed scale values when Options is set to Use Fixed Scale. Enter values for X, Y, or Z.

# Display Tab (Marker Style Dialog Box)

Use this tab to edit the display and visibility of the marker symbol.

For more information, see Display Tab (Style Dialog Box) (page 1801).

# Summary Tab (Marker Style Dialog Box)

Use this tab to display information about a particular marker style. This information can be copied and pasted to the clipboard.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Shape Style Dialog Box

Use this dialog box to define a shape style, which controls the way a subassembly shape component is displayed in a drawing.

## Information Tab (Shape Style Dialog Box)

Use this tab to edit the shape style name and description information and to review details, such as when the style was most recently modified.

For more information, see Information Tab (Style Dialog Box) (page 1801).

## Display Tab (Shape Style Dialog Box)

Use this tab to change the display and visibility of the shape's border and hatch pattern. You can also specify the hatch pattern style for this shape using this tab.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Shape Style Dialog Box)

Use this tab to display information about a particular shape style. This information can be copied and pasted to the clipboard.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Subassembly Properties Dialog Box

Use this dialog box to view or edit the properties of a subassembly in a drawing.

## Information Tab (Subassembly Properties Dialog Box)

Use this tab to view or edit the subassembly object name and description.

Name
Specifies the name of the current subassembly.

Description
Specifies an optional description of the current subassembly.

Show Tooltips
Controls whether a tooltip description is displayed for the subassembly object in the drawing.

## Parameters Tab (Subassembly Properties Dialog Box)

Use this tab to view information about subassembly input and output parameters, to edit input parameter values, and or to display the Help topic for the subassembly.

This tab also displays the method that was used to create (define) this subassembly (VBA, .NET, or from polyline).

### Input Values

Lists information on the input parameter values that are used to calculate the size, shape, and geometry of the subassembly. You can edit an input parameter value by clicking on a value in the Default Input Value column.

**NOTE** To enter values for grades, enter % values with the percent symbol included. To enter values for slopes, you can enter a ratio such as 4:1, with the colon included between two numbers, or you can enter a number that gets converted into a percent value when you click OK or Apply.

Value Name

This read-only field displays the name of each input parameter associated with the subassembly.

Default Input Value

Displays the input parameter value used in the processing for the subassembly. You can click on a value to edit it. When you edit a value and click OK or Apply, the subassembly object in the drawing is updated.

## Output Values

Lists read-only information on any output parameter values used during processing for the subassembly. These output values can be used as input values for other subassemblies. The actual output values are calculated only when the assembly is applied.

Value Name

Displays the name of any output parameters used for the subassembly.

Output Value

Displays the value for any output parameters from the subassembly.

## Defined From

This read-only field displays the method that was used to create this subassembly. If the subassembly was created using .NET, .NET is displayed. If the subassembly was created from a polyline, Entities is displayed. If the subassembly was created using .NET, .NET is displayed.

.NET Class Name

If the subassembly is created from .NET, this field displays the name of the .NET class that defines this subassembly. If the subassembly is created from VBA, or from a polyline, this field is not displayed.

.NET Assembly Name

Displays the name of the file that defines this subassembly. If the subassembly is created from VBA, or from a polyline, this field is not displayed.

Macro Name

If the subassembly is created from VBA, this field displays the name of the macro file that defines this subassembly. If the subassembly is created from a polyline, this field is not available. If the subassembly is created from .NET, this field is not displayed.

Project Name

If the subassembly is created from VBA, this field displays the name of the project that defines this subassembly. If the subassembly is created from a polyline, this field is not available. If the subassembly is created from .NET, this field is not displayed.

Subassembly Help

Clicking [...] opens the Help topic that describes the construction, behavior, and other definitions of this subassembly. If the subassembly is created from a polyline, a Help topic is not available.

# Codes Tab (Subassembly Properties Dialog Box)

Use this tab to view or edit display styles for the codes associated with the selected subassembly.

Code Set Style

Specifies the current code set style for the subassembly. For more information, see Select Style Dialog Box (page 1805).

**NOTE** When a subassembly is attached to an assembly, the code set style is governed by the assembly object's code set style, and all controls on this tab are disabled.

The properties table contains the following columns:

Name
Displays an expandable tree with a collection for each type of code: Link, Point, and Shape. Expand the collections to display the individual codes.

Description
Displays the description of each code.

Style
Displays the style assigned to each code.

Label Style
Displays the label style assigned to each code or <none> if no label style is assigned.

Render Material
Displays the render material assigned to each code or <none> if no render material is assigned.

Material Area Fill Style
Displays the Material Area Fill style assigned to each code or <none> if no label style is assigned.

■ Understanding Point, Link, and Shape Codes (page 1406)

■

# Building Site Import Dialog Boxes

# 47

The following topics provide information about building site feature settings, the Import Building Site wizard pages, and the Building Site Style and Building Site Properties dialog boxes.

## Edit Feature Settings - Import Building Site

Use this dialog box to view and change settings that relate to building site objects.

This topic lists settings in all Edit Settings dialog boxes (drawing-level, feature-level, and command-level) that relate to building site objects.

■ Drawing-level ambient settings are identified by the  drawing icon.

■ Building site feature settings are identified by the  Building Site object icon.

■ Building site command settings are identified by the  command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

### Default Styles

Use these settings to specify the default styles assigned to building sites.

Building Site Style

Specifies the default building site style (page 1688). Click in the Value column, and click [...] to select a style in the Building Site Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

### Default Name Format

Use this setting to specify the default name format for new building site objects.

1793

Building Site Name Template

Specifies the default name format for building site objects. Click in the Value column, and click  to make changes in the Name Template dialog box (page 1806).

**Related procedures:**

■ Editing a Building Site Style (page 1688)

# Import Building Site Wizard

Use this wizard to specify the settings for the imported ADSK package file.

## Select File Page (Import Building Site Wizard)

Use this page to select the ADSK package file that contains the building site model data referenced in the AutoCAD Civil drawing.

### File Information

Enter Or Browse To The File

Specifies the name and location of the ADSK package file.

Click to select the file in the Autodesk Design Package File dialog box.

Building Site Name

Specifies the name of the building site object. The name you specify becomes the name of the Building Site collection on the Prospector tab of the AutoCAD Civil Toolspace.

Click to display the Name Template dialog box. See Name Template dialog box (page 1806).

Preview

Provides a visualization of the building site object.

**Related procedures:**

■ Using the Wizard to Import a Building Site Object (page 1686)

## Confirm Units Page (Import Building Site Wizard)

Use this page to confirm drawing units referenced in the Revit architectural model.

All fields on this page are read-only. Use them for reference information.

### Building Site Units

Unit

Specifies the unit of the building site model, as it is defined in the ADSK package file.

Scale Factor

Specifies the scaling factor that is applied to Revit architectural model data during import.

### Civil Drawing Units

Drawing Units
Specifies the unit of the current Civil drawing.

Drawing Scale
Specifies the scaling factor of the current Civil drawing session.

Angular Units
Specifies the angular units of the current Civil drawing.

### Zone

Coordinate System Zone Code
Specifies the code of the coordinate system used in the Civil drawing.

Description
Specifies a description of the current zone used in the Civil drawing.

Projection
Specifies the projection method for the coordinate system.

Datum
Specifies the abbreviation for the datum on which the coordinate system is based.

**Related procedures:**

■ Using the Wizard to Import a Building Site Object (page 1686)

## Display Properties Page (Import Building Site Wizard)

Use this page to specify the display properties for the imported building site object.

### Display Properties

Building Site Layer
Displays the default layer specified in the ImportBuildingSite command settings.

Click to change the default layer in the Object Layer dialog box. See Object Layer dialog box (page 1985).

Building Site Style
Displays the default style of the building site object specified in the ImportBuildingSite command settings.

Click to modify the default style. See Editing a Building Site Style (page 1688).

**Related procedures:**

■ Using the Wizard to Import a Building Site Object (page 1686)

## Insertion Point Page (Import Building Site Wizard)

Use this page to confirm the insertion point information of the building site object in the AutoCAD Civil drawing.

**Insertion Point Information**

Specify In Drawing
  Specifies whether you wish to specify the coordinates in the drawing. Selecting this option makes the coordinate value controls unavailable.

Northing (Y)
  Specifies the northing coordinate value of the building site base point read from the ADSK package file.

Easting (X)
  Specifies the easting coordinate value of the building site base point read from the ADSK package file.

Elevation (Z)
  Specifies the elevation coordinate value of the building site base point read from the ADSK package file.

Rotation Angle
  Specifies the rotation angle of the building site base point read from the ADSK package file.

Preview
  Click to zoom in to the extents of the building site object as it would be located on the drawing.

Finish
  Click to insert the building site object at the specified coordinates. Specify In Drawing must be cleared.

**Related procedures:**

- Using the Wizard to Import a Building Site Object (page 1686)

# Building Site Style Dialog Box

Use this dialog box to specify the display properties of the building site object.

# Information Tab (Building Site Style Dialog Box)

Use this tab to specify the information related to the building site object.

Name
  Specifies the name of the style.

Created By
  Specifies the name of the person who created the style.

Date Created
  Specifies the date the style was created.

Last Modified By
  Specifies the name of the last person who modified the style.

Date Modified
  Specifies the date the style was modified.

**Related procedures:**

- Editing a Building Site Style (page 1688)

# Markers Tab (Building Site Style Dialog Box)

Use this tab to specify the style of the utility connection marker.

**Utility Connection Marker Style**

Marker Style

Specifies the marker style for the Utility Connection component of the building site object.

Click to modify the marker style in the Marker Style dialog box. See Marker Style dialog box (page 1788).

Click to view the details of the marker style in the Style Detail dialog box. See Style Detail dialog box (page 1804).

**Related procedures:**

■ Editing a Building Site Style (page 1688)

# Display Tab (Building Site Style Dialog Box)

Use this tab to modify the layer and the viewing mode for each component of the building site object.

**View Direction**

Specify one of the following views:

Plan

Displays building site components in the top-down 3D view.

Model

Displays building site components in the Model view (all but top-down view).

**Component Display**

Specify the Visibility, Layer, and Linetype properties of the following building site object components:

Building Footprint

Specifies the footprint of the architectural model.

Property Lines

Specifies the property lines that relate to the building site object.

Utilities

Specifies the utilities and utility connections that relate to the architectural model.

Site Model

Specifies the site details that relate to the architectural model, such as topography, parking, and landscaping.

Building Model

Specifies the 3D model of the building.

**Related procedures:**

■ Editing a Building Site Style (page 1688)

## Summary Tab (Building Site Style Dialog Box)

Use this tab to view a summary of the specified styles.

Information
Specifies the information associated with the building site object.

Display
Specifies the style of the building site marker.

Collapse All
Click to collapse all items in the Property column.

Expand All
Click to expand all items in the Property column.

**Related procedures:**

■ Editing a Building Site Style (page 1688)

# Building Site Properties Dialog Box

Use this dialog box to modify the name, description, and style of the building site object.

Name
Specifies the name of the building site object.

Description
Specifies any additional information about the building site object.

Building Site Style
Specifies the style of the building site object.

Click to modify the default base layer in the Object Layer dialog box.

Click to modify the default building site object style.

**Related procedures:**

■ Updating a Building Site Object Definition (page 1689)

# Common AutoCAD Civil Dialog Boxes and Tabs

# 48

Use the following links to access information about the common dialog boxes that are used by several AutoCAD Civil features.

## Edit Feature Settings - General Dialog Box

Use this dialog box to view and change general feature and command settings.

This topic documents settings in all general Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

- Drawing-level ambient settings are identified by the ▭ drawing icon.

- General feature settings are listed near the top of this dialog box, after the General property group, and are identified by the 🔳 general icon.

- General command settings are identified 🔲 command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

### 🔳 Default Styles

Use these settings to establish the default styles assigned to label components:

General Note Label Style

> Specifies the default style to use when inserting Note labels. Click in the Value column, and click ⋯ to select a style in the General Note Label Style dialog box.

General Line Label Style

> Specifies the default style to use when inserting Line labels. Click in the Value column, and click ⋯ to select a style in the General Line Label Style dialog box.

General Curve Label Style

Specifies the default style to use when inserting Curve labels. Click in the Value column, and click ▣ to select a style in the General Curve Label Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

## ▣ Curve Tessellation Option

**NOTE** This property group is displayed when accessing the settings from the CreateArcByBestFit, CreateLineByBestFit, and CreateParabolaByBestFit commands.

Use these settings to specify the default behavior when curve entities are used as an input option for best fit arc, line, and parabola creation.

Tessellate Curve

Specifies whether to tesselate curve segments if they are included as an input option.

Mid-ordinate Tolerance

Specifies the mid-ordinate tolerance based on a distance across the tessellated curve segments. Enter a length in the Value column or click ▣ and select two points along a curve.

## ▣ Regression Graph Option

**NOTE** This property group is displayed when accessing the settings from the CreateArcByBestFit, CreateLineByBestFit, and CreateParabolaByBestFit commands.

Use this setting to specify the default behavior for regression analysis graphs in best fit arc, line, and parabola creation.

Spline Fit For Regression Analysis Graph

Specifies whether the regression graph displays splines on the green line that represents the best fit entity.

## ▣ Mapcheck

**NOTE** This property group is displayed when accessing the settings from the MapCheck command.

Use these settings to specify the default behavior for Mapcheck.

Use Command Line Input

Specifies whether Mapcheck will accept commands from the command line interface. Selecting No causes Mapcheck to accept input only from the Mapcheck vista.

Default Side Type

Specifies the default type of any side created using Mapcheck.

Default Curve Direction

Specifies the default direction of any curve created using Mapcheck.

Default Angle Type

Specifies the default type of any angle created using Mapcheck.

Mapcheck Color

Specifies the color for Mapcheck lines and curves which are not part of the current mapcheck. Click in the Value column, and click ▣ to select a color in the *Select Color dialog box*.

Current Mapcheck Color

Specifies the color for the current mapcheck. Click in the Value column, and click ▣ to select a color in the Select Color dialog box.

Current Point Of Beginning Color

Specifies the color of the beginning not for a selected mapcheck. Click in the Value column, and click  to select a color in the Select Color dialog box.

Current Side Color

Specifies the color for the current selected side. Click in the Value column, and click  to select a color in the Select Color dialog box.

# Styles Dialog Box

This topic describes how to use the Information, Display, and Summary tabs that are common to all object styles. Other object-specific tabs are described in the style section for each object.

# Information Tab (Style Dialog Box)

Use this tab to change the object style name and description information, and to review details, such as when the style was most recently modified.

Name

Specifies a name for the current style. This name appears on the Settings tab in Toolspace and in the style selection dialog box.

Description

Specifies an optional description for the current style.

Created By

Displays the AutoCAD login name of the person who created the style.

Date Created

Displays the date and time the style was created.

Last Modified By

Displays the AutoCAD login name of the person who last modified the style.

Date Modified

Displays the date and time the style was last modified.

**Related procedures:**

■ Changing Common Settings in Styles (page 56)

# Display Tab (Style Dialog Box)

Use this tab to control the visibility and display characteristics for each component that makes up an object. To change a setting, click the current value.

For Color, Linetype, Lineweight, and Plot Style, you can select specific values or you can use the reference settings of ByLayer or ByBlock. These settings are indirect and require some planning. For more information, see Using ByLayer and ByBlock to Assign Display Values (page 1803).

**NOTE** The values you enter on the Display tab take precedence over other AutoCAD Property Settings and AutoCAD Layer Settings.

## View Direction

Object styles have unique display values and varying numbers of displayed components, depending on the view direction that is selected. You can set style characteristics that control how the object components are displayed in plan view, model view, profile view, and section view. For example, you may want to set the object styles differently depending on the view direction that is selected.

Plan

Specifies how the object is displayed in plan view.

Model

Specifies how the object is displayed in model view.

Profile

Specifies how the object is displayed in a profile view.

Section

Specifies how the object is displayed in a section view.

## Component Display

Use this grid to specify the visibility and layer use for components of each object. In the Color, Linetype, and Lineweight columns you can select a specific value or set the value to BYLAYER or BYBLOCK. For more information, see Using ByLayer and ByBlock to Assign Display Values (page 1803).

Component Type

Specifies the component. The number and type of object components varies, depending on the object and whether the view is 2D or 3D.

Visible

Specifies the component visibility. Click the light bulb on or off to change the visibility.

Layer

Specifies the display layer for components, which is referenced if you select a ByLayer setting for any values. A setting of 0 means that the display layer is the same as the layer on which the component is drawn.

Color

Specifies a color for the component. Click to select a specific value or specify ByLayer or ByBlock.

Linetype

Specifies the line type for the component. You can click in the Linetype column and use the Select Linetype dialog box.
If you choose ByLayer, the linetype value is determined by examining the properties of the layer referred to in the Display tab pane.
If you choose ByBlock, the value is determined by examining the properties of the object for layer override settings first. If the object doesn't have layer overrides, the layer referred to in the Display tab pane is used to determine the properties.

LT Scale

Specifies the linetype scale for the component.

**NOTE** The Current Object Scale value controls the CELTSCALE system variable, which sets the linetype scale for new objects. The CELTSCALE value is multiplied by the LTSCALE to get the displayed linetype scale.

Lineweight

Specifies the lineweight for the component. You can click in the lineweight column and select a new lineweight in the Lineweight dialog box.

Plot Style
    Specifies the plot style for the component.

**Component Hatch Display**

Use this grid to specify the hatch patterns and properties for each object component.

Component Type
    Lists the object components that have hatch patterns.

Pattern
    Specifies the hatch pattern for the component. You can click in the column and select a new pattern from the Hatch Pattern dialog box.

Angle
    Specifies the angle value for the component.

Scale
    Specifies the scale for the hatch pattern.

**Related procedures:**

■ Layers (page 58)

# Using ByLayer and ByBlock to Assign Display Values

You can set component display properties by referencing the attributes of a drawing layer (ByLayer) or a block definition (ByBlock).

This method is less direct than setting specific values, as shown in the following example for color selection.

| If you click in the... | The component... |
| --- | --- |
| Layer column and select a specific layer | Is displayed in the color assigned to that layer. |
| Color column and select a specific color | Is displayed in that specific color. |
| Color column and select ByLayer | Is displayed in the color specified by the Layer column. |
| Color column and select ByBlock | The software determines if you made changes to the AutoCAD Layer Properties or AutoCAD Color Properties.<br>■ if you made changes, the component color reflects those changes.<br>■ if you did not make changes, the component is displayed in the color specified in the Layer column of the Display tab. |

# Summary Tab (Style Dialog Box)

This tab lists the object style properties and assigned values.

You can edit any values that appear black, but not those that are shaded (gray). To copy the Summary tab to the clipboard, right-click a cell. If you paste the contents into Excel, the column format is maintained.

Property
Displays all object style properties.

Value
Displays the value for each property.

**Related procedures:**

■ Changing Common Settings in Styles (page 56)

# Style Detail Dialog Box

Use this dialog box to preview styles that have been defined in a drawing in the AutoCAD Civil/Data/Preview folder.

After you establish styles for a particular phase of a project, you can save the drawing with those styles to the Preview folder. When you click , the Style Detail dialog box is displayed with an Information tab that contains creation information and a description, and a Preview tab that lists the drawings in the Preview folder. AutoCAD Civil has several default Preview drawings.

**NOTE** Some styles are not supported in the Style Detail Preview. Styles that are not supported display only the name and creation information.

Style List
Lists the object styles.

Preview List
Lists the defined previews in the current drawing.

**Information Tab**

Description
Displays the description of the current style.

Created By
Displays the AutoCAD login name of the person who created the style.

Date Created
Displays the date and time the style was created.

Last Modified By
Displays the AutoCAD login name of the person who last modified the style.

Date Modified
Displays the date and time the style was last modified.

**Preview Tab**

Style List
Displays a list of available styles for the object.

Preview List
Displays a list of available previews for the object.

Preview Window
Displays the selected style preview.

# Select Style Dialog Box

Use this dialog box to specify a style for an object, to create a new style, or to copy or edit an existing style.

Style List
Specifies the following options for style selection:

■ Create New

■ Copy Current Selection

■ Create Child of Current Selection (Labels only)

■ Edit Current Selection

■ Pick from Drawing

Specifies the style options. You can create a new style, copy or edit the current style selection, or pick a style from drawing.

Opens the Style Detail dialog box where you can preview the style and creation information.

**Related procedures:**

■ Object Styles (page 53)

# Select Render Material Dialog Box

Use this dialog box to specify a render material for an object.

Render Material List
Lets you specify a render material in the following ways:

■ ByBlock: Uses the render material of an associated block.

■ ByLayer: Uses the render material of the current layer that the object is on.

■ Global: Uses the Global render material.

■ Use a specified render material. You can select from the list of available render materials in the drawing.

Click to select a render material of an object in the drawing.

**Related procedures:**

■ Object Rendering (page 1577)

# Name Template Dialog Box

Use this dialog box to specify the object name when you create an object.

This name is displayed in Toolspace, and you can edit the name by changing the object properties.

### Name Formatting Template

Property Fields List

Displays the object properties that you can use as part of the name format.

Insert

Click to add the specified property to the name. The property is inserted where the cursor is placed in the Name field.

Name

Specifies the name format, which can include specified properties and text.

### Incremental Number Format

Number Style List

Specifies the number format for the specified property field.

Starting Number

Specifies the starting number for the specified property field.

Increment Value

Specifies the number that is added to each value to get the next value for the specified property field.

# Duplicate Station Selection Dialog Box

When you add a station equation to an alignment, you often create duplicate station values. Use this dialog box to specify which of the duplicate stations you want to work with.

Raw Station Back

Displays the original (raw) station values, unaffected by station equations. Select the station you want to use.

Duplicate Station

Displays the duplicate station values.

# Customize Columns Dialog Box

Use this dialog box to create and modify column display configurations.

You can create and save different views of the columns in the table from which you accessed this dialog box.

New Configuration

Displays the configuration names. The default configuration is named 'Standard'. Click New to create additional configurations.

Index

Displays the order in which the columns are displayed.

### Column

Name

Displays the name of the column.

Visibility

Specifies if the column is visible. Clear the check box to hide the column.

Width

Specifies the width of the column.

New

Click to create a new configuration. The Enter New Name dialog box is displayed from which you can enter the name of the configuration.

Delete

Click to delete the selected configuration.

---
**NOTE** You cannot delete the Standard configuration.

---

**Related procedures:**

■ Changing the Contents of a Column in a List View (page 85)

# Enter New Name Dialog Box

Use this dialog box to specify the name for a new column configuration.

The configuration details are specified in the Customize Columns dialog box.

Enter a configuration name in the field and click OK.

# Multipurpose Styles Feature Settings

Use this dialog box to specify the feature settings for Multipurpose Styles.

For more information, see Working with the Standard Settings Dialog Box Controls (page 62).

# Projection Styles Dialog Box

Use this dialog box to define styles that control the display of AutoCAD objects projected into profile views and section views.

This dialog box controls the projection style for AutoCAD objects only.

**See also:**

■ Feature Line Style Dialog Box (page 1896)

■ Point Style Dialog Box (page 2114)

■ Survey Figure Style Dialog Box (page 2390)

■ Using ByLayer and ByBlock to Assign Display Values (page 1803)

# Information Tab (Projection Style Dialog Box)

Use this tab to record basic information about the style.

For more information, see Information Tab (Style Dialog Box) (page 1801).

# Profile Tab (Projection Style Dialog Box)

Use this tab to control how this style displays AutoCAD objects in profile views.

Select object types for configuration, one at a time, and repeat as required.

Select Object

Specify the type of object to configure: AutoCAD points, solids, 3D polylines, blocks, or multi-view blocks

Object Display

Specify As Drawn or select a marker style for the current object. If a suitable marker style is not available from the list, you can create a new style and select a custom marker or AutoCAD block. The marker is displayed in the Preview pane.

**Related procedures:**

■ Marker Style Dialog Box (page 1788)

# Section Tab (Projection Style Dialog Box)

Use this tab to control how this style displays AutoCAD objects in section views.

# Display Tab (Projection Style Dialog Box)

Use this tab to configure the displayed elements of this style.

For more information, see Display Tab (Style Dialog Box) (page 1801).

# Summary Tab (Projection Style Dialog Box)

Use this tab to review and edit style settings in summary form.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Projection Properties Tab

Use this tab to set properties of projected objects in profile views and section views.

This tab appears on the dialog boxes for Profile View Properties (page 2178), and Section View Properties (page 2281) when the view includes one or more projected objects.

You can change the elevation of a projected object, modify its object style, or remove it from the view.

Name

Displays all projected objects in the current view. If you click a name, the object is highlighted in the view. Right-click a name for options to pan or zoom to the object or remove it from the view.

Style

Specifies the style of the projected object. Click a style name to change it. If you want to set a consistent style for all objects of the same type, click the main heading for the object type and select the style.

Elevation Options

Specifies how the elevation of the projected object is determined:

■ Use Object. Projected object is at the same elevation as the source object in plan view.

■ Manual. Elevation of the projected object is set manually.

- Surface. Projected object is at the elevation of the selected surface.

- Profile. Projected object is at the elevation of the selected profile.

Elevation Value

Displays the current elevation of the projected object. If the elevation option is Manual, you can change the elevation in this column.

Pick Objects

Click to select additional objects to project into the current view.

# Edit Settings Dialog Box

Use the standard Edit Settings dialog box to edit drawing ambient settings, object (feature) level settings, and command level settings.

The following describes the controls displayed in the standard Edit Settings dialog box. For a description of a specific category or setting, display the dialog box and click Help.

**Property column**

Contains settings categories and settings property names.

Category names, which display in bold, contain a list of one or more settings. Click plus (+) or minus (-) next to a category name to expand or collapse the list of settings.

**Value column**

Indicates the current value for the setting. The value is either derived from a dependency on a higher level setting or you enter the value.

**Override column**

Identifies the derivation of a setting value and whether there are any higher level dependencies. A cleared check box indicates that the value is dependent on a higher level setting. A selected check box indicates that the value has been explicitly set at the current level.

If you clear the check box, then the value you entered at the current level is reset to the value of a higher level setting.

If no check box is displayed, there is no high level dependency.

**Child Override column**

Override Indicator

Indicates that a value has been overridden at a lower level. Click to remove the lower level setting override value and replace the setting value with the current setting. The icon then changes to . When you click either OK or Apply in the dialog box, the override values are removed and replaced with the current setting.

**Lock**

Protects a settings value by assuring that any lower-level setting is fixed at the value specified at this level.

To lock a setting, click to change it to . The lock cannot be set if a child override is set.

---

**NOTE** When a setting is locked at a higher level setting, the lower-level settings display a lock to the left of the property name to indicate that it is dependent on the higher-level setting and cannot be changed.

---

**Control Icons**

 Collapse All Categories

Collapses all open categories in the dialog box.

 Expand All Categories

Expands all categories in the dialog box.

 Override All Dependencies

Selects all check boxes in the Override column and creates settings that are not dependent on upper-level settings.

When you select all Override check boxes, this option is unavailable. It is also unavailable in the highest, or the drawing level, dialog box.

**Status Update in Dialog Box**

In the lower-left corner of the dialog box, the status of overrides is displayed as you select an item in the dialog box.

**Property**

Displays the selected property name followed by a single line description of the property.

**Parent Value**

Indicates the value that the setting will have if a dependency on the higher level value is maintained.

**Parent**

Indicates the higher level setting from which this default setting is derived.

**Related procedures:**

■ Working with the Standard Settings Dialog Box Controls (page 62)

# Select Object(s) Dialog Box

Use this dialog box to select one or more objects either from a list or from the drawing area.

Object Listing

Lists the objects that are available for selection. You can select a single or multiple objects, depending on the feature you are using. To select multiple objects, hold down the SHIFT key and select the objects.

Click to select one or more objects in the drawing. The selected objects in the drawing are then displayed as selected in the object listing.

# Edit Enumeration Dialog Box

Use the arrows in this dialog box to edit the order of the enumeration values. Click in a cell to edit the current value or click in an empty cell to add an enumeration value.

# User-defined Property Classification Dialog Box

Use this dialog box to specify a name for the classification.

# New User-defined Property Dialog Box

Use this dialog box to define the properties in the classification.

Name

Specifies the name for the classification.

Description

Specifies an optional description.

Type

Specifies the property data type.

■ Boolean: Supports true or false values.

■ String: Provides a list of characters.

■ Enumeration: Provides a list of indexed values.

■ Integer: This value is not formatted.

■ Double: This value is formatted using the Unitless type.

The default values for the following data types are formatted according to the settings on the Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856) in the Drawing settings:

■ Angle

■ Area

■ Coordinate

■ Dimension

■ Direction

■ Distance

■ Elevation

■ Grade/Slope

■ Latitude

■ Longitude

■ Station

■ Volume

Lower Bound Inclusive

Specifies whether or not the lower bound value is included in the property.

Lower Bound Value

Specifies the lower bound value.

Upper Bound Inclusive

Specifies whether or not the upper bound value is included in the property.

Upper Bound Value

Specifies the upper bound value.

> **NOTE** If the property type you select is Boolean, String, or Enumeration, the lower and upper bound values are not available.

Default Value check box

Specifies whether the default property value is applied to new points when they are created.

Default Value

Specifies the default value.

Enumeration

Specifies the enumeration value by clicking in a cell and entering a new value.

**Related procedures:**

■ User-Defined Property Classifications (page 416)

# Duplicate Item Name Dialog Box

Use this dialog box to resolve situations where an item of the same name exists in the destination drawing you are attempting to copy an item to.

These items can be styles, criteria, pipe rules, and so on. The affected item is listed at the top of the dialog box.

Duplicate Item Name Resolution

Specifies how duplicate items are resolved.

■ **Overwrite**: The item in the destination drawing is overwritten with the copy.

■ **Rename**: The item in the destination drawing is renamed so it will not be overwritten. The item you are copying is copied to the drawing with its original name.

■ **Skip**: The item is not copied and the original is not overwritten.

Apply To All Duplicate Items

Specifies how the resolution is applied.

■ **Selected**: Applies the resolution to all items you are currently attempting to copy.

■ **Cleared**: Applies the resolution to the current item only. You are prompted to resolve any additional conflicts.

# Corridors Dialog Boxes

# 49

The following topics provide information about the Corridors dialog boxes:

## Apply To A Range Of Stations Dialog Box

Use this dialog box to specify a range of stations for which to apply an assembly override.

Start Station

Specifies the first station for which to apply the assembly override.

To edit the station start, enter a value or click ⬚ to select a location in the drawing window.

End Station

Specifies the last station for which to apply the assembly override.

To edit the station start, enter a value or click ⬚ to select a location in the drawing window.

**Related procedures:**

■ Viewing and Editing Corridor Sections (page 1361)

## Corridor Boundary Definition Dialog Box

Use this dialog box to view and modify the properties of a corridor surface boundary.

Feature Line

Displays the names of the feature lines that form the boundary definition.

Baseline

Displays the baseline alignment for the feature lines.

Reverse Direction

Specifies whether the boundary is to be drawn in the reverse direction of the corridor station order.

Start Point

Specifies the start point along the corridor for the boundary. To edit the start point, enter a value or click ⬚ to select a location in the drawing.

**End Point**

Specifies the end point along the corridor for the boundary. To edit the end point, enter a value or click

 to select a location in the drawing.

Adds a new feature line to the boundary definition.

Deletes the selected feature line from the boundary definition.

Moves the selected feature line up in the boundary draw order.

Moves the selected feature line down in the boundary draw order.

Previews the boundary in the drawing as a green polyline.

Verifies that the boundary polygon is well-formed (that is, it does not cross on itself). A message is displayed indicating if the boundary is well-formed or is ill-formed with crossing edges.

**Related procedures:**

■   Adding and Editing Corridor Boundaries (page 1355)

# Corridor Parameter Override Stations Dialog Box

Use this dialog box to view and delete assembly overrides to stations in the selected region.

**Assembly Name**

Displays the name of the assembly used in the region.

**Start Station**

Displays the value of the first station in the region's range.

**End Station**

Displays the value of the last station in the region's range.

Deletes the override applied to the station selected in the list of stations.

**Delete All**

Deletes all the overrides applied to stations in the selected region and clears the list of stations.

**NOTE** Deleting one or all stations from the list only deletes the overrides applied to the stations.

The table displays a list of overridden stations and the override method.

**Station**

Displays the station's value.

**Parameter**

Displays whether or not the assembly has been edited by overriding subassembly parameters.

Geometry
   Displays whether or not a subassembly located at the station has been added, deleted, or edited by adding or deleting points or links.

**Related procedures:**

■ Editing Corridor Sections (page 1365)

■ Viewing and Deleting Overridden Stations (page 1343)

# Corridor Properties Dialog Box

Use this dialog box to change the properties of a corridor.

**See also:**

■ Managing and Editing Corridors (page 1333)

# Information Tab (Corridor Properties Dialog Box)

Use this tab to view or change general information for the corridor using the following settings:

Name
   Specifies the name of the current corridor.

Description
   Specifies an optional description for the current corridor.

Object Style
   Specifies the default corridor style used to display corridor components, such as region boundaries and assembly insertion stations. Select a style from the list or use the standard selection tools. For more information about the standard selection tools, see the Select Style (page 1805) dialog box.

Show Tooltips
   Specifies whether tooltips are displayed for the object in the drawing (not over toolbar icons).

**Related procedures:**

■ Creating Corridors (page 1330)

■ Editing Basic Corridor Information (page 1336)

# Parameters Tab (Corridor Properties Dialog Box)

Use this tab to view and edit the parameters of the current corridor including the baselines, regions, and controlling offsets, and setting targets.

⬚▾

   Expands all baseline categories.

⬚▴

   Collapses all baseline categories.

Turns on all baselines.

Turns off all baselines.

**Add Baseline**

Adds a baseline (alignment) to the corridor definition.

**Set All Frequencies**

Opens the Frequency To Apply Assemblies dialog box (page 1836), where you can map targets from subassembly definitions to appropriate drawing object names for the entire corridor.

**Set All Targets**

Opens the Target Mapping dialog box (page 1840), where you can map targets from subassembly definitions to appropriate drawing object names for the entire corridor. For more information, see Setting and Editing Targets (page 1343).

The parameters table contains the following columns:

**Name**

Displays a tree listing all baselines, regions, and corresponding offset alignments.

**NOTE** Offset alignments are displayed if the assembly is defined with assembly offsets. For more information, seeCreating an Assembly Offset (page 1382).

The check boxes next to the baselines or region names specify whether to show (selected) or hide (cleared) the baselines or regions. If the check box is cleared, that section of corridor is not reprocessed when underlying elements (for example, alignments, subassemblies, or surfaces) change.

**NOTE** The check boxes have a tri-state display. If only one of the regions is selected under a baseline, the check box is dimmed and unavailable.

**Alignment**

Specifies the alignment for a baseline or offset alignment. Click this field to open the Pick Horizontal Alignment dialog box where you can select an alignment.

**Profile**

Specifies the profile for a baseline offset alignment. Click this field to open the Select A Profile dialog box where you can select a profile.

**Assembly**

Specifies the assembly for the corridor region. Click to open the Select An Assembly dialog box where you can select an assembly.

**Start Station**

Specifies the start station for the corridor region or controlling offset. By default, for the first region added to a baseline, this value is set to the start station of the baseline. If one or more corridor regions already exist, this value is set to the end station of last region. Enter a value or click  to select a location in the drawing area.

**End Station**

Specifies the end station for the corridor region or controlling offset. By default, for the first region added to a baseline, this value is set to the end station of the baseline. Enter a value or click  to select a location in the drawing area.

Frequency

Specifies the frequency at which assemblies are placed for a given region. Click this field to open the Frequency To Apply Assemblies dialog box (page 1836), where you can modify the station frequency and manually add stations.

Target

Opens the Target Mapping dialog box (page 1840), where you can modify the mapping of targets from subassembly definitions to appropriate drawing object names. For more information, see Setting and Editing Targets (page 1343).

Overrides

Opens the Corridor Parameter Override Stations dialog box (page 1814), where you can view and delete assembly overrides to stations in the selected region.

Select Region From Drawing

Selects a region in the drawing to display in the parameters table.

**Related procedures:**

■ Editing Corridor Parameters (page 1336)

■ Viewing and Editing Corridor Sections (page 1361)

## Codes Tab (Corridor Properties Dialog Box)

Use this tab to view all point, link, and shape codes that are used to define the corridor.

These codes are from the subassemblies (used in assemblies) that are applied to the corridor.

---

**NOTE** To change the style, description, or label style for any of the codes displayed in this tab, edit the code set style (page 1415).

---

Code Set Style

Specifies the code set style for the corridor. Select a style or use the standard style selection tools. For information, see the Select Style dialog box (page 1805).

The properties table contains the following columns:

Name

Displays an expandable tree with a collection for each type of code: Link, Point, and Shape. Expand the collections to display the individual codes. For information about codes, see Understanding Point, Link, and Shape Codes (page 1406).

Description

Displays the description of each code.

Style

Displays the style assigned to each code.

Label Style

Displays the label style assigned to each code or <none> if no label style is assigned.

Render Material

Specifies the render material (page 1577) associated with the corridor surface.

Material Area Fill Style

Specifies the fill displayed for the material areas of the corridor surface.

**Related procedures:**

- Using Codes and Code Set Styles (page 1405)
- Editing the Code Set Style (page 1346)

## Feature Lines Tab (Corridor Properties Dialog Box)

Use this tab to change the feature line display styles or to modify how a corridor's feature lines are connected.

Code Set Style

Specifies the code set style. Select a style in the Code Set Style list or use the standard style creation tools to edit or create a style. For more information about the style creation tools, see the Select Style (page 1805) dialog box.

### Specify Feature Lines To Create

Code

Displays point codes that are used in the subassemblies for the corridor.

Description

Specifies descriptions for the corresponding point codes.

Connect

Specifies whether the point codes at each station are connected. By default, all identical point codes are connected as longitudinal feature lines. To delete feature lines between point codes, clear the check box for the applicable point code.

**NOTE** If the Connect check box is unavailable, the feature line is being used in a corridor surface definition. It cannot be disconnected. For more information, see Creating and Editing Corridor Surfaces (page 1350).

Feature Line Style

Specifies the feature line style. To change the style, click in a cell and click ⊹⊡ .

Branching

Specifies how the feature lines for the corridor are branched if a point code is used a varying number of times at different stations:

- **Inward**: The feature lines branch inward joining the innermost point codes.
- **Outward**: The feature lines branch outward, joining the outermost point codes.

Connect Extra Points

Specifies whether feature lines are joined between stations where there are a varying number of the same point codes. To connect the points, select the check box.

**Related procedures:**

- Editing Feature Lines (page 1347)

## Surfaces Tab (Corridor Properties Dialog Box)

Use this tab to create corridor surfaces.

**NOTE** Corridor surfaces use standard surface display styles.

Creates an empty corridor surface to which you can subsequently add data using the Add Data fields.

Creates individual corridor surfaces from all link codes. The corridor surfaces are listed in the grid where you can view and modify them.

Opens the Name Template (page 1806) dialog box, where you can modify the surface corridor naming template.

Deletes the surface or data component that is currently selected in the Name column of the grid.

**Add Data**

Data Type

Specifies the data type from which to create a corridor surface:

- **Feature Lines**: Creates the surface from the feature lines that connect the specified point codes.

- **Links**: Creates the surface from the specified link.

Specify Code

Specifies the available links or features lines, depending on whether the Data Type is set to Feature Lines or Links.

Adds the data specified with the Data Type and Specify Code fields to the selected surface.

---

**NOTE** You must first select a corridor surface before adding the data.

---

The properties table contains the following columns:

Name

Specifies the corridor surface name. Click ⊞ next to the surface name to display its data (link codes and feature lines).
Select or clear the check box next to the surface name to specify whether or not a dynamic surface is added to the Surfaces collection on the Toolspace Prospector tab.

Surface Style

Specifies the surface style associated with the corridor surface. Click this field to open the Pick Corridor Surface Style dialog box where you can select a style. The value is also specified on the surface properties Information tab.

Render Material

Specifies the render material  (page 1577)associated with the corridor surface. Click this field to open the Select Render Material dialog box and select the render material.

Add as Breakline

Specifies whether the corridor surface is built using breaklines (page 618).

Overhang Correction

Specifies whether an overhang is to be corrected when rendered, and whether it is to be corrected following the top links or bottom links.

Description

Specifies a description for the corridor surface.

**Related procedures:**

■ Creating and Editing Corridor Surfaces (page 1350)

## Boundaries Tab (Corridor Properties Dialog Box)

Use this tab to create boundaries on corridor surfaces.

Use boundaries to prevent triangulation outside of the daylight line of a corridor surface and prevent them from being displayed, or to render a section of the corridor surface as a material style.

**NOTE** A corridor surface must exist before you can create a boundary. For information about creating a corridor surface, see Creating and Editing Corridor Surfaces (page 1350).

The properties table contains the following columns:

Name

Specifies the corridor surface names and their corresponding boundaries. Click ⊞ next to the surface name to display its boundaries. To add a boundary to a surface, right-click the corridor surface name and click Add Interactively, Add Automatically, or Add From A Polygon.

Description

Specifies the description for the corridor surface boundary.

Render Material

Specifies the render material style (page 1577)associated with the corridor surface boundary. Click this field to open the Select Render Material dialog box and select the render material.

Definitions

Specifies the boundary definition. Click **[...]** to open the Corridor Boundary Definition (page 1813) dialog box, where you can view and modify the boundary definition.

Use Type

Specifies the boundary type:

■ **Render Only**. Renders specified areas of the corridor surface with different materials (when rendering), for example, asphalt and grass.

■ **Hide Boundary**. Creates void areas or punches holes in the corridor surface.

■ **Outside Boundary**. Defines the outer boundary of a corridor surface.

**Related procedures:**

■ Adding and Editing Corridor Boundaries (page 1355)

■ Rendering Corridor Models (page 1374)

## Slope Patterns Tab (Corridor Properties Dialog Box)

Use this tab to add slope patterns between a set of corridor feature lines.

Add Slope Pattern >>

Adds a slope pattern to the corridor. You are prompted to select the feature lines that define the slope pattern.

✖

Deletes the selected slope pattern.

The properties table contains the following columns:

Index

Displays a numerical identifier for the slope pattern.

Feature Line1

Displays the point code of the first feature line selected to define the slope pattern.

Feature Line2

Displays the point code of the second feature line selected to define the slope pattern.

Slope Pattern Style

Specifies the slope pattern style. Click ![icon] and select a style in the Pick Style dialog box or use the standard style creation tools to edit or create a style. For more information about the style creation tools, see the Select Style Dialog Box (page 1805).

Baseline

Displays the feature line's corresponding baseline.

Station Start

Specifies the start station for the slope pattern display. To edit the station start, enter a value or click ![icon] to select a location in the drawing area.

Station End

Specifies the end station for the slope pattern display. To edit the station end, enter a value or click ![icon] to select a location in the drawing area.

**Related procedures:**

■ Creating and Editing Corridor Slope Patterns (page 1359)

# Corridor Parameter Editor Vista

Use this vista to view and modify the parameters of assemblies at stations along a corridor.

**Assembly Parameters**

The assembly parameters section of the vista displays the following columns:

Name

Displays an expandable tree view of selected assemblies, subassembly groups, subassemblies, and subassembly parameters used by the selected corridor alignment.

At the top of the vista, click ![icon] to expand or ![icon] to collapse the tree view.

Design Value

Displays the default value set for the subassembly parameters.
If the default value is overridden by manually editing the subassembly in the corridor section view (for example, by grip editing subassembly parts), the values cannot be edited.

Override

Specifies subassemblies that have been edited manually in the corridor section view (for example, by grip editing subassembly parts) and the parameters that have overrides on their design values. A selected check box is displayed for any subassembly parameter that is overridden. A selected check box is displayed at the assembly level, if any of its subassemblies or parameters are overridden.

To clear an override and set the subassemblies or parameters to their design value, clear the check box. To set an override, select or enter an override value for any subassembly in the Value column. To all overrides for an assembly's subassemblies or parameters to their design values, clear the check box at the assembly level.

Value

Specifies the override value for a parameter.

When you override a value in this column, the Override column displays a check box.

**NOTE** Grayed out fields indicate that the value cannot be changed from the default.

Comment

Specifies an optional comment for overridden parameters.

For subassemblies that have been edited manually in the corridor section view (for example, by grip editing subassembly parts), a comment is added automatically to indicate that they have been edited. For subassemblies created by editing the subassembly parameters, you can edit the comment as required.

**Related procedures:**

■ Viewing and Editing Corridor Sections (page 1361)

# Corridor Section Editor Ribbon

Use this ribbon to view and modify cross-sections at stations along a corridor.

## General

Inquiry

Performs an inquiry at a selected station.

## Baselines and Offsets

Select a Baseline

Specifies the baseline alignment for a corridor for which you want to view or edit sections. Click the down arrow to select from the available alignments.

## Station Selection

Displays the corridor section view at the first or Start Station on the corridor.

Use the Start Station button and the Next Station button to view the change in daylight elevation along the corridor.

Displays the corridor section view at the Previous Station on the corridor.

Select a Station

Lists all the stations for which there are corridor section views. If you click Show Overridden Stations, this list displays only stations where assemblies were edited with override parameters. Click to select a station.

▷

Displays the corridor section view at the Next Station on the corridor.

▷|

Displays the corridor section view at the End Station on the corridor.

Use the End Station button and the Previous Station button to view the change in daylight elevation along the corridor.

**Show Overridden Stations**

Specifies that only stations with assembly overrides are displayed in the station list.

If you click this button a second time, all stations are available for display.

## Corridor Edit Tools

**Parameter Editor**

Edits the subassembly parameters of selected corridor sections.

Edit the override locations and values of selected subassemblies in the Corridor Parameter Editor vista.

**Apply to a Station Range**

Applies the subassembly overrides to a list of stations. Click to open the Apply to a Range of Stations (page 1813) dialog box, where you can specify the range.

Only the overrides that you create by editing the subassembly parameters can be applied to a range of stations. Geometric overrides, such as adding or deleting points and links, cannot be applied to a range of stations.

**Update Corridor**

Rebuilds the corridor using the subassembly overrides.

All corridor surfaces and any other data that derives from the corridor are updated with the subassembly overrides. Has no effect when no overrides are present or when the corridor is set to rebuild automatically.

**NOTE** When you close View/Edit Corridor Section Ribbon, the corridor is automatically rebuilt with the changes.

**Add Point**

Prompts you to add points to a subassembly by selecting a link in the corridor section view. The point is placed at the midpoint of the link.

The points at the end of the links retain the codes from the original link.

**Delete Point**

Prompts you to delete points from a subassembly by selecting a point in the corridor section view.

All links connected to deleted points are also deleted.

**Add Link**

Prompts you to add links by selecting points within a subassembly to connect.

You cannot add a link by connecting points from two different subassemblies.

**Delete Link**

Prompts you to delete links from a subassembly by selecting links in the corridor section view.

The points that were connected in order to create the deleted link are not deleted.

 Add Subassembly

Prompts you to add subassemblies by attaching a new subassembly to an existing subassembly or by inserting a new subassembly between two existing subassemblies.

If you insert a subassembly between two existing subassemblies, the Override column (in the assembly parameters) displays True.

 Delete Subassembly

Prompts you to delete subassemblies by selecting a subassembly to delete in the corridor section view.

If the deleted subassembly connected two subassemblies, the remaining subassemblies are attached to each other.

 Edit User Defined Code

Prompts you to edit or delete user-defined feature codes by selecting a subassembly point marker, link, or shape in the corridor section view.

If the corridor is not set to rebuild automatically, click Rebuild. Corridor surfaces and any other data that is derived from the corridor are updated using overrides.

### View Tools

 Edit/View Options

Sets the view/edit corridor section options.

In the View/Edit Corridor Section Options dialog box you can specify a new view scale, section view, or code set style, and select to automatically rebuild the corridor.

 Zoom to Extents

Click to zoom to the extents of the corridor section view.

 Zoom to an Offset and Elevation

Click to lock the zoom to elevation and offset.

 Zoom to Subassembly

Click to lock the zoom to a subassembly object. Opens the Pick Subassembly dialog box.

### Close

 Close

Closes the Corridor Section Editor ribbon and exits the corridor section view.

**Related procedures:**

■ Viewing and Editing Corridor Sections (page 1361)

# Corridor Style Dialog Box

Use this dialog box to make it easier to locate and work with corridor region boundaries and assembly insertion stations by changing their display.

The corridor style controls the appearance of corridor region boundaries, assembly insertion stations, and stations where the default properties of the subassemblies are overridden. The other elements within the corridor object such as feature lines, corridor sections, and surfaces, are controlled by their own display styles and labels.

## Information Tab (Corridor Style Dialog Box)

Use this tab to change the corridor style name and description information, and to review details about the style, such as when it was most recently modified. For more information, see Information Tab (Style Dialog Box) (page 1801).

## Display Tab (Corridor Style Dialog Box)

Use this tab to change the display and visibility of some corridor object components.

The corridor components controlled by the corridor style include:

Region Boundaries: A closed polyline entity that shows the extents of a corridor region. It follows the outermost feature line on either side of the baseline for the region, from the region start station to the region end station.

Assembly Insertion Stations: Stations where an assembly is inserted to create the corridor model geometry. A line segment that is drawn between the outermost design points on the left and right sides at the baseline alignment station where an assembly is inserted.

Parametric Override Stations: Stations where the design parameters of a subassembly have been numerically edited without changing the default values for the subassembly.

Geometric Override Stations: Stations where the design parameters of a subassembly have been manually edited using grips without changing the default values for the subassembly.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Corridor Style Dialog Box)

Use this tab to review all the information about the current corridor style.

This information can be copied and pasted to the clipboard. For more information, see Summary Tab (Style Dialog Box) (page 1803).

## Create COGO Points Dialog Box

Use this dialog box to export corridor points as COGO points.

For Entire Corridor Range
  Specifies that all points are exported for the entire length of the corridor.

For User Specified Range
  Specifies that points are exported for a certain range along the corridor. When selected, Select Baseline, Alignment Start, and Alignment End are available.

Select Baseline

Specifies the baseline alignment from which to extract the points. Select a baseline or click  to select an alignment in the drawing. Available only if For User Specified Range is selected.

Alignment Start

Specifies the start of the range along the alignment from which to extract points. To edit the start point, enter a value or click  to select a location in the drawing.

Alignment End

Specifies the end of the range along the alignment at which to extract points. To edit the end point, enter a value or click  to select a location in the drawing.

New Point Group Name

Specifies the name of the point group that will contain all the extracted points. For information about point groups, see Point Groups (page 521).

Select Point Codes To Export

Specifies the available point codes to export. Select the check box next to the point code to export the points for the specified point code. Clear the check box if you do not want to export the points.

**Related procedures:**

■ Exporting Corridor Points as COGO Points (page 1372)

# Create Corridor Dialog Box

Use this dialog box to specify the parameters for the new corridor including baselines, regions, and controlling offsets.

Corridor Name

Specifies the name of the corridor.

**NOTE** To name the corridor, click on its default name and enter a new name or use the naming template.

Opens the Name Template (page 1806) dialog box, where you can modify the surface corridor naming template.

Description

Specifies a description for the corridor.

Corridor Layer

Displays the layer that the corridor will be created on.

Opens the Object Layer dialog box where you can select a different layer for the corridor.

Corridor Style

Displays the style that is used to display corridor components, such as region boundaries and assembly insertion stations. For more information, see Corridor Styles and Display (page 1329).

Add Baseline

Adds another baseline (alignment) to the corridor definition.

Set All Targets

Opens the Target Mapping (page 1840) dialog box, where you can map targets from subassembly definitions to appropriate drawing object names for the entire corridor. If you subsequently add an assembly region that uses the same set (or subset) of targets, the mappings are automatically assigned. For more information, see Setting and Editing Targets (page 1343).

NOTE If targets are required and not set, messages are displayed in the Event Viewer. To display the Event Viewer, click General ➤ Utilities ➤ Event Viewer. For more information on the event viewer, see The Event Viewer Vista (page 1626).

The properties table contains the following columns:

Name

Displays a tree listing all baselines, regions, and corresponding offset alignments.

NOTE Offset alignments are displayed if the assembly is defined with assembly offsets. For more information, seeCreating an Assembly Offset (page 1382).

The check boxes beside the baselines and regions specify whether to show (selected) or hide (cleared) the baselines or regions. If the check box is cleared, that section of corridor is not reprocessed when underlying elements (for example, alignments, subassemblies, or surfaces) change.

NOTE The check boxes have a tri-state display. If only one of the regions is selected under a baseline, the check box is dimmed and unavailable.

Alignment

Specifies the alignment for a baseline or offset alignment. Click this field to open the Pick Horizontal Alignment dialog box where you can select an alignment.

Profile

Specifies the profile for a baseline offset alignment. Click this field to open the Select A Profile dialog box where you can select a profile.

Assembly

Opens the Select An Assembly dialog box where you can select an assembly for the corridor region.

Start Station

Specifies the start station for the region or controlling offset. By default, for the first region added to a baseline, this value is set to the start station of the baseline. If one or more corridor regions already exist, this value is set to the end station of last region. Enter a value or click ⊹ to select a location in the drawing area.

End Station

Specifies the end station for the region or controlling offset. By default, for the first region added to a baseline, this value is set to the end station of the baseline. Enter a value or click ⊹ to select a location in the drawing area.

Frequency

Specifies the frequency at which assemblies are placed for a given baseline or region. Click ⬚ to open the Frequency To Apply Assemblies dialog box (page 1836), where you can modify the station frequency and manually add stations.

Target

Click ⬚ to open the Target Mapping dialog box (page 1840), where you can map targets from subassembly definitions to appropriate drawing object names for the region. For more information, see Setting and Editing Targets (page 1343).

Overrides

This field is disabled when you are creating a corridor. For more information, see Viewing and Deleting Overridden Stations (page 1343).

**Related procedures:**

■ Creating a Corridor (page 1332)

■ Editing Corridor Parameters (page 1336)

# Create Corridor Baseline Dialog Box

Use this dialog box to create a baseline for a corridor.

Baseline Name

Specifies the format of the corridor baseline (alignment) name. Click ⬚ to open the Name Template dialog box.

Horizontal Alignment

Lists the horizontal alignments that are available. Click ⬚ to select an alignment in the drawing. The alignment selected in the drawing is then displayed as the selected alignment in the list.

**Related procedures:**

■ Adding Baselines (page 1340)

# Create Corridor Region Dialog Box

Use this dialog box to create a corridor region.

Region Name

Specifies the format of the corridor region name. Click ⬚ to open the Name Template dialog box.

Assembly Name

Lists the assemblies that are available. Click ⬚ to select an assembly in the drawing. The assembly selected in the drawing is then displayed as the selected assembly in the list.

**Related procedures:**

■ Adding and Editing Corridor Regions (page 1337)

# Create Corridor Surfaces Dialog Box

Use this dialog box to export corridor surfaces as (DTM) surface objects.

Surface

Displays the names of the corridor surfaces available for export.

Select

Specifies whether to export the corresponding surface.

Surface Style

Specifies the style for the surface. Click to open the Pick Corridor Surface Style dialog box where you can select a style.

Render Material

Specifies the render material style (page 1577) associated with the surface. Click this field to open the Select Render Material Style dialog box where you can select a style.

**Related procedures:**

■ Exporting Corridor Surfaces (page 1373)

# Create Feature Line From Corridor Dialog Box

Use this dialog box to specify feature line settings when creating a feature line from a corridor.

Site

Specifies the site in which to place the feature line. Select a site from the list or click  to select a site from the drawing.

Name

Specifies the name of the feature line. Select the check box and click  to open the Name Template dialog box.

Style

Select the check box and select a feature line style in the list. Click  to edit the style. Click  to preview the selected style. A style is optional for a feature line, but it provides useful display options and allows you to control color, visibility, and other settings.

Layer

Specifies the layer on which the feature line should be created. Click  to open the Object Layer dialog box and specify the layer. Click Use Current Layer to specify that layer be used.

Smoothing

Select this check box to enable the curve smoothing settings.

Horizontal Deviation

Specifies the maximum 2D distance within which the non-colinear points must be located from the resulting smooth curve. If set to 0, the curve will interpolate all points.

Weeding Distance

Specifies the minimum distance between co-linear points in the resulting smooth curve. The intermediate co-linear points are weeded.

Arc Inclusion Distance

Specifies the maximum distance within which the non-collinear points must be located to be converted into arcs.

Create Dynamic Link to the Corridor

Creates a dynamic link to the corridor. Then, the feature line updates dynamically with any changes to the corridor. If the feature line is created with the dynamic link, the link can be disabled with the Feature Line Properties dialog box (page 1910). When the dynamic link is disabled, it cannot be restored. However, when the feature line is not linked to the corridor, it can be edited with any of the feature line editing commands.

**Related procedures:**

- Creating Feature Lines (page 743)

- Exporting Feature Lines as Grading Feature Lines (page 1370)

## Create Simple Corridor Dialog Box

Use this dialog box to specify the initial corridor creation parameters, including corridor name, description, and layer.

Name

Specifies the name of the corridor.

> **NOTE** To name the corridor, click on its default name and enter a new name or use the naming template.

Opens the Name Template (page 1806) dialog box, where you can modify the corridor naming template.

Description

Specifies a description for the corridor.

Corridor Style

Displays the style that is used to display corridor components, such as region boundaries and assembly insertion stations. For more information, see Corridor Styles and Display (page 1329).

Corridor Layer

Displays the layer that the corridor will be created on.

Opens the Object Layer dialog box, where you can select a different layer for the corridor.

**Related procedures:**

- Creating a Simple Corridor (page 1331)

## Edit Feature Settings - Corridor Dialog Box

Use this dialog box to view and change corridor-related settings.

This topic documents settings in all corridor-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

- Drawing-level ambient settings are identified by the 🗋 drawing icon.

- Corridor feature settings are listed near the top of this dialog box, after the General property group, and are identified by the 🖾 corridor icon.

- Corridor command settings are identified by the 🖾 command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856).

## Default Styles

Use these settings to establish the default styles assigned to corridor components:

Alignment Style

Specifies the default style for an alignment created from the corridor. Click in the Value column, and click to select a style in the Alignment Style dialog box.

Slope Pattern Style

Specifies the default style for the slope patterns added to corridors. Click in the Value column, and click to select a style in the Slope Pattern Style dialog box.

Code Set Style

Specifies the default code set style. Click in the Value column, and click to select a style in the Code Set Style dialog box.

Alignment Label Set

Specifies the default style for the alignment label sets created from corridors. Click in the Value column, and click to select a style in the Alignment Label Set dialog box.

Corridor Surface Style

Specifies the default corridor surface style. Click in the Value column, and click to select a style in the Corridor Surface Style dialog box.

Corridor Style

Specifies the default style for the corridor. Click in the Value column, and click to select a style in the Corridor Style dialog box.

Profile Label Set

Specifies the default profile label set style. Click in the Value column, and click to select a style in the Profile Label Set dialog box.

Profile Style

Specifies the default style for a profile created from the corridor. Click in the Value column, and click to select a style in the Profile Style dialog box.

Feature Line Style

Specifies the default style for a feature line created from a corridor. Click in the Value column, and click to select a style in the Feature Line Style dialog box.

Render Material Style

Specifies the default render material style for the corridor. Click in the Value column, and click to select a style in the Render Material Style dialog box.

For information about style selection, see .

## Default Name Format

Use these settings to specify the default name formats for corridors and corridor surfaces, as well as for

alignments and profiles from feature lines. Click in the Value column, and click to make changes in the .

## Region Highlight Graphics

Use these settings to establish the default styles assigned to corridor region:

**Highlight Baseline**

Specifies whether the baseline of a corridor region is highlighted by default. Click in the Value column, and select Yes or No.

**Baseline Color**

Specifies the color for the baseline. Click in the Value column, and click ⬚ to select a color in the *Select Color dialog box*.

**Baseline Lineweight**

Specifies the default baseline lineweight. Click in the Value column, and click ⬚ to select a style in the Lineweight dialog box.

**Highlight Region Boundary**

Specifies whether the boundary of a corridor region is highlighted by default. Click in the Value column, and select Yes or No.

**Region Boundary Color**

Specifies the color for the region boundary. Click in the Value column, and click ⬚ to select a color in the Select Color dialog box.

**Region Boundary Lineweight**

Specifies the default region boundary lineweight. Click in the Value column, and click ⬚ to select a style in the Lineweight dialog box.

**Highlight Horizontal Targets**

Specifies whether the horizontal targets of a corridor region are highlighted by default. Click in the Value column, and select Yes or No.

**Horizontal Targets Color**

Specifies the color for horizontal targets. Click in the Value column, and click ⬚ to select a color in the Select Color dialog box.

**Horizontal Targets Lineweight**

Specifies the default horizontal targets lineweight. Click in the Value column, and click ⬚ to select a style in the Lineweight dialog box.

**Highlight Internal Assemblies**

Specifies whether the internal assemblies of a corridor region are highlighted by default. Click in the Value column, and select Yes or No.

**Internal Assemblies Color**

Specifies the color for internal assemblies. Click in the Value column, and click ⬚ to select a color in the Select Color dialog box.

**Internal Assemblies Lineweight**

Specifies the default internal assemblies lineweight. Click in the Value column, and click ⬚ to select a style in the Lineweight dialog box.

## Profile Creation Option

**NOTE** This property group is displayed when you access the settings from the CreateAlignfromCorridor command.

Use this setting, to establish the defaults when exporting alignments and profiles from a corridor.

Create Profile From Corridor

Specifies whether a profile is automatically created when creating an alignment from a corridor feature line. If set to Yes, the profile is automatically added to the profile view.

## Feature Line Export Option

**NOTE** This property group is displayed when you access the settings from the CreateAlignfromCorridor or CreateGradingFeatureLine commands.

Use this setting to establish the defaults when exporting feature lines from a corridor:

Smoothen Extracted Entities

Specifies whether corridor feature lines are smoothed when exported.

## Assembly Insertion Defaults

**NOTE** This property group is displayed when you access the settings from the CreateCorridor or CreateSimpleCorridor commands.

Use these settings to establish the defaults assigned to corridor creation.

Frequency Along Tangents

Specifies the corridor station placement frequency along the tangent portion of an alignment. Enter a distance in the Value column or click  and select a distance in the drawing area.

Frequency Along Curves

Specifies the corridor station placement frequency along the curve portion of an alignment. Enter a distance in the Value column or click  and select a distance in the drawing area.

Frequency Along Spirals

Specifies the corridor station placement frequency along the spiral portion of an alignment. Enter a distance in the Value column or click  and select a distance in the drawing area.

Horizontal Geometry Points

Specifies whether corridor stations are placed at horizontal geometry points.

Superelevation Critical Points

Specifies whether corridor stations are placed at superelevation critical points (such as 'end normal crown,' 'level crown,' 'reverse crown,' and 'begin full super').

Profile Geometry Points

Specifies whether corridor stations are placed at profile geometry points.

Profile High Low Points

Specifies whether assemblies are inserted at the high and low points of the profile geometry.

Frequency Along Profile Curves

Specifies the corridor station placement frequency along curve portions of the profile geometry. Enter a distance in the Value column or click  and select a distance in the drawing area.

## Feature Line Creation

**NOTE** This property group is displayed when you access the settings from the CreateGradingFeatureLine command.

Use these settings to specify the defaults when creating feature lines.

Feature Line Name

Specifies whether a name is applied to feature lines when created.

Use Feature Line Style

Specifies whether a style is applied to feature lines when created.

Layer Setting

Specifies the layer that is applied to feature lines when created. The settings are: Use The Layer Setting (from the drawing settings); and Use The Current Layer.

Create Dynamic Link To Alignment

Specifies whether a dynamic link is created between the feature line and the alignment.

Smooth The Feature Line

Specifies whether feature lines are smoothed when exported.

Horizontal Deviation

Specifies the maximum 2D distance within which the non-collinear points must be located from the resulting smooth curve. If set to 0, the curve will interpolate all points.

Inclusion Distance

Specifies the maximum distance within which the non-collinear points must be located to be converted into arcs.

Weeding Distance

Specifies the minimum distance between co-linear points in the resulting smooth curve. The intermediate co-linear points are weeded.

## Criteria-Based Design Options

**NOTE** This property group is displayed when you access the settings from the CreateProfileFromCorridor command.

Use these settings to specify the defaults used when creating a profile using design criteria.

**NOTE** The design criteria values of the parent alignment take precedence over the default design criteria values of the profile. If the parent alignment does not use design criteria values, then the criteria-based design options in the profile are used.

Use Design Criteria File Option

Specifies whether to associate a design criteria file with the profile.
The first XML file found in the *<install directory>\Data\Corridor Design Standards\<units>* is used by default.

Use Design Checks Option

Specifies whether to associate a design check set with the profile.

Default Design Check Set

Specifies the default design check set. Click in the Value column, and click ⬚ to select a set in the Default Design Check Set dialog box.

**NOTE** This setting is not available if the Use Design Checks Option is set to False.

## View/Edit Options

**NOTE** This property group is displayed when you access the settings from the ViewEditCorridorSection command.

Use these settings to establish the default behavior for viewing corridor sections.

Default View Scale

Specifies the scale factor to use when viewing the corridor sections. For example, enter **1** to fit the section exactly to the viewing area.

NOTE The new view scale is used for the next section that is viewed.

Turn Off Unassociated Layers

Specifies whether drawing layers unassociated with the corridor are turned off or on.

Rebuild on Edit

Specifies whether the corridor model is automatically rebuilt when you edit a subassembly using the Corridor Section Editor Ribbon (page 1822).

Front Clip

Specifies the visible extent of 3D objects displayed in a corridor section, measured forward from the sampled section.

Back Clip

Specifies the visible extent of 3D objects displayed in a corridor section, measured from the sampled section back.

Station Tracker in Multiple Viewports

Specifies whether the station tracker is on.

## Grid Settings

NOTE This property group is displayed when you access the settings from the ViewEditCorridorSection command.

Use these settings to establish the default behavior for corridor section view grids:

Display Horizontal Grid

Specifies whether there are horizontal grid lines.

Display Vertical Grid

Specifies whether there are vertical grid lines.

Horizontal Grid Interval

Specifies the interval between horizontal grid lines. Enter a distance in the Value column or click and select a distance in the drawing area.

Vertical Grid Interval

Specifies the interval between vertical grid lines. Enter a distance in the Value column or click and select a distance in the drawing area.

Grid Color

Specifies the color for grid lines. Click in the Value column, and click to select a color in the *Select Color dialog box*.

Display Center Axis

Specifies whether there is a center axis line for the grid.

Center Axis Color

Specifies the color for the center axis line. Click in the Value column, and click to select a color in the Select Color dialog box.

###  Grid Text Settings

**NOTE** This property group is displayed when you access the settings from the ViewEditCorridorSection command.

Use these settings to establish the default behavior for viewing corridor section grid text:

Text Style

Specifies the text style. Click in the Value column, and click  to select a style in the Select Text Style dialog box.

Color

Specifies the color for grid text. Click in the Value column, and click  to select a style in the Select Color dialog box.

Text Height Percentage

Specifies the height of grid text as a percentage of the height of the grid.

Center Axis Annotation

Specifies whether there is annotation for the center axis line of the grid.

**Related procedures:**

■   Editing Corridor Settings (page 1333)

# Frequency to Apply Assemblies Dialog Box

Use this dialog box to add stations to a corridor.

The properties table displays the following settings:

## General

Displays general information about the corridor.

Corridor Name

Displays the corridor name.

Baseline Name

Displays the corridor baseline (alignment) name.

Current Range Start

Displays the value for the first station for the current assembly region.

Current Range End

Displays the value for the last station for the current assembly region.

## Apply Assembly

Specifies the frequency and placement settings for stations along the corridor.

**NOTE** Change the default values for the frequency and placement settings from the Edit Feature Settings dialog box for the CreateCorridor and CreateSimpleCorridor commands. For information, see Changing Corridor Creation Settings (page 1334).

Along Tangents

Specifies the assembly insertion frequency along the tangent portion of an alignment. Enter a value or click  and select a distance in the drawing.

Along Curves

Specifies the assembly insertion frequency along the curve portion of an alignment. Enter a value or click

[...] and select a distance in the drawing.

Along Spirals

Specifies the assembly insertion frequency along the spiral portion of an alignment. Enter a value or click

[...] and select a distance in the drawing.

Along Profile Curves

Specifies the assembly insertion frequency along curve portions of the profile geometry. Enter a value or

click [...] and select a distance in the drawing.

At Horizontal Geometry Points

Specifies whether the assembly should be inserted at horizontal geometry points where the horizontal alignment geometry changes (such as the start of a curve).

At Superelevation Critical Points

Specifies whether the assembly should be inserted at superelevation critical points (such as 'end normal crown,' 'level crown,' 'reverse crown,' and 'begin full super').

At Profile Geometry Points

Specifies whether the assembly should be inserted at profile geometry points where the profile geometry changes.

At Profile High/Low Points

Specifies whether the assembly should be inserted at the high and low points of the profile geometry.

---

**NOTE** If both an assembly frequency setting that references horizontal geometry and a setting that references vertical geometry apply to a portion of a corridor, the setting that results in a smaller interval is used. For example, if a segment is both a horizontal tangent and a vertical curve, and the vertical curve frequency adds assemblies at more frequent intervals, the frequency specified for vertical curves is used.

---

➕

Adds a station. You are prompted to select a station location in the drawing. The station is added to the table of stations.

✖

Deletes the station selected in the table of stations.

The stations table displays the following columns:

Station

Displays the station value on the baseline.

Description

Specifies a description for the station. Click to enter a description.

**Related procedures:**

■ Adding and Editing Corridor Regions (page 1337)

■ Editing Corridor Settings (page 1333)

# Select a Feature Line Dialog Box

Use this dialog box to select a feature line when you have made an ambiguous selection in the drawing.

Feature Line

Lists the feature lines that you can select within the picked region. Click a feature line to select it.

**Related procedures:**

■  Managing and Editing Corridors (page 1333)

# Select a Profile Dialog Box

Use this dialog box to select a profile either from a list or from the drawing area.

Select An Alignment

Lists the horizontal alignments that are available.

Click to select an alignment in the drawing. The alignment selected in the drawing is then displayed as the selected alignment in the horizontal alignment listing.

Select A Profile

Displays the profiles that are available for selected alignment.

Click to select a profile in the drawing. The profile selected in the drawing is then displayed as the selected profile in the Select A Profile list.

**Related procedures:**

■  Creating Profiles (page 1046)

# Select a Subassembly to Insert

Use this dialog box to select a detached subassembly to insert when you are using the Edit/View Corridor Section Tools to override corridor and assembly parameters.sections:

Name

Lists the subassemblies in the current drawing.

Description

Specifies the optional description of the subassembly.

Click to select a subassembly in the drawing.

**Related procedures:**

■  Editing Corridor Sections (page 1365)

**Related procedures:**

■  Setting and Editing Targets (page 1343)

# Select Entities by Layer Dialog Box

Use this dialog box to select feature lines, survey figures and polylines to target either for width or offset, or for slope or elevation.

### Select feature lines, survey figures and polylines by layer

Layer Name

Displays the name of each layer with named entities.

Select

Click to select all entities on a layer for targeting.

Number Of Entities Found

Displays the number of entities found on the named layer.

**NOTE** All entities on any selected layer will be listed in Selected Entities To Target list in either the Set Width Or Offset Target or the Set Slope Or Elevation Target dialog box.

# Set Slope or Elevation Target Dialog Box

Use this dialog box to select an object to target for slope or elevation.

Select An Object Type To Target

Select whether to target Profiles or Feature Lines, Survey Figures, And 3D Polylines.

### Profiles

Select An Alignment

Select from the list any alignment whose profiles you intend to target.

Click to select an alignment in the drawing. The alignment selected in the drawing is then displayed as the selected alignment in the horizontal alignment listing.

Select Profiles

Select from the list any profile you intend to target.

Click to select a profile in the drawing. The profile selected in the drawing is then displayed as the selected profile in the Select Profiles list.

Add >>

Click to add a selected profile to the Selected Entities To Target list.

### Feature Lines, Survey Figures, And 3D Polylines

Select From Drawing

Click to select a feature line, survey or 3D polyline from the drawing.

Select By Layer

Click to select objects in the Select Entities By Layer dialog box.

Selected Entities To Target

Lists all selected target objects by Number (in order of addition to the list), Type and Name.

**NOTE** All entities on any layer selected in the Select Entities By Layer dialog box will be listed in Selected Entities To Target list.

Deletes the selected object from the target entities list.

Selection Choice If Multiple Targets Are Found

Specifies whether to select Target To Nearest Object or Target To Farthest Object, if there are two or more targets in the Selected Entities To Target list.

**Related procedures:**

■ Setting and Editing Targets (page 1343)

## Set Width or Offset Target Dialog Box

Use this dialog box to select an object to target for width or offset.

Select An Object Type To Target

Specify whether to target Alignments or Feature Lines, Survey Figures, And Polylines.

Alignments

Select from the list any alignment you intend to target and click Add >>, or click  to select an alignment from the drawing.

### Feature Lines, Survey Figures, And Polylines

Select From Drawing

Click to select a feature line, survey or polyline in the drawing.

Select By Layer

Click to select objects in the Select Entities By Layer dialog box.

Selected Entities To Target

Lists all selected target objects by Number (in order of addition to the list), Type and Name.

**NOTE** All entities on any layer selected in the Select Entities By Layer dialog box will be listed in Selected Entities To Target list.

Deletes the selected object from the target entities list.

Selection Choice If Multiple Targets Are Found

Specifies whether to select Target To Nearest Object or Target To Farthest Object, if there are two or more targets in the Selected Entities To Target list.

**Related procedures:**

■ Setting and Editing Targets (page 1343)

## Target Mapping Dialog Box

Use this dialog box to set and edit the mapping of targets in subassemblies to the names of actual objects in the drawing.

Corridor Name

Displays the name of the corridor.

Assembly Name

Displays the name of the assembly. If you are viewing the target for an entire corridor, for which there is more than one baseline, '**Varies**' is displayed.

Start Station

Displays the start station for the assembly's region or the start station on the corridor baseline. If you are viewing the target for the entire corridor for which there is more than one baseline, '**Varies**' is displayed.

End Station

Displays the end station for the assembly's region or the end station on the corridor baseline. If you are viewing the target for the entire corridor for which there is more than one baseline, '**Varies**' is displayed.

The properties table contains the following columns:

Target

Lists targets that are required by the corridor's subassemblies, categorized into three groups: Surfaces, Width Or Offset Targets, and Slope Or Elevation Targets.

Object Name

Opens either the Pick A Surface, Set Width Or Offset Target, Set Slope Or Elevation Target or Select Pipe Network dialog box, where you can select the AutoCAD Civil object name to map to the subassembly target.

**NOTE** To quickly set all surface targets to the same surface object, click <Click Here To Set All> next to the Surfaces collection and select the surface object.

Subassembly

Displays the name of the subassembly that requires the target.

Assembly Group

Displays the name of the assembly group.

**Related procedures:**

■ Setting and Editing Targets (page 1343)

# View/Edit Corridor Section Options Dialog Box

Use this dialog box to edit corridor section viewing and editing settings.

**View/Edit Options**

Code Set Style

Specifies the code set style for the corridor section view. Select a style from the list or use the standard style selection tools. For information, see the Select Style dialog box (page 1805).

Default View Scale

Specifies the scale factor to use when viewing the corridor sections. For example, enter **1** to fit the section exactly to the viewing area.

**NOTE** The new view scale is used for the subsequent section that is viewed.

Rebuild On Edit

Specifies whether the corridor model is automatically rebuilt when you edit a subassembly using the View/Edit Corridor Section Tools toolbar (page 1822).

Front Clip

Specifies the visible extent of 3D objects displayed in a corridor section, measured forward from the sampled section.

Back Clip
Specifies the visible extent of 3D objects displayed in a corridor section, measured from the sampled section back.

Station Tracker In Multiple Viewports
Specifies whether the station tracker is on.

## Grid Settings

Horizontal Grid
Specifies whether there are horizontal grid lines.

Vertical Grid
Specifies whether there are vertical grid lines.

Horizontal Grid Interval
Specifies the interval between horizontal grid lines.

Vertical Grid Interval
Specifies the interval between vertical grid lines.

Grid Color

Specifies the color for grid lines. Click  to open the Select Color dialog box.

Center Axis
Specifies whether there is a center axis line for the grid.

Center Axis Color

Specifies the color for the center axis line. Click  to open the Select Color dialog box.

## Grid Text Settings

Text Style
Specifies the text style.

Color

Specifies the color for grid text. Click  to open the Select Color dialog box.

Text Height Percentage
Specifies the height of grid text as a percentage of the height of the grid.

Center Axis Annotation
Specifies whether there is annotation for the center axis line of the grid.

**Related procedures:**

■ Viewing and Editing Corridor Sections (page 1361)

# Criteria-Based Design
# Dialog Boxes

# 50

The following topics provide information about the Criteria-Based Design dialog boxes.

## Design Criteria Editor Dialog Box

Use this dialog box to modify the design criteria file.

The design criteria file contains standards tables for design speed, superelevation attainment method, and minimum speed, radius, and length of individual alignment and profile sub-entities. If your local agency standards differ from the standards in the supplied design criteria file, you can use the Design Criteria Editor dialog box to customize the file to support your local standards.

### General Controls and Toolbar (unlabled)

New Button

Creates an empty design criteria file containing the Units, Alignments, and Profiles nodes in the design criteria hierarchy panel.

Open Button

Opens a browse dialog box, which allows you to select another design criteria file to edit.

Save Button

Saves unsaved changes to the currently open design criteria file.

Save As Button

Saves the currently open design criteria file using a new, user-specified name.

Undo Button

Reverses the most recent change to the currently open design criteria file.

Redo Button

Reverses the most recent undo operation in the currently open design criteria file.

**Make File Read-Only Check Box**

Prevents the currently open design criteria file from being modified. If selected, the Save, Save As, Undo, and Redo buttons are not available.

**Save And Close Button**

Saves unsaved changes to the currently open design criteria file and closes the Design Criteria Editor dialog box.

**Cancel Button**

Clears unsaved changes to the currently open design criteria file and closes the Design Criteria Editor dialog box.

**Help Button**

Opens the Design Criteria Editor dialog box help topic.

## Design Criteria Hierarchy Panel (Unlabeld)

The design criteria hierarchy panel displays the basic categories of information in the design criteria file.

Nodes that are preceded by ⊘ are containers for criteria tables or other container nodes. Nodes that are preceded by ⊞ are criteria tables, which contain the design criteria property values that are applied to the alignment or profile. Right-cli ⊘ node to add new ⊘ or ⊞ nodes to it. Click a ⊞ node to edit the table contents in the Attributes panel.

⊟ **Collapse All Button**

Collapses all the categories in the design criteria panel.

⊟ **Expand All Button**

Expands all the categories in the design criteria panel.

⊘ **Units Node**

Specifies the units of measure for the design criteria file. This value can be either Metric or Imperial. Select a units value, and then specify the individual unit values in the Attributes panel.

⊘ **Alignments Node**

Contains the design criteria for alignments. Select a ⊞ criteria table, and then specify the individual criteria values in the Attributes panel. The following categories and criteria are available this node:

■ Minimum Radius Tables

■ Superelevation Attainment Methods: Standard or Planar (Continuing or Opposing)

■ Superelevation Tables: Design Speed (Superelevation Design Speed or Transition Length Tables)

⊘ **Profiles Node**

Contains the design criteria for profiles. Select a ⊞ criteria table, and then specify the individual criteria values in the Attributes panel. You can create multiple Minimum K Tables in this category. Each Minimum K Table can contain any of the following criteria tables:

■ Stopping Sight Distance

■ Passing Sight Distance

■ Headlight Sight Distance

### Attributes Panel (Unlabled)

➕ o Add Button

Adds a row to the attribute table. If an existing row is selected, the new row is added below the selected row. If a row is not selected, the new row is added to the end of the attribute table.

❌ Delete Button

Deletes the currently selected rows.

Attribute Columns

Specify the attributes for the currently selected criteria table. Values in the individual cells are editable.

### Comments Panel

User-specified comments for the currently selected container or criteria table node. Comments may be added to any node in the design criteria hierarchy panel.

**Related procedures:**

- Design Criteria Files (page 867)

- Profile Standards in the Design Criteria File (page 1045)

# Design Check Editor Dialog Box

Use this dialog box to set up design checks that you can use to check your alignment or profile design against its associated design criteria.

The tables contained in the design criteria file (page 2472) contain most of the criteria used for alignment and profile design. Other criteria must be checked using mathematical expressions, which in the context of criteria-based design are known as design checks (page 2472).

Design checks are created and managed in the same manner as label expressions. To apply a design check to an alignment or profile, you must add it to a design check set (page 2472).

Design checks differ from label expressions in that they always return a true or false value. For example, a design check may be created to verify minimum tangent length. If a tangent length is greater than or equal to the minimum value defined in the design check, no notification is issued. If a tangent length is less than the minimum value defined in the design check, a warning notification is issued.

For examples of design checks, see Design Check Examples (page 871). For instructions on how to create a design check, see Creating a Design Check (page 873).

**NOTE** Do not enter functions, constants, or logical operators inside the { } brackets that surround Properties such as {Minimum Radius}.

To set up a design check, you can use the buttons in the dialog box and the keypad on your keyboard. There are menus in the dialog box from which you can choose Properties and functions to insert into the design check.

If you enter a combination of items that is invalid, a parse error appears when you click OK.

**NOTE** Because design checks return either a true or false value, they must contain one of the following logical operators: > (greater than), < (less than), >= (greater than or equals), <= (less than or equals), != (not equals), = (equals).

Name

Specifies a name for the design check.

Description
   Specifies a description that appears in the Settings tab item list view.

Design Check Box
   Displays the design check as defined from the functions and properties. You can also click in this box and enter characters such as numbers.

Calculator Buttons
   Enter numbers and logical operators (page 1848) into the Design Check box to define the expression.

Insert Property
   Inserts a property into the design check. Click the icon to display a list of properties relevant to the design check type. Select a property to insert it into the design check.

Insert Function
   Inserts a function into the expression. See functions (page 1846) for more information.

## Functions

**NOTE** Functions can be either upper case or lower case but not mixed case. The editor buttons always insert functions in upper case. Unless otherwise stated, theta is in radians.

| | |
|---|---|
| ABS(x) | Returns absolute value of x |
| ACOS(x) | Returns arccosine of x |
| ASIN(x) | Returns arcsin of x |
| ATAN(x) | Returns arctangent of x |
| ATAN2(y,x) | Returns arctangent of y/x in the correct quadrant based on signs of x and y |
| CEIL(x) | Returns the smallest integer that is greater-than or equal to x |
| COS(theta) | Returns the cosine of theta |
| COSH(theta) | Returns the hyperbolic cosine of theta |
| COT(theta) | Retruns the cotangent of theta |
| COTH(theta) | Returns the hyperbolic cotangent of theta |
| CSC(theta) | Returns the cosecant of x |
| CSCH(theta) | Returns the hyperbolic cosecant of x |
| DEG2GRD(theta) | Converts theta in degrees to gradients |
| DEG2RAD(theta) | Converts theta in degrees to radians |
| DRVSTN(x) | Returns x at the derived station along the corridor |
| EXP(x) | Returns exponential of x |

| FLOOR(x) | Returns the largest integer that is less-than or equal to x |
|---|---|
| FMOD(x,y) | Returns the floating point remainder of x/y |
| GRD2DEG(theta) | Converts theta in gradients to degrees |
| GRD2RAD(theta) | Converts theta in gradients to radians |
| IF(test,true_val,false_val) | Evaluates test - if test is non-zero evaluates and returns true_val else evaluates and returns false_val. True_val and false_val can be any expression. For example, where x is a Property: IF(x=0,1,sin(x)/x) This function tests x to see if it is zero, and if it is, the expression returns 1. If x is non-zero, the expression returns sin(x)/x. |
| LOG(x) | Returns the log (base e) of x |
| LOG10(x) | Returns the log (base 10) of x |
| MAX(a,b) | Returns maximum value of a and b |
| MIN(a,b) | Returns minimum value of a and b |
| POW(x,y) | Returns x raised to the y power |
| POW10(x) | Returns x raised to 10 |
| RAD2DEG(theta) | Converts theta in radians to degrees |
| RAD2GRD(theta) | Converts theta in radians to gradients |
| ROUND(x) | Rounds x to the nearest integer |
| SEC(theta) | Returns the secant of theta |
| SECH(theta) | Returns the hyperbolic secant of theta |
| SIN(theta) | Returns the sin of theta |
| SINH(theta) | Returns the hyperbolic sin of x |
| SQR(x) | Returns x squared (that is, x*x) |
| SQRT(x) | Returns the square root of x |
| TAN(theta) | Returns the tangent of theta |
| TANH(theta) | Returns the hyperbolic tangent of theta |
| TRUNC(x) | Truncates x to an integer value |

### Logical Operators

**NOTE** Logical operators return 1 for true and 0 for false. Since they return values, you can perform logical AND and OR with addition and multiplication. For example: ((a<b) + (b>c)) tests for a < b or b > c. ((a<b)*(b>c)) tests for a<b and b>c.

| Symbol | Operator Definition |
|--------|---------------------|
| = | logical equals |
| != | logical not equals |
| ! | logical not |
| < | logical less-than |
| > | logical greater-than |
| <= | logical less-than or equals |
| >= | logical greater-than or equals |
| + | binary addition |
| - | binary subtraction |
| * | binary multiplication |
| / | binary division |
| - | unary minus |
| + | unary plus |
| ^ | power |

**Related procedures:**

- Alignment Design Checks (page 871)

- Profile Design Checks (page 1045)

- Design Check Examples (page 871)

# Design Check Set Dialog Box

Use this dialog box to create a group of design checks for alignments or profiles.

A design check set consists of design checks for a combination of design check types. For example, you can create a design check set that consists of separate design checks for minimum and maximum A values for spirals, minimum radius for curves, and minimum spiral transition lengths.

**See also:**

- Alignment Design Check Sets (page 875)

# Information Tab (Design Check Set Dialog Box)

Use this tab to change the design check set name and description information, and to review details about the last time the design check set was modified.

Name

Specifies the name of the current design check set.

Description

Specifies the description of the current design check set.

Created By

Displays the AutoCAD login name of the person who created the design check set.

Date Created

Displays the date and time the design check set was created.

Last Modified By

Displays the AutoCAD login name of the person who last modified the design check set.

Date Modified

Displays the date and time the design check set was last modified.

# Design Checks Tab (Design Check Set Dialog Box)

Use this tab to edit the contents of an alignment or profile design check set.

Type

Specifies the type of design check to add to the design check set. The types that are available are dependent on the object for which you are creating the design check set. Alignments use Line, Curve, Spiral, and Tangent Intersection types. Profiles use Spiral, Line, and Curve types.

<Type> Checks

Specifies the user-defined design checks that are available for the design check type specified in the Type list. Select a design check from this list, and then click Add to add it to the design check set.

Label Style Control

Creates a design check, edits the current design check, or creates a copy of the current design check.

Add>> Add Label Style

Adds the design check selected in the <type> Checks list to the design check set.

Delete Design Check

Removes a design check from the design check set. Select the design check to delete by clicking in the row in the lower part of the dialog box.

## List of Selected Design Checks

When you add a design check to a set, it appears into the list in the lower part of the dialog box.

Design Check Column

Displays the names of the design checks in the current design check set.

Type Column

Displays the entity types to which the design checks apply.

Apply To Column

For profile curve design checks, specifies the type of curve that the design check will validate. Select one of the following options:

- Crest And Sag Curves

- Crest Curves Only

- Sag Curves Only

---

**NOTE** This column is not available for alignment design check sets.

---

**Related procedures:**

- Alignment Design Check Sets (page 875)

# Drawing Settings Dialog Box

# 51

The following topics provide information about the Drawing Settings dialog box.

## Units and Zone Tab (Drawing Settings Dialog Box)

Use this tab to select linear and angular units, intended plot scale, and coordinate zone for the current drawing.

Drawing Units

Specifies the linear units (feet or meters) for drawing entities in AutoCAD model space.

Angular Units

Specifies the angular units for drawing entities in AutoCAD model space:

- Degrees

- Grads

- Radians

Imperial To Metric Conversion

Specify one of the following conversion settings from the drop-down list:

- International Foot (one foot = 0.3048 Meters)

- US Survey Foot (39.37 Inches per Meter)

Scale Objects Inserted From Other Drawings

Specifies that objects inserted from another drawing will be scaled if necessary to match drawing units in the current drawing.

Set AutoCAD Variables to Match

Synchronizes AutoCAD settings with AutoCAD Civil settings. If there are no equivalent AutoCAD settings, a message appears asking if you want to match as closely as possible. The AutoCAD settings that are synchronized to the AutoCAD Civil settings include the AUNITS, DIMAUNIT, INSUNITS, and MEASUREMENT AutoCAD system variables (sysvars).

Scale

Specifies the intended plot scale in imperial or metric units.

Custom Scale

Specifies the plotted size of various annotation-related components, such as label text, ticks, and band heights. If you change the scale, all annotation objects adjust accordingly.

### Zone

NOTE If you know the code of the coordinate system you want, you can enter it directly in the Selected Coordinate System Code box. A period (.) in this box means no zone has been selected.

Categories

Specifies the geographic zone.

Available Coordinate Systems

Specifies the coordinate system within the selected zone category. If you do not select a zone category, then the default (No Datum, No Projection) is enabled. If you select a zone category but do not select a coordinate system, then, by default, the first entry in the list is selected.

Selected Coordinate System Code

Displays the coordinate system code.

Description

Displays a description of the selected zone.

Projection

Displays the projection method for the coordinate system.

Datum

Displays the abbreviation for the datum on which the coordinate system is based.

**Related procedures:**

■ Specifying Units and Zone Settings (page 63)

# Transformation Tab (Drawing Settings Dialog Box)

Use this tab to transform the coordinate system specified on the Units And Zone tab to local specifications.

Zone Description

Displays the description of the zone that is selected on the Units And Zone tab.

Apply Transform Settings

Specifies whether to apply the settings for coordinate system zone transformation. Selecting this check box enables all the other settings in the dialog box. You cannot select this check box if a zone is not specified on the Units and Zone tab.

### Apply Sea Level Scale Factor

Specifies whether to apply the settings for curvature correction to survey data so that measured horizontal distances are reduced to the distances at the mean seal level (*geodetic distances*).

Elevation

Specifies the mean elevation value of your project site with respect to the mean sea level.

Spheroid Radius

Displays the spheroid radius for the spheroid used by the coordinate system. This value is the radius of a spheroid close to the shape of the Earth at sea level, approximately 6,370 km. The value shown in this box is derived from the ellipsoid for the current zone.

## Grid Scale Factor

Computation

Specifies the type of scale factor:

- **Unity:** Uses 1.00 for all points within the zone.

- **User Defined:** Allows you to specify your own scale factor. For example, you can enter the average scale factor of the points in your survey. This value is used for all points or locations within the zone and is constant.

- **Reference Point:** Uses the scale factor of the specified reference point as the grid scale factor for all points within the zone.

- **Prismoidal Formula:** Uses the prismoidal formula to calculate the grid scale factor. This method is recommended because it accounts for the fact that every point has a different scale factor. The following equation is used to calculate prismoidal scale factor.

$$K_{eff} = \frac{K_{ref} + K_{pt} + K_{mid} \times 4}{6}$$

**Where:**

- Keff is the grid scale factor

- Kref is the scale factor of the reference point

- Kpt is the scale factor of the current point

- Kmid is the scale factor of the midpoint between the reference point and the current point.

A different value is used for each point or locations within the zone.

Scale Factor

Specifies the grid scale factor. Enabled only when you select User Defined for Computation.

## Reference Point

Use this section to specify a reference point for transformation. The reference point could be a benchmark that was used in a survey. It can be any point for which you know both the local coordinates and the grid coordinates.

⬚ Select Point In Drawing

Click to pick a reference point on the screen.

Point Number, Local Northing, Local Easting, Grid Northing, Grid Easting

Specifies a reference point by its point number, Local Northing and Easting values, or Grid Northing and Easting values.

## Rotation Point

Use this section to specify a rotation about the reference point in one of two ways: specify a rotation point, or apply a grid rotation angle.

⬚ Select Point In Drawing

Click to pick a rotation point on the screen to set the local Northing and Easting.

Point Number, Local Northing, Local Easting, Grid Northing, Grid Easting
Specifies a rotation point by its point number, Local Northing and Easting values, or Grid Northing and Easting values.

### Specify Grid Rotation Angle

Click to apply a rotation angle to grid north and azimuth instead of using a rotation point.

To North

Specifies the rotation angle to north. Enter an angle or click ⬚ and pick a point or line in the drawing. The rotation to grid north is the difference between the local coordinate system's north meridian and the grid north meridian of the current zone. If you are using True North, this value may equal the convergence angle. If you are using Magnetic North, this value is derived from the declination angle and the convergence angle.

Azimuth

Specifies the direction of the azimuth. Enter an angle or click ⬚ and pick a point or line in the drawing. Grid azimuth is the angle between the drawing north and the line defined by reference grid and rotation grid points.

### Related procedures:

- [Specifying Transformation Settings](#) (page 65)

# Object Layers Tab (Drawing Settings Dialog Box)

Use this tab to specify layers for various objects in AutoCAD Civil. For example, you can specify that you want all alignments on layer C-ROAD, all parcels on C-PROP, and so on. You can also specify prefixes and suffixes for the layer names.

If desired, label layers can be controlled through their label style. However, label object groups and single labels are individual AutoCAD entities, and they always reside on a given AutoCAD layer, as with all other objects. Use this tab to specify the default layer the labels will be on when initially created. These labels include the following:

- Note (use the General Note Label setting)

- Line & Curve (use the General Segment Label setting)

- Alignment Station Offset (use the Alignment-Labeling setting)

- Profile View Station Elevation (use the Profile View-Labeling setting)

- Surface Spot Elevation (use the TIN Surface-Labeling setting)

- Section View Offset Elevation (use the Section View-Labeling setting)

- Profile-Labeling setting

- Section-Labeling setting

- Pipe-Labeling setting

- Structure-Labeling setting

- Sample Line-Labeling setting

**NOTE** For pipes and structures, when indicating the "object name" as the modifier, use the parent network name, not the name of the pipe or structure. For the Sample Line Labeling setting, the modifier will be the Sample Line Group name, not the name of the individual sample lines.

Object

Lists all object types in AutoCAD Civil.

Layer

Displays the layer on which the object is drawn. Click to open the Layer Selection dialog box.

Modifier

Specifies whether the layer name includes a text-string modifier, and if so, the location of the modifier:

- **None:** No modifier.

- **Prefix:** Modifier is added at the beginning of the layer name.

- **Suffix:** Modifier is added at the end of the layer name.

Value

Specifies the text string to use as the modifier. You can enter an asterisk (**\***) to include the object name as the modifier in the layer name and to put each named object on its own layer. For example, if C-ROAD is the name specified for alignment layers and you add **-\*** as a suffix, an alignment named overpass is created on layer C-ROAD-OVERPASS.

Locked

Specifies whether layer settings are locked for the drawing to prevent overrides for individual objects.

Immediate And Independent Layer On/Off Control Of Display Components

Specifies whether object display is controlled by layer visibility.

- Selected: If an object layer is turned off, the visibility of object subcomponents is not affected if the subcomponents are on a different layer. For example, in a situation where an alignment is on layer C-ROAD and the tangents are on layers C-ROAD_LINE and C-ROAD_CURVE, if you turnoff the object layer C-ROAD the lines and curves will still display. However the labels will not display because the label object recognizes that the object layer is turned off.

- Cleared: If an object layer is turned off, the object subcomponents are also turned off (or not drawn) even in situations where the subcomponents are on a different layer.

**Related procedures:**

- Specifying Object Layer Settings (page 66)

# Abbreviations Tab (Drawing Settings Dialog Box)

Use this tab to control various default abbreviations used in drawing labels and reports.

For example, the default abbreviation for Spiral-Tangent Intersect is TS, meaning any spiral-tangent intersections in a drawing are labeled TS. If you need spiral-tangent intersection labels to be more detailed or different, change the abbreviation by clicking in the value column and changing the TS value.

In the Alignment Geometry Point Entity Data section the values also contain format strings that describe entity properties that will display in the label. For more information see, Property Field Modifiers (page 1509).

**NOTE** For individual abbrviation definitions, see the Glossary (page 2467).

### General Text

Used for abbreviations that are not feature specific.

Infinity

Applied to alignment spiral radius property values where infinity is returned as the value.

Left/Right

Supported as a unique label text component property field name Offset Side. The left and right side is determined by looking up-station along the entity.

### Alignment Geometry Point Text

Used for abbreviations that are specific to alignment geometry points.

Property

Specifies the geometric point or other entity.

### Alignment Geometry Point Entity Data

Used for abbreviations that are specific to alignment geometry point entities that are part of lines, curves, and spirals.

Property

Specifies the geometric point entity data.

### Superelevation

Used for abbreviations that are specific to superelevation.

Property

Specifies the superelevation specification properties.

### Profile

Used for abbreviations that are specific to profile geometry points.

Property

Specifies the geometric point or other entity.

**Related procedures:**

- Specifying Abbreviation Settings (page 67)

## Ambient Settings Tab (Drawing Settings Dialog Box)

Use this tab to specify default ambient (background) settings for a variety of settings, including units of measurement. These units and settings are used throughout AutoCAD Civil, unless they are overridden at the feature or command level.

For information about working with this dialog box, including the use of the override columns, see Working with the Standard Settings Dialog Box Controls (page 62).

### General

These settings specify a variety of features, some of which control how to display text, numbers, and units.

Plotted Unit Display Type

Specifies how to display numbers in interface controls and on the command line:

- Decimal: Display numbers with decimal points. If the drawing units are metric, this is the only option.

- Fractional: Display numbers with fractions.

Save Command Changes To Settings

Specifies whether any changes made to the settings during a command are saved for the drawing, even if the setting is marked as "locked" in the settings dialog box.

Show Event Viewer

Specifies whether the Event Viewer is displayed automatically when an event occurs.

Show Tooltips

Specifies whether to display tooltips in the drawing. This setting does not affect tooltips for toolbar icons. For example, if you move your cursor near an alignment, you see a tooltip that shows the station and offset location of the cursor. Tooltips can also show surface elevation, point, profile, and section information.

---

**NOTE** You can also control tooltip display at the feature settings level and by editing the properties of an individual object.

---

Imperial To Metric Conversion

Displays the conversion method specified on the Units and Zone tab as either US Survey Foot or International Foot.

New Entity Tool Tip State

Specifies whether to display tooltips by default for new objects.

Drawing Unit

Displays the linear units that are used in the model space of the drawing. Set this value on the Units And Zone tab of this dialog box.

Drawing Scale

Displays the intended plot scale. Set this value on the Units And Zone tab of this dialog box.

Scale Inserted Objects

Displays whether objects are scaled when they are inserted from other drawings. Set this value on the Units And Zone tab of this dialog box.

Driving Direction

Determines how curb return alignments are drawn for intersection objects. Left Side of the Road is typically selected for projects where vehicls travel on the left side of the road; for example, in countries such as the United Kingdom. In this case, curb return alignments in intersection objects are drawn starting from the left side of the outgoing road, and ending on the left side of the merging road. Right Side of the Road is typically selected for projects where vehicles travel on the right side of the road; for example, in countries such as the United States. In this case, curb return alignments in intersection objects are drawn starting from the right side of the outgoing road, and ending on the right side of the merging road. For more information, see Setting Driving Direction (page 1430).

Independent Layer On

Has the same effect as the Immediate And Independent Layer On/Off Control Of Display Components setting on the Object Layers (page 1854) tab.

**Labeling**

This setting specifies the default method for prompting for objects when inserting labels that contain Referenced Text components.

Labeling Prompt Method

- Command Line: When inserting a label that contains Referenced Text, you are prompted at the command line to select the objects to refer to in the label.

- Dialog: When inserting a label that contains Referenced Text, the Label Properties dialog box is displayed.

- Suppress Prompts: When inserting a label that contains Referenced Text, all prompting for objects is suppressed.

## Unitless

These settings specify how to display numeric values that are not specifically defined by the unit type settings in this dialog box such as distance and coordinate.

Precision

Specifies the number of digits to show to the right of the decimal.

Rounding

Specifies how numbers are rounded up or down to the number of decimal places specified in Precision:

- Round Normal: If the last displayable digit is even, and the next digit is exactly 5, the program rounds down. If the last displayable digit is odd, and the next digit is exactly 5, the program rounds up. An input value of 100.12345 with precision of 4 would be displayed as 100.1234.
  If the next digit after the last displayable digit is greater than 5, the program rounds up. If the next digit after the last displayable digit is less than 5, the program rounds down.

  **NOTE** AutoCAD is limited to 8 displayed decimal places. However, the actual precision beyond the display capability will still effect rounding. For example, 25.12500000001 would round to 25.13 with two place precision labeling.

- Round Up: Numbers are always rounded up. The value 100.12345 with precision of 4 would be 100.1235 and with precision 2 would be 100.13.

- Truncate: Numbers are limited to the specified number of decimal places without rounding. The value 100.12345 with precision of 4 would be 100.1234 and with precision 2 would be 100.12.

Sign

Specifies how to mark numbers as positive or negative:

- Sign Negative: A sign is used only with negative values. Example: 100.00, -100.00

- Bracket Negative: Brackets enclose negative values. Example: 100.00, (100.00).

- Sign Always +/-: A sign is used with both positive and negative values. Example: +100.00, -100.00

## Distance

These settings specify how to display linear distances.

Unit

Specifies the linear unit to use:

- Meter

- Kilometer

- Decimeter

- Centimeter

- Millimeter

- Foot

- Inch

- Yard

- Mile

Precision

For information, see the Unitless section of this topic.

Rounding

For information, see the Unitless section of this topic.

Sign

For information, see the Unitless section of this topic.

## Dimension

These settings specify how to display linear dimensions.

Unit

Specifies the linear unit to use:

- Meter

- Kilometer

- Decimeter

- Centimeter

- Millimeter

- Foot

- Inch

- Yard

- Mile

Precision

For information, see the Unitless section of this topic.

Rounding

For information, see the Unitless section of this topic.

Sign

For information, see the Unitless section of this topic.

## Coordinate

These settings specify how to display X and Y coordinates.

Unit

Specifies the linear unit to use:

- Meter

- Kilometer

- Decimeter

- Centimeter

- Millimeter

- Foot

- Inch

- Yard

- Mile

Precision

For information, see the Unitless section of this topic.

Rounding

For information, see the Unitless section of this topic.

Sign

For information, see the Unitless section of this topic.

## Elevation

These settings specify how to display surface elevations.

Unit

Specifies the linear unit to use:

- Meter
- Kilometer
- Decimeter
- Centimeter
- Millimeter
- Foot
- Inch
- Yard
- Mile

Precision

For information, see the Unitless section of this topic.

Rounding

For information, see the Unitless section of this topic.

Sign

For information, see the Unitless section of this topic.

## Area

These settings specify how to display surface areas.

Unit

Specifies the drawing unit to use:

- Square Meter
- Square Foot
- Acre
- Hectare
- Square Kilometer
- Square Mile
- Square Yard

Precision

For information, see the Unitless section of this topic.

Rounding

For information, see the Unitless section of this topic.

Sign

For information, see the Unitless section of this topic.

## Volume

These settings specify how to display terrain volumes.

Unit

Specifies the drawing unit to use:

- Cubic Meter

- Cubic Foot

- Cubic Yard

Precision

For information, see the Unitless section of this topic.

Rounding

For information, see the Unitless section of this topic.

Sign

For information, see the Unitless section of this topic.

## Speed

These settings specify how to display speeds for design criteria.

Unit

Specifies the speed as:

- Kilometer/hr.

- Meter/sec.

- Foot/sec.

- Mile/hr.

Precision

For information, see the Unitless section of this topic.

Rounding

For information, see the Unitless section of this topic.

Sign

For information, see the Unitless section of this topic.

## Angle

These settings specify how to display deflection angles between two vectors.

Unit

Specifies the angular unit to use:

- Radian

- Degree

- Grad

**Precision**

For information, see the Unitless section of this topic.

**Rounding**

For information, see the Unitless section of this topic.

**Format**

Specifies how to display angles:

- Decimal (DD.DDDDDD)

- DD°MM'SS.SS" (no spaces)

- DD° MM' SS.SS" (spaced)

- DD.MMSSSS (decimal DMS)

**Sign**

For information, see the Unitless section of this topic.

**Drop Decimal For Whole Numbers**

Specifies whether to display whole numbers with zeros after decimals:

- Yes (example: North 90.00)

- No (example: North 90)

**Drop Leading Zeros For Degrees**

Drops leading zeros before values less than 10.

## Direction

These settings specify how to display directions.

**Unit**

Specifies the angular unit to use:

- Radian

- Degree

- Grad

**Precision**

For information, see the Unitless section of this topic.

**Rounding**

For information, see the Unitless section of this topic.

**Format**

Specifies how to display angles:

- Decimal (DD.DDDDDD)

- DD°MM'SS.SS" (no spaces)

- DD° MM' SS.SS" (spaced)

- DD.MMSSSS (decimal DMS)

Direction

Specifies how to display directions:

- Long Name (example: North 50° 45' East)

- Short Name (example: N 50° 45' E)

- Long Name Spaced

- Short Name Spaced

Capitalization

Specifies how to display direction names:

- Preserve Case

- Upper Case (example: NORTH)

- Lower Case (example: north)

- Title Caps. (example: North)

Sign

For information, see the Unitless section of this topic.

Measurement Type

Specifies how to calculate the direction of a vector:

- Bearings

- North Azimuth

- South Azimuth

Bearing Quadrant

Specifies which bearing quadrant to use:

- 1 - NE

- 2 - SE

- 3 - SW

- 4 - NW

Drop Decimal For Whole Numbers

Specifies whether to display whole numbers with zeros after decimals:

- Yes (example: North 90.00)

- No (example: North 90)

Drop Leading Zeros For Degrees

Drops leading zeros before values less than 10.

## Lat Long

These settings specify how to display latitude and longitude.

Unit

Specifies the angular unit to use:

- Radian

- Degree

■ Grad

**Precision**

For information, see the Unitless section of this topic.

**Rounding**

For information, see the Unitless section of this topic.

**Format**

Specifies how to display angles:

■ Decimal (DD.DDDDDD)

■ DD°MM'SS.SS" (no spaces)

■ DD° MM' SS.SS" (spaced)

■ DD.MMSSSS (decimal DMS)

**Direction**

Specifies the format of lat/long labels:

■ Prefix Short Name (example: N 50° 45')

■ Prefix Long Name (example: North 50° 45')

■ Suffix Short Name (example: 50° 45' N)

■ Suffix Long Name (example: 50° 45' North)

■ Signed: Includes minus signs for negative values (example: -72° 45' 35.45678")

■ Prefix Short Name Spaced

■ Prefix Long Name Spaced

■ Suffix Short Name Spaced

■ Suffix Long Name Spaced

**Capitalization**

Specifies how to display direction names:

■ Preserve Case

■ Upper Case (example: NORTH)

■ Lower Case (example: north)

■ Title Caps. (example: North)

**Sign**

For information, see the Unitless section of this topic.

**Drop Decimal For Whole Numbers**

Specifies whether to display whole numbers with zeros after decimals:

■ Yes (example: North 90.00)

■ No (example: North 90)

**Drop Leading Zeros For Degrees**

Drops leading zeros before values less than 10.

## Grade/Slope

These settings specify how to display grade and slope measurements.

Precision

  For information, see the Unitless section of this topic.

Rounding

  For information, see the Unitless section of this topic.

Format

  Specifies how to display grade and slope values:

  ■ Rise:Run (example 1:5)

  ■ Run:Rise (example 5:1)

  ■ Percent (example 20%)

  ■ Decimal (DD.DDDDDD) (example 0.20)

  ■ Per Mille (example 150‰)

Sign

  For information, see the Unitless section of this topic.

## Grade

These settings specify how to display grade measurements.

Precision

  For information, see the Unitless section of this topic.

Rounding

  For information, see the Unitless section of this topic.

Format

  Specifies how to display grade values:

  ■ Percent (example 20%)

  ■ Decimal (DD.DDDDDD) (example 0.20)

  ■ Per Mille (example 150‰)

Sign

  For information, see the Unitless section of this topic.

## Slope

These settings specify how to display slope measurements.

Precision

  For information, see the Unitless section of this topic.

Rounding

  For information, see the Unitless section of this topic.

Format

  Specifies how to display grade and slope values:

  ■ Rise:Run (example 1:5)

  ■ Run:Rise (example 5:1)

Sign

For information, see the Unitless section of this topic.

## Station

These settings specify how to display linear features that use station or chainage.

Unit

Specifies the drawing unit to use:

- Meter

- Decimeter

- Centimeter

- Millimeter

- Kilometer

- Foot

- Inch

- Yard

- Mile

Format

Specifies the station format in labels, tooltips, and elsewhere:

- Station Format: Specifies that normal station formatting is used (example: 0+010.123).

- Station Index Format: Specifies that indexing is used and applies the Station Index Increment that is specified on the Labels tab of the Alignment Properties dialog box. For example, if the Station Index Increment is 200m, then the station at 200m will appear as 1+00 and the station at 400m will appear as 2+00, and so on. To view this format in labels, you must set up the station label style to use Station Index Format (page 979) also.

- Decimal: Specifies that stations appear as decimal numbers (example: 0010.123).

Precision

For information, see the Unitless section of this topic.

Rounding

For information, see the Unitless section of this topic.

Sign

For information, see the Unitless section of this topic.

Station Delimiter Character

Specifies the separator character used to display stations:

- Plus Sign '+'

- Minus Sign '-'

- Automatic (plus or minus depending on whether the station value is positive or negative)

- Underscore '_'

- None

Station Delimiter Position

Specifies the scale to use for major stations:

- 1+0

- 1+00

- 1+000

- 1+0000

- 1+00000

Drop Decimal For Whole Numbers

Specifies whether to display station whole numbers with zeroes after decimals:

- Yes (example: 120+00)

- No (example: 120+00.000)

Drop Leading Zeros Right of Station Character

Drops leading zeros before the station character for whole number station values.

Minimum Display Width

Specifies the minimum display width for the station value, which allows leading zeros to be added if necessary. For example, assuming a minimum display width of 10 and a precision of 2, a station value of 1234.234 would be displayed as 0012+34.23.

## Transparent Commands

These settings specify the prompting behavior of transparent commands across all features. The formats used to prompt for grade and slope values are set using the Grade and Slope ambient settings.

Prompt For 3D Points

Specifies the prompt sequence (X,Y or X, Y, Z) when creating a point in 3D:

- True (prompt for 3D points)

- False (no Z prompt)

Prompt For Y before X

Specifies whether commands prompt for the Y coordinate before the X coordinate:

- True (Y first)

- False (X first)

Prompt For Easting Then Northing

Specifies whether commands prompt for the Easting before the Northing:

- True (Easting first)

- False (Northing first)

Prompt For Longitude Then Latitude

Specifies whether commands prompt for the Longitude before the Latitude:

- False (Latitude first)

- True (Longitude first)

■ Specifying Ambient Settings (page 68)

# Google Earth Import and Export Dialog Boxes

# 52

The following topics provide information about the wizard pages for publishing Civil data files to Google Earth.

## Publish AutoCAD DWG to Google Earth Wizard

Use this wizard to export 3D design data from AutoCAD Civil to Google Earth for quick visualization of the model within the context of the Earth's surface imagery.

## Describe Page (Publish AutoCAD DWG to Google Earth Wizard)

Use this page to specify information about the drawing to be published. This information is displayed in the Google Earth Places panel under My Places.

Name
    Specifies the name of the DWG model (required).

Description
    Specifies the details about the published DWG file (optional).

Hyperlink
    Specifies the url related to the description field. Only available if the description is specified.

**Related procedures:**

■ Publishing Civil Data to Google Earth (page 1669)

## Items Page (Publish AutoCAD DWG to Google Earth Wizard)

Use this page to select the entities to be published. You can choose to publish either all or selected model space entities. You can also specify whether you want to publish entity information or object-specific elements, such as text or render materials.

All Model Space Entities
    Select to specify all model space entities to publish in Google Earth.

Selected Model Space Entities

Activates the specific entities selection mode. Select to specify individual model space entities to publish in Google Earth.

Click to select model space entities from the drawing to publish in Google Earth.

Publish Text

Select to include all text strings from the drawing in the published file. The text strings are displayed in the Google Earth data file as named placemarks.

**NOTE** All text elements are formatted based on Google Earth default style. Your original formatting may not be preserved.

Publish Entity Information

Select to include additional object-specific information with the published DWG file, for example, length, grade, and diameter for pipes.

Publish Materials

Select to include render materials associated with the model space entities.

**NOTE** If timespan information (page 1670)is attached to model space entities, this information is not published to Google Earth when you select to publish render materials.

**Related procedures:**

■ Publishing Civil Data to Google Earth (page 1669)

# Geo-Reference Page (Publish AutoCAD DWG to Google Earth Wizard)

Use this page to transform the linear coordinates of the drawing to the geographical coordinates of the Google Earth image.

## Drawing Coordinate System Transform

If you have defined a mapping coordinate system for your drawing, select this option to automatically transform X, Y, Z coordinates of the drawing into geographical coordinates used in Google Earth. This option is not available if the drawing does not have a coordinate system defined. Use the User-Defined Transform options to perform manual coordinates transformation.

## User-Defined Transform

Select to manually transform the drawing data into the geographical coordinates of Google Earth.

Collect From Image

Click to collect the location information from the imported Google Earth image.

DWG Location

Specifies the coordinate value in the DWG linear units. Specify the following:

■ X: The X-coordinate of the point in the drawing to be associated with the specific longitudinal position on the Earth's surface.

■ Y: The Y-coordinate of the point in the drawing to be associated with the specific latitudinal position on the Earth's surface.

Click to select a point in the drawing to be associated with the specific position on the Earth's surface.

Earth Position (in Decimal Degrees)

Specifies the coordinate values of the points on the Earth's surface in decimal degrees. Specify the following:

■ Longitude: The longitudinal position of the point on the Earth's surface that is associated with the X-coordinate of a specific point on the drawing.

■ Latitude: The latitudinal position of the point on the Earth's surface that is associated with the Y-coordinate of a specific point on the drawing.

Click to open the Geographic Location dialog box. See Geographic Location Dialog Box (page 1872).

Orientation of DWG Y-axis to North

Specifies the rotation (in decimal degrees) of the positive Y-axis in the drawing to the North direction in Google Earth.

Click to open the Geographic Location dialog box. See Geographic Location Dialog Box (page 1872).

**Related procedures:**

■ Publishing Civil Data to Google Earth (page 1669)

# Nudge Page (Publish AutoCAD DWG to Google Earth Wizard)

Use this page to fine-tune the location of the DWG model by offsetting its final position in Google Earth.

Offset (in DWG Linear Units)

Specifies the offset values for the DWG model in Google Earth. Specify the following:

■ North/South: Specify the amount to offset in the North/South direction.

■ East/West: Specify the amount to offset in the East/West direction.

■ Elevation: Specify the amount to offset the altitude.

Elevation Relative to Ground

Select to set the elevation values of the published entities to be relative to the ground level at the location of the DWG model in Google Earth.

Elevation Relative to Sea Level

Select to set the elevation values of the published entities to be relative to the sea level in Google Earth.

Drape Entities on Ground

Select to set the elevation values of the published entities to the ground elevation directly under the entity.

**Related procedures:**

■ Publishing Civil Data to Google Earth (page 1669)

## File Page (Publish AutoCAD DWG to Google Earth Wizard)

Use this page to specify the name and location for your published file.

File

Specify the name and extension of the published data file. Google Earth supports both *.kmz* (compressed) and *.kml* (uncompressed) files.

⊡

Click to browse to the location where you want to save your DWG model data file.

**NOTE** Using the *.kml* extension may result in large data files. Use the *.kmz* extension to reduce file size.

**Related procedures:**

■  Publishing Civil Data to Google Earth (page 1669)

## Publish and View Page (Publish AutoCAD DWG to Google Earth Wizard)

Use this page to view the status of the publishing operation.

Publishing Status

Shows the publishing operation status bar.

View button

Click to view the published model in Google Earth.

**Related procedures:**

■  Publishing Civil Data to Google Earth (page 1669)

# Geographic Location Dialog Box

Use this dialog box to determine geographical coordinates of a point and specify more precisely the North direction orientation in relation to major cities around the world.

### Latitude

Specifies latitude and direction information in decimal values.

Latitude

Specifies the latitude of the current location. You can specify the value or select the location on the map. The valid range is 1 - 90.

Direction

Specifies the latitude vertical direction.

### Longitude

Specifies the longitude and direction in decimal values. Positive values represent west longitudes.

Longitude

Specifies the longitude of the current location. You can specify the value or select the location on the map. The valid range is 1 - 180.

Direction

Specifies the longitude horizontal direction.

**North Direction**

Specifies the North direction. By default, North is the positive Y direction in the world coordinate system (WCS).

Angle

Specifies the angle from 0 for the North direction.

Displays the North Direction. Move the bar to adjust the North direction angle value.

Map

Specifies a location by using the pointing device. The latitude and longitude values are updated when you select a location. If you enter latitude and longitude values, the pointer moves to show the location.

Nearest Big City

Uses the latitude and longitude values for the nearest big city that you select.

Region

Specifies the region of the world.

Nearest City

Specifies a city in the selected region.

Time Zone

Specifies the time zone. Time zones are estimated by reference to the location. You can set the time zone directly.

# Timespan for Google Earth Dialog Box

Use this dialog box to assign the temporal data to objects in your drawing to be able to display the published model data as they change over the specified period of time.

**Use Start Time**

Specifies the start time for the object display. By default, the date is set to the current date.

Date

Specifies the date when you want the object display to start.

**Use End Time**

Specifies the the end time for the object display. By default, the date is set to the current date

Date

Specifies the date when you want the object display to finish.

**Related procedures:**

■ Attaching Time Information to Model Data (page 1670)

# Grading Dialog Boxes

# 53

The following topics provide information about the Grading dialog boxes.

## Edit Feature Settings - Grading Dialog Box

Use this dialog box to view and change grading-related settings.

This topic documents settings in all grading-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

- Drawing-level ambient settings are identified by the drawing icon.

- Grading feature settings are listed near the top of this dialog box, after the General property group, and are identified by the grading icon.

- Grading command settings are identifie command icon.

The precision and number format display used by all grading commands and used to display grading values is specified in the drawing ambient settings.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

### Default Styles

Use these settings to specify the default styles for for new feature lines and grading groups.

Feature Line Style

Specifies the default style to apply when creating feature lines. Click in the Value column, and click to select a style in the Feature Line Style dialog box.

Grading Style

Specifies the default style to apply when creating grading. Click in the Value column, and click to select a style in the Grading Style dialog box.

Cut Slope Grading Style

Specifies the default style to apply when creating cut slope grading. Click in the Value column, and click ⋯ to select a style in the Cut Slope Grading Style dialog box.

Fill Slope Grading Style

Specifies the default style to apply when creating fill slope grading. Click in the Value column, and click ⋯ to select a style in the Fill Slope Grading Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

## 🏷 Default Name Format

Use these settings to specify the default name formats for new feature lines and grading groups. Click in the Value column, and click ⋯ to make changes in the Name Template dialog box (page 1806).

## ☑ Feature Line Creation

**NOTE** This property group is displayed (in different forms) when accessing the settings from the CreateFeatureLineFromAlign, CreateFeatureLines, and DrawFeatureLine commands.

## ☑ Feature Line Creation (CreateFeatureLineFromAlign)

Use these settings to specify the default behavior for creating feature lines from alignments.

Feature Line Name

Specifies whether a name is applied to feature lines when created.

Use Feature Line Style

Specifies whether a style is applied to feature lines when created.

Layer Setting

Specifies what layer is applied to feature lines when created. The default is Use the Layer Setting which is from drawing settings.

Weed Points

Specifies whether to open the Weed Vertices dialog box so you can weed the objects when converting to a feature line. Change this value to True to open the Weed Vertices dialog box.

Create Dynamic Link

Specifies whether to create a dynamic link to the alignment. Change this value to False to prevent dynamic link creation.

Mid-ordinate Distance

Specifies the mid-ordinate distance for tessellating curves into short line segments. The default is 0.100.

Spiral Tesselation Factor

Specifies the factor for tessellating spirals into short line segments. The default is 0.25.

For more information, see Creating Feature Lines from Alignments (page 745)

## ☑ Feature Line Creation (CreateFeatureLines)

Use these settings to specify the default behavior for creating feature lines from objects.

Feature Line Name

Specifies whether a name is applied to feature lines when created.

Use Feature Line Style

Specifies whether a style is applied to feature lines when created.

Layer Setting

Specifies what layer is applied to feature lines when created. Use the layer setting (from drawing settings). Use the current layer. Use the selected entity layer.

Erase Existing Entities

Specifies whether creation commands erase selected objects when they are converted to feature lines. By default objects are erased. Change this value to False to have objects remain in the drawing.

Weed Points

Specifies whether to open the Weed Vertices dialog box so you can weed the objects when converting to a feature line. Change this value to True to open the Weed Vertices dialog box.

Assign Elevations

Specifies whether to open the Assign Elevations dialog box.

Elevation Source

Specifies whether to assign elevations from a surface, from selected gradings or to set a fixed elevation.

Include Intermediate Elevation Breaks

Specifies whether to include intermediate elevation breaks when assigning elevations from a surface or grading group.

For more information, see Creating Feature Lines from Objects (page 743)

## Feature Line Creation (DrawFeatureLine)

Use these settings to specify the default behavior for drawing feature lines.

Feature Line Name

Specifies whether a name is applied to feature lines when created.

Use Feature Line Style

Specifies whether a style is applied to feature lines when created.

Layer Setting

Specifies the default layer setting when feature lines are created.

For more information, see Drawing Feature Lines (page 748)

## Grading Creation

**NOTE** This property group is displayed when accessing the settings from the CreateGrading command.

Use this setting to specify the default behavior for creating grading.

Transition Region Length

Specifies the default length for transition regions. Enter a length in the Value column or click 🖼️ and select a distance in the drawing area. Creation commands prompt for the transition length if you select the start point of a grading to be within or near to an existing grading.

For more information, see Creating Grading from a Footprint (page 791)

## Grading Group Creation

**NOTE** This property group is displayed when accessing the settings from the CreateGradingGroup command.

Use these settings to specify the default behavior for creating grading groups.

Grading Surface Creation

Specifies whether a grading group generates an automatic surface by default.

Use Group Name

Specifies whether the automatic surface is named after the grading group by default.

Surface Style

Specifies the default style for the grading group. Click in the Value column, and click ⋯ to select a style in the Surface Style dialog box.

Surface Tessellation Increment

Specifies the default maximum distance along the feature line to add supplemental surface triangle lines

for better definition of the grading group surface. Enter a length in the Value column or click 🔲 and select a length in the drawing area.

Surface Cone Tessellation Angle

Specifies the default maximum angle between supplemental projection lines on exterior corners. Enter

an angle in the Value column or click 🔲 and select an angle in the drawing area.

**Tessellation settings control the placement of breaklines along rounded exterior corners and straight grading segments**

For more information, see Creating a New Grading Group (page 741)

## Feature Line Fit Curve

**NOTE** This property group is displayed when accessing the settings from the FitCurveFeature command.

Use these settings to specify the default behavior for creating feature lines along arcs.

Tolerance

Specifies the maximum distance from a PI along the feature to the arc that is to be inserted. When an arc is inserted, it should pass through all the feature line points (between the start and end points). The tolerance specifies how much any one point can be off of the arc that is averaged through all the points.

**Fit Curve Tolerance**

Minimum Number Of Segments

Specifies the minimum number of segments that must be identified before creating an arc. This setting is ignored when the Points option is used.

For more information, see Converting Tessellated Lines to Arcs (page 777)

### Grading Elevation Editor

**NOTE** This property group is displayed when accessing the settings from the GradingElevEditor command.

Use these settings to specify the default behavior for the Elevation Editor, when editing feature lines.

Raise/Lower Increment

Specifies the default vertical distance used for each increment when the feature lines of a grading are raised or lowered to adjust volumes.

Show Grade Breaks Only

Specifies whether only the feature line start/end points and any grade breaks in between are displayed. This option simplifies the editing process by allowing elevation edits to span multiple points.

For more information, see Editing Feature Lines with the Grading Elevation Editor (page 755)

### Grading Layout Tools

**NOTE** This property group is displayed when accessing the settings from the GradingTools command.

Use these settings to specify the default criteria for grading layout.

Grading Criteria Set

Specifies the default Criteria Set to use when creating grading. Click in the Value column, and click  to select a criteria set in the Grading Criteria Set dialog box.

Grading Criteria

Specifies the default Criteria to use when creating grading. Click in the Value column, and click  to select criteria in the Grading Criteria dialog box.

For more information, see Creating Grading (page 790)

## ✅ Grading Volume Tools

**NOTE** This property group is displayed when accessing the settings from the GradingVolumeTools command.

Use these settings to specify the default criteria for grading volumes.

Raise/Lower Elevation Increment

Specifies the default vertical distance used for each increment when the feature lines of a grading are

raised or lowered to adjust volumes. Enter a incremental length in the Value column or click ![icon] and select a length in the drawing area.

Limit Feature Selection To Current Group

Specifies whether features outside the current grading group can be selected for raising or lowering in the volume calculations.

For more information, see Displaying and Adjusting Surface Volumes (page 802)

## ✅ Join Features

**NOTE** This property group is displayed when accessing the settings from the JoinFeatures command.

Use this setting to specify the default tolerance for joining feature lines.

Tolerance

Specifies how close feature lines must be when using the Join (page 771) command.

## ✅ Feature Line Weed

**NOTE** This property group is displayed when accessing the settings from the WeedFeatures command.

Use these settings to specify the default for weeding vertices.

Apply Angle Factor

Specifies whether the Angle factor in the Weed Vertices dialog box is selected by default.

Angle Factor

Specifies the default Angle factor. Enter an angle in the Value column or click ![icon] and select an angle in the drawing area.

Apply Grade Factor

Specifies whether the Grade factor in the Weed Vertices dialog box is selected by default.

Grade Factor

Specifies the default Grade factor. Enter a percentage in the Value column or click ![icon] and select a percentage in the drawing area.

Apply Length Factor

Specifies whether the Length factor in the Weed Vertices dialog box is selected by default.

Length Factor

Specifies the default Length factor. Enter a length in the Value column or click ![icon] and select a length in the drawing area.

Close Point Removal

Specifies whether the 3D Distance factor in the Weed Vertices dialog box is selected by default.

Close Point 3D Distance

Specifies the default 3D Distance factor. Enter a distance in the Value column or click  and select a distance in the drawing area.

For more information, see Weeding Vertices (page 781)

**Related procedures:**

■   Changing Grading Feature Settings (page 736)

# Auto-Balance Volumes Dialog Box

Use this dialog box to specify the required net surface volume (negative for cut or positive for fill) when adjusting the elevation of grading objects.

Required Volume

Specifies the net surface volume for the grading object. When you enter a value and click OK, the grading object is edited so that the required volume is met. The grading object may be adjusted up or down in elevation to meet this value, for example. The action that is performed is recorded in the Description column of the History table in the expanded part of the Grading Volume Tools (page 1899)  dialog box.

# Create Grading Group Dialog Box

Use this dialog box to create a new grading group.

Name

Specifies the name of the new grading group. AutoCAD Civil automatically generates a sequential number.

Description

Specifies an optional description of the grading group.

Automatic Surface Creation

Specifies whether the grading group automatically creates a dynamic surface. If selected, this option activates all of the following fields in this dialog box.

Use the Group Name

Specifies whether to use the grading group name for the name of the dynamic surface. If cleared, the surface is named according to the default name format in the CreateSurface command settings.

Tessellation Spacing

Used for surface creation. Specifies the distance along the footprint to add supplemental breaklines for better definition of the grading group surface.

Tessellation Angle

Used for surface creation. Specifies the angular spacing of supplemental breaklines added around rounded exterior corners, for better definition of the grading group surface.

**Tessellation settings control the placement of breaklines along rounded exterior corners and straight grading segments**

Volume Base Surface

    Specifies the surface to use for comparison with the grading group surface in volume calculations.

**Related procedures:**

■ Using Grading Groups (page 741)

■ Creating a New Grading Group (page 741)

# Grading Criteria Dialog Box

Use this dialog box to manage and create collections of grading criteria for different types of grading.

## Information Tab (Grading Criteria Dialog Box)

Use this tab to change the grading criteria name and description information, and to review details such as when the criteria was most recently modified.

Name

    Specifies the name of the current criteria.

Description

    Specifies a text description of the current criteria.

Created By

    Displays the AutoCAD login name of the person who created the style.

Date Created

    Displays the date and time the style was created.

Last Modified By

    Displays the AutoCAD login name of the person who last modified the style.

Date Modified

    Displays the date and time the style was last modified.

**Related procedures:**

- Using Grading Criteria (page 739)
- Editing Grading Criteria (page 793)

# Criteria Tab (Grading Criteria Dialog Box)

Use this tab to create new grading criteria definitions.

---

**NOTE** The parameters that are displayed under the Grading Method and Projection groups vary, depending on the Target and Projection parameters. For example, if you select Elevation for the target, the Elevation parameter is displayed below Target. You can then enter the elevation.

---

If a criteria is currently used by one or more grading objects, you cannot edit the values for Target or Projection.

## Grading Method

Target

Specifies the target method for the grading. Click one of the following:

- **Surface**: Specifies that the grading projection lines will be extended from the footprint until they match into a surface. You are prompted to select a target surface when you create a grading that uses these criteria.

    **Surface as target (section view)**

- **Elevation**: Specifies that the grading projection lines will be extended from the footprint until they reach a specified elevation. Enter a positive or negative number in the Elevation field.

**Elevation as target (section view)**

fixed elevation as target

footprint

daylight

specified elevation

■ **Relative Elevation**: Specifies that the grading projection lines will be extended from the footprint until they reach an elevation (depth or height) relative to the footprint. Enter a positive or negative number in the Relative Elevation field.

**Relative elevation as target (section view)**

relative elevation as target

footprint

relative elevation

daylight

■ **Distance**: Specifies that the grading projection lines will be extended from the footprint until they are match a specified horizontal distance. Enter a positive number in the Distance field.

**Distance as target (section view)**

horizontal distance as target

footprint

daylight

Projection

Specifies the type of projection. Choices vary according to the target method.

- **Cut/Fill Slope**: Creates the grading by projecting a specific slope value towards a target that can occur both above and below the footprint, such as a surface or elevation target. Slope is always a positive value, as the type of slope determines whether it is going up or down from the footprint. Slope can be formatted as a slope value (run:rise or rise:run), or a grade value (percent or decimal). Related parameter for surface target: see Search Order.

- **Cut Slope**: Creates the grading by projecting a specific slope value up to a target. Slopes can be formatted as a slope value (run:rise or rise:run), or a grade value (percent or decimal).

- **Fill Slope**: Creates the grading by projecting a specific slope value down to a target. Slopes can be formatted as a slope value (run:rise or rise:run), or a grade value (percent or decimal).

- **Distance**: Creates the grading with projection lines that extend a fixed horizontal distance from the footprint.

- **Slope**: Creates the grading by projecting to a specific (absolute) elevation using a specific slope value. Enter a positive or negative value. Slopes can be formatted as a slope value (run:rise or rise:run), or a grade value (percent or decimal).

- **Elevation**: Creates the grading by projecting to a specific (absolute) elevation value.

- **Relative Elevation**: Creates the grading by projecting to an elevation value that is measured relative to the elevation of the footprint.

Search Order

Specifies whether to search first for cut or fill slopes in cases where both would work. For example, where the target surface has a steep slope, both cut and fill slopes may intersect the surface.

- **Cut First**: Creates the grading by trying to grade up from the footprint. If no solution is found, it will grade down.

- **Fill First**: Creates the grading by trying to grade down from the footprint. If no solution is found, it will grade up.

**Different results achieved based on Cut First and Fill First settings (section view)**

Cut First grades up

Fill First grades down

**NOTE** Technically both of these situations are "fill". However, AutoCAD Civil treats the up-slope direction as cut and the down-slope direction as fill.

## (Cut Slope/Fill Slope/Distance/Elevation/Relative Elevation) Projection

**NOTE** The values available for Projection type vary according to the selected Target type.

Format

Specifies how the slope should be represented. Click either Slope or Grade in the list. The format can be further edited in the Grading Settings dialog box (page 1875).

Distance

Specifies the fixed distance from the footprint for the projection. Enter a value, or click  to select a distance in the drawing area.

Slope

Specifies the slope value. Enter a positive value in the form of run:rise or rise:run.

Grade

Specifies the grade value. Enter a positive value as a decimal percent.

## Conflict Resolution

Interior Corner Overlap

Specifies how interior corner projections are cleaned up when the footprint corner has different elevations. This situation results in two possible daylight point elevations. You can choose to average the slopes to reach the same point, or increase or decrease one of the slopes.

**Corner elevation conflict (plan view)**

- **Use Average Slope**: Averages the slopes to reach same daylight point.

- **Hold Slope As Maximum**: Holds the specified grade or slope as the maximum and flattens out the slope projected from the footprint on one side.

- **Hold Slope As Minimum**: Holds the specified grade or slope as the minimum and increases the slope projected from the footprint on one side.

**Related procedures:**

- [Using Grading Criteria](#) (page 739)
- [Editing Grading Criteria](#) (page 793)

# Grading Criteria Set Properties Dialog Box

Use this dialog box to edit name and description properties for the selected criteria set.

Name
> Specifies the name of the current grading criteria set.

Description
> Contains the description of the current grading criteria set.

Created By
> Displays the AutoCAD login name of the person who created the criteria set.

Date Created
> Displays the date and time the criteria set was created.

Last Modified By
> Displays the AutoCAD login name of the person who last modified the criteria set.

Date Modified
> Displays the date and time the criteria set was last modified.

**Related procedures:**

- [Creating Grading Criteria](#) (page 739)

# Grading Editor Dialog Box

Use this dialog box to edit the grading criteria values and change the start or end point of a grading.

You can edit unlocked grading criteria values and apply criteria to grading in the drawing. Editing a value updates the grading in the drawing. Locked values are read-only.

For information about the criteria that you can edit, see the Grading Criteria dialog box (page 1882).

**Select a Grading**

Selects a different grading for editing.

**Related procedures:**

■ Editing Grading Criteria (page 793)

■ Using Grading Criteria (page 739)

# Elevation Editor Dialog Box

Use this dialog box to edit the elevations and grades for feature line, lot line, or survey figure segments. You cannot change the values of the stations or segment lengths.

Green triangles indicate primary geometry points. Green circles indicate intermediate elevation points.

White triangles indicate split points, where two features lines cross with neither having a geometry point at that location. Split points cannot be directly edited. When a vertex shares a point with another intersecting feature line, a small plus symbol is added to the icon for that row. The gray point icons in the grid control and the drawing glyphs represent read-only objects, such as daylight lines and dynamically linked feature lines. For more information, see Editing Feature Lines with the Grading Elevation Editor (page 755).

Use the Shift key to select multiple rows for editing with the Raise/Lower commands.

**Select Line**

Selects a feature line, lot line, or survey figure for editing.

**Zoom To**

Zooms the drawing display to the selected point of intersection (PI) or elevation point.

**Quick Profile**

Creates a quick profile (page 1058) of the feature line.

**Raise/Lower**

Adjusts the elevation of rows either upward or downward. If no rows are selected, prompts for a new elevation for the first point, then adjusts all rows by the same relative amount. If rows are selected, prompts for the new elevation of the first selected row, then adjusts all the selected rows by the same relative elevation.

**Raise Incrementally**

Adjusts the elevations of all points upward by the increment value. If no rows are selected, the option adjusts all points, otherwise it adjusts the points only for the selected rows.

**Lower Incrementally**

Adjusts the elevations of all points downward by the increment value. If no rows are selected, it adjusts all points, otherwise it adjusts the points for the selected rows.

**Set Increment**

Specifies the value to be used by the Raise and Lower commands. Enter the value.

 Flatten Elevations

Specifies that the elevations of all selected rows are flattened to either the same elevation as the first row in the selection, or a constant grade from the start elevation to the end elevation of the selection. Click to open the Flatten dialog box.

 Insert Elevation Point

Inserts an elevation point between the start and end stations of the footprint, creating an intermediate elevation point.

 Delete Elevation Point

Deletes an elevation point between the start and end stations of the footprint. You can delete only a single-row selection of intermediate elevation points.

 Elevations From Surface

Selects an elevation from a surface in the drawing. If there is only one surface, it automatically uses that surface to retrieve the elevations. If there is more then one surface, it prompts you to select the desired surface. If no rows are selected, it updates the elevation of all points. Otherwise, it updates just the selected rows. If the feature line is off the surface, it displays a warning message. If some elevations are updated, but one or more points are off the surface, it displays a message indicating the number of points off the surface that could not be assigned elevations. This option is disabled if the drawing has no surfaces.

 Reverse

Changes the direction of feature lines. Updates the editor so that the order of points is reversed. This command affects the labeling and stationing of feature lines.

 Show Grade Breaks Only

Displays only the feature line start/end points and any grade breaks in between. This option simplifies the editing process by allowing elevation edits to span multiple points. By default, the table displays all feature line points.

 Unselect All Rows

Clears any selected rows so that the Raise, Lower, and Flatten commands to affect the entire length of the footprint.

Station

Identifies the point that starts the current segment.

Elevation

Specifies the elevation of the point identified by the Station.

Length

Displays the length of the current segment.

Grade Ahead

Specifies the end elevation of the current segment in the forward direction. Modifying this grade will change the elevation of the segment. This is the elevation of the next Station point in the next row of the grid.

**NOTE** To edit the grade of multiple rows, select the desired rows and edit the grade of one of the selected rows. The new grade will be applied to all selected rows.

Grade Back

Specifies the grade of the current segment from its end to start. Modifying this grade will change the start elevation of the segment, which is the point at the beginning of the current row.

**Related procedures:**

- [Editing the Elevations of a Feature Line](#) (page 753)

# Elevation Editor - Flatten Dialog Box

Use this dialog box to edit the elevations and grades for feature line, lot line, or survey figure segments to either a constant elevation or a constant grade.

Select **Constant Elevation** to modify the points to a constant elevation. If no rows are selected it flattens the entire feature line using the elevation of the start point. If some rows are selected it flattens just those using the elevation of the first selected row. Select **Constant Grade** to edit the selected rows to a constant grade. The entire feature line grade is modified if no rows are selected. It holds the start elevation and the end elevation and sets the points in between to the same grade, in effect eliminating the grade breaks.

Select Constant Elevation to select multiple rows for editing with the Raise/Lower commands.

**Related procedures:**

- [Editing the Elevations of a Feature Line](#) (page 753)

# Grading Group Properties Dialog Box

Use this dialog box to view and edit the properties of the selected grading group.

**See also:**

- [Grading Properties](#) (page 799)

# Information Tab (Grading Group Properties Dialog Box)

Use this tab to view or change general information for the grading group. The options for automatic surface creation and volume base surface are usually set when the grading group is created, but they can be changed here.

Name

Specifies the name of the grading group.

Description

Specifies an optional description of the group.

Automatic Surface Creation

Specifies whether the grading group automatically creates and updates a dynamic surface. Default surface name is the grading group name.

- **Selected**: If the check box is already selected, it means a surface exists for the grading group. You can clear the check box to either delete the dynamic surface or to create a detached surface. When you clear the check box, you are prompted to delete the surface. If you click No, the surface is detached from the grading group.

- **Cleared**: If the check box is already cleared, no dynamic surface exists for the grading group. You can select the check box to create a dynamic surface, and the Create Surface dialog box is opened.

Tessellation Spacing

Specifies the gap between projection lines on the grading group surface.

Tessellation Angle

Specifies the angular distance between radial projection lines on exterior corners of the grading group surface.

Volume Base Surface

Specifies the surface to use for comparison with the grading group surface in volume calculations.

**Related procedures:**

■ Create Grading Group Dialog Box (page 1881)

■ Using Grading Groups (page 741)

## Properties Tab (Grading Group Properties Dialog Box)

Use this read-only tab to review properties of the grading group.

You can see basic statistics such as

■ Area covered by the grading group

■ Range of elevations and slopes

■ Volume report

■ Number of times the grading group used specific grading criteria and styles

**Related procedures:**

■ Grading Group Properties (page 799)

## Grading Creation Tools

Use this toolbar to quickly create new grading, apply grading criteria and styles, and edit existing grading.

Set The Grading Group

Opens the Select Grading Group dialog box (page 1900). Select the current grading group, or create a new group.

Set The Target Surface

Opens the Select Surface dialog box. Select the surface to use as a target. Applies only when the Grading Criteria uses Surface as the Target.

Set The Grading Layer

Opens the Set Grading Layers dialog box. Specify on which layer the grading should be created.

Select a Criteria Set

Sets the current criteria set, from which you can select specific criteria.

Select a Criteria

Click the Down arrow to select a criteria to apply to the grading.

Style Picker

Use these options to edit the current criteria or create a new criteria.

## Grading Creation Tools

Create Grading

Creates grading by using prompts on the command line. The grading uses the current style and criteria.

Copy Create Grading

Creates a grading by copying the criteria and style from an existing grading object.

Create Transition

Creates a transitional slope between two different criteria or two different values.

Create Infill

Creates a grading face that has no criteria to fill in any holes that are left by creating grading.

## Grading Editing Tools

Edit Grading

Provides a series of command line prompts for you to change the criteria of a grading object.

Delete Grading

Deletes a grading and removes it from the grading group.

Change Grading Group

Prompts you to select the grading objects and then opens the Select Grading Group dialog box (page 1900). Select a grading group to move the grading objects into.

## Grading Utilities

Grading Volume Tools

Opens the Grading Volume Tools (page 1899). Raise or lower the grading group to meet target cut and fill volumes.

Create Detached Surface

Creates a new surface that is not associated with the grading group, and therefore does not update to reflect changes in the group.

Grading Editor

Prompts you to select an existing grading and opens the Grading Editor dialog box.

Grading Elevation Editor

Prompts you to select an existing feature line or lot line, then displays the Grading Elevation Editor dialog box.

Grading Group Properties

Opens the Grading Group Properties dialog box (page 1891).

Grading Properties

Opens the Grading Properties dialog box (page 1894). Note that this is the only place to view the properties of an individual grading.

Expand

Shows or hides the current grading criteria values and the style selectors. You can view the criteria values here.

**Related procedures:**

- Creating Grading (page 790)

# Grading Properties Dialog Box

Use this dialog box to view and change the styles and properties for the selected grading.

Grading Group

Specifies the grading group for the selected grading.

Style Name

Specifies the grading style for the selected grading.

Property & Value

Displays information about the grading type and grading criteria.

**Related procedures:**

- Grading Object Properties (page 800)

# Grading Style Dialog Box

Use this dialog box to control the display of each grading component.

# Information Tab (Grading Style Dialog Box)

Use this tab to change the grading style name and description information, and to review other details, such as when the style was most recently modified.

Name

Specifies the name of the current grading style.

Description

Displays a description of the current grading style.

Created By

Displays the AutoCAD login name of the person who created the style.

Date Created

Displays the date and time the style was created.

Last Modified By

Displays the AutoCAD login name of the person who last modified the style.

Date Modified

Displays the date and time the style was last modified.

**Related procedures:**

■ Using Grading Styles (page 737)

## Center Marker Tab (Grading Style Dialog Box)

Use this tab to specify the size of the triangular marker for the center of a grading.

Size

Specifies the size of the marker and how it is calculated:

■ **Percentage Of Screen**: Marker size is a fixed percentage of the size of the drawing window, and resizes for the current zoom level. Default option.

■ **Plotted Size**: Marker size is based on the current drawing scale (inches or millimeters).

■ **Fixed Size**: Marker size is specified in the current drawing units (usually feet or meters).

**Related procedures:**

■ Using Grading Styles (page 737)

## Slope Pattern Tab (Grading Style Dialog Box)

Use this tab to configure the pattern used to mark grading slopes.

Slope patterns are not applied to infill gradings.

Slope Pattern

Specifies whether to use a slope pattern with the current grading style. Select a slope pattern style and edit a style or create a new one.

Slope Range

Specifies whether the slope pattern is applied to a limited range of slope values, and specifies the range.

**Related procedures:**

■ Using Grading Styles (page 737)

## Display Tab (Grading Style Dialog Box)

Use this tab to specify the defaults for the separate components of a grading object.

View Direction

Specifies the type of view: either 2D or 3D.

Component

Specifies the name of the grading component.

Visible

Controls component visibility.

Layer
    Opens the AutoCAD Layer Selection dialog box. You can assign components to a layer that you create during drawing setup or you can click the New button and create a new layer for the component.

Color
    Specifies the component's color. You can select a color for the component from the Select Color dialog box, or you can specify that the component should derive its color BYLAYER or BYBLOCK.

Linetype
    Displays the Select Linetype dialog box, which allows you to specify the linetype for the component.

Lineweight
    Displays the Select Lineweight dialog box, which allows you to specify the lineweight for the component.

Linetype Scale
    Specifies the linetype scale for the component.

Plot Style
    Sets the plot style for the component.

**Related procedures:**

■ Using Grading Styles (page 737)

## Summary Tab (Grading Style Dialog Box)

Use this tab to view summary information about the grading. You can edit the Name and Description.

**Information**

Name
    Specifies the name of the current grading style.

Description
    Specifies the description of the current grading style.

Created By
    Displays the AutoCAD login name of the person who created the style.

Date Created
    Displays the date and time the style was created.

Last Modified By
    Displays the AutoCAD login name of the person who last modified the style.

Date Modified
    Displays the date and time the style was last modified.

**Related procedures:**

■ Using Grading Styles (page 737)

# Feature Line Style Dialog Box

Use this dialog box to control the display of each grading feature line component.

# Information Tab (Feature Line Style Dialog Box)

Use this tab to change the grading style name and description information, and to review other details, such as when the style was most recently modified.

Name

Specifies the name of the current feature line style.

Description

Displays a description of the current feature line style.

Created By

Displays the AutoCAD login name of the person who created the style.

Date Created

Displays the date and time the style was created.

Last Modified By

Displays the AutoCAD login name of the person who last modified the style.

Date Modified

Displays the date and time the style was last modified.

**Related procedures:**

■ Applying Feature Line Styles (page 746)

# Profile Tab (Feature Line Style Dialog Box)

Use this tab to specify the appearance of marker symbols for a feature line projected into a profile view.

You can specify different styles for the markers at the beginning, internal vertices, and the end of the feature line. Click  to edit the style. Click  to preview the selected style.

**Related procedures:**

■ Applying Feature Line Styles (page 746)

# Section Tab (Feature Line Style Dialog Box)

Use this tab to specify the appearance of the feature line marker symbol in a section view.

**Related procedures:**

■ Applying Feature Line Styles (page 746)

# Markers Tab (Feature Line Style Dialog Box)

Use this tab to specify the appearance of the feature line marker symbol in the drawing. This marker symbol is for displaying the feature line in a section view.

Marker Style

Select the check box and specify a marker style in the list. Click  to edit the style. Click  to preview the selected style.

**Related procedures:**

■ Applying Feature Line Styles (page 746)

## Display Tab (Feature Line Style Dialog Box)

Use this tab to specify the default display for the components of a feature line.

View Direction

Specifies the context for which you are setting the display:

■ Plan – the printed drawing

■ Model – the on-screen design window

■ Profile – projected into a profile view (line and vertex markers)

■ Section – projected into a section view (crossing markers)

Component Type

Specifies the name of the feature line component.

Visible

Controls component visibility.

Layer

Opens the AutoCAD Layer Selection dialog box. You can assign components to a layer that you create during drawing setup or you can click the New button and create a new layer for the component.

Color

Specifies the component's color. You can select a color for the component from the Select Color dialog box, or you can specify that the component should derive its color BYLAYER or BYBLOCK.

Linetype

Displays the Select Linetype dialog box, which allows you to specify the linetype for the component.

LT Scale

Specifies the linetype scale for the component.

Lineweight

Displays the Select Lineweight dialog box, which allows you to specify the lineweight for the component.

Plot Style

Sets the plot style for the component.

**Related procedures:**

■ Using Grading Styles (page 737)

## Summary Tab (Feature Line Style Dialog Box)

Use this tab to view summary information about the feature line. You can edit the Name and Description.

**Information**

Name

Specifies the name of the current feature line style.

Description

Specifies the description of the current feature line style.

Created By

Displays the AutoCAD login name of the person who created the style.

Date Created

Displays the date and time the style was created.

Last Modified By

Displays the AutoCAD login name of the person who last modified the style.

Date Modified

Displays the date and time the style was last modified.

**Related procedures:**

■  Using Grading Styles (page 737)

# Grading Volume Tools

Use this toolbar to adjust the cut and fill volumes for a grading group.

Controls on this toolbar are not available (dimmed) if any required data is unavailable. For example, this can occur if a grading group has not been selected, or if one of the required surfaces has not been defined.

Set the Grading Group

Click to specify the grading group to adjust. The name of the group is displayed along the bottom of the toolbar.

Grading Group Properties

Opens the Grading Group Properties dialog box (page 1891).

Entire Group

Click to adjust the elevation of the whole grading group.

Selection

Click to select one or more features. Click to select the features to adjust.

Raise the Grading Group

Raises the elevation of the grading group by the amount in the box.

Lower the Grading Group

Lowers the elevation of the grading group by the amount in the box.

Automatically Raise/lower to Balance Volumes

Opens the Auto-Balance Volumes dialog box (page 1881). Specify a target value for net volume and automatically balance cut and fill volumes to approach the target.
Auto-balancing volumes to the target is an iterative process due to surface irregularities. The system aims to reach the target volume, with a tolerance of 0.1% of the difference between the starting and target volumes. If necessary, re-run the command to get closer to the target.

**NOTE** This button is unavailable unless the Automatic Surface Creation setting is selected and a Volume Base Surface is specified in the Grading Group Properties  to display the Grading Group Properties dialog box.

 **Expand the Grading Volume Tool**

Shows or hides the history of cut and fill adjustments. This history is erased when you close the toolbar.

Volume Display

Displays the current cut and fill volumes and the resulting net requirements for the grading group. This display updates whenever you modify either of the two surfaces involved in the comparison.

**Related procedures:**

■ Editing the Elevations of a Feature Line (page 753)

# Insert PVI Dialog Box

Use this dialog box to display and edit the values of individual PVIs that you add to a grading feature line. This dialog box is displayed when you click the Insert PVI button in the Elevation Editor dialog box and select a feature line.

Station

Specifies the station of the new PVI. Edit the station definition if needed.

Elevation

Specifies the elevation of the PVI. Edit the elevation if needed.

**Related procedures:**

■ Editing PVIs (page 1093)

# New Slope Pattern Component Dialog Box

Use this dialog box to specify the position of a new component in relation to existing slope pattern components.

Components are numbered in left to right order.

Insert New Component At Position

Specifies the position at which the new component is placed. A new component is placed at the end of the series by default. If you select a different position, existing components in that and higher positions are incremented by one.

**Related procedures:**

■ Creating Grading Styles (page 737)

# Select Grading Group Dialog Box

Use this dialog box to select the grading group to which an individual grading belongs.

Site Name

Select the site you want from the list of the sites in the current drawing. Click  to select a site in the drawing.

Group Name

Select the group you want from the list of the grading groups in the current drawing. Click ![icon] to select a grading group in the drawing. Click ![icon] to create a new grading group.

Description

Displays the description of the grading group, if one has been defined.

**Related procedures:**

- Using Grading Groups (page 741)
- Changing the Grading Group of a Grading Object (page 742)

# Set Grading Layers Dialog Box

Use this dialog box to override the layer settings for the grading objects you create.

Grading Layer

Specifies the layer name the grading is on.

The Object Layer dialog box is used to specify default base layers for drawing objects. The base layer is where the object physically resides.

![icon]

Opens the Object Layers dialog box, which allows you to specify the layer.

# Slope Pattern Style Dialog Box

Use this dialog box to specify the format of a slope pattern.

# Information Tab (Slope Pattern Style Dialog Box)

Use this tab to change the style name and description information, and to review other details, such as when the style was most recently modified.

Name

Specifies the name of the current slope pattern style.

Description

Specifies the description of the style.

Created By

Displays the AutoCAD login name of the person who created the style.

Date Created

Displays the date and time the style was created.

Last Modified By

Displays the AutoCAD login name of the person who last modified the style.

Date Modified

Displays the date and time the style was last modified.

**Related procedures:**

■ Using Grading Styles (page 737)

# Layout Tab (Slope Pattern Style Dialog Box)

Use this tab to configure the appearance of a slope pattern.

Each line in the slope pattern is a separate component.

Component

Specifies the name of the slope pattern component represented in the table of parameter values. You can use the buttons next to this field to add, copy, or delete a component.

 Add Component

Creates a new component using the default parameters. Opens the New Slope Pattern Component dialog box. Specify the position of the new component in relation to existing components.

 Copy Component

Creates a new component using the same parameters as the current component. Opens the New Slope Pattern Component dialog box (page 1900). Specify the position of the new component in relation to existing components.

 Delete Component

Removes the current component from the slope pattern. Not available if only one component exists.

## Slope Line Parameters

Pattern Start

Specifies whether the pattern begins at the top or bottom of the slope.

Length Type

Specifies how to determine the line length for this component. Each option invokes one or more additional parameters, as described:

■ **Length**: Specifies that Line length is a fixed value. Related parameter Length specifies the value in drawing units (usually feet or meters). The line is trimmed if the slope is shorter than this length.

■ **Percent of Length**: Specifies that Line length is a percentage of the slope length, up to a specified maximum. Related parameters: Percent of Length specifies the percentage value; Maximum Length specifies the maximum line length in drawing units.

■ **Slope Ratio**: Specifies that line length varies directly with the steepness of the slope. Related parameters: Slope 1 and Slope 2 specify outside limits for slope values that are represented by line length; Percent of Length 1 specifies the line length as a percent of slope length for Slope 1; Percent of Length 2 specifies the same value for Slope 2. Example: Slope 1 = 6:1, Percent of Length 1 = 20%, Slope 2 = 2:1, Percent of Length 2 = 80%. On a 10-feet long slope, a 6:1 slope is marked with a 2-feet line and a 2:1 slope is marked with an 8-feet line. An intermediate value, 4:1, is marked with a 5-feet line. An outside value, 10:1, is marked with a 1-foot line.

Color

Specifies the color of the line.

Linetype

Opens the Select Linetype dialog box. Specify the linetype for the component.

Lineweight

    Opens the Select Lineweight dialog box. Specify the lineweight for the component.

## Slope Line Offset Parameters

Offset Type

    Specifies how to determine the offset distance between this component and the previous component in the slope line style. Distances are measured as a linear value along the feature and an angular value around exterior corners. Each option invokes additional parameters as described.

■ **Percent of Length**: Specifies that Offset is a percentage of the slope length at the position being offset from. Related parameters: Percent of Length specifies the percentage; Minimum Distance and Maximum Distance specify values for minimum and maximum offsets in drawing units; Radial Offset Angle specifies the angular value.

■ **Distance**: Specifies that Offset is a fixed value. Related parameters: Distance specifies the linear value in drawing units (usually feet or meters); Radial Offset Angle specifies the angular value. The Radial Offset Angle parameter is not used in corridors.

■ **Divide**: Specifies that Offset evenly divides the distance between the previous and the next components to insert one or more instances of the current component. This option is not available if the previous or next component is set to Divide. Related parameter: Number of Lines specifies the number of instances of this component to insert.

## Slope Line Symbol

Symbol Type

    Specifies whether a symbol is added to the beginning of the slope line, and if so, the type of symbol:

■ **None**: No symbol.

■ **AutoCAD Block**: Adds a block that is defined in the drawing. Related parameter: Block Name specifies the block to insert.

■ **Triangle**: Adds a triangle.

■ **Filled Triangle**: Adds a triangle with a solid fill.

■ **Tapered Lines**: Adds a set of lines parallel to the edge of the slope, tapering toward the slope line in a triangular pattern. A gap exists between the last tapered line and the slope line. Related parameter: Number of Lines specifies the number of lines to include in the set.

■ **Tapered Lines (No Gap)**: Adds a set of tapered lines, and attaches the last tapered line to the slope line. Related parameter: Number of Lines specifies the number of lines to include in the set.

Length Type

    Specifies how to determine the length of the symbol. Each option invokes an additional parameter:

■ **Length**: Specifies that Symbol length is a fixed value. Related parameter Length specifies the value in drawing units (usually feet or meters).

■ **Percent of Length**: Specifies that symbol length is a percentage of the slope length. Related parameter Percent of Length specifies the percentage value.

Width Ratio

    Specifies the ratio of the symbol's width to its length along the slope line (width = length * width ratio).

Color

    Specifies the color of the symbol.

Linetype

Opens the Select Linetype dialog box. Specify the linetype for the symbol.

Lineweight

Opens the Select Lineweight dialog box. Specify the lineweight for the symbol.

**General Properties**

Minimum Display Length

Specifies the minimum slope length on which to display the slope pattern.

Use the following parameters to configure the sample slope in the preview window.

Preview Feature Length

Specifies the length of feature line to display.

Preview Slope Length

Specifies the length of slope to display.

Preview Slope

Specifies the slope value to display.

**Related procedures:**

■ Using Grading Styles (page 737)

# Edit Geometry Panel

Use this panel to edit feature lines, 2D and 3D polylines, survey figures, and parcel lines.

This is a standard panel that you access by selecting Modify tab ➤ Edit Geometry panel.

---

**NOTE** See Editing Feature Lines (page 751) for a list of supported objects for each command. Supported objects are also listed at the command line when you run the command.

---

Break

Breaks a feature line into two feature lines. (page 784)

Trim

Trims a feature line. (page 785)

Join

Joins multiple feature lines, creating a single object. (page 771)

Reverse

Reverses the direction of feature lines for stationing purposes. (page 772)

Fillet

Rounds the corners of feature lines. (page 776)

Fit Curve

Converts tessellated curves to true arcs for better grading results. (page 777)

 Smooth

Smooths out jagged feature lines. (page 779)

 Weed

Deletes vertices and elevation points from feature lines. (page 781)

 Stepped Offset

Offsets feature lines at an elevational difference. (page 783)

# Edit Elevations Panel

Use this panel to edit feature lines, 2D and 3D polylines, survey figures, and parcel lines.

This is a standard panel that you access by selecting Modify tab ➤ Edit Elevations panel.

**NOTE** See Editing Feature Lines (page 751) for a list of supported objects for each command. Supported objects are also listed at the command line when you run the command.

 Elevation Editor

Edits feature line elevations using the Elevation Editor. (page 753)

 Quick Elevation Edit

Edits the elevations of a feature line by snapping to points that you can edit in the drawing. (page 754)

 Edit Elevations

Edits feature-line or lot-line elevations, using the command line. (page 753)

 Set Grade/Slope Between Points

Specifies the grade or slope between selected points on a feature line. (page 758)

 Set Elevation By Reference

Sets the feature line elevation in relation to an existing elevation in the drawing. (page 759)

 Insert Elevation Point

Inserts an elevation point (page 765)

 Delete Elevation Point

Deletes elevation points. (page 767)

 Insert High/Low Elevation Point

Inserts high or low elevation points into feature lines. (page 767)

 Raise/Lower

Raises and lowers feature line elevations. (page 764)

**Elevations From Surface**

Creates feature-line elevations from a surface. (page 768)

**Insert PI**

Inserts points of intersection. (page 769)

**Delete PI**

Deletes points of intersection. (page 771)

**Set Elevation By Reference**

Sets an elevation by referencing from a selected point. (page 759)

**Raise/Lower Elevation By Reference**

Raises or lower elevations by referencing a selected point. (page 761)

**Adjacent Elevations By Reference**

Sets elevations by referencing an adjacent feature line. (page 762)

**Break**

Breaks a feature line into two feature lines. (page 784)

**Trim**

Trims a feature line. (page 785)

**Join**

Joins multiple feature lines, creating a single object. (page 771)

**Reverse**

Reverses the direction of feature lines for stationing purposes. (page 772)

**Fillet**

Rounds the corners of feature lines. (page 776)

**Fit Curve**

Converts tessellated curves to true arcs for better grading results. (page 777)

**Smooth**

Smooths out jagged feature lines. (page 779)

**Weed**

Deletes vertices and elevation points from feature lines. (page 781)

**Stepped Offset**

Offsets feature lines at an elevational difference. (page 783)

# Feature Line Contextual Commands

Use these commands to create and edit feature line properties.

You can access these commands by selecting a feature line and then select Feature line tab ➤ Modify panel.

**NOTE** See Editing Feature Lines (page 751) for a list of supported objects for each command. Supported objects are also listed at the command line when you run the command.

Feature Line Properties
   Draws a feature line. (page 748)

Apply Feature Line Names
   Applies optional names to feature lines. (page 746)

Apply Feature Lines Styles
   Applies styles to feature lines. (page 746)

Remove Dynamic Links
   Removes feature line dynamic links to alignments and corridors. (page 747)

# Create Feature Lines Dialog Box

Use this dialog box to specify feature line settings when drawing a feature line or creating a feature line from objects.

Site

   Specifies the site in which to place the feature line. Select a site in the list or click  to select a site from the drawing.

Name

   Specifies the name of the feature line. To name the feature line, click on its default name and enter a new name or use the naming template. Click  to open the Name Template Dialog Box (page 1806), where you can modify the feature line naming template.
   Feature line names are optional and can be used to name significant feature lines in the drawing. When there are named feature lines you can select feature lines to edit by name from a list.

Style

   When selected, specifies a feature line style. Select a style in the list. Click  to edit the style. Click  to preview the selected style. A style is optional for a feature line, but it provides useful display options and allows you to control color, visibility, and other settings. A style is also used to set the control the feature line split point resolution.

Layer
   Opens the Object Layer dialog box, where you can specify the layer the feature line should be created on. This layer cannot be specified if Use Selected Entity Layers is selected under Conversion Options.

Use Current Layer
   Places the new feature lines on the current layer.

Use Selected Entity Layer

Specifies the layer where the converted feature lines are placed.

- ■ **Selected**: Places feature lines on the same layer as the selected objects.

  NOTE This can make it difficult to select the feature line if the Erase Existing Entities check box is cleared.

- ■ **Cleared**: Places the feature lines on the layer specified by the Layer setting above.

## Conversion Options

Erase Existing Entities

Specifies whether the selected objects are erased when they are converted to feature lines.

- ■ **Selected**: Erases the selected objects from the drawing.
- ■ **Cleared**: Does not erase the selected objects.

Assign Elevations

Specifies whether to assign elevations to the entities being converted.

- ■ **Selected**: Click OK to open the Assign Elevations dialog box.
- ■ **Cleared**: The Assign Elevations dialog box is not opened.

Weed Points

Specifies whether the selected objects are weeded when they are converted to feature lines.

- ■ **Selected**: Click OK to open the Weed Vertices dialog box.
- ■ **Cleared**: The Weed Vertices dialog box is not opened.

**Related procedures:**

- ■ Creating Feature Lines (page 743)
- ■ Weeding Vertices (page 781)

# Assign Elevations Dialog Box

Use this dialog box to assign elevations when creating feature lines from objects. You can access this dialog from the Create Feature Lines dialog box.

These options override the elevations of the objects that you are converting to feature lines.

Elevation

Assigns a fixed elevation to the feature line.

From Gradings

Creates a temporary surface from selected gradings to compute the feature line elevation. This produces the same result as selecting the grading group surface if you have not created a grading group surface.

From Surface

Assigns elevations to the feature line from a surface in the drawing.

Select Intermediate Grade Break Points

Inserts intermediate grade breaks when the entity crosses surface TIN lines, creating elevation points at these locations.

**Related procedures:**

■

# Create Feature Line From Alignment Dialog Box

Use this dialog box to specify feature line settings when creating a feature line from an alignment.

Alignment

Displays the name of the source alignment.

Site

Specifies the site in which to place the feature line. Select a site in the list or click  to select a site in the drawing.

NOTE The feature line can not be created in the same site as the alignment. If the alignment is in a site, that site will not be available in the site list.

Name

Specifies the name of the feature line. Select the check box and click  to open the Name Template dialog box. In addition to the style and counter properties, there are properties to include the alignment and profile names in the feature line name.

Profile

Specifies a vertical alignment from which to acquire the elevations for the feature line. Click  to select a profile in the drawing. If the alignment does not have a vertical alignment, you can create the feature line only while the dynamic link option is disabled. For the dynamic link, a vertical alignment is required.

Mid-ordinate Distance

Sets the vertical curve tessellation factor.

Spiral Tessellation Factor

Sets the clothoid spiral tessellation factor.

Weed Points

Specifies whether to open the Weed Vertices dialog box so you can weed the objects when converting to a feature line. Change this value to True to open the Weed Vertices dialog box.

Style

Select the check box and specify a feature line style in the list. Click  to edit the style. Click  to preview the selected style. A style is optional for a feature line, but it provides useful display options, allowing you to control color, visibility, and other settings.

 Layer

Opens the Object Layer dialog box. Specify the layer on which the feature line should be created. This layer cannot be specified if Use Selected Entity Layers is selected under Conversion Options.

Create Dynamic Link to the Alignment

Creates a dynamic link to the alignment so that the feature line updates dynamically with any changes to the alignment or the selected vertical alignment. If the feature line is created with the dynamic link,

the link can be disabled, using the Feature Line Properties (page 1910) dialog box. If the dynamic link is disabled, it cannot be restored.

■ **Selected**: The feature line is linked to the alignment.

■ **Cleared**: The feature line is not linked to the alignment and can be edited with any of the feature line editing commands.

**Related procedures:**

■ Creating Feature Lines (page 743)

■ Creating Feature Lines from Alignments (page 745)

# Feature Line Properties Dialog Box

## Information Tab (Feature Line Properties Dialog Box)

Use this dialog box to assign a style to a feature line or to change the style assigned to a feature line.

Name

■ Specifies that a name is applied to the feature line. Click  to edit the name template.

Style check box

■ **Selected**: Specifies that a style is applied to the feature line.

■ **Cleared**: Style selection options are not available.

Style

Specifies the style for the feature line.

Specifies the style options. You can create a new style, copy or edit the current style selection, or pick a style from drawing.

Opens the Style Detail dialog box where you can preview the style and creation information.

Dynamic Link

■ Displays the name of the alignment and profile to which the feature line is linked. You can change the profile that is used to set the elevations and the mid-ordinate distance can be changed.

Mid-ordinate Distance

Specifies the mid-ordinate distance for tessellating curves into short line segments. The default is 0.100.

Weed Points

Specifies whether to open the Weed Vertices dialog box so you can weed the objects when converting to a feature line. Change this value to True to open the Weed Vertices dialog box.

**Related procedures:**

■ Feature Line Properties (page 801)

## Statistics Tab (Feature Line Properties Dialog Box)

This dialog box displays read-only feature line statistics.

Count
  Displays the total number of points.

PI Points
  Displays the total number of PI points.

Elevation Points
  Displays the total number of intermediate elevation points.

2D Length
  Displays the total 2D length.

3D Length
  Displays the total 3D length.

Minimum Elevation
  Displays the minimum elevation.

Maximum Elevation
  Displays the maximum elevation.

Minimum Grade
  Displays the minimum grade.

Maximum Grade
  Displays the maximum grade.

### Breakline Data

If the feature line is used by any surfaces as breakline data, the following list is displayed.

Surface
  Displays the name of the surface.

Breakline Group
  Displays the breakline group.

### Related procedures:

■ Adding a Feature Line to a Surface as a Breakline (page 786)

# Weed Vertices Dialog Box

Use this dialog box to specify settings for removing vertices and elevation points from feature lines, parcel lines, and 2D or 3D polylines.

### Weeding Factors

Select one or more weeding factor to apply. Larger values remove more points. If more than one factor is specified, both factors have to be met before the point is selected for weeding.

When you change a value, the display in the drawing is updated with red glyphs to show the points that will be weeded.

Angle
  Specifies the weeding angle.

weeding angle factor (plan view)

possible vertex to be
deleted

if angle < angle factor, then the vertex will be deleted

**Grade**

Specifies the weeding grade.

weeding grade factor (profile view)

G1 %

G2 %

possible vertex to be deleted

if the difference between G1 and G2 < grade factor,
then the vertex will be deleted

**Length**

Specifies the weeding distance. Enter the distance value or click to select it in the drawing.

weeding length factor (plan view)

possible vertex to be deleted

L

if L < length factor, then the vertex will be deleted

## Close Point Removal

**3D Distance**

Specifies the 3D distance for weeding. Points that are close together in plan view, with slightly different elevations can be weeded using this setting.

weeding 3D distance factor (profile view)

D

possible vertex to be deleted

if D is < 3D distance factor, then the vertex will be deleted

**Related procedures:**

■ Weeding Vertices (page 781)

# Fit Curve Dialog Box

Use this dialog box to specify the tolerance and minimum number of segments for applying the Fit Curve command.

Tolerance

Specifies the maximum distance from a PI along the feature to the arc that is to be inserted. When an arc is inserted, it should pass through all the feature line points (between the start and end points). The tolerance specifies how much any one point can be off of the arc that is averaged through all the points.

**Fit Curve Tolerance**

Minimum Number Of Segments

Specifies the minimum number of segments that must be identified before creating an arc. This setting is ignored when the Points option is used.

**Related procedures:**

■ Converting Tessellated Lines to Arcs (page 777)

# Set Elevations From Surface Dialog Box

Use this dialog box to select the surface from which to obtain feature line elevations.

Surface Selection List

Select a surface in the list or click  to select it in the drawing.

Insert Intermediate Grade Break Points

Inserts an elevation point (page 2473) at each location where the feature line crosses a surface TIN line.

**Related procedures:**

■   Setting Feature Line Elevations from a Surface (page 768)

# Statistics Tab (Feature Line Site Properties Dialog Box)

Use this tab to view the combined statistics for all feature lines in the site. This data cannot be edited.

Feature Lines

Displays the total number of feature lines.

PI Points

Displays the total point of intersection (PI) points.

Elevation Points

Displays the total elevation points.

2D Length

Displays the total 2D length.

3D Length

Displays the total 3D length.

Minimum Elevation

Displays the minimum elevation.

Maximum Elevation

Displays the maximum elevation.

Minimum Grade

Displays the total point of intersection (PI) points.

Maximum Grade

Displays the maximum grade.

# Grouped Statistics Tab (Feature Line Site Properties Dialog Box)

Use this tab to view the combined statistics for all feature lines in the site. This data cannot be edited.

The data is grouped in two list boxes allowing you to extract data based on layer and/or style. The following information is listed for each style or layer.

Count

Displays the total number of feature lines.

2D Length

Displays the total 2D length.

**3D Length**

Displays the total 3D length.

**Minimum Elevation**

Displays the minimum elevation.

**Maximum Elevation**

Displays the maximum elevation.

**Minimum Grade**

Displays the total point of intersection (PI) points.

**Maximum Grade**

Displays the maximum grade.

## Options Tab (Feature Line Site Properties Dialog Box)

Use this dialog box to determine feature line style priority.

When two feature lines with different styles intersect, the one with the higher set priority determines the elevation. Feature lines without a style have the lowest priority. If two feature lines have the same style or no style, then priority is given to the last edited feature line.

**Feature Line Crossings: Split Point Resolution**

Displays the feature line style priority from highest to lowest. You can drag and drop styles in the list or use the up/down arrows to specify priority. When new styles are created, they are added to the end of the list.

**Filter Unused Styles**

Filters out unused styles and displays styles referenced in the current site. You can edit the style priority in the filtered state, but some styles may be hidden. You can move a style between two visible styles that have been filtered. If the style moves to a lower priority, it is placed above the filtered styles immediately following the style it was placed after. If the style was moved up, it is placed below the filtered styles, immediately above the style it was moved ahead of.

**Copy From Site**

Selects a different site in the drawing in order to copy the style priority order. If there is only one site in the drawing, this option is unavailable.

**Apply to All Sites**

Applies the current style priority order to all sites in the drawing. If there is only one site in the drawing, this option is unavailable.

**Save as Default**

Sets the default command setting to the currently set priority.

## Apply Feature Line Names Dialog Box

Use this dialog box to edit the names for a selection set of feature lines.

**Name**

Toggles the feature line names on or off. If only a single feature line was edited, you can use the name

template, or type in a new name. Click  to access the Name Template Dialog Box (page 1806), where you can modify the feature line naming template. If multiple feature lines are selected, use the name template to apply unique names to the selection set. If you attempt to use a name template that does not include the counter, an error message will display.

**Related procedures:**

■ Applying Feature Line Names (page 746)

# Apply Feature Line Styles Dialog Box

Use this dialog box to specify a style for a selection set of feature lines.

Style List

Specifies the following options for style selection:

■ Create New

■ Copy Current Selection

■ Create Child of Current Selection (Labels only)

■ Edit Current Selection

■ Pick from Drawing

Specifies the style options. You can create a new style, copy or edit the current style selection, or pick a style in the drawing.

Opens the Style Detail dialog box, where you can preview the style and creation information. You can also use the checkbox to turn off styles for the selected feature lines.

**Related procedures:**

■ Applying Feature Line Styles (page 746)

# Edit Feature Line Curve Dialog Box

Use this dialog box to edit the radius of a feature line (or survey figure) arc. You can also delete the arc from the feature line.

These options override the elevations of the objects you are converting to feature lines.

Radius

Specifies the radius of the arc.

Length

Displays the length of the arc.

Chord

Displays the length of the chord.

Tangent

Displays the length of the tangent.

Maintain Tangency

When the curve is not tangent, the Maintain Tangency button is activated. If you toggle this button the curve will be adjusted, to making it tangent to the adjacent segments. If the curve is tangent, the button is disabled.

**Edit Previous Curve**

Moves to the previous curve on the feature line. If the current curve has been edited it will be saved before moving to the previous curve. If there is no previous curve, this option is disabled

**Edit Next Curve**

Moves to the next curve on the feature line. If the current curve has been edited, it will be saved before moving to the next curve. If there is no following curve this option is disabled.

---

**NOTE** The left and right arrow keys can also be used to navigate the curves. You can edit the radius, then press the arrow key to move without using the mouse.

---

**Pick Curve Radius**

Selects points in the drawing to specify the curve radius. If the radius is valid, the value appears in the Radius edit box and the arc preview updates. If the radius is too large for the feature line, an error message is displayed.

# Intersections Dialog Boxes

# 54

## Edit Feature Settings - Intersections Dialog Box

Use this dialog box to view and change intersection-specific settings.

This topic documents settings in all intersection-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

- Drawing-level ambient settings are identified by the ▯ drawing icon.

- Intersection feature settings are listed after the General and Labeling property groups, and are identified by the ✚ intersection icon.

- Intersection command settings are identified by the 🗹 command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

### 🗹 Assembly Insertion Defaults

**NOTE** This property group is displayed when accessing the settings from the CreateIntersection command.

Use these settings to specify the defaults assigned during intersection object creation. For more information, see Changing Corridor Assembly Frequency (page 1451).

Frequency Along Tangents
  Specifies the frequency to insert assemblies along tangent segments of the intersection area corridor baseline.

Frequency Along Curves
  Specifies the frequency to insert assemblies along curved segments of the intersection area corridor baseline.

Frequency Along Spirals
  Specifies the frequency to insert assemblies along spiral segments of the intersection area corridor baseline.

Horizontal Geometry Points

Specifies whether to add assemblies at horizontal geometry points of the corridor baselines in the intersection area.

Superelevation Critical Points

Specifies whether to add assembies atsuperelevation critical points of the corridor baselines in the intersection area.

Profile Geometry Points

Specifies whether to add assembies at profile geometry points of the corridor baselines in the intersection area.

Profile High Low Points

Specifies whether to add assemblies to the highest and lowest points of the profile to define intersection corridor.

Frequency Along Profile Curves

Specifies the frequency that intersection object assemblies are inserted along curved segments of the profile.

## Intersection Options

**NOTE** This property group is displayed when accessing the settings from the CreateIntersection command.

Use these settings to specify the default styles assigned to intersection creation.

Intersection Type

Specifies the corridor grade option for the corridors created in the intersection area. Primary Road Crown Maintained: When this option is selected, the primary road crown is maintained through the intersection. All Crowns Maintained: When this option is selected, the crowns of both roads included in the intersection are maintained through the intersection.

Default Exit and Entry Length - Primary Road

Specifies the intersection extents along the primary road as it enters and exits the intersection. If the curb returns are defined, then this parameter is not used, and instead the extents are calculated by the curb return extents on either side of intersection.

Default Exit and Entry Length - Secondary Road

Specifies the intersection extents of the secondary road as it enters and exits the intersection. If the curb returns are defined, then this parameter is not used, and instead the extents are calculated by the curb return extents on either side of intersection.

Create Curb Return Alignments

Specifies whether to create curb return alignments.

Create Curb Return Profiles

Specifies whether to create curb return profiles.

Create Intersection Corridors

Specifies whether to create intersection corridors.

## Default Offsets

**NOTE** This property group is displayed when accessing the settings from the CreateIntersection command.

Use these settings to specify the default styles assigned to intersection creation.

Primary Road - Left Offset

Specifies the offset distance from the centerline on the left side of the primary road.

**Primary Road - Right Offset**

Specifies the offset distance from the centerline on the right side of the primary road.

**Secondary Road - Left Offset**

Specifies the offset distance from the centerline on the left side of the secondary road.

**Secondary Road - Right Offset**

Specifies the offset distance from the centerline on the right side of the secondary road.

**Offset Length Options**

Specifies how the length of the offset alignment is determined. When To Intersection Extents is selected, offset alignments are extended to the length of the extent of the intersection object. When Alignment Start To End is selected, offset alignments are created the length of the parent alignment.

## Default Cross Slopes

**NOTE** This property group is displayed when accessing the settings from the CreateIntersection command.

Use these settings to specify the default styles assigned to intersection creation.

**Primary Road - Left Cross Slope**

Specifies the cross slope of the left side of the primary road.

**Primary Road - Right Cross Slope**

Specifies the cross slope of the right side of the primary road.

**Secondary Road - Left Cross Slope**

Specifies the cross slope of the left side of the secondary road.

**Secondary Road - Right Cross Slope**

Specifies the cross slope of the right side of the secondary road.

## Curb Return Parameters

**NOTE** This property group is displayed when accessing the settings from the CreateIntersection command.

Use these settings to specify the default styles assigned to intersection creation.

**Curb Return Type**

Specifies the type of curb return used for the intersection: Chamfer, Circular Fillet, or 3-Centered Arcs.

**Circular Fillet Radius**

When Circular Fillet is selected as the curb return type, this option lets you specify the radius for the circular fillet on the curb return.

**Radius of Curve (X)**

When 3-Centered Arcs is selected as the curb return type, this option lets you specify the radius for each of the three curves on the curb return.

**Length of Curve (X)**

When 3-Centered Arcs is selected as the curb return type, this option lets you specify the length for the first and third curves on the curb return.

**Chamfer Fillet Length - Along Incoming\Outgoing Lane**

When Chamfer is selected as the curb return type, this option lets you specify the length of the curb return's chamfer fillet along the incoming or outgoing lane.

## Default Widening Parameters

**NOTE** This property group is displayed when accessing the settings from the CreateIntersection command.

Use these settings to specify the default styles assigned to intersection creation. For more information, see Widenings (page 896), or Editing Offset Alignments and Widenings (page 1005).

Widening At Incoming Lane
Specifies whether to widen the incoming lane as it enters the intersection.

Widening At Outgoing Lane
Specifies whether to widen the outgoing lane as it exits the intersection.

Widened Offset
Specifies the offset distance applied to the widened regions, at both the entrance to the intersection, and as it exits the intersection.

Widening Segment Length
Specifies the length of the widened portion of the curb return at both the entrance to the intersection, and as it exits the intersection.

Transition Type
Specifies the type of transition used for the widening: Linear, Curve-Line-Curve, Curve-Curve -Reverse Curve, or Curve - Reverse Curve.

Linear Transition Type
When Linear is selected as the Transition Type, this option lets you specify the type of linear transition used for the widening: By Length or By Taper Ratio.

Transition Length
When By Length is selected as the Linear Transition Type, this option lets you specify the length of the transition for the widening.

Taper Ratio
When By Taper Ratio is selected as the Linear Transition Type, this option lets you specify the ratio of the tapering for the widening.

Radius of Curve X
When a curve option is selected as the Transition Type, this option lets you specify the radius for the first and second curves used in the widening.

Radius of Reverse Curve
When Curve-Curve - Reverse Curve is selected as the Transition Type, this option lets you specify the radius for the first and second curves used in the widening.

## Secondary Road Profile Rules

**NOTE** This property group is displayed when accessing the settings from the CreateIntersection command.

Use these settings to specify the default styles assigned to intersection creation.

Apply Grade Rules
Specifies whether to apply grade rules.

Maximum Grade
Specifies the maximum grade that can be used in the profile for the secondary road.

Maximum Grade Change
Specifies the maximum grade change that can be used in the profile for the secondary road.

Distance Rule to Adjust the Grade

Specifies the method that is used to adjust the grade of the secondary road profile. When To Intersection Extents is selected, the grade of the secondary road profile is adjusted to within the extents of the intersection object. When Specify Distance is used, the grade of the secondary road profile is adjusted by the value that is entered in the Distance Value.

Distance Value

Specifies the distance that is used to adjust the incoming and outgoing grade along the secondary road profile when Specify Distance is selected for Distance Rule to Adjust the Grade.

## Curb Return Profile Rules

**NOTE** This property group is displayed when accessing the settings from the CreateIntersection command.

Use these settings to specify the default styles assigned to intersection creation.

Define Curb Return Profile By

Specifies the method that is used to define the curb return profile.

Extend Profile Along Incoming Lane

Specifies whether to extend the curb return profile along the incoming lane of the intersection.

Length To Extend Along Incoming Lane

When Extend Profile Along Incoming Lane is set to Yes, this option lets you specify the length to extend the curb return profile along the incoming lane of the intersection.

Extend Profile Along Outgoing Lane

Specifies whether to extend the curb return profile along the outgoing lane of the intersection.

Length To Extend Along Outgoing Lane

When Extend Profile Along Incoming Lane is set to Yes, this option lets you specify the length to extend the curb return profile along the outgoing lane of the intersection.

## Default Styles

Use these settings to specify the default styles assigned to intersection object components.

Intersection Style

Specifies the default style for intersections. Click in the Value column, and click ⋯ to select a style in the Intersection Style dialog box.

Intersection Label Style

Specifies the default style for intersection object labels. Click in the Value column, and click ⋯ to select a label style. Note that there is no placement option available for an intersection label. The label is always placed at the intersection point. If that point is already labeled, then a second label is placed on top of the existing label.

Offset Alignment Style

Specifies the default style for offset alignments. Click in the Value column, and click ⋯ to select a style in the Offset Alignment Style dialog box.

Curb Return Alignment Style

Specifies the default style for curb return alignments. Click in the Value column, and click ⋯ to select a style in the Curb Return Alignment Style dialog box.

Offset Profile Style

Specifies the default style for offset profiles. Click in the Value column, and click ⊡ to select a style in the Offset Profile Style dialog box.

Curb Return Profile Style

Specifies the default style for curb return profiles. Click in the Value column, and click ⊡ to select a style in the Curb Return Profile Style dialog box.

Offset Alignment Label Set

Specifies the default style for offset alignment label sets. Click in the Value column, and click ⊡ to select a style in the Offset Alignment Label Set dialog box.

Curb Return Alignment Label Set

Specifies the default style for curb return alignment label sets. Click in the Value column, and click ⊡ to select a style in the Curb Return Alignment Label Set dialog box.

For general information about style selection, see Select Style Dialog Box (page 1805).

## ⊞ Default Name Format

Use these settings to specify the default name templates used for the following components associated with an intersection object:

■ intersection object

■ intersection quadrant

■ offset alignment

■ curb return alignment

■ offset profile

■ curb return profile

■ corridor region

Click in the Value column, and click ⊡ to select a style in the Name Template dialog box (page 1806).

# Intersection Properties Dialog Box

Use this dialog box to view the properties of an intersection object, such as the object name, description, and style.

The Intersection Properties dialog box also lists details about the intersecting alignments and the corridor regions included in the intersection.

**See also:**

■ Editing Intersection Properties (page 1441)

# Information Tab (Intersection Properties Dialog Box)

Use this tab to view or change general information for the intersection object.

Name

Specifies the name of the current intersection object.

Description

Specifies an optional description for the current intersection.

Object Style

Specifies the default style used to display intersections. Select a style in the list or use the standard style selection tools. For more information about the standard style selection tools, see the Select Style (page 1805) dialog box.

Show Tooltips

Specifies whether tooltips are displayed for the object in the drawing (not over toolbar icons).

# Intersection Details Tab (Intersection Properties Dialog Box)

Use this tab to view or change the parameters of the current intersection object.

Alignment Details

This section displays information about the intersecting alignments in the intersection object. It displays the names of the intersecting alignments, the station of the point of intersection, and the profile associated with each alignment. If there are multiple profiles available, you can change the profile associated with the alignment by clicking in the Profile cell selecting a new profile from the drop-down list, and clicking Apply.

Intersection Quadrants

In this section, you can click Previous and Next to advance through the quadrants in this intersection. For each quadrant, the names of the incoming and outgoing alignments, as well as the intersection angle, are displayed. Most of this information is read-only, however you can change the name of the intersection quadrant if desired.

# Intersection Style Dialog Box

Use this dialog box to make it easier to locate and work with intersection objects by changing their display.

The intersection style controls the appearance of intersection objects.

**See also:**

■ Intersection Styles and Display (page 1425)

# Information Tab (Intersection Style Dialog Box)

Use this tab to change the intersection style name and description information, and to review details about the style, such as when it was most recently modified.

For more information, see Information Tab (Style Dialog Box) (page 1801).

# Marker Tab (Intersection Style Dialog Box)

Use this tab to specify the appearance of the marker that is used for intersection objects in the drawing.

**Use AutoCAD POINT For Marker**

Specifies that the assembly component is displayed using the current AutoCAD point symbol, which is specified by the AutoCAD PDMODE and PDSIZE system variables.

**Use Custom Marker**

When this is selected, the specified symbol is used to display the intersection object in the drawing.

Custom Marker Style

Specifies the symbol that is used to display the marker for the intersection object. Click one of the five symbols to the left to use as a base symbol. Optionally, click the sixth symbol, the seventh symbol, or both, to superimpose them over the base symbol.

## Use AutoCAD Block Symbol For Marker

When this is selected, intersection objects are displayed in the drawing using a reference to the selected AutoCAD block. The block is scaled using the options specified in the Size section of this dialog box.

The list displays block definitions available in the drawing. Do one of the following:

- Click a block name to select the block to be used for the assembly symbol.

- Right-click in the block list window and click Browse to select a block located in another folder.

The specified block is displayed in the Preview window.

## Marker Rotation Angle

Specifies the rotation angle for the symbol. Applies to all three symbol types (AutoCAD Point, Custom Marker, and AutoCAD Block). Enter a value or click ⬚ to specify an angle.

## Size

Options

Specifies symbol scaling:

- Use Drawing Scale: Determines size of the marker by multiplying the specified value by the drawing scale. Enter the scale factor.

- Use Fixed Scale: Activates the Fixed Scale options.

- Use Size in Absolute Units: Specifies that the marker size is an absolute value based on the displayed units. Enter the value.

- Use Size Relative to Screen: Specifies that the size of the marker is a percentage of the drawing screen size. Enter the percentage.

Fixed Scale

Specifies independent fixed scale values when Options is set to Use Fixed Scale. Enter values for X, Y, or Z.

## Orient Marker To World Coordinates

Specifies that the maker rotation angle is relative to the world coordinate system.

## Orient Marker To View

Specifies that the maker rotation angle is relative to the current AutoCAD view direction.

# Display Tab (Intersection Style Dialog Box)

Use this tab to change the display and visibility of intersection objects.

## View Direction

Some object styles can have unique display values and varying numbers of displayed components, depending on whether they are being displayed in Plan, Profile, Section, or Model views. You can create and set style characteristics for each supported view direction type using the View Direction list.

Intersection objects support display styles in plan and model view.

Plan and Model

Select Plan or Model to specify display style settings when the intersection object is displayed in plan or model view.

### Component Display

Marker

This is the closed polyline entity that represents the extents of an intersection object. You can set the following style characteristics for this component: Visibility, Layer, Color, Linetype, LT Scale, Lineweight and Plot Style.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Intersection Style Dialog Box)

Use this tab to review general the information about the current intersection object style.

You can copy and paste this information to the clipboard. For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Create Intersection Wizard

Use this wizard to create an intersection object after selecting the point where two alignments intersect.

This wizard quickly leads you through the process of creating an intersection. After selecting the point where two alignments intersect, you can configure a variety of parameters related to the intersection using the choices available on the wizard dialog boxes.

Reviewing and changing the settings on each wizard page is optional. From any page of the wizard, clicking Create Intersection creates the intersection using the current values specified.

Before creating an intersection object, make sure you understand the necessary object and drawing data that must exist. See Before You Begin (page 1429) for more information.

Once created, the intersection object is displayed in the drawing and in the Prospector tree. For information about editing intersection objects, see Editing Intersections (page 1439).

## General Page (Create Intersection Wizard)

Use this page of the wizard to specify general details for the intersection object, such as object name and style.

### Intersection Name

Enter a name for the intersection object, or accept the name specified by the default name template for intersection objects. For more information, see Name Template dialog box (page 1806).

### Description

Enter an optional description for this intersection object.

### Intersection Marker Style

Style List

Displays the current style for intersection object markers. Click the arrow to display the intersection marker styles in the drawing.

Style Selection

Specifies the style options. Create a new style, copy or edit the current style selection, or pick a style from the drawing.

 Style Detail

Opens the Style Detail dialog box, where you can preview the style and creation information.

## Intersection Marker Layer

Specifies the layer of the intersection object marker. Click  to open the Object Layer dialog box where you can select a different layer for the intersection object marker.

## Intersection Label Style

Style List

Displays the current style for intersection object labels. Click the arrow to display the intersection label styles in the drawing. Note that there is no placement option available for an intersection label. The label is always placed at the intersection point. If that point is already labeled, then a second label is placed on top of the existing label.

Style Selection

Specifies the style options. Create a new style, copy or edit the current style selection, or pick a style from the drawing.

 Style Detail

Opens the Style Detail dialog box, where you can preview the style and creation information.

## Intersection Corridor Type

Specifies how crowns will be maintained for this intersection. For more information, see Intersection Corridor Type (page 1434)

Primary Road Crown Maintained

When this option is specified, the crown of the primary road is maintained, while the crown (profile) of the secondary road is adjusted to match the edge of the primary road and the intersection point. The crown (profile and edges) of the primary road are not affected. A conceptual graphic representing this type of intersection is displayed on the wizard dialog box.

All Crowns Maintained

When this option is specified, the profile of the side road is adjusted to match the main road elevation at the intersection point. The main road profile is not affected. The edges are blended together along the curb returns (via the curb return profiles). A conceptual graphic representing this type of intersection is displayed on the wizard dialog box.

**NOTE** Once an intersection object is created, you cannot change the value of the intersection Corridor Type property.

On this dialog box, you can click Next to move to the next wizard dialog box, Create Intersection to create the intersection using the currently selected setting, or Cancel to cancel creating the intersection.

# Geometry Details Page (Create Intersection Wizard)

Use this page of the wizard to specify a variety of details about the geometry of the intersection object.

## Intersecting Alignments

Use this section to view information on the alignments included in this intersection. You can view the alignment name, priority, the station where the intersection occurs, and the profile associated with the alignment. If other profiles exist, you can select a different profile from the drop-down list.

Priority

The priority determines how profile locking occurs for the profiles associated with the intersection. You can change the priority of an alignment (road) during intersection creation by selecting an alignment in this list and using the arrows. It is important to note that when you do this, the associated profiles may change. Once an intersection object is created, you cannot change the value of the priority property. See Changing Road Priority (page 1433) for more information.

## Offset and Curb Returns

Specifies information on the alignment offsets and curb returns for this intersection.

Create Or Specify Offset Alignments

When this option is selected, offset alignments will be created for the intersection. If you do not want offset alignments included in the intersection, remove the check mark from this option. If you do not select an existing alignment from the current drawing, then a new offset alignment object is created. To select an existing offset alignment from the drawing, click the Offset Parameters button, set Use An Existing Alignment to Yes, then select the alignment by clicking ⋯ next to the Alignment Name field.

Offset Parameters

Before deciding to create offset alignments, you can view or edit the parameters that will be used for creating the offset alignments by clicking the Offset Parameters button. This displays the Intersection Offset Parameters dialog box (page 1931) which lets you specify an existing alignment to use, or create a new one according to the offset value you specify. For more information, see Editing Offsets in Intersections (page 1445).

Create Curb Return Alignments

When this option is selected, curb return alignments will be created for the intersection. If you do not want curb return alignments included in the intersection, remove the check mark from this option.

Curb Return Parameters

Before deciding to create curb returns, you can view or edit the parameters that will be used for creating the curb returns by clicking the Curb Return Parameters button. This displays the Intersection Curb Return Parameters dialog box (page 1932), which lets you specify the curb return type (chamfer, circular fillet, or 3-centered arcs), and other details, such as radius for the curb return. For more information, see Editing Curb Returns in Intersections (page 1447).

## Offset and Curb Return Profiles

These options let you create offset and curb return profiles for this intersection. If the intersecting alignments do not have profiles associated with them, these options are not available.

Create Offset and Curb Return Profiles

Selecting this option creates offset and curb return profiles for this intersection. This option is not available when the intersecting alignments selected for this intersection do not have profiles associated with them.

Lane Slope Parameters

Clicking this button displays the Intersection Lane Slope Parameters dialog box where you can view or edit the lane slopes for the roads included in the intersection object. This option is not available when the intersecting alignments selected for this intersection do not have profiles associated with them.

Curb Return Profile Parameters

Clicking this button displays the Intersection Curb Return Profile Parameters dialog box where you can view or edit the parameters for the curb return profile included in the intersection object. This option is not available when the intersecting alignments selected for this intersection do not have profiles associated with them.

On this dialog box, you can click Back to return to previous wizard dialog boxes, Next to move to the next wizard dialog box, Create Intersection to create the intersection using the currently selected setting, or Cancel to cancel creating the intersection.

## Corridor Regions Page (Create Intersection Wizard)

Use this page of the wizard to specify details about the corridor regions included in the intersection object.

### Create Corridors in the Intersection Area

When this option is selected, new corridor objects are created in the intersection area when the intersection is created. When this option is not selected, the rest of the options on this page of the wizard are unavailable. For more information, see Creating Corridors in the Intersection Area (page 1435).

Create a New Corridor

When this option is selected, a new corridor object will be created for this intersection.

Add to an Existing Corridor

When this option is selected, you can select an existing corridor to add to for this intersection. If you do not have corridor objects in the drawing, this option is not available.

Select Surface to Daylight

Specifies a surface to use for daylighting. If you do not have surfaces in the drawing, this option is not available. Also, you cannot target a surface that is an output of another corridor.

### Select Assembly Set to Import

Specifies the assembly set to use for creating the intersection. If desired, you can choose a different assembly set to import for use with creating this intersection. For more information, see Assembly Sets (page 1457).

Browse

Click this button to browse to a location for selecting an assembly set to use for creating this intersection.

Save As Set

Saves the currently selected assembly set to an xml file. When you click this button, you are prompted to choose a name and location for the assembly set.

### Corridor Region Section Type

Specifies the assembly that defines each section (component) in each corridor region included in the intersection. Click the items listed in this section to display a conceptual graphic that updates with each selection.

Assembly to Apply

Displays the name of the assembly that is specified (referenced) in the selected assembly set for each

component. If there are assemblies available in the current drawing, you can click to select a different assembly to apply. If you click an assembly in the list, the location where the assembly will be applied along the intersection is highlighted in the conceptual graphic.

On this dialog box, you can click Back to return to previous wizard dialog boxes, Create Intersection to create the intersection using the currently selected settings, or Cancel to cancel creating the intersection.

When you create an intersection object, the following objects are added to the current drawing:

■ intersection object

■ corridor(s)

■ assemblies

■ subassemblies

■ offset alignments

■ curb return alignments

**Related procedures:**

■ Creating Corridors in the Intersection Area (page 1435)

# Intersection Offset Parameters Dialog Box

Use this dialog box to view and edit the parameters of the offset alignments included in the intersection object.

Click the expand ⬚▾ and collapse ⬚▴ buttons at the top right to expand and collapse the information displayed in this dialog box.

You can select offset alignments for the primary or secondary road in the intersection.

When you select an item on this dialog box, the affected object is highlighted in the drawing, and the conceptual graphic on the dialog box updates to indicate the location affected by the edit. For more information, see Intersection Editing Visual Cues (page 1443).

### Left or Right Offset Alignment Definition

Specifies the definitions of the offset alignments included in the intersection.

Use an Existing Alignment

When No is specified, the offset alignment is created during intersection object creation. When Yes is specified, an existing alignment from the current drawing can be used to create the left and right alignment offsets.

Offset Value

Specifies the offset distance for the offset alignment. This property is automatically set to Varies if an alignment is selected that is not a dynamic offset alignment based on a centerline.

Alignment Name

Displays the name of the offset alignment currently specified. When Use an Existing Alignment is set to Yes, you can click ⬚ to specify another alignment from the current drawing. When you do this, the Offset Value property is automatically set to Varies, if the selected alignment is not a dynamic offset alignment based on a centerline. It is also important to note that if you do select another offset alignment from the drawing, the original offset alignment that was created during intersection object creation is not deleted.

**Related procedures:**

■ Editing Offsets in Intersections (page 1445)

- Widenings (page 896)
- Editing Offset Alignments and Widenings (page 1005)

# Intersection Curb Return Parameters Dialog Box

Use this dialog box to view and edit the parameters of the curb returns included in the intersection object.

When you select a property item on this dialog box, the affected object, or area of the intersection is highlighted in the drawing, and the conceptual graphic on the dialog box updates to indicate the location affected by the edit. For more information, see Intersection Editing Visual Cues (page 1443).

**Previous and Next Buttons**

The Previous and Next buttons let you select each of the quadrants in the intersection sequentially. The currently selected quadrant is highlighted in the drawing.

**Intersection Quadrant**

This drop-down list lets you select each of the quadrants in the intersection.

**Expand and Collapse Buttons**

Click the expand and collapse buttons at the top right to expand and collapse the property information displayed in this dialog box.

**Widen Turn Lane For Incoming or Outgoing Road**

When you select either of these options, the incoming or outgoing road in the intersection is widened.

**Intersection Quadrant Details**

Specifies details for the quadrants in the intersection.

Intersection Quadrant Name

Displays the name of the intersection quadrant currently selected. You can change the name here, if desired.

Incoming Road Centerline Name

Displays the name of the centerline alignment for the incoming road.

Outgoing Road Centerline Name

Displays the name of the centerline alignment for the outgoing road.

Intersection Quadrant Angle

Specifies the angle in degrees that is created by the two alignments that intersect, forming this intersection quadrant.

**Curb Return Parameters**

Specifies parameters for the curb returns in the intersection.

Curb Return Type

Specifies the type of curb return: chamfer, circular fillet, or 3-centered arcs.

Radius

If the radius type is circular fillet or 3-centered arc, you can specify radius parameters.

Length Along Incoming or Outgoing Road

Specifies the length of the curb return for the incoming or outgoing road.

Curve (X) Radius

Specifies the radius for the curves in the curb return.

Curve (X) Length

Specifies the length for each curved section in the curb return.

Copy These To All Quadrants

On this dialog box, you can right-click the "Curb Return Parameters" node in the Property column, and select Copy These To All Quadrants. When this option is selected, the curb return parameters currently selected are automatically applied to all quadrants in the intersection.

### Widening At Incoming\Outgoing Lane

When widening options at the top of this dialog box are selected, you can specify details for the widening at the incoming and outgoing lanes in the intersection.

Transition Details

Specifies the transition details for the incoming or outgoing lanes in the intersection.

Widening Details

Specifies the widening details for the incoming or outgoing lanes in the intersection.

**Related procedures:**

■ Editing Curb Returns in Intersections (page 1447)

## Secondary Road Profile Rules Dialog Box

Use this dialog box to view and edit the parameters of the profile for the secondary roads included in the intersection object.

Click the expand and collapse buttons at the top right to expand and collapse the information displayed in this dialog box.

When you select an item on this dialog box, the affected object is highlighted in the drawing, and the conceptual graphic on the dialog box updates to indicate the location affected by the edit. For more information, see Intersection Editing Visual Cues (page 1443).

### Secondary Road Profile Rules

Apply Grade Rules

Specifies whether to apply grade rules for this secondary road profile.

Maximum Grade

Specifies the maximum grade that can be used for the secondary road profile in the intersection.

Maximum Grade Change

Specifies the maximum grade change that can be used to adjust the secondary road profile in the intersection.

Distance Rule to Adjust the Grade

Specifies to adjust the grade of the secondary road profile within the intersection extents, or by specifying a distance.

Distance Value

When Distance Rule to Adjust the Grade option is set to Specify Distance, this specifies the distance value used to adjust the incoming and outgoing grade of the secondary road profile in the intersection.

**Related procedures:**

■ Editing Side Road Profiles for Intersections (page 1448)

# Intersection Lane Slope Parameters Dialog Box

Use this dialog box to view and edit the parameters of the lane slopes for the roads included in the intersection object.

Click the expand ⬚▼ and collapse ⬚▲ buttons at the top right to expand and collapse the information displayed in this dialog box.

When you select an item on this dialog box, the affected object is highlighted in the drawing, and the conceptual graphic on the dialog box updates to indicate the location affected by the edit. For more information, see Intersection Editing Visual Cues (page 1443).

### Left or Right Edge Profile Definition

Specifies the parameters defining the left and right edge of the slope.

Use an Existing Profile

When Yes is selected, you can select a profile from the available profiles in the current drawing. When No is selected, this indicates that the profile was created during intersection creation.

Cross Fall From Centerline

Specifies the slope of the grade from the centerline.

Profile Name

Displays the name of the profile associated with this edge profile definition. When Use An Existing Profile is set to Yes, you can select a new profile from available profiles in the current drawing.

### Related procedures:

■ Editing Lane Slopes for Intersections (page 1449)

# Intersection Curb Return Profile Parameters Dialog Box

Use this dialog box to view and edit the parameters of the curb returns included in the intersection object.

Click the expand ⬚▼ and collapse ⬚▲ buttons at the top right to expand and collapse the information displayed in this dialog box.

When you select an item on this dialog box, the affected object is highlighted in the drawing, and the conceptual graphic on the dialog box updates to indicate the location affected by the edit. For more information, see Intersection Editing Visual Cues (page 1443).

### Intersection Quadrant

This drop-down list lets you specify each quadrant in the intersection. You can also click Next and Previous to advance through the quadrants.

### Incoming\Outoging Lane Details

Specifies curb return profile details for the incoming and outgoing lanes.

Incoming or Outgoing Road Centerline Name

Displays the name of the centerline alignment for the incoming and outgoing road.

Side

Displays which side of the road this profile reflects.

### Curb Return Profile Parameters

Use these settings to view or change the parameters of the curb return profiles included in the intersection creation.

Define Curb Return Profile By

Displays the method that was used to define the curb return profile. For version 2010, the only supported method for defining curb return profiles is by joining tangents.

Extend Profile Along Incoming Lane

Specifies whether to extend the curb return profile along the incoming lane of the intersection.

Length To Extend Along Incoming Lane

When Extend Profile Along Incoming Lane is set to Yes, this option lets you specify the length to extend the curb return profile along the incoming lane of the intersection.

Extend Profile Along Outgoing Lane

Specifies whether to extend the curb return profile along the outgoing lane of the intersection.

Length To Extend Along Outgoing Lane

When Extend Profile Along Incoming Lane is set to Yes, this option lets you specify the length to extend the curb return profile along the outgoing lane of the intersection.

**Related procedures:**

■ Editing Curb Return Profiles for Intersections (page 1450)

# Intersection Corridor Regions Dialog Box

Use this dialog box to view and edit the parameters of the corridor regions included in the intersection object.

**NOTE** If you have made any changes to the corridor in the intersection area, those changes will be lost (overwritten) when you apply new assemblies by clicking Recreate on this dialog box.

For more information, see Creating Corridors in the Intersection Area (page 1435).

Create a New Corridor

Specifies to create a new corridor object to the intersection object.

Add to an Existing Corridor

Specifies to add regions to a corridor object that already exists in the intersection object. If you do not have corridor objects in the intersection drawing, this option is not available.

Select Surface to Daylight

Specifies a surface for daylighting. If there are other available surfaces in the current drawing, you can select a different surface to use for daylighting. If you do not have surfaces in the drawing, this option is not available.

**Apply an Assembly Set**

Specifies an assembly set file that specifies the assemblies used to create the intersection corridors. For more information, see Assembly Sets (page 1457).

Browse

Click this button to browse to and select a new assembly set file.

**Corridor Region Section Type**

Expand the items in this column to display the assemblies that define each section of the corridor region. The left column (Corridor Region Section Type) displays the names of the required sections of the corridor, and is not editable. The right column (Assembly To Apply), displays the names of the assemblies that are currently specified, and you can select different assemblies to apply, if desired.

Assembly to Apply

Displays the names of the assembly that is applied for each section of the corridor region. When you click an assembly in this list, the conceptual graphic on this dialog box displays the location where the assembly is applied in the intersection corridor.

Save As Set

If desired, you can save the set of assemblies currently displayed on this dialog to a new or existing assembly set. For more information, see Assembly Sets (page 1457).

**Related procedures:**

■ Updating Corridor Regions in Intersections (page 1452)

■ Recreating Corridor Regions in Intersections (page 1454)

# Offset Alignment Parameters Dialog Box

Use this dialog box to view and edit the parameters of the currently selected offset alignment.

Click the expand ⊟▼ and collapse ⊟▲ buttons to expand and collapse the region information displayed in this dialog box.

When you select an item on this dialog box, the affected object is highlighted in the drawing. For more information, see Intersection Editing Visual Cues (page 1443).

## Alignment Name

Displays the name of the currently selected offset alignment. Use the drop-down list to select another offset alignment in the drawing.

## Nominal Offset

Specifies the length of the nominal offset for the currently selected offset alignment. If desired, you can change the nominal offset value on this dialog box.

## Add a Widening

Click this button to add widening to the selected offset alignment. Click the button to remove widening.

Region Type

Specifies the type of region this offset alignment is associated with. Use the drop-down list to specify Nominal or Specific.

Start Station

Specifies the start station for the currently selected offset alignment. You can specify a different station by entering a value, or by clicking a station along this alignment in the drawing.

End Station

Specifies the end station for the currently selected offset alignment. You can specify a different station by entering a value, or by clicking a station along this alignment in the drawing.

Region Length

Specifies the length of the region this offset alignment is associated with.

**Related procedures:**

■ Widenings (page 896)

■ Editing Offset Alignments and Widenings (page 1005)

# Label Dialog Boxes

# 55

Use the following links to access information about Label dialog boxes.

## Standard Edit Label Style Defaults Dialog Box

The same standard settings are available in each of the Edit Label Style Defaults dialog boxes. See The Hierarchy of Label Settings (page 1468) for information about how each level of setting affects the others.

### Label

Text Style

Specifies a default text style for all label text components in a drawing. The default is Standard. Select a text style from the list of all AutoCAD text styles defined in the current drawing.

Visibility

Specifies whether all label styles in a drawing are visible.

---

**TIP** Use this setting to quickly turn all labels in the drawing off or on.

---

Layer

Specifies the default layer for all label styles in a drawing.
The default layer is 0. When the layer is set to 0, the labels use the properties of the parent object layer specified on the Object Layers tab of the Drawing Settings dialog box.

Click  to display the Layer Selection dialog box.

---

**NOTE** This setting specifies the layer from which the labels obtain their display properties. The labels are drawn on the parent object layer.

---

### Behavior

Orientation Reference

Specifies the orientation reference of the labels.

■ **Object**: Rotates labels relative to the zero direction of the object. You can determine the zero direction of the object based on its start and end points. If the object vector changes at the anchor point on the label, the orientation updates automatically. This is the default setting.

■ **View**: Forces labels to realign to a screen-view orientation in both model and layout views. Always assumes the zero angle is horizontal, regardless of UCS or Dview twist. If the view changes, the label orientation updates with it.

- **World Coordinate System**: Adjusts the labels with respect to the angle between the current view and world view. Changing the view or current UCS does not affect label rotation with respect to the world coordinate system.

For more information, see Changing Label Orientation (page 1488).

Forced Insertion

Specifies the position of a label relative to an object. Applies only when the Orientation Reference option is set to Object and the objects are lines, arc segments, or spline segments.

- **None**: Maintains label position as composed relative to the object. This is the default setting.

- **Top**: Adjusts label position to above an object.

- **Bottom**: Adjusts label position to below an object.

**NOTE** Plan Readable should be set to True when using the Top or Bottom settings.

Force Inside Curve

Specifies whether labels are placed inside or outside a curve. Available only for curve label styles. This setting has precedence over any forced insertion setting.

- **True**: Moves label components on the outside of curve to the inside of curve. The components maintain the same offset and rotation.

- **False**: All label components remain as composed. This is the default setting.

**NOTE** These settings apply only when the Orientation Reference option is set to Object.

## Plan Readability

Plan Readable

Specifies the text rotation to insure that all text components in labels can be read easily in plan view.

- **True**: Rotates text to insure that it can be read easily in plan view or as if viewed from an angle at the bottom or right side of the screen/paper. This is the default setting.
  Any text with an angle greater than the angle specified in the Readability Bias setting, or with an angle less than the Readability Bias plus 180 degrees, is in violation of plan readability, and is adjusted automatically.

  For more information about plan-readable text, see Using Plan-Readability (page 1489).

- **False**: Displays text as inserted.

This option applies only to text components in labels.

Readability Bias

Specifies the angle at which label text flips 180 degrees to remain plan readable.

Flip Anchors With Text

- True: Ensures that if text is rotated to make plan-readable, the anchors will also be flipped.

- False: The flipped label always looks like a mirror of the original.

## Components

Text Height

Specifies the plotted height for label text. Enter a positive value greater than zero. The value is applied to all text components.

Color

Specifies the color for label components. Click  to open the Select Color dialog box.

Linetype

Specifies the linetype for label components. Click  to open the Select Linetype dialog box.

Lineweight

Specifies the lineweight for label components. Click  to open the Lineweight dialog box.

Span Outside Segments

Specifies whether the label style component should span outside segments.

**NOTE** This setting applies to parcel line and curve label styles only).

- **True**: Labels the outer boundary of parcels, rather than the individual parcel segments. For example, if four parcels share an outer boundary, use this option to label the combined outer boundary.

- **False**: Labels individual parcel segments.

## Leader

Arrow Head Style

Specifies an arrow head style for a leader.
Select an arrow head style from the list. Or, select None to display leaders without arrow heads. The default arrow head style is Closed Filled.
For more information about arrow head styles, see "Choose Dimension Arrowheads" in AutoCAD Help.

Arrow Head Size

Specifies the size of the arrow head. The default arrow head size is defined in plot units (either inches or millimeters). The plot units are determined by the drawing units established in the drawing settings.
Enter zero or a positive number. A value of zero means that a leader is displayed without an arrow head.

Visibility

Specifies whether leaders are visible when you drag a label from its original position.

Type

Specifies the shape of the leader.

- **Straight Leader**: Draws a straight leader when you drag a label. This is the default leader type.

- **Spline Leader**: Draws a spline (or smooth curve) leader.

Color

Specifies the color for leaders. Click  to open the Select Color dialog box.

Linetype

Specifies the linetype for leaders. Click  to open the Select Linetype dialog box.

Lineweight

Specifies the lineweight for leaders. Click  to open the Lineweight dialog box.

**Dragged State Components**

Display

Specifies how label content is displayed after it is dragged from its default position.

- **As Composed**: Maintains the original settings for orientation and composition. When selected, all other properties in the Dragged State Components category are unavailable for editing. This is the default.

- **Stacked Text**. Reformats labels based on the settings in this Dragged State Components category.

---

**NOTE** When Display is set to Stacked Text, all blocks, lines, and direction arrows are removed. The text components are stacked vertically based on the order in which the text components were created in the label style.

---

Border Visibility

Specifies whether a border is visible for dragged labels.

Border Type

Specifies the shape of the border.

- **Rectangular**: Draws a rectangle.

- **Rounded Rectangular**: Draws a rectangle with rounded corners.
  The radius used to create a rounded rectangle is calculated by adding the border and leader gap value and half the overall text height (including descending characters, and subscript and superscript characters).

- **Circular**: Draws a circular border.

Border and Leader Gap

Specifies the distance between the leader and the label text. Enter a positive value greater than zero. The gap value is also used to define the space between the border and the label text.

Text Height

Specifies the plotted height for all text components. Enter a positive value greater than zero.

---

**NOTE** When Display is set to As Composed, this property is unavailable for editing.

---

Leader Attachment

Specifies the location where a leader hook is drawn in relation to label content.

- Top Of Top Line (of multiple lines of text)

- Middle Of Top Line (of multiple lines of text)

- Middle (of single line of text)

- Middle Of Bottom Line (of multiple lines of text)

- Bottom Of Bottom Line (of multiple lines of text)

Middle is the default setting.

Leader Justification

Specifies how label text is justified in relation to the leader.

- **True**. Text is left-justified when the leader is on the left, and right-justified when the leader is on the right, as shown in the following illustration. This is the default setting.

■ **False**. Text is left-justified regardless of leader location, as shown in the following illustration:

Color

Specifies the color for dragged components. Click [icon] to open the Select Color dialog box.

Linetype

Specifies the linetype for dragged components. Click [icon] to open the Select Linetype dialog box.

Lineweight

Specifies the lineweight for dragged components. Click [icon] to open the Lineweight dialog box.

[icon] Collapse All Categories

Collapses the property categories to show only the top-level item.

[icon] Expand All Categories

Expands categories to show all properties.

[icon] Override All Dependencies

Selects all the check boxes in the Override column, which prevents the setting from being changed if the value is changed at a higher level setting. This option is not available at the drawing level.

# Edit Label Style Defaults Dialog Box (Drawing Level)

Use this dialog box to set default settings for all labels in the current drawing.

For a description of the controls, see Standard Edit Label Style Defaults Dialog Box (page 1937).

The defaults that you set in this dialog box are global until overridden by changes made to default settings at the object collection level (such as Point, Parcel, Surface, and Alignment); at the label-style-type-level; or at the label style level. For a description of override controls unique to managing the hierarchy of default label settings, see Managing Overrides in Label Style Dialog Boxes (page 1960).

**Related procedures:**

■ Default Settings for All Label Styles in a Drawing (page 1475)

# Edit Label Style Defaults Dialog Box (Feature Level)

Use this dialog box to set default settings for all label styles for an object type.

For a description of the controls, see Standard Edit Label Style Defaults Dialog Box (page 1937).

These default settings can be dependent on the higher default settings at the drawing level (page 1941), or you can override the higher settings by clicking the property and entering a value. Editing the property places a check mark in the Override column, and the changes you make are applied to lower-level settings and in individual label styles. For a description of override controls that are unique to managing the hierarchy of default label settings, see Managing Overrides in Label Style Dialog Boxes (page 1960).

**Related procedures:**

■ Default Settings for All Label Styles in a Feature (page 1475)

# Edit Label Style Defaults Dialog Box (Label Style Type Level)

Use this dialog box to define default settings for all labels belonging to a specific label style type.

For a description of the controls, see Standard Edit Label Style Defaults Dialog Box (page 1937).

These default settings can be dependent on higher settings at the drawing level (page 1941) or at the feature (page 1941) level.

You can override those settings by clicking the property and entering another value. For a description of override controls unique to managing the hierarchy of default label settings, see Managing Overrides in Label Style Dialog Boxes (page 1960).

**Related procedures:**

■ Default Settings for All Labels in a Label Type (page 1476)

# Label Style Composer Dialog Box

Use this dialog box to create new label styles or edit both the format and content of existing label styles.

**NOTE** The controls and settings available in the dialog box vary for each object type.

## Information Tab (Label Style Composer Dialog Box)

Use the Information tab to change the label style name and description information, and to review details, such as when the style was most recently modifed.

Name

Specifies a name for the current style.

**NOTE** Label styles names are case sensitive. "Standard" is not the same as "standard".

Description

Specifies a description of the current style.

Created By

Displays the AutoCAD login name of the person who created the style.

Date Created

Displays the date and time the style was created.

Last Modified By

Displays the AutoCAD login name of the person who last modified the style.

Date Modified

Displays the date and time the style was last modified.

## General Tab (Label Style Composer Dialog Box)

Use this tab to specify whether the label displays as a label or tag, the label visibility, and label orientation.

Property column

Lists categories and label properties. By clicking +/- next to a category name, you can expand or collapse the list of label properties for that category.

When a lock 🔒 is displayed to the left of the property name, the property's value has been locked at a higher level setting and all lower settings are also locked.

Value column

Specifies the current value of the property. The value is either derived from a dependency on a higher setting or it can be set explicitly at the current level.

## Label

Text Style

Specifies the default text style on which all text components are based.

Visibility

Specifies whether labels of the current style are visible in the drawing.

Display Mode

Specifies whether labels are displayed as labels or tags.

- **Label**: Displays label components that are assigned either the Label Mode or the Label And Tag Modes "Used In" setting on the Layout tab.

- **Tag**: Displays label components that are assigned either the Tag Mode or the Label and Tag Modes "Used In" setting on the Layout tab.

---

**NOTE** Only the label styles that support tables contain this property.

---

Layer

Specifies the layer for all components in a label style.

Click ⋯ to open the Layer Selection dialog box, and select a layer.
If you set the layer to 0, the labels use the properties of the parent object layer specified on the Object Layers tab of the Drawing Settings dialog box.

---

**NOTE** There are two options for the style to reference a layer for display control, when using ByBlock or ByLayer controls. Reference the layer as specified in the style or reference the layer that the the object resides on (by setting the Layer to 0 in the style. If layer 0 is selected, any ByBlock and ByLayer components will display according to the actual layer that the layer object is residing on in AutoCAD. If a layer other than 0 is selected, any ByBlock or ByLayer components will display according to the layer as specified in the style.

---

## Behavior

Orientation Reference

Specifies the orientation reference of a label.

- **Object**: Rotates labels relative to the zero direction of the object. You can determine the zero direction of the object based on its start and end points. If the object vector changes at the anchor point on the label, the orientation updates automatically. This is the default setting.

- **View**: Forces labels to realign to a screen-view orientation in both model and layout views. Always assumes the zero angle is horizontal, regardless of UCS or Dview twist. If the view changes, the label orientation updates with it.

- **World Coordinate System**: Adjusts the labels with respect to the angle between the current view and world view. Changing the view or current UCS does not affect label rotation with respect to the world coordinate system.

**Forced Insertion**

Specifies the position of a label relative to an object. Applies only when the Orientation Reference option is set to Object and the objects are lines, arc segments, or spline segments.

- **None**: Maintains label position as composed relative to the object.

- **Top**: Adjusts label position to above an object.

- **Bottom**: Adjusts label position to below an object.

> **NOTE** Plan Readable should be set to True when using the Top or Bottom settings.

**Force Inside Curve**

Specifies whether labels are placed inside or outside a curve. Available only for curve label styles. This setting has precedence over any forced insertion setting.

- **True**: Moves label components on the outside of curve to the inside of curve. The components maintain the same offset and rotation.

- **False**: All label components remain as composed.

> **NOTE** This setting applies only when the Orientation Reference option is set to Object.

### Plan Readability

**Plan Readable**

Specifies the text rotation to insure that all text components in labels can be read easily in plan view.

- **True**: Rotates text to insure that it can be read easily in plan view or as if viewed from an angle at the bottom or right side of the screen/paper.
  Any text with an angle greater than the angle specified in the Readability Bias setting, or with an angle less than the Readability Bias plus 180 degrees, is in violation of plan readability, and is adjusted automatically.

- **False**: Displays text as inserted.

**Readability Bias**

Specifies the angle at which label text flips 180 degrees to remain plan readable.

**Flip Anchors With Text**

- True: Ensures that if text is rotated to make plan-readable, the anchors will also be flipped.

- False: The flipped label always looks like a mirror of the original.

### Preview Pane

Dynamically displays changes to the label style. Right-click the preview pane to access view-related commands. To change the view, select a preview drawing from the list. For more information, see Previewing Label Styles (page 1472).

**Related procedures:**

- Managing General Properties for Label Styles (page 1486)

## Layout Tab (Label Style Composer Dialog Box)

Use this tab to create and edit label components.

See the following topics to access information about defining layout properties for each label component.

**See also:**

■ Managing Layout Properties for Label Styles (page 1492)

## Common Elements of the Layout Tab

Use controls at the top of the Layout tab to select, create, copy, delete, or change the draw order of label components.

Component Name

Displays a list of existing label components defined for the label style. Select a component from this list to edit its properties.

Create Component

Creates a new label component. Select a component type from this list to create a new text, text for each, block, direction arrow, tick, or line component. The Property and Value columns display settings you can change to define the appearance, location, and orientation of that particular component. Not all components are available for all label types.

Copy Component

Copies the selected component.

Delete Component

Deletes the selected component.

Change Draw Order

Displays the Component Draw Order (page 1958) dialog box.

Preview Pane

Dynamically displays changes to the label style. Right-click the preview pane to access view-related commands. To change the view, select a preview drawing from the list. For more information, see Previewing Label Styles (page 1472).

Color

Specifies colors for components, borders, and leaders.

Click the Value column, and then click to open the Select Color dialog box.

Linetype

Specifies linetypes for components and borders.

Click the Value column, and then click to open the Select Linetype dialog box.

Lineweight

Specifies the lineweights for components and borders.

Click the Value column, and then click to open the Lineweight dialog box.

## Text Component Layout (Label Style Composer Dialog Box)

Use the Layout tab to create a text component for a label style.

From the Create Component list , click to create a new text component.

## General

Name

Specifies the name of the text component.

The default name, such as "Text.1," is the component name with a numeric increment. If the text component exists in a parent label style, then the name cannot be edited.

Visibility

Specifies whether the text component is visible in the label style.

Used In

Specifies whether the component is displayed in Tag Mode, Label Mode, or both. Select a mode on the General tab (page 1942) in the Label Style Composer.

- **Label Mode**: Displays the text component when Display Mode is set to Label.

- **Tag Mode**: Displays the text component when Display Mode is set to Tag.

- **Label and Tag Modes**: Displays the text component regardless of the display mode setting.

**NOTE** If a label style type does not support tables, then this control is not available.

Anchor Component

Specifies a reference object for positioning the text component. You can select <Feature> (which is the object being labeled) or another existing label component.

Anchor Point

Specifies the location on the Anchor Component where the text component is attached.

- When <Feature> is the Anchor Component, Label Location is the only option available. This option places the anchor point at the location where the label is attached to the object.

- When the Anchor Component is another label component, you have a choice of anchor points depending on whether the anchor is a text, block, tick, line, or direction arrow component. For example, if the anchor is a text component, you can select from the points shown in the following illustration:

Span Outside Segments

Specifies whether the label style component should span outside segments.

**NOTE** This setting applies to parcel line and curve label styles only.

- **True**: Labels the outer boundary of parcels, rather than the individual parcel segments. For example, if four parcels share an outer boundary, use this option to label the combined outer boundary.

- **False**: Labels individual parcel segments.

## Text

Contents

Specifies the content of the text component. When a text component is first created, displays "Label Text" by default.

Click the Value column, and then click ⌷ to open the Text Component Editor (page 1961) dialog box where you can create and edit the label content.

Text Height

Specifies the plotted height for text. Enter a positive value greater than zero.

Rotation Angle

Specifies the angle for the text component. Enter a positive or negative value, or click to select an angle in the drawing.

The angle direction is always counterclockwise, and the zero (0) direction is determined by the anchor component type.

If the text component is anchored to a feature, then the zero direction is determined in relation to the following Orientation Reference settings on the General (page 1942) tab:

- **Object**: Calculates the zero angle by examining the object's construction and then measuring the zero angle from the start to the end of the object. If the object is a curve, then the zero angle is tangent to the curve.

- **View**: Sets the zero angle equal to the world coordinate system (WCS) base angle of East (horizontal, left to right).

- **World Coordinate System:** Sets the zero angle equal to the WCS base angle of East (horizontal, left to right).

| If the text component is anchored to... | then the zero angle is measured... |
|---|---|
| another text component, a block component, tick component | along the component's zero angle. |
| line component or vertex arrow component | from the start of the line to the end of the line. |

Attachment

Specifies the location on the text component that is attached to the anchor point. Attachment points are calculated based on a rectangle that encompasses the text, the size of which is determined by including the Gap value specified in the Border category. The following illustration shows text attachment points:

X Offset

Specifies the offset distance between the attachment point and the anchor point in the X direction (zero angle direction).

The X direction is determined by the object to which the text component is anchored. If the text component is anchored to the label insertion point, then the X direction is determined in relation to the following Orientation Reference settings on the General (page 1942) tab:

- **Object**: Calculates the X direction by examining the object's construction and measuring the zero angle direction from the start to the end of the object. If the object is a curve, then the zero angle is located tangent to the curve.

- **View**: The X direction is always horizontal, left to right, regardless of the User Coordinate System (UCS) or Dview twist direction.

- **World Coordinate System**: The X direction is the same as the User Coordinate System (UCS) base angle of East (horizontal, left to right).

Y Offset

Specifies the offset distance between the attachment point and the anchor point in the Y direction, which is 90 degrees counterclockwise to the X direction.

Allow Curved Text

Specifies whether text is drawn along a curve for curve label styles.

## Border

Visibility

Specifies whether the border is visible.

Type

Specifies the shape of the border.

- **Rectangular**: Draws a rectangle around the text component.

- **Rounded Rectangular**: Draws a rectangle with round corners around the text component.
  The radius used to create a rounded rectangle is calculated by adding the gap value and half the overall text height (including descending, subscript, and superscript characters).

Gap

Specifies the distance between the border and text. The Gap is still applied if Border Visibility is set to False.

Background Mask

Specifies whether a mask is applied to the component using the border shape and size.

without mask

1234

with mask

1234

**Related procedures:**

■ Text (page 1502)

■ Managing Layout Properties for Label Styles (page 1492)

## Text-For-Each Component Layout (Label Style Composer Dialog Box)

Use the Layout tab to create a Text-For-Each component for a label style.

Text-For-Each components label each object associated with a parent object (the object you are labeling). For example, you can use a Text-For-Each component in a structure label style to include labels for pipes associated with that structure. For more information, see Text-For-Each (page 1511).

From the Create Component list  , click  to create a new Text-For-Each component.

The Select Type (page 1949) dialog box is displayed, where you select the type of data to include in the Text-For-Each component.

**NOTE** The Text-For-Each component type is available only for structure label styles.

After you select the Text-For-Each type, your selection is displayed on the Layout tab in the General section.

The remainder of the settings that you specify for a Text-For-Each component are identical to the settings for a text component. For more information, see Text Component Layout (Label Style Composer Dialog Box) (page 1945).

## Select Type Dialog Box

Use the Select Type dialog box to select the type of Referenced Text or Text-For-Each label component to create.

### Referenced Text Options

Alignment
   Creates a Referenced Text component with property fields you can use to refer to alignment data.

Profile
   Creates a Referenced Text component with property fields you can use to refer to profile data.

Surface
   Creates a Referenced Text component with property fields you can use to refer to surface data.

Parcel
   Creates a Referenced Text component with property fields you can use to refer to parcel data.

**Text-For-Each Options**

Structure All Pipes

When inserted into a structure label style, adds labels for all pipes coming into or out of the structure.

Structure In Flow Pipes

When inserted into a structure label style, adds labels for all pipes coming into the structure.

Structure Out Flow Pipes

When inserted into a structure label style, adds labels for all pipes going out of the structure.

## Referenced Text Component Layout (Label Style Composer Dialog Box)

Use the Layout tab to create a Reference Text component for a label style.

Reference Text components refer to other objects in the drawing, instead of to the object you are labeling.

From the Create Component list ![A icon] , click ![A icon] to create a new Referenced Text component.

The Select Type (page 1949) dialog box is displayed, where you select the type of data to include in the Referenced Text component.

**NOTE** The Referenced Text component type is available for all new label objects. See Label Objects (page 1463)for a list of supported label objects.

After you select the Referenced Text type, the object type you selected is displayed on the Layout tab in the General section.

**NOTE** Once you specify the object type, it cannot be changed. If you want to insert references to a different object type, you must create a new Referenced Text component and select the other object type when you create the new component.

The remainder of the settings that you specify for a Referenced Text component are identical to the settings for a text component. For more information, see Text Component Layout (Label Style Composer Dialog Box) (page 1945). However, when you set up the label contents, you select Properties that refer to the referenced object.

**Related procedures:**

■ Creating Note Labels (page 1480)

■ Inserting Note Labels (page 1530)

## Block Component Layout (Label Style Composer Dialog Box)

Use the Layout tab to create a block component for a label style.

From the Create Component list ![A icon] , click ![block icon] to create a new block component.

**General**

Name

Specifies the name of the block component.
The default name, such as "Block.1," is the component name with a numeric increment. If the block component exists in a parent label style, then the name cannot be edited.

**Visibility**

Specifies whether the block component is visible in the label style.

**Used In**

Specifies whether the component is visible in tag mode, label mode, or both. Select a mode on the General tab (page 1942) in the Label Style Composer.

- **Label Mode**: Displays the block component when Display Mode (on the General tab) is set to Label.

- **Tag Mode**: Displays the block component when Display Mode is set to Tag.

- **Label and Tag Modes**: Displays the block component regardless of the display mode setting.

---

**NOTE** If a label style type does not support tables, then this control is not available.

---

**Anchor Component**

Specifies a reference object for positioning the block component. You can select <Feature> (which is the object being labeled) or another existing label component.

**Anchor Point**

Specifies the location on the Anchor Component where the block component is attached.

- When <Feature> is the Anchor Component, Label Location is the only option available. This option places the anchor point at the location where the label is attached to the object.

- When the Anchor Component is another label component, you have a choice of anchor points depending on whether the anchor is a text, block, tick, line, or direction arrow component.

## Block

**Block Name**

Specifies the block to use in the block component.

Click the Value column, and then click ⊡ to open the Select A Block dialog box.

In the Select A Block dialog box, click 🔍 to open a Viewer in which you can use standard AutoCAD viewing tools to preview the block.

---

**NOTE** The block must exist in the current drawing.

---

**Block Height**

Specifies the height to which the block is scaled to fit. The block's extents in the X direction are used for scaling the height. The block's aspect ratio is maintained when scaled.

**Rotation Angle**

Specifies the angle for the block component. Enter a positive or negative value, or click to select an angle in the drawing.
The angle direction is always counterclockwise, and the zero (0) direction is determined by the anchor component type.

Attachment

Specifies the location on the block component that is attached to the anchor point. Attachment points are calculated based on a rectangle that encompasses the block, the size of which is determined by including the Gap value specified in the Border category. The following illustration shows block attachment points:

X Offset

Specifies the offset distance between the attachment point and the anchor point in the X direction (zero angle direction).

The X direction is determined by the object to which the block component is anchored. If the block component is anchored to the label insertion point, then the X direction is determined in relation to the following Orientation Reference setting on the General (page 1942) tab:

- **Object**: Calculates the X direction by examining the object's construction and measuring the zero angle direction from the start to the end of the object. If the object is a curve, then the zero angle is located tangent to the curve.

- **View**: The X direction is always horizontal, left to right, regardless of the User Coordinate System (UCS) or Dview twist direction.

- **World Coordinate System**: The X direction is the same as the User Coordinate System (UCS) base angle of East (horizontal, left to right).

Y Offset

Specifies the offset distance between the attachment point and the anchor point in the Y direction, which is 90 degrees counterclockwise to the X direction.

**Related procedures:**

- Blocks (page 1513)

- Managing Layout Properties for Label Styles (page 1492)

## Line Component Layout (Label Style Composer Dialog Box)

Use the Layout tab to create a line component for a label style.

From the Create Component list , click to create a new line component.

A line component can be defined in two ways, depending on the Use End Point Anchor setting:

- **Start Point, Length, and Angle**: Use this method to anchor the start point of the line component to the anchor component. Set the Use End Point Anchor setting to False, and then specify the Length and Angle.

- **Start Point and End Point**: Use this method to anchor the start and end point of the line component. Set the Use End Point Anchor setting to True, and then specify the End Point Anchor Component and End Point Anchor Point. The length and angle of the line are determined by the position of the anchor objects, and adjust if the anchor components are edited.

## General

Name

Specifies the name of the line component.
The default name, such as "Line.1," is the component name with a numeric increment. If the line component exists in a parent label style, then the name cannot be edited.

Visibility

Specifies whether the line component is visible in the label style.

Used In

Specifies whether the component is visible in tag mode, label mode, or both. Select a mode on the General tab (page 1942) in the Label Style Composer.

- **Label Mode**: Displays the line component when Display Mode is set to Label.

- **Tag Mode**: Displays the line component when Display Mode is set to Tag.

- **Label and Tag Modes**: Displays the line component regardless of the display mode setting.

**NOTE** If a label style type does not support tables, then this control is not available.

Start Point Anchor Component

Specifies a reference object for positioning the start point of the line component. You can select <Feature> (which is the object being labeled) or another existing label component.

Start Point Anchor Point

Specifies the location on the Start Point Anchor Component where the start point of the line component is attached.

- When <Feature> is the Anchor Component, Label Location is the only option available. This option places the anchor point at the point where the label is attached to the object being labeled.

- When another label component is the Anchor Component, you have a choice of anchor points depending on whether the anchor is a text, block, tick, line, or direction arrow component.

Use End Point Anchor

Specifies the method for defining the line component.

- **True**: Uses the Start Point and End Point method to define the line component.
  The Length and Angle properties in the Line category become unavailable for editing.

- **False**: Uses the Start Point, Length, and Angle method to define the line component.
  The End Point Anchor Component, End Point Anchor Point, End Point X Offset, and End Point Y Offset properties become unavailable for editing.

End Point Anchor Component

Specifies a reference object for positioning the end point of the line component.
This property is unavailable when the Use End Point Anchor property is set to False.

End Point Anchor Point

Specifies the location on the End Point Anchor Component where the end point of the line component is attached.
This property is unavailable when the Use End Point Anchor property is set to False.

## Line

Length

Specifies the length of the line component.
This property is unavailable when the Use End Point Anchor property is set to True.

Angle

Specifies the angle of the line component from the start point. Enter a positive or negative value, or click to select an angle in the drawing.

This property is unavailable when the Use End Point Anchor property is set to True.

Start Point X Offset

Offsets the line start point from the start point anchor point in the X direction.

The X direction is determined by the object to which the line component is anchored. If the line component is anchored to the label insertion point, then the X direction is determined in relation to the following Orientation Reference settings on the General (page 1942) tab:

- **Object**: Calculates the X direction by examining the object's construction and measuring the zero angle direction from the start to the end of the object. If the object is a curve, then the zero angle is tangent to the curve.

- **View**: The X direction is always horizontal, left to right, regardless of the User Coordinate System (UCS) or Dview twist direction.

- **World Coordinate System**: The X direction is the same as the User Coordinate System (UCS) base angle of East (horizontal, left to right).

Start Point Y Offset

Offsets the line start point from the start point anchor point in the Y direction.

End Point X Offset

Offsets the line end point from the end point anchor point in the X direction.

This property is unavailable when the Use End Point Anchor property is set to False.

End Point Y Offset

Offsets the line end point from the end point anchor point in the Y direction.

This property is unavailable when the Use End Point Anchor property is set to False.

**Related procedures:**

- Lines (page 1512)

- Managing Layout Properties for Label Styles (page 1492)

## Tick Component Layout (Label Style Composer Dialog Box)

Use the Layout tab to create a tick component for a label style.

From the Create Component list , click  to create a new tick component.

**NOTE** Unlike other label components, ticks are always anchored to the feature that is being labeled. Therefore ticks do not have Anchor Component or Anchor Point properties.

### General

Name

Specifies the name of the tick component.

The default name, such as "Tick.1," is the component name with a numeric increment. If the tick component exists in a parent label style, then the name cannot be edited.

Visibility

Specifies whether the tick component is visible in the label style.

Used In

Specifies whether the component is visible in Tag Mode, Label Mode, or both. Select a mode on the General tab (page 1942) in the Label Style Composer.

- **Label Mode**: Displays the tick component when Display Mode is set to Label.

- **Tag Mode**: Displays the tick component when Display Mode is set to Tag.

- **Label and Tag Modes**: Displays the tick component regardless of the display mode setting.

**NOTE** If a label style type does not support tables, then this control is not available.

## Tick

Block Name

Specifies the block to use for the tick component.

Click the Value column, and then click ⬚ to open the Select A Block dialog box.

In the Select A Block dialog box, click 🔍 to open a Viewer in which you can use standard AutoCAD viewing tools to preview the block.

**NOTE** The block must exist in the current drawing.

Block Height

Specifies the height to which the tick block is scaled to fit. The block's extents in the X direction are used for scaling the height. The block's aspect ratio is maintained when scaled.

Rotation Angle

Specifies the angle for the tick component. Enter a positive or negative value, or click to select an angle in the drawing.

Align With Object

Specifies whether the tick is inserted at an angle relative to the object.

- **True**: Inserts the tick at an angle relative to the object:

- **False**: Inserts the tick at an angle relative to the UCS setting:

**NOTE** The specified Rotation Angle is applied in conjunction with this setting.

**Related procedures:**

- Ticks (page 1514)

- Managing Layout Properties for Label Styles (page 1492)

# Direction Arrow Component Layout (Label Style Composer Dialog Box)

Use the Layout tab to create a direction arrow component for a label style.

From the Create Component list , click to create a new direction arrow component.

### General

Name
> Specifies the name of the direction arrow component.
> The default name, such as "Direction Arrow.1," is the component name with a numeric increment. If the arrow component exists in a parent label style, then the name cannot be edited.

Visibility
> Specifies whether the direction arrow component is visible in the label style.

Used In
> Specifies whether the component is visible in tag mode, label mode, or both. Select a mode on the General tab (page 1942) in the Label Style Composer.

> - **Label Mode**: Displays the direction arrow component when Display Mode is set to Label.

> - **Tag Mode**: Displays the direction arrow component when Display Mode is set to Tag.

> - **Label and Tag Modes**: Displays the direction arrow component regardless of the display mode setting.

> **NOTE** If a label style type does not support tables, then this control is not available.

Anchor Component
> Specifies a reference object for positioning the direction arrow component. You can select <Feature> (which is the object being labeled) or another existing label component.

Anchor Point
> Specifies the location on the Anchor Component where the direction arrow component is attached.

> - When <Feature> is the Anchor Component, Label Location is the only option available. This option places the anchor point at the point where the label is attached to the object being labeled.

> - When the Anchor Component is another label component, you have a choice of anchor points depending on whether the anchor is a text, block, tick, line, or direction arrow component.

Span Outside Segments
> Specifies whether the label style component should span outside segments.

> **NOTE** This setting applies to parcel line and curve label styles only).

> - **True**: Labels the outer boundary of parcels, rather than the individual parcel segments. For example, if four parcels share an outer boundary, use this option to label the combined outer boundary.

> - **False**: Labels individual parcel segments.

**Direction Arrow**

Arrow Head Style

Specifies the arrow head style. Select an arrow head style from the list.

**NOTE** Select None to create a direction arrow without an arrow head.

Arrow Head Size

Specifies the size of the arrow head in plot units.

**NOTE** A value of zero creates a direction arrow without an arrow head.

**NOTE** The direction arrow length must be at least twice that of the specified arrow head size. If not, the arrow head is not displayed. For example, if you specify an arrow head size of 0.2, the arrow length must be at least 0.4. This behavior is similar to AutoCAD leaders.

**Arrow head is not displayed when arrow length is decreased**

Fixed Length

Specifies whether the arrow length is controlled by the Length setting or by the length of the object being labeled.

■ **True**: Uses the Length setting.

■ **False**: Draws the length of the direction arrow to match the length of the object being labeled.

Length

Specifies the overall length of the direction arrow, including the arrow head.
The Length setting is unavailable when the Fixed Length property is set to False.

X Offset

Specifies the offset distance between the mid-point of the direction arrow and the anchor component in the X direction.

Y Offset

Specifies the offset in the Y direction.
The following illustration shows X and Y offsets for a direction arrow:

**Related procedures:**

■ Direction Arrows (page 1515)

■ Managing Layout Properties for Label Styles (page 1492)

## Component Draw Order Dialog Box

Use this dialog box to control how label text is drawn. Move a component up in the display order to ensure it appears on top of other components.

Component List

Lists the defined components in their current draw order. The component at the top is drawn last. Click a component name and then click the Top or Bottom arrows to move the component to a different draw order location.

# Dragged State Tab (Label Style Composer Dialog Box)

Use this tab to define properties for labels when they are dragged away from their insertion points.

### Leader

Arrow Head Style

Specifies the arrow head style for the leader. Select an arrow head style from the list.

**NOTE** Select None to create a leader without an arrow head.

Arrow Head Size

Specifies the size of the arrow head in plot units.

**NOTE** A value of zero creates a leader without an arrow head.

Visibility

Specifies whether the leader is visible when a label is dragged from its default position.

Type

Specifies the shape of the leader.

■ **Straight Leader**: Draws a straight leader.

■ **Spline Leader**: Draws a spline leader.

### Dragged State Components

Display

Specifies how label content is displayed after it is dragged from its default position.

■ **As Composed**: Labels maintain the original settings for composition and orientation.
When you select As Composed, all other properties in the Dragged State Components category become unavailable for editing.

■ **Stacked Text**: Reformats labels based on the settings in this Dragged State Components category.
When you select Stacked Text, all blocks, lines, ticks, and direction arrows are removed. The text components are stacked vertically in the order they were defined in the label style.

**NOTE** The Summary tab of the Label Style Composer dialog box lists the components in the order in which they were defined.

Border Visibility

Specifies whether the border is visible when a label is dragged from its original position.

Border Type

Specifies the shape of the border.

- **Rectangular**: Draws a rectangle around text.

- **Rounded Rectangular**: Draws a rectangle with round corners around text.
  The radius used to create the round corners of the rectangle is calculated by adding the gap value and
  half the overall text height (including descending, subscript, and superscript characters).

Border And Leader Gap

Specifies the distance between the leader and text.

Text Height

Specifies the plotted height for text.

Leader Attachment

Specifies the location where the leader hook is drawn relative to the label content.

Leader Justification

Specifies how label text is justified in relation to the leader.

- **True**: Text is left-justified when the leader is on the left of the text, and is right-justified when the
  leader is on the right.

- **False**: Text is left-justified regardless of the leader location.

**Related procedures:**

- Managing Dragged Properties for Label Styles (page 1517)

# Summary Tab (Label Style Composer Dialog Box)

Use this tab to review all settings for a label style.

Label Content Summaries (Component 1, and so on)

Lists the label components as defined in the label style. The components are listed numerically in the
order in which they were created. For example, if the label style contains multiple components, the
categories are Component 1, Component 2, Component 3, and so on.
The properties are listed under each component prefixed with the category of the component. The values
of each of the properties replicate those made in the General, Layout, and Dragged State tabs of the Label
Style Composer dialog box.

Collapse All Categories

Collapses the property categories to show only the top level item.

Expand All Categories

Expands categories to show all properties.

Override All Dependencies

Selects all the check boxes ☑ in the Override column, which prevents the style from being changed if
values change at a higher-level setting (either in label settings or in a parent label style).

**Status Update**

At the bottom of the Summary tab the status of overrides is displayed as you select an item. For more
information, see Managing Overrides in Label Style Dialog Boxes (page 1960).

# Managing Overrides in Label Style Dialog Boxes

Use override options in label style dialog boxes to disconnect a setting from higher-level settings, and to restore settings to the higher-level settings.

Property column

Contains label categories and label property names.
Category names (in bold text) contain a list of one or more label properties (in normal text). Click plus (+) or minus (-) next to a category name to expand or collapse the list of property names.

Value column

Displays the current value for each property. When you change the default value in this column, a check mark is displayed in the Override column.

---

**NOTE** Even if you don't want to change the default value, you can manually select the check box in the Override column to prevent the setting from being affected by changes to a higher-level setting.

---

Override column

Identifies whether a property is overridden at the current level. A clear check box ☐ indicates the value is the same as the higher level default setting.

A selected check box ☑ indicates that the value has been explicitly set at the current level. If you click the check box to clear it, the setting is restored to the default, higher-level setting.
You can clear the check box to clear the override and set the value back to the value of its parent setting. Even if you don't specifically change a value, you can select the check box manually to disconnect the setting from the higher-level setting. This prevents it from changing if the higher-level setting changes.

Child Override column

⬇ Indicates that the value setting has been overridden at a lower level.

⬇ Displays when you click ⬇ and removes lower-level overrides in other settings and styles when you click OK or Apply.

---

**WARNING** Using this option resets the property in subordinate settings and/or styles even if they are locked.

---

Lock

Prevents the property value from being changed at a subordinate level. To lock a value, click 🔓 to change it to 🔒 . The lock cannot be set if there is a child override set.

⬇ Override All Dependencies

Selects all the check boxes ☑ in the Override column, which prevents the properties from being affected by changes to higher-level settings.

**Status Update**

At the bottom of the Summary tab in the Label Style Composer dialog box and in the three different Edit Label Style Defaults dialog boxes, the override status is displayed as you select an item.

Property

Displays the selected property name followed by a single line description of the property.

Parent

Displays the name of the parent from which the default value was derived. This is always the next-highest level at which the value was explicitly specified or overridden. Parents can include the following:

- Drawing Settings

- <Feature Name> Settings

- <Label Style Type Name> Settings

- <Parent Label Style Name>

For example, if you are reviewing a label style, the parent may be the Drawing Settings if none of the intermediate settings were changed. However, if an intermediate setting was changed, for example, at the feature level, then the <Feature Name> settings is listed as the parent.

Parent Value

Displays the value of the property as defined in the parent setting or style.

**Related procedures:**

- The Hierarchy of Label Settings (page 1468)

# Text Component Editor Dialog Box

Use this dialog box to add content to a label style.

You can override the content of an individual label by adding property fields for dynamic text, entering static text, and specifying formatting options. These edits do not modify the style being used by the label.

Access this dialog box on the Layout tab of the Label Style Composer by clicking the button in the Contents Value column, as shown in the following illustration:

**See also:**

- Text (page 1502)

- Adding Text Components to Labels (page 1503)

- Formatting Text (page 1505)

- Adding Property Fields to Label Text Components (page 1507)

- Editing Text in the Text Component Editor (page 1507)

## Common Elements of the Text Component Editor Dialog Box

Some common elements in the Text Component Editor are available when either the Properties or Format tab is selected.

Text Component Editor Window

Contains the property fields for the text component.

When you select a property and click  , the property field is inserted into the window. For more information, see Properties Tab (Text Component Editor Dialog Box) (page 1962).

You can also type text directly into this window. For more information, see Text Editor (Text Component Editor Dialog Box) (page 1964).

Import Text

Imports static text into the Text Component Editor window. Click Import Text to open the Select File dialog box. You must select a file that is either ASCII or RTF format.
You can format imported text by using the options on the Format tab (page 1963).

## Properties Tab (Text Component Editor Dialog Box)

Use this tab to add property fields to text components.

Property fields control the label content. Labels that contain property fields are linked to drawing objects and update dynamically when the drawing changes. For more information, see Property Fields (page 1507).

When a property field is added to a text component in the text editor window, the text content is constructed of modifier codes within a two character bracket symbol <[########]>.

**WARNING** The angle and square bracket combination is reserved for use by property fields. If you enter an angle and square bracket combination manually, it will cause an error in the text component. Also, manually editing modifier codes causes an error in the property field. The errors are displayed as three question marks (???) in the label when the property fields are processed. To change a property field in the Text Component Editor window, delete the property field completely from the window (including the angle and square bracket combinations), and insert a new property field.

Properties

Specifies a property to insert into the label text component. Properties are based surface spot elevation. When you select a property, Modifiers and their Values are displayed in the grid below it.

**NOTE** Edit the values as needed before clicking the Add Properties button. If you make changes to the values after you insert the property, you must delete and reinsert the property.

Filter

Opens the Property Filter (page 1963) dialog box where you can select which type of properties to include in the Properties list. This restricts the Properties list so it shows only relevant properties for the label type you are creating. For example, this is useful when you are creating a pipe label and want to restrict the properties shown to those relevant only to a particular type, such as circular pipes. Not available for all label types.

Add Properties

Inserts the property field into the Text Component Editor window at the cursor location.

Modifier

Lists all modifiers supported by the selected property field. For example, these modifiers may include unit, precision, and angle format. For more information, see Property Field Modifiers (page 1509).

Value

Lists the value for each modifier. The values and the method of formatting them vary according to the type of modifier.

**Related procedures:**

■ Text (page 1502)

■ Adding Text Components to Labels (page 1503)

## Property Filter Dialog Box

Use this dialog box to restrict the available properties in the Properties list on the Layout tab of the Text Component Editor dialog box.

By selecting filter options in this dialog box, you can limit the contents of the Properties list so you can more easily see the properties that are relevant to the label type you are composing.

Property

Lists the categories of filters available.

Value

Specifies the filter to use. Select a specific filter or specify one of the following:

■ **<All>**: Resets the filter to include all properties. A restrictive filter remains active until you use this option.

■ **<None>**: Excludes all such properties from the Properties list.

**NOTE** After you select a filter, it remains active for new label styles also. If you do not see the properties you expect in the Text Component Editor, click the Filter icon to determine whether the Properties list is filtered. Use the <All> option to turn filters off.

## Format Tab (Text Component Editor Dialog Box)

Use this tab to define how label text is formatted.

Text Style

Displays the text style on which all text components are based.

**NOTE** The text style for a label is specified on the General (page 1942) tab of the Label Style Composer dialog box.

Justification

Specifies how the entire text component is justified.

■  **Left**: Text is left justified.

■  **Center**: Text is centered.

■  **Right:** Text is right justified.

Font

Specifies the font for new or selected text.

TrueType® fonts  are listed by font family name. AutoCAD compiled shape (SHX) fonts  are listed by the name of the file in which the fonts are stored. Custom fonts or third-party fonts are substituted with Autodesk-supplied proxy fonts. A custom SHX font is available for character formatting overrides only if it is defined for a text style in the drawing.

Color

Specifies the text color.

Select a color from the list or click  to open the Select Color dialog box.

### Formatting options

**B** Bold

Turns bold formatting on and off for new or selected text. This option is available only for characters using TrueType fonts.

*I* Italic

Turns italic formatting on and off for new or selected text. This option is available only for characters using TrueType fonts.

U Underline

Turns underlining on and off for new or selected text.

◁ Undo

Reverses the most recent action in the Text Component Editor, including changes to either text content or text formatting.

**NOTE** You can also press Ctrl+Z to undo the most recent change.

▷ Redo

Reverses the effects of the last Undo that you performed, including changes to either text content or text formatting. The Redo option must immediately follow the Undo command.

ᵇ/ₐ Stack/Unstack

Stacks selected text that is formatted using stack characters, or unstacks stacked text. For more information, see Creating Stacked Characters (page 1505).

[ Symbol ▼ ]

Inserts special characters and symbols.

**NOTE** Diameter symbols appear as %%c in the Text Component Editor window but are converted to Ø in labels.

The Other option in the Symbol list displays the Character Map dialog box. To insert a character from this dialog box, select it, and then click Select. Select all the characters you want to use and then click Copy. Then right-click in the Text Component Editor window, and click Paste.

**Related procedures:**

- Formatting Text (page 1505)
- Creating Stacked Characters (page 1505)
- Editing Text in the Text Component Editor (page 1507)

## Text Editor (Text Component Editor Dialog Box)

Use the Text Editor window, which is the area on the right side of the Text Component Editor dialog box, to construct a text component.

The Text Editor window has three purposes:

- It contains the property fields that you specify for the text component
- It allows you to add static text to a label

■ It allows you to select text for formatting and editing

Property fields should not be edited or the label will not be created correctly. You can, however, enter text in the window and use the following shortcut menu items to format it:

Shortcut Menu

Select the text, and right-click to display a shortcut menu for quick formatting options. The menu is context sensitive to cursor position, text selection, and stacked text.
The shortcut menu is divided into three parts. The top part has standard editing commands: Undo, Redo, Cut, Copy, and Paste.
The lower part of the shortcut menu contains specific formatting options.

■ **Select All**: Selects all text in the editor window.

■ **UPPERCASE**: Changes all selected text to uppercase characters.

■ **lowercase**: Changes all selected text to lowercase characters.

■ **Remove Formatting**: Removes any formatting, such as underline, bold, italic, and word-wrapping.

■ **Combine Paragraphs**: Removes all line returns.

■ **Stack**: Stacks selected text. This option appears only when text that is formatted with stacking characters is selected. For more information, see Creating Stacked Characters (page 1505).

■ **Unstack**: Unstacks text. This option appears only when stacked text is selected.

■ **Properties**: Displays the AutoCAD Stack Properties dialog box. This option appears only when stacked text is selected.

**Related procedures:**

■ Editing Text in the Text Component Editor (page 1507)

# Label Style Control

Use this control to create a new label style, edit the current selection, or select a style from the drawing.

The Label Style control is available in many dialog boxes.

Create New

Creates a new label of the same type in the Label Style Composer dialog box.

Copy Current Selection

Creates a copy of the current label style.

Create Child Of Current Selection

Creates a child from the current label style.

Edit Current Selection

Opens the Label Style Composer, where you can edit the current label style.

Pick From Drawing

Displays a pickbox so you can select a label style directly from the drawing.

# Label Properties Dialog Box

Use this dialog box to change the properties of labels in the drawing.

Different properties are available, depending on the type of label selected. The most general properties are listed first.

**General**

Reset Label Defaults

Returns all properties to original values. Use this option to reset the properties after you have made changes. This option works only within the current instance of the command; it does not restore previously-changed properties.

Label Style

Displays the style used by the selected label. Click the Value column, and then click  to open the Label Style dialog box and to select a different style.

Visibility

Specifies whether the label is visible in the drawing.

■ **True**: Displays the label.

■ **False**: Hides the label. This setting deletes the label unless it is reset before you close the dialog box.

Flip Label

Specifies whether the label is flipped.

■ **True**: Flips the label components to the opposite side of a line or curve object.

■ **False**: Leaves label as is.

Label Is Pinned

Specifies whether the label is fixed to its location.

■ **True**: Pins a label to its current location regardless of edits to the object referenced by that label.

■ **False**: Label can be moved if the object is edited.

**Bearing Labels**

Reverse Direction

Reverses the direction of labels that contain bearings.

■ **True**: Reverses direction label.

■ **False**: Leaves direction label as is.

**Referenced Text Objects**

Referenced Text Objects

Specifies the object to refer to in labels that contain Referenced Text. Click in the Value column and then click  to display the Property Field Object dialog box. Select the object to refer to and click OK.

**Surface Spot Elevation Labels**

**Profile View, Section View, Surface Spot Elevation Labels**

Point Style

   Specifies a point style which controls the appearance of the label insertion point for profile view, section view, and surface spot elevation labels. Select a point style from the list.

## Alignment Offset Labels

Leader Attachment Option

   Specifies the point attachment location for the label leader line.

   - **Point**: Leader line attaches to the point.

   - **Marker Extents**: Leader line attaches to the extents of the marker.

Marker Style

   Displays the style used by the currently selected marker. Click in the Value column and then click ⊡ to display the Marker Style dialog box and to select a different style.

Fixed XY

   Specifies the label position for fixed point alignment station/offset labels.

   - **True**: Moves the label with the alignment.

   - **False**: Leaves label as is.

## Profile View and Section View Labels

Profile 1 Object

   Specifies a profile to be used as "Profile 1" in the profile view labels. Use this option to include specific profile data in a label. For more information, see Setting Up Profile and Section View Labels (page 1526).

Profile 2 Object

   Specifies a profile to be used as "Profile 2" in the profile view labels.

Section 1

   Specifies a section to be used as "Section 1" in the section view labels.

Section 2

   Specifies a section to be used as "Section 2" in the section view labels.

Dimension Anchor Option

   Specifies the location of the dimension line anchor used to position dimension lines for certain profile view labels, such as vertical curve labels.

   - **Default**: Leaves the anchor position as is.

   - **Above**: Moves the dimension line anchor up the distance specified in the Dimension Anchor Value.

   - **Below**: Moves the dimension line anchor down the distance specified in the Dimension Anchor Value.

   - **Fixed**: Places the dimension line anchor at a fixed elevation on a profile view. Specify the elevation in the Dimension Anchor Value field.

Dimension Anchor Value

   Specifies the dimension line anchor value to be applied using the Dimension Anchor Option.

**Pipe and Structure Labels**

Alignment Name

Specifies the alignment that the pipe or structure references for labeling purposes. All alignments in the drawing are listed, as well as <Default>. <Default> is the alignment that the part was associated with when it was created. Changing the alignment name in the label properties changes only the data that appears in labels; it does not change the actual association between the part and alignment.

**Related procedures:**

■ Modifying Labels in a Drawing (page 1533)

# Label Set Dialog Box

Use this dialog box to create a group of label styles for alignments, profiles, or sections.

# Information Tab (Label Set Dialog Box)

Use this tab to change the label set name and description information, and to review details, such as when the label set was most recently modified.

Name

Specifies the name of the current label set.

Description

Specifies the description of the current label set.

Created By

Displays the AutoCAD login name of the person who created the label set.

Date Created

Displays the date and time the label set was created.

Last Modified By

Displays the AutoCAD login name of the person who last modified the label set.

Date Modified

Displays the date and time the label set was last modified.

**Related procedures:**

■ Creating a Label Set (page 1547)

# Labels Tab (Label Set Dialog Box)

Use this tab to select the label styles to add to an alignment, profile, or section label set.

After you add a label style to a set, you can define certain properties for the label style, such as increment. The properties vary depending on whether you are defining an alignment, profile, or section label set.

Type

Specifies the type of label to add to the label set.

<Type> Label Style

Displays the label styles available for the specified label type. Select a label style from this list, and click Add to add it to the label set.

Label Style Control

Creates a new label style, edits the current selection, or selects a style from the drawing.

 Style Detail

Opens the Style Detail dialog box where you can preview the selected label style.

 Add Label Style

Adds the label style selected in the Label Style list to the label set.

 Delete Label Style

Removes a label style from the label set. Select the label style to delete by clicking in the row in the lower part of the dialog box.

## List of Selected Styles

When you add a label style to a set, it is inserted into the list in the lower part of the dialog box. You can use this area to define properties for the label style and to change the selected label style.

Type Column

Displays the label types in the current label set.

Style Column

Specifies the label style to include in the set. Click  to open the Pick Label Style dialog box.

Increment Column

Specifies the increment at which to insert major and minor station labels.

> **NOTE** This setting is available for station labels only.

Geometry Points To Label Column

Specifies the geometry points to label for the Geometry Points, Profile Geometry Points, and Superelevation Critical Points label types. You can label a selection of geometry points in a label type using a selected style. You can then add another instance of the same label type, which can label a second selection of geometry points using a different style. Click  to select the geometry points to label.

Stagger Labels Column

Specifies the location of the label staggering line: No staggering, Stagger both sides, Stagger to right, or Stagger to left. The staggering options are available for the following labels: Profile (Grade Breaks, Major/Minor Station, Horizontal Geometry), and Section labels (Major/Minor Offsets and Grade Break).

Stagger Line 1 Height Column

Specifies the height of the first profile or section view data band label stagger line.

Stagger Line 2 Height Column

Specifies the height of the second profile or section view data band label stagger line.

## Profile Label Properties

After you add a profile label style to a label set, you can specify the following property values that are unique to profile label sets:

Dim Anchor Opt

Specifies the location of the dimension line anchor used to position dimension lines for certain profile view labels, such as vertical curve labels.

- **Distance Above**: Moves the dimension line anchor up the distance specified in the Dim Anchor Val field.

- **Fixed Elevation**: Places the dimension line anchor at a fixed elevation on a profile view. Specify the elevation in the Dim Anchor Val field.

- **Distance Below**: Moves the dimension line anchor down the distance specified in the Dim Anchor Val field.

Dim Anchor Val

Specifies the dimension line anchor value to be applied using the Dim Anchor Opt.

Weeding

Specifies a label exclusion distance for grade break labels only. Use this setting to remove overlapping labels and make it easier to read the remaining labels. If another break occurs within the specified distance from a given grade break, it is not labeled.

**NOTE** This setting is available for Grade Break labels only.

**Related procedures:**

- Creating a Label Set (page 1547)

# Add Labels Dialog Box

Use this dialog box to label objects in a drawing.

The Add Labels dialog box is common to most objects. Options available in the dialog box change depending on the feature selected.

Feature

Specifies the feature to label.

Label Type

Specifies the type of label to add. This list changes depending on the feature selected.

Edit Command Settings

Opens the Edit Command Settings dialog box where you can specify the default styles to use for each type of label.

Label Style list

Specifies the label style to use for new labels.

Label Style Control

Creates a new label style, edits the current selection, or selects a style from the drawing.

Style Detail

Displays the Style Detail dialog box where you can preview the selected label style.

Marker Style list

Specifies a marker style which controls the appearance of the label insertion point for profile view, section view, and surface spot elevation labels. Select a marker style to use from the list.

Reference Text Object Prompt Method

Specifies the method for selecting Referenced Text (page 1509) objects. Used only for label types that support Referenced Text.

- **Command Line**: When inserting a label that contains Referenced Text, you are prompted at the command line to select the objects to refer to in the label.

- **Dialog**: When inserting a label that contains Referenced Text, the Label Properties dialog box is displayed. Click in the Value column and then click ⊡ to display the Property Field Object dialog box. Select the object to refer to and click OK.

- **Suppress Prompts**: When inserting a label that contains Referenced Text, all prompting for objects is suppressed. No objects are specified for Referenced Text fields that may exist in the label style. You can edit the label properties later to specify the objects to refer to.

Table Tag Numbering

Accesses the Table Tag Numbering dialog box.

Add

Inserts labels of the selected style into the drawing after you select the object. The prompts that are displayed after you click Add vary based on the label style.

**Related procedures:**

- Adding Labels to Drawings (page 1522)

# Table Tag Numbering Dialog Box

Use this dialog box to define how line, curve and spiral components are numbered and renumbered.

There are two numbering counters:

If you create a number of components at the same time, the Starting Number property is used to generate the starting number and the numbering automatically increments by one unless you edit the increment number. The starting number is only changed automatically when a table tag is created and numbered. If there is a duplicate with the starting number, it increments up by the increment amount. If there is still a duplicate, it increments up, until an unused tag number is found and applied. The starting number is then set to the next number according to the increment (even if it is a duplicate).

The starting point for the increment is always the starting number. For example, if the Starting Number is 11, and the Increment is 10 and you attempt to create a tag but the starting number 11 is already used. The next starting number is now 21. If that is also used, it will increment to 31. If 31 is available, the tag will be numbered with 31, and the new starting number set to 41.

---

NOTE When creating tags, the renumbering starting number and increment will not be changed (unless you manually change them in the Table Tag Numbering dialog box.

---

### Table Tag Creation

Lines Starting Number

Specifies the starting number for new lines to be created in the site. The numbering is incremented with creation of new lines.

Lines Increment

Specifies the difference between numbers in the numbering sequence.

Curves Starting Number

Specifies the starting number for new curve tags to be created in the site. The numbering is incremented with creation of new tags.

Curves Increment

Specifies the difference between numbers in the numbering sequence.

Spirals Starting Number
  Specifies the starting number for new spiral tags to be created in the site. The numbering is incremented with creation of new tags.

Spirals Increment
  Specifies the difference between numbers in the numbering sequence.

**Table Tag Renumbering**

Lines Starting Number
  Specifies the starting number for new line tags to be renumbered.

Lines Increment
  Specifies the difference between numbers in the numbering sequence..

Curves Starting Number
  Specifies the starting number for new curve tags to be renumbered.

Curves Increment
  Specifies the difference between numbers in the numbering sequence.

Spirals Starting Number
  Specifies the starting number for new spiral tags to be created on alignments in the site. The numbering is incremented with creation of new tags.

Spirals Increment
  Specifies the difference between numbers in the numbering sequence.

**Related procedures:**

■ Creating a Site (page 723)

■ Editing Site Properties (page 724)

# Select Text Component Dialog Box

Use this dialog box to select a label text component to override.

Text Component
  Lists the text components in the label style. Select the component to override and click OK.
  A check mark appears next to any component that has already been overridden.

**Related procedures:**

■ Overriding Label Text (page 1535)

# Select Overridden Text Component Dialog Box

Use this dialog box to select an overridden text component in order to clear the overrides.

Text Component
  Lists the overridden text components in the label style. Select one or more components and click OK.
  You can use the Shift and Ctrl keys to select multiple components.

**Related procedures:**

■ Overriding Label Text (page 1535)

# Expressions Dialog Box

Use this dialog box to set up mathematical expressions that you can insert into label styles.

For example, you can set up an expression for parcel segments that converts feet to meters:

```
{Segment Length} *.3084
```

For other examples, see Expression Examples (page 1549). For procedures, see Setting Up Expressions (page 1548).

**Tips for creating expressions**

■ Do not enter functions, constants, or logical operators inside the curly brackets that surround Properties such as {Segment Length}.

■ Do not enter plain text, such as "meters" in expressions. You can add this text later when you set up a label style that includes the expression.

To set up an expression, you can use the buttons in the dialog box, and the keypad on your keyboard. There are menus in the dialog box from which you can choose Properties and functions to insert into the expression.

If you enter a combination of items that is invalid, you will receive a parse error when you click OK.

Name

Specifies a name for the expression. It is recommended that you use a clear naming convention such as "Parcel line expression: Length in meters". Expressions are listed by name along with all the other label properties in the Label Style Text Component Editor.

Description

Specifies a description that appears in the Settings tab item list view.

Editor Box

Displays the expression as defined from the functions and properties. You can also click in this box and type characters such as numbers.

Calculator Buttons

Enter numbers and operators (page 1848) into the Editor box to define the expression.

Insert Property

Inserts a property into the expression. Click the icon to display a list of properties relevant to the expression type. Select a property to insert it into the expression. These are the same Properties (page 1507) that are available for label styles.
Properties are inserted inside brackets. Do not add operators or functions within these brackets.

Insert Function

Inserts a function into the expression. See Functions (page 1846) below for more information.

Format Result As

Specifies how the expression results are formatted.

■ **Double**: This value is formatted using the Unitless type.

> **NOTE** The following are all of type Double but are formatted according to the settings on the Ambient Settings tab (page 1856) in the Drawing settings:

■ Angle

■ Area

■ Coordinate

- Dimension

- Direction

- Distance

- Elevation

- Grade/Slope

- Latitude

- Longitude

- Station

- Volume

## Functions

NOTE Functions can be either upper case or lower case but not mixed case. The editor buttons will always insert functions in upper case. Unless otherwise stated, theta is in radians.

| | |
|---|---|
| ABS(x) | Returns absolute value of x |
| ACOS(x) | Returns arccosine of x |
| ASIN(x) | Returns arcsin of x |
| ATAN(x) | Returns arctangent of x |
| ATAN2(y,x) | Returns arctangent of y/x in the correct quadrant based on signs of x and y |
| CEIL(x) | Returns the smallest integer that is greater-than or equal to x |
| COS(theta) | Returns the cosine of theta |
| COSH(theta) | Returns the hyperbolic cosine of theta |
| COT(theta) | Retruns the cotangent of theta |
| COTH(theta) | Returns the hyperbolic cotangent of theta |
| CSC(theta) | Returns the cosecant of x |
| CSCH(theta) | Returns the hyperbolic cosecant of x |
| DEG2GRD(theta) | Converts theta in degrees to gradients |
| DEG2RAD(theta) | Converts theta in degrees to radians |
| DRVSTN(x) | Returns x at the derived station along the corridor |
| EXP(x) | Returns exponential of x |

| FLOOR(x) | Returns the largest integer that is less-than or equal to x |
| --- | --- |
| FMOD(x,y) | Returns the floating point remainder of x/y |
| GRD2DEG(theta) | Converts theta in gradients to degrees |
| GRD2RAD(theta) | Converts theta in gradients to radians |
| IF(test,true_val,false_val) | Evaluates test - if test is non-zero evaluates and returns true_val else evaluates and returns false_val. True_val and false_val can be any expression.<br>For example, where x is a Property:<br>IF(x=0,1,sin(x)/x)<br>The above tests x to see if it is zero, and if it is, the expression returns 1. If x is non-zero, the expression returns sin(x)/x. |
| LOG(x) | Returns the log (base e) of x |
| LOG10(x) | Returns the log (base 10) of x |
| MAX(a,b) | Returns maximum value of a and b |
| MIN(a,b) | Returns minimum value of a and b |
| POW(x,y) | Returns x raised to the y power |
| POW10(x) | Returns x raised to 10 |
| RAD2DEG(theta) | Converts theta in radians to degrees |
| RAD2GRD(theta) | Converts theta in radians to gradients |
| ROUND(x) | Rounds x to the nearest inetger |
| SIN(theta) | Returns the sin of theta |
| SEC(theta) | Returns the secant of theta |
| SECH(theta) | Returns the hyperbolic secant of theta |
| SINH(theta) | Returns the hyperbolic sin of x |
| SQR(x) | Returns x squared (i.e. x*x) |
| SQRT(x) | Returns the square root of x |
| TAN(theta) | Returns the tangent of theta |
| TANH(theta) | Returns the hyperbolic tangent of theta |
| TRUNC(x) | Truncates x to an integer value |

## Logical Operators

**NOTE** Logical operators return 1.0 for true and 0.0 for false. Since they return values, you can perform logical AND and OR with addition and multiplication. For example: ((a<b) + (b>c)) tests for a < b or b > c. ((a<b)*(b>c)) tests for a<b and b>c.

| Symbol | Operator Definition |
|--------|---------------------|
| = | logical equals |
| != | logical not equals |
| ! | logical not |
| < | logical less-than |
| > | logical greater-than |
| <= | logical less-than or equals |
| >= | logical greater-than or equals |
| And | & Boolean "and" |
| ~ | logical approximately equal |
| <~ | logical less-than or approximately equal |
| >~ | logical greater-than or approximately equal |
| Or | \| - Boolean "or" |
| + | binary addition |
| - | binary subtraction |
| * | binary multiplication |
| / | binary division |
| - | unary minus |
| + | unary plus |
| ^ | power |

**Related procedures:**

■ Expressions (page 1547)

# LandXML Dialog Boxes

# 56

Use the following links to access information about the AutoCAD Civil LandXML dialog boxes.

## Import LandXML Dialog Box

Use this dialog box to select the LandXML data to import into AutoCAD Civil.

Alignments Site

Specifies a site for imported alignments. Select a site from the drop-down list or click ![icon] to select an object (parcel, alignment, or grading) contained in the site to which you want to add the new objects.

NOTE The default selection is <None>, which places the alignments in the top-level Alignments collection in Prospector. See Alignment and Site Interaction (page 721) for more information.

Parcels Site

Specifies a site for any imported parcels. Select a site from the drop-down list or click ![icon] to select an object (parcel, alignment, or grading) contained in the site to which you want to add the new objects.

NOTE If no sites exist in the drawing, the objects are placed in a default site.

Edit LandXML Settings

Opens the LandXML Settings dialog box (page 1978).

Data Tree

Lists the LandXML header information for each data component that can be imported. Expand each of the collections to display all of the subcomponents.
Select or clear the check boxes to the left of each data component name to filter the data that is imported into AutoCAD Civil. By default, all data components are selected for import.

NOTE The check boxes have a tri-state display. If only some items are selected under a collection, the check box is shaded ![icon] . If all items are selected, the check box is selected ![icon] . If all items below the collection are cleared, the check box for the collection is cleared ![icon] .

OK

Converts LandXML data into AutoCAD Civil objects. Imports each object from the LandXML file into the AutoCAD Civil drawing using the name as specified in the LandXML file.

Each object uses the appropriate creation behavior based on the command setting for the object being imported. For example, if the Surface Default Style is set to High Altitude, any surfaces imported with this operation will use the High Altitude style.

**NOTE** As each object is imported, the Event Viewer Vista (page 2455) dialog box can display the status of each operation. For more information, see The Event Viewer Vista (page 1626).

Browse

Opens the Open dialog box. Select another LandXML file from which to import data.

**Related procedures:**

■ Importing LandXML Drawing Data (page 1681)

# LandXML Settings Dialog Box

Use this dialog box to manage a variety of settings related to the LandXML import and export properties.

## Import Tab (LandXML Settings Dialog Box)

Use this tab to define how data is imported from a LandXML file to AutoCAD Civil.

You can set the data translation, rotation, and conversion settings. In addition, there are options to control the import of point, surface, and pipe network data.

### Translation

Translate

Specifies whether to translate data to new coordinates when importing the data from the LandXML file. Select On to translate the data on import. For more information, see Translating and Rotating LandXML Data (page 1679).

**NOTE** If Translate is set to Off, all other data translation options are unavailable.

Base Point Northing

Specifies the base point northing coordinate from which all import values are translated.

**NOTE** The units used for base point and translated values are set at the drawing level in the Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856).

Base Point Easting

Specifies the base point easting coordinate from which all import values are translated.

Base Point Elevation

Specifies the base point elevation from which all import values are translated.

Translated Coordinate Northing

Specifies the northing coordinate value used to translate data from the base point.

Translated Coordinate Easting

Specifies the easting coordinate value used to translate data from the base point.

Translated Coordinate Elevation

Specifies the elevation value used to translate data from the base point.

**Rotation**

Rotate

Specifies whether to rotate data when importing it from the LandXML file. Select On to rotate the data on import.

NOTE If Rotate is set to Off, all other data rotation options are disabled.

Angle

Specifies the angle about the base point where the LandXML data is rotated.

NOTE The angle units are set at the drawing level in the Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856).

Direction

Specifies the direction of rotation. Select this option to calculate the angle in a clockwise or counter-clockwise rotation about the base point.

## Point Import Settings

Point Description

Specifies how to map the 'desc' and 'code' attributes to the point descriptions:

- **Use "Code" Value**: Uses the "code" attribute value for the point description.

- **Use "Desc" Value**: Uses the "desc" attribute value for the point description.

- **Use "Code" Then "Desc"**: Attempts to use the "code" attribute value for the point description. If a point does not have a "code" attribute, the "desc" attribute value, if available, is used.

- **Use "Desc" Then "Code"**: Attempts to use the "desc" attribute value for the point description. If a point does not have a "desc" attribute, the "code" attribute value, if available, is used.

## Surface Import Settings

Surface Data

Specifies how to import the data:

- **Quick Import**: Imports the surface information as points. Creates a surface that has identical northing/easting/elevation points as the surface definition in the LandXML file. However, the triangulation may be different from the original surface.

- **Full Import**: Imports both the points and the surface faces, if available. Creates the surface information from the face edges and creates a surface that is identical to the surface definition in the LandXML file.

  NOTE If the LandXML surface you intend to import has only breaklines (for example, no other points and faces definition data is present), the resulting AutoCAD Civil surface is built from the breakline data. However, the breaklines are not available for editing (that is, they do not appear in the Prospector tree).

Create Snapshot After Import

After importing surface data, a snapshot can automatically be created. By creating a snapshot after importing a LandXML file, AutoCAD Civil does not attempt to find and open the LandXML file each time the surface is built. Select On to create a snapshot. For more information on snapshots, see Using Surface Snapshots (page 681).

Create Source Data In Drawing

Imports the surface source data (breaklines, contours, points, and chains) into the drawing as 3D polylines and points.

- Breaklines, contours, and chains are created as 3D polylines.

■ DataPoints are created as COGO points in a point group named <surface name>_DataPoints.

This data is created on the following layers prefixed with the surface name:

■ <surface name>_Breaklines

■ <surface name>_Contours

■ <surface name>_Chains

■ <surface name>_DataPoints_PntList3D

---

**NOTE** This data is not added to the surface definition in the Prospector tree. You can manually add it if desired, or create a different surface from it for comparison purposes.

---

### Pipe Network Import Settings

Parts List For Part Family Size Matching

Specifies the pipe network parts list that is used during import to match pipe network part types in a LandXML file with pipe network part types in a AutoCAD Civil parts list. Review these settings prior to import to verify that settings are appropriate for your data. For more information, see Part Catalog and Parts Lists (page 1237).

Match <Part Type> With:

Specify individual part types to use when importing pipe network parts from a LandXML file into AutoCAD Civil. Review these settings prior to import to verify that settings are appropriate for your data. You may use the defaults, or click ⊡ to specify other parts in the Part Catalog dialog box.

### Conflict Resolution Settings

Conflict Resolution

Specifies how objects with the same name are handled.

■ **Skip**: Does not import conflicting objects.

■ **Update**: On import, replaces unlocked drawing object with object in LandXML file.

■ **Append**: Imports conflicting objects but renames the imported copy using the default name format that is specified in the feature settings.

### Default Diameter Units

On import, AutoCAD Civil reads the <LandXML>.<Units>.diameterUnits, and if they are defined, those units are used for both pipes and structures. If units are not defined, the following unit settings are applied. Either the Imperial or Metric diameter settings are applied, based on the defined <LandXML>.<Units>.linearUnit in the file.

Imperial

Defines the default imperial pipe and structure diameter units that are applied when units are not specified in the source LandXML file.

Metric

Defines the default metric pipe and structure diameter units that are applied when units are not specified in the source LandXML file.

**Related procedures:**

■ Importing LandXML Drawing Data (page 1681)

■ Viewing and Editing LandXML Drawing Settings (page 1678)

# Export Tab (LandXML Settings Dialog Box)

Use this tab to define how data is exported from AutoCAD Civil to a LandXML file.

## Identification

Write Identification Elements

Specifies whether the identification properties are written to the LandXML file. Select On to write populated identification properties to the LandXML file.

**NOTE** If Write Identification Elements is set to Off, all other identification options are disabled.

Creator

Specifies the creator of the LandXML file.

Email Address

Specifies the creator's email address.

Company

Specifies the creator's company.

Company URL

Specifies the company's URL.

## Data Settings

Imperial Units

Specifies how to tag LandXML data when working in Imperial units:

- **International Foot**: Tags the data in the LandXML file as International feet.

- **Survey Foot**: Tags the data in the LandXML file as Survey feet.

Angle/Direction Format

Specifies the units of the exported angles and directions:

- **Degrees Decimal (DDD.DDDDDD)**: Exports angles and directions as decimal degrees. Decimal degrees express the minutes and seconds of an angle as its decimal equivalent. For example, 3°30'36" equals 3.51 decimal degrees.

- **Degrees Decimal dms (DDD.MMSSSS)**: Exports angles and directions using the degrees, minutes, and seconds convention, in which the numbers after the decimal are read as minutes and seconds, not decimal degrees. For example, 3°30'36" equals 3.303600.

- **Grads**: Exports angles and directions using grads (where one grad equals 1/100 of a 90° angle, or 360° = 400 grads).

- **Radians**: Exports angles and directions using radians (where 2PI radians equals 360°).

**NOTE** Directions are always reported in azimuths. The LandXML schema does not support bearings.

Create Read-Only File

Specifies whether the LandXML file is created as a read-only file. This is done in two places: a tag is inserted into the LandXML, and the operating system file attributes on the file are set to read only. Select On to specify read only.

## Point Export Settings

Code Attribute

Specifies the field that is used for the 'code' attribute in the LandXML file:

- **Disabled**: Does not export the point description to a 'code' attribute.

- **Raw Description**: Exports a point raw description to the 'code' attribute.

- **Full Description**: Exports a point full description to the 'code' attribute.

---

**NOTE** Typically you would export the raw description to the 'code' attribute. For more information, see Point Description and Code Matching (page 1680).

---

Desc Attribute

Specifies the field that is used for the 'desc' attribute in the LandXML file:

- **Disabled**: Does not export the point description to a 'desc' attribute.

- **Raw Description**: Exports a point raw description to the 'desc' attribute.

- **Full Description**: Exports a point full description to the 'desc' attribute.

---

**NOTE** Typically, you would export the full description to the 'desc' attribute. If you select Disabled for both the Code Attribute and Desc Attribute, then no descriptions are exported. For more information, see Point Description and Code Matching (page 1680).

---

Skip Full When Same As Raw

Specifies whether to export the full description if it is the same as the raw description:

- **On**: Does not export the full description if it is the same as the raw description. For example, if the raw and full descriptions are the same, then only one value is exported. This would occur when points do not have defined description keys.

- **Off**: Exports both values.

Export Point References

Specifies whether to export point references. Point references substitute a known point name instead of using northing and easting coordinates. Select On to export point references.
For example, if the start point of a line element dose not have a point reference, it is written as follows:
<Start>5447.73530 4525.60643</Start>
If it has a point reference, it is written as follows:
<Start pntRef="371"></Start>
For more information, see Point Reference Export Options (page 1680).

Point Reference Tolerance

Specifies the tolerance value for point references.
For example, if you enter 0.001, only those points that are located within 0.001 units of the point of interest (for example, a start point) are exported as references.

Export Description Keys

Specifies whether the description key definitions are exported. Select On to export all description key definitions in the drawing. If there are description keys in the drawing, a message dialog box is displayed.

## Surface Export Settings

Surface Data

Specifies how to export the surface data:

- **Points Only**: Exports surface information as points. Creates a surface that has northing, easting, and elevation points that are identical to the surface definition. However, the triangulation may be different from the original surface.

- **Points and Faces**: Exports both the points and the surface faces, if available. Creates the surface information from the face edges and creates a surface that is identical to the surface definition.

Watersheds

Specifies whether to export watershed information with the surface data. Select On to export watershed information to the LandXML file.

**Parcel Export Settings**

Parcel Direction

Specifies the direction from the parcel start point for exporting parcel segments. Parcel segments are exported in sequence in either a clockwise or counter-clockwise direction.

- **Clockwise**: Exports parcel segments in a clockwise direction.

- **Counter-clockwise**: Exports parcel segments in a counter-clockwise direction.

**Alignment Export Settings**

Export Cross Sections

When set to On, exports cross section data if sample lines are defined for the alignment.

**Related procedures:**

- Exporting LandXML Drawing Data (page 1682)

- Viewing and Editing LandXML Drawing Settings (page 1678)

# Export To LandXML Dialog Box

Use this dialog box to select the data in the drawing to export in LandXML format.

This dialog box is used for exporting LandXML data as well as for generating LandXML-based reports.

Data Tree

Lists the AutoCAD Civil data that you can export in LandXML format. Expand each of the collections to display all of the subcomponents.
Select or clear the check box to the left of each feature name to filter the data that you want to export in LandXML format.

**NOTE** The check boxes have a tri-state display. If only some items are selected under a collection, the check box is shaded ☑ . If all the items are selected, the check box is selected ☑ . If all the items below the collection are cleared, the check box for the collection is cleared ☐ .

Specify LandXML Version

Specifies the LandXML schema version. Select from 1.0, 1.1, or 1.2.

Pick From Drawing

Specifies objects to export by selecting from the drawing.

**NOTE** If you access this dialog box by right-clicking a collection in the Prospector tree and selecting Export LandXML, the Pick From Drawing button is not available.

OK

Converts AutoCAD Civil objects to LandXML format and exports the LandXML data.

**Related procedures:**

- Exporting LandXML Drawing Data (page 1682)

1984

# Layers Dialog Boxes

# 57

Use the following links to access information about the dialog boxes for managing drawing layers.

## Object Layer Dialog Box

Use this dialog box to specify default layers for drawing objects. For example, when changing the layer for a point group in the Point Group Properties.

Base Layer Name

Displays the name of the layer to which the object is assigned in the Object Layers tab of the Drawing Settings dialog box. Use the layer selection button to select a different layer.

Layer selection button

Opens the standard Layer Selection dialog box. You can select a layer to change the base layer for the object. This button is disabled when the object layer settings (page 66) are locked.

Modifier

Specifies whether the layer name includes a text-string modifier, and if so, the location of the modifier:

- **None:** No modifier.

- **Prefix:** Modifier is added at the beginning of the layer name.

- **Suffix:** Modifier is added at the end of the layer name.

Modifier Value

Specifies the text string to use as the modifier. You can enter an asterisk (*) to include the object name as the modifier in the layer name and to put each named object on its own layer. For example, if C-ROAD is the name specified for alignment layers and you add -* as a suffix, an alignment named overpass is created on layer C-ROAD-OVERPASS.

Preview

Displays the final name of the layer for any newly created objects.

**Related procedures:**

- Layers (page 58)

# Layer Selection Dialog Box

Use this dialog box to select the layer on which to create objects of the selected type. Click anywhere in the row to select the layer, then click Apply.

When you select a layer from a source outside the current drawing, the layer is created in the current drawing. If you select a layer that exists in the current drawing, a warning dialog box is displayed, where you can overwrite the current layer definition or cancel the command.

Layer Source
   Specifies the drawing that contains the layer. Select one of the open drawings.

Layer
   Displays the name of the layer.

Color
   Displays the color of the layer.

Linetype
   Displays the linetype of the layer.

Lineweight
   Displays the lineweight of the layer.

Plot
   Displays whether the layer is plotted or not.

Plot Style
   Displays the plot style of the layer.

New
   Creates a layer using the Create Layer (page 1986) dialog box. This option is available only if the current open drawing is selected for the Layer Source.

# Create Layer Dialog Box

Use this dialog box to set the properties for the new layer.

**Layer Properties**

Layer Name
   Specifies the layer name.

Color
   Specifies the layer color.

Linetype
   Specifies the layer linetype. Select a linetype from the drawing or from those defined in the drawing.

Lineweight
   Specifies the layer lineweight.

Locked
   Specifies whether the layer is locked. On a locked layer, you cannot select or modify objects.

On
   Specifies whether the layer is visible.

Freeze
   Specifies whether the layer is frozen or thawed. A frozen layer is not updated.

Plot Style
   Specifies the plot style.
Plot
   Specifies whether the layer can be plotted.

# Lines and Curves Dialog Boxes

# 58

## Entity by Best Fit Dialog Box

Use this dialog box to create an AutoCAD, Alignment, or Profile entity by best fit. You can create the entity from a series of AutoCAD Civil points, AutoCAD points, existing entities, or by clicking on screen.

Use this dialog box to select the source objects from which you want to create a best fit entity. You may create the following types of entities by best fit:

### AutoCAD Entities

- Line

- Arc

- Parabola

### Alignment Entities

- Fixed Line

- Floating Line

- Fixed Curve

- Floating Curve

- Free Curve

### Profile Entities

- Fixed Tangent

- Floating Tangent

- Fixed Vertical Curve

- Floating Vertical Curve

■    Free Vertical Curve

---

**NOTE**  The From AutoCAD Points and From COGO Points input options are not available on the Parabola By Best Fit dialog box.

---

**Input Options**

From COGO Points

Specifies that two or more COGO points or survey points will be used for best fit entity creation.

From AutoCAD Points

Specifies that two or more AutoCAD points will be used for best fit entity creation.

From Entities

Specifies that one or more existing lines, arcs, polylines, feature lines, survey figures, or profile objects will be used for best fit entity creation.

By Clicking On The Screen

Specifies that the user will click points on screen for best fit entity creation.

Tessellate Arc Segments

Tessellates the selected sample arc segments.

Mid-Ordinate Tolerance

Specifies the mid-ordinate tolerance based on a distance across the tessellated arc segments. Enter a known value or click  to select two points along a curve.

**Related procedures:**

■    Creating Entities by Best Fit (page 582)

■    Adding Lines, Curves, and Spirals to an Alignment (page 898)

■    Adding Tangents and Curves to a Layout Profile (page 1059)

# Regression Data Vista (for Best Fit Entity Analysis)

Use this vista to view and edit the results of the best fit regression data.

**Entity Property Tree**

This tree lists attributes of the best fit entity. Attribute values cannot be edited.

**Regression Points Toolbar**

  Copy to Text Editor

Copies the regression data to the text editor that is associated with AutoCAD.

  Copy to Clipboard

Copies regression data to the clipboard with the appropriate formatting. This tool is useful for importing the regression data into a spreadsheet.

  Add More Points

Adds more regression points. This button launches the appropriate **Create Object by Best Fit** dialog box, which allows you to select more points to include in the regression analysis.

**✖** Delete Selected Points

Deletes selected points (rows) from the regression points table.

**↩** Undo

Reverses the last action.

**↪** Redo

Reverses the last undo command.

**▽** Out of Sync

Indicates that the best fit entity has been modified and its parameters do not match the best fit regression data. Click this button to force the entity to match the original best fit regression data.

**↻** Empty Current Regression Sample Data

Resets the regression points table and leaves the Regression Data dialog box open. New points may be

added by clicking **✛** .

**▣** Create Entity and Continue to Edit the Data

Creates the entity based on the data in the regression points table and leaves the Regression Data vista open.

**✔** Dismiss this Vista

Creates the entity based on the data in the regression points table and closes the Regression Data vista. Other vistas in Panorama remain open.

**?** Display Help Topic

Opens the Regression Data Vista (for Best Fit Entity Analysis) help topic.

**✕** Close

Closes the Regression Data vista and all open vistas in Panorama. Hides temporary graphics in the drawing window. Regression data and temporary graphics are saved and will reappear when the Best Fit command is reentered.

## Regression Points Table

Pt No.

Sequential number generated in the order in which the regression points were generated. Number is adjusted if regression points are added or deleted.

Exclude

Specifies the regression points to exclude from the best fit analysis.

Pass Through

Specifies a regression point which the best fit entity must pass through. Only one pass-through point may be selected for a line. Two pass-through points may be selected for an arc or parabola.

Point Northing

Regression point's Northing value. This value may be edited.

Point Easting

Regression point's Easting value. This value may be edited.

Point Station

For best fit profile entities, the regression point's station value. This value may be edited.

Point Elevation

For best fit profile entities, the regression point's elevation value. This value may be edited.

Weight

Specifies the regression point's preference in relation to other points. A higher value gives a point preference over points with lower values. This value may be edited, but it must be greater than zero.

Offset to Entity

Specifies the distance of the regression point from the best fit entity.

Northing on Entity

Specifies the Northing ordinate from the best fit entity.

Easting on Entity

Specifies the Easting ordinate from the best fit entity.

**Regression Graph**

This graph displays the regression points' relationship to the best fit entity. The red line represents the regression points and the green line represents the best fit entity. Selecting a row in the Regression Points table displays an **X** and dashed line in the graph to indicate the location of the selected point. The selected point is also highlighted in the drawing window.

**Related procedures:**

■ Creating Entities by Best Fit (page 582)

# Specify Station Range Dialog Box

Use this dialog box to specify a range of stations within a profile from which to sample data for a best fit entity regression.

Start Station

Specifies the beginning station of the range from which to take the sample. To edit the start station, enter a value or click ⬚ to select a location on the profile.

End Station

Specifies the ending station of the range from which to take the sample. To edit the end station, enter a value or click ⬚ to select a location on the profile.

**Related procedures:**

■ Creating Entities by Best Fit (page 582)

# Curve Calculator Dialog Box

Use this dialog box to calculate curve parameters from input.

**NOTE** To change the units used in the Curve Calculator dialog box, use the Ambient Settings tab of the Drawing Settings dialog box. Under Angle, change the Format value to the unit you want to use. For more information, see To specify ambient settings for a drawing (page 68).

**The following illustration shows the curve parameters used by AutoCAD Civil.**

Degree Of Curve Definition

Specifies whether the degree of curve will be based on the arc or the chord.

- **Chord Definition**: Specifies that the degree of curve is determined by the chord. Use this option if the curve is a railway curve. For a railway curve, the degree of curve is the angle at the center of a circular curve subtended by a chord of 100 units.

- **Arc Definition**: Specifies that the degree of curve is determined by the arc. Use this option if the curve is a roadway curve. For a roadway curve, the degree of curve is the central angle subtended by a circular arc of 100 units.

**The following illustration shows the degree of curve
definition for arcs and chords.**

**Degree of Curve Arc Definition**

**Degree of Curve Chord Definition**

Fixed Property

Specifies which property to hold as fixed while performing calculations.

- **Radius**: Specifies that the radius will be fixed.

- **Delta Angle**: Specifies that the delta angle will be fixed.

Degree Of Curve

Specifies the degree of curve.

Delta Angle

Specifies the delta angle of the curve. This option is not adjustible if Delta Angle is specified as the Fixed Property.

Radius

Specifies the radius of the curve. This option is not adjustible if Radius is specified as the Fixed Property.

Tangent Distance

Specifies the tangent length of the curve.

Arc Distance

Specifies the arc length of the curve.

Chord Distance

Specifies the chord length of the curve.

External Distance
    Specifies the external secant length of the curve.

Mid-ordinate Distance
    Specifies the mid-ordinate length of the curve.

    Sends the current value to the command line.

    Optionally selects an arc in the drawing and displays its values in the calculator. No edits you subsequently make in the calculator are updated in the drawing.

# Migration Dialog Box

# 59

Use the following link to access information about the AutoCAD Civil Migration dialog box.

## Import Data from Autodesk Land Desktop Project Dialog Box

Use this dialog box to convert and import data from an Autodesk Land Desktop project into an AutoCAD Civil drawing.

**Land Desktop Project Path**

Specifies the path of the Autodesk Land Desktop project containing the data that you want to import.

Enter a valid path or click ![folder icon] to browse to the location. For example, *C:\Land Projects 2009*.

**Project Name**

Specifies the name of the project that contains the data you want to import. After the path is specified, select a project in the list.

**Alignments Site**

Specifies a site for any alignments that are being imported. Select a site from the drop-down list or click ![icon] to select an object (parcel, alignment, or grading object) contained in the site to which you want to add the new alignments.

> **NOTE** The default selection is <None>, which places the alignments in the Alignments (Centerline or Miscellaneous Alignments) collection in Prospector. See Alignment and Site Interaction (page 721) for more information.

**Parcels Site**

Specifies a site for any parcels that are being imported. Select a site from the drop-down list or click ![icon] to select an object (parcel, alignment, or grading object) contained in the site to which you want to add the new parcels.

**Overwrite Existing Data**

Specifies whether existing data that already exists in the drawing is overwritten.

**<details area>**

Imports the specified data. Navigate to the desired data and select or clear the check boxes for one or more import options:

- **Description Keys**: Imports description keys.

- **Surfaces**: Imports surface data.

- **Alignments**: Imports alignment data.

- **Profiles**: Imports both EG and FG profile data.

- **Parcels**: Imports parcel data.

- Pipe Runs: Imports pipe data.

To iteratively import data, you can use the Apply button and check the messaging information.

For better results, import one data type at a time. To import points from Autodesk Land Desktop, use the Import Point option of the Create Points command and select External Project Point Database as the format type.

For more information about importing Autodesk Land Desktop data, see Tools for Moving Land Desktop Data into AutoCAD Civil.

# Parcels Dialog Boxes

# 60

Use the following links to access information about the Parcels dialog boxes.

## Edit Feature Settings - Parcel Dialog Box

Use this dialog box to view and change parcel-related settings.

This topic documents settings in all parcel-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

■ Drawing-level ambient settings are identified by the ▢ drawing icon.

■ Parcel feature settings are listed near the top of this dialog box, after the General property group, and are identified by the ◳ parcel icon.

■ Parcel command settings are identified by the ▣ command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

### ◳ Default Styles

Use these settings to specify default styles for creating and labeling parcels.

Parcel Style

Specifies the default parcel style. Click in the Value column, and click ⋯ to select a style in the Parcel Style dialog box.

Parcel Area Label Style

Specifies the default parcel area label style. Click in the Value column, and click ⋯ to select a style in the Parcel Area Label Style dialog box.

Parcel Line Label Style

Specifies the default parcel line label style. Click in the Value column, and click [...] to select a style in the Parcel Line Label Style dialog box.

Parcel Curve Label Style

Specifies the default parcel curve label style. Click in the Value column, and click [...] to select a style in the Parcel Curve Label Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

## Table Creation

**NOTE** This property group is displayed when accessing the settings from the  AddParcelCurveTable, AddParcelLineTable, AddParcelSegmentTable, or AddParcelTable commands.

Use these settings to specify defaults for creating tables with parcels.

Table Style

Specifies the style for a table. Click in the Value column, and click [...] to select a style in the Table Style dialog box.

Split Table

Specifies whether a table is split into two or more sections after a specified maximum number of rows has been met.

Maximum Number of Rows

Specifies the maximum number of rows to include per section. If the number of data rows exceeds the specified maximum, the table is split into sections, and they are displayed either side by side (left to right), or stacked vertically.

Maximum Tables Per Stack

Specifies the maximum number of tables to include in each stack.

Table Spacing

Specifies the spacing between tables.

Tile Direction

Specifies the direction in which the table tiles (Across or Down).

## Default Options

**NOTE** This property group is displayed when accessing the setting from the AddParcelSegmentLabels command.

Use this setting to specify defaults for creating labels with parcel segments.

Labeling Direction

Specifies the segment labeling direction (Clockwise or Counter-clockwise).

## Parcel Sizing

**NOTE** This property group is displayed when accessing the settings from the CreateParcelByLayout command.

Use these settings to specify defaults for sizing parcels.

Parcel Selection Method

Specifies whether the Pick Point Within Parcel or Select Parcel Area Label selection method is used.

Minimum Area

Specifies the minimum area for a new parcel.

Minimum Frontage

Specifies the minimum frontage (page 2474) for a new parcel.

Use Minimum Frontage At Offset

Specifies whether Use Minimum Frontage At Offset is used.

Frontage offset

Specifies the frontage offset (page 2474) for a new parcel. Must be greater than zero.

Minimum Width

Specifies the Minimum width for a new parcel. Must be greater than or equal to zero.

Minimum Depth

Specifies the minimum depth for a new parcel.

Use Maximum Depth

Specifies whether maximum depth is used.

Maximum Depth

Specifies the maximum depth for a new parcel. Must be greater than or equal to zero.

## Preview Graphics

**NOTE** This property group is displayed when accessing the settings from the CreateParcelByLayout command.

Use these settings to specify defaults for temporary parcel layout preview graphics.

Frontage Color

Specifies the default color for the frontage preview.

Frontage Offset Color

Specifies the default color for the frontage offset preview.

New Parcel Color

Specifies the default color for the new parcel preview.

Minimum Frontage Color

Specifies the default color for the minimum frontage preview.

Minimum Width Color

Specifies the default color for the minimum width preview.

Minimum Depth Color

Specifies the default color for the minimum depth preview.

## Automatic Layout

**NOTE** This property group is displayed when accessing the settings from the CreateParcelByLayout command.

Use these settings to specify defaults for automatic parcel layout.

Automatic Mode

Specifies whether the automatic mode is set for parcel layout.

Remainder Distribution

Specifies remainder from a new parcel is distributed:
- Create Parcel From Remainder

- Place Remainder In Last Parcel

- Redistribute Remainder

## ✅ Convert from Entities

**NOTE** This property group is displayed (in different forms) when accessing the settings from the CreateParcelByLayout and CreateParcelFromEntities commands.

Use these settings to specify defaults for creation of parcels.

Erase All Existing Entities

Specifies whether existing entities are erased when a new parcel is created. (CreateParcelFromEntities command only)

Auto Add Segment Label

Specifies whether segment labels are automatically added to a new parcel.

## ✅ Create Parcel Right of Way

**NOTE** This property group is displayed when accessing the settings from the CreateParcelROW command.

Use this setting to specify default offset for creation of parcel rights of way.

Offset from Alignment

Specifies the offset from the alignment for the new right of way. Enter a width in the Value column or

click  and select a width in the drawing area.

## ✅ Cleanup at Parcel Boundaries

**NOTE** This property group is displayed when accessing the settings from the CreateParcelROW command.

Use these settings to specify default offset for cleanup at parcel boundaries.

Fillet Radius at Parcel Boundary Intersections

Specifies the width of the radius of the fillet at parcel boundary intersections. Enter a width in the Value

column or click  and select a width in the drawing area.

Cleanup Method

Specifies whether the cleanup method is Fillet, Chamfer, or None.

## ✅ Cleanup at Alignment Intersections

**NOTE** This property group is displayed when accessing the settings from the CreateParcelROW command.

Use these settings to specify default offset for cleanup at alignment intersections.

Fillet Radius at Alignment Intersections

Specifies the width of the radius of the fillet at alignment intersections. Enter a width in the Value column

or click  and select a width in the drawing area.

Cleanup Method

Specifies whether the cleanup method is Fillet, Chamfer, or None.

## ✅ Parcels

---
**NOTE** This property group is displayed when accessing the settings from the CreateSite command

---

Use these settings to specify default increments for parcel numbering.

Parcel: Next Automatic Area Counter
Specifies the increment by which the next new parcel area is automatically numbered.

Parcel: Next Manual Area Counter
Specifies the increment by which the next new parcel area is manually numbered.

Parcel Line: Next Automatic Tag Counter
Specifies the increment by which the next new parcel line tag is automatically numbered.

Parcel Line: Next Manual Tag Counter
Specifies the increment by which the next new parcel line tag is manually numbered.

Parcel Curve: Next Automatic Tag Counter
Specifies the increment by which the next new parcel curve tag is automatically numbered.

Parcel Curve: Next Manual Tag Counter
Specifies the increment by which the next new parcel curve tag is manually numbered.

## ✅ Alignment

---
**NOTE** This property group is displayed when accessing the settings from the CreateSite command

---

Use these settings to specify default increments for alignment tag numbering.

Alignment Spiral: Next Manual Tag Counter
Specifies the increment by which the next new alignment spiral tag is manually numbered.

Alignment Spiral: Next Automatic Tag Counter
Specifies the increment by which the next new alignment spiral tag is automatically numbered.

Alignment Curve: Next Manual Tag Counter
Specifies the increment by which the next new alignment curve tag is manually numbered.

Alignment Curve: Next Automatic Tag Counter
Specifies the increment by which the next new alignment curve tag is automatically numbered.

Alignment Line: Next Manual Tag Counter
Specifies the increment by which the next new alignment line tag is manually numbered.

Alignment Line: Next Automatic Tag Counter
Specifies the increment by which the next new alignment line tag is automatically numbered.

## ✅ Feature Line

---
**NOTE** This property group is displayed when accessing the settings from the CreateSite command

---

Use this setting to specify defaults for feature line style priority.

Feature Line Style Priority

Specifies the default feature line style priority. Click in the Value column, and click ··· to select a style in the Options Tab (Feature Line Site Properties Dialog Box) (page 1915).

### ⊞ Parcel Analysis

**NOTE** This property group is displayed when accessing the settings from the ExportParcelAnalysis command.

Use these settings to specify defaults for parcel analysis.

Analysis Type
   Specifies whether Inverse Analysis or Mapcheck Analysis is used.

Enable Mapcheck Across Chord
   Specifies whether mapcheck across chord is enabled or disabled.

Process Counter-clockwise
   Specifies whether segments will be processed in counter-clockwise or clockwise order.

**Related procedures:**

■  Editing Parcel Settings (page 824)

■  Editing Parcel Command Settings (page 825)

# Parcel Styles Dialog Box

Use this dialog box to edit settings for parcel styles.

## Information Tab (Parcel Styles Dialog Box)

Use this tab to change a parcel style name or description, or to review details, such as when the parcel style was most recently modified.

Name
   Specifies the name of the parcel style.

Description
   Specifies the description of the parcel style. Enter an optional description.

Created By
   Displays the Windows login name of the person who created the parcel style.

Date Created
   Displays the date and time the parcel style was created.

Last Modified By
   Displays the Windows login name of the person who last modified the parcel style.

Date Modified
   Displays the date and time the parcel style was modified.

For more information, see Information Tab (Style Dialog Box) (page 1801).

**Related procedures:**

■  Parcel Styles (page 828)

## Design Tab (Parcel Styles Dialog Box)

Use this tab to change parcel style settings for fill distance or parcel name template (naming convention).

The fill distance defines the width of the filled area inside the parcel boundary. If the fill distance is observed, the pattern fill is applied to the boundary area only.

Observe Fill Distance
Specifies whether the fill distance is observed. Select the check box to apply the fill to the boundary area only; otherwise, the fill is applied to the entire parcel.

Fill Distance
Specifies the width of the boundary area.

Parcel Name Template
Displays the parcel name template. Click  to open the Name Template dialog box (page 1806). Select or enter values for the parcel name format.

**Related procedures:**

■ Parcel Styles (page 828)

## Display Tab (Parcel Styles Dialog Box)

Use this tab to specify parcel style settings which affect the following parcel segments or area fill: Layer, Color, Linetype, LT Scale, Lineweight, and Visibility. For area fill, you can specify additional settings for a hatch: Pattern, Angle, or Scale.

For more information, see Display Tab (Style Dialog Box) (page 1801).

**Related procedures:**

■ Parcel Styles (page 828)

## Summary Tab (Parcel Styles Dialog Box)

Use this tab to review Information or Design settings for a parcel style. You can copy this information to a spreadsheet.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

**Related procedures:**

■ Parcel Styles (page 828)

# Create Parcels - Layout Dialog Box

Use this dialog box to review settings that are applied to new parcels.

Site
Specifies the site for the new parcels.

Parcel Style
Specifies the parcel style for the new parcels.

**Layers**

Parcel Layer
Specifies the layer for the new parcels.

Parcel Segment Layer
   Specifies the layer for the new parcel segments.

**Label Styles**

Area Label Style
   Specifies the area label style for new parcels.

Line Segment Label Style
   Specifies the line segment label style for new parcels.

Curve Segment Label Style
   Specifies the curve segment label style for new parcels.

Automatically Add Segment Labels
   Specifies whether to add segment labels while segments are created.

Erase Existing Entities
   When creating parcels from objects, specifies whether to erase original objects after parcels are created.
   When the Xref option is selected, this option is disabled.

**Related procedures:**

■

■

# Parcel Layout Parameters Dialog Box

Use this dialog box to change the properties of parcel segments.

Attributes displaying as black text can be edited. Areas that are dimmed (gray) are not available.

---

**NOTE** The constraint definition for each parcel subentity determines which parameters are displayed in the Parcel Layout Parameters window.

---

You cannot dock the Parcel Layout Parameters dialog box. You can pin it, and resize the window.

Use the horizontal and vertical scroll bars when the list is longer or wider than the window.

**General**

Type
   Specifies either Line or Curve as the entity type.

Constraint 1
   Specifies either Fixed, Free, or Floating as the general constraint type.

Constraint 2
   Specifies a detailed description of the entity constraints.

**Geometry (Line)**

Length
   Specifies the line length.

Direction
   Specifies the direction of the line.

**Start Station**

Specifies the starting station of the line for the parcel segment.

**End Station**

Specifies the end station of the line for the parcel segment.

**Start Point**

Specifies the XY coordinates for the start point of the line.

**End Point**

Specifies the XY coordinates for the endpoint of the line.

**Pass Through Point 1**

Specifies the XY coordinates of the first user-specified pass-through point.

**Pass Through Point 2**

Specifies the XY coordinates of the second user-specified pass-through point.

## Geometry (Curve)

**Length**

Specifies the length of the curve entity.

**Radius**

Specifies the radius of the curve entity.

**Delta Angle**

Specifies the included angle of the solved portion of the curve.

**Start Station**

Specifies the starting station of the curve for the solved portion of the alignment. Unsolved curves do not display a start station.

**End Station**

Specifies the end station of the curve for solved portions of the alignment. Unsolved curves do not display an end station.

**Start Direction**

Specifies the direction of the tangent coming into the curve.

**End Direction**

Specifies the direction of the tangent going out of the curve.

**Start Point**

Specifies the XY coordinates of the start point of the curve.

**End Point**

Specifies the XY coordinates of the endpoint of the curve.

**Center Point**

Specifies the XY coordinates of the center point.

**Pass Through Point1**

Specifies the XY coordinates of the first user-specified pass-through point.

**Pass Through Point2**

Specifies the XY coordinates of the second user-specified pass-through point.

**Pass Through Point3**

Specifies the XY coordinates of the third user-specified pass-through point.

Chord Length

    Specifies the distance along the line joining the beginning of the curve (PC) and the end of the curve (PT).

Chord Direction

    Specifies the direction along the line joining the beginning of the curve (PC) and the end of the curve (PT).

Mid-Ordinate

    Specifies the distance from the midpoint of the curve, perpendicular to the midpoint of the chord.

External Tangent

    Specifies the distance from the beginning of the curve (PC) to the PI or from the PI to the end of the curve (PT).

External Secant

    Specifies the radial difference from the PI to the midpoint of the curve.

PI Included Angle

    Specifies the included angle between the incoming and outgoing tangents of the curve.

**Related procedures:**

■  Editing Parcels by Layout (page 820)

# Edit Parcel Properties Dialog Box

Use this dialog box to edit the properties of a group of parcels.

After specifying the parcel style, area label styles, and user-defined properties for one parcel, you can apply them to all selected parcels.

**General**

Left and Right Arrows

    Displays the name of the first selected parcel. Use the arrow keys to view or edit the properties of other parcels.

Parcel Style

    Specifies the parcel style. Editing a style only affects the currently selected parcel. Click  to apply the style to all selected parcels.

Area Selection Label Style

    Specifies the Area Selection Label Style that is applied to the parcel. Click  to apply the area selection label style to all selected parcels.
    Specifies the current area label styles. Click to apply these area label styles to all selected parcels. If you try to add a style that is already in the list, you are prompted to select another style. Click  to add an area style label.

    Click  to delete one or more area label styles. If you do not select at least one style in the list box, you are prompted to select one. If there is only one area label style and you try to delete it, an error message displays.

Area Label Styles

    Specifies the Area Label Styles that are applied to the parcel. Click  to apply these area label styles to all selected parcels.

Specifies the current area label styles. Click to apply these area label styles to all selected parcels. If you try to add a style that is already in the list, you are prompted to select another style. Click ✚ to add an area style label.

Click ✖ to delete one or more area label styles. If you do not select at least one style in the list box, you are prompted to select one. If there is only one area label style and you try to delete it, an error message displays.

User Defined Properties

Lists user-defined properties in the parcel that you are editing. Only the value field can be edited. Click ⟳ to apply the selected property to all selected parcels. If you do not select a property in the list you are prompted to do so. Each parcel must have its own unique number, a parcel number cannot be applied to other parcels.

**Related procedures:**

■ Editing Parcels by Layout (page 820)

■ Editing Parcel Properties (page 825)

# Parcel Layout Tools

Use this toolbar to access tools for working with parcel segments and setting parameters for parcel size.

Create Parcel

Opens the Create Parcels - Layout dialog box (page 2005) where you can change default parcel settings during a layout session.

## Lot Line Tools

Add Fixed Line - Two Points

Draws a lot line as a line segment. Click a starting point and an endpoint in the drawing.

Add Fixed Curve - Three Points

Draws a lot line as a curve segment. Define a starting point, pass-through point, and endpoint.

Add Fixed Curve - Two Points And Radius

Draws a lot line as a curve segment. Define a starting point, radius value, curve direction, and endpoint.

Draw Tangent-Tangent With No Curves

Draws a connected series of lot line segments. Click a sequence of points.

## Parcel Sizing Tools

These tools precisely control the position of individual lot lines while respecting user-defined parameters. The Parcel Sizing Tools create or edit attached lot lines.

Use either the Slide Line Create or Swing Line Create command in automatic mode to create a series of evenly sized adjacent parcels. For manual layout, specify the new location for a lot line by picking a point or dragging the line using OSNAP.

When Parcel Sizing parameters or Automatic Layout options are selected or specified, a corresponding preview graphic displays at the bottom of the Parcel Layout Tools dialog box.

**Slide Line - Create**

Creates one or more new lot lines that you define with start and end points along the frontage, and optionally, an angle relative to the frontage or an absolute direction for the lot line. Relative angles are measured in + degrees, from 0 (toward the endpoint) through 180 (toward the start point). Note that 90 degrees is perpendicular/radial to the frontage definition. Define the direction by means of azimuth, bearing, or two points in the drawing.

**Slide Line - Edit**

Moves a lot line. You can retain or change the line's frontage angle or absolute direction.

**Swing Line - Create**

Creates a lot line defined with start and end points along the frontage and a fixed swing point on the opposite side of the parcel. Adjust the size of the parcel by swinging the lot line to intersect a different point along the frontage, subject to a minimum area and frontage limit.

**Swing Line - Edit**

Moves a lot line by swinging it from one end. Select which end to use as the swing point.

**Free Form Create**

Creates a new lot line. Define an attachment point and a bearing, azimuth, or second attachment point.

### PI Editing Tools

**Insert PI**

Inserts a vertex at the point you click on a parcel segment.

**Delete PI**

Deletes a vertex that you select on a parcel segment, and redraws the lot line between the vertices on either side.

**Break Apart a PI**

Separates end points at the vertex you select. Specify a separation distance.

**NOTE** Breaking a PI does not delete or merge parcels, as deleting segments does. It merely makes parcels incomplete. Affected segments revert to geometry elements, and parcel labels disappear. Geometry elements become parcels again if you reconnect loose vertices to make closed figures.

### Other Tools

**Delete Sub-Entity**

Deletes a parcel subentity, such as a lot line or curve. If you delete a subentity that is not shared by another parcel, the entire parcel is deleted. If you delete a shared subentity, the two parcels that shared it are merged.

**Parcel Union**

Joins two adjacent parcels. The first parcel you select determines the identity and properties of the joined parcel.

**Pick Sub-Entity**

Selects a parcel subentity for display in the Parcel Layout Parameters dialog box. Click Sub-entity Editor before you click this button.

**Sub-Entity Editor**

Opens the Parcel Layout Parameters dialog box (page 2006) where you can review or edit attributes of the selected parcel subentity.

**Undo**

Cancels the previous command.

**Redo**

Repeats the cancelled command.

**Expand the Toolbar**

Opens a property sheet where you can change parameters for new parcel sizing, automatic layout, and manual layout.

## Parcel Sizing Parameters

When a parcel sizing parameter is selected, a graphic displays to illustrate how the parameter affects the result of the current parcel sizing command.

Minimum Area

Specifies the minimum area criteria for new parcels. This value can be changed at anytime during the current command and must be greater than zero.

**NOTE** If the minimum frontage criteria is met, but the minimum area has not, the parcel frontage will be increased until the minimum area is obtained.

Minimum Frontage

Specifies the minimum frontage criteria for new parcels.

**NOTE** If the minimum area criteria is met, but the minimum frontage has not, the parcel area will be increased until the minimum frontage is obtained.

**Use Minimum Frontage At Offset**

Enables/disables the use of the minimum frontage at offset during the parcel sizing commands. This value can be changed at anytime during the current command.

**Frontage Offset**

Specifies the default value for the frontage offset.

**Minimum Width**

Sets the default value for Minimum width. This value must be greater than or equal to zero.

**Minimum Depth**

Specifies the minimum depth criteria used to size new or edit existing parcels. The minimum depth starts at the mid-point of the resulting frontage of the new or edited parcel and is oriented normal (perpendicular) to the intersected frontage segment.

**NOTE** If the minimum area and frontage criteria are met, but not the minimum depth, the frontage and area are increased until the minimum depth is obtained. If no solution is found, a command prompt displays.

**Use Maximum Depth**

Specifies whether the maximum depth criteria is used when creating or editing parcels.

**Maximum Depth**

Specifies the maximum depth criteria for a new or edited parcel.

**NOTE** If the minimum area and frontage criteria are met, and the maximum depth is exceeded, a command prompt displays that no solution is found.

**Multiple Solution Preference**

In certain situations, multiple valid solutions may occur during the creation of new parcels. When multiple valid solutions occur, you can specify which solution is displayed.

Use Shortest Frontage: Specifies that the solution with the shortest frontage is displayed.

Use Smallest Area: Specifies that the solution with the smallest area is displayed.

## Automatic Layout

Automatic Mode

Specifies whether automatic mode is enabled for parcel sizing commands.
On: Enables automatic mode.

Off: Disables automatic mode.

Remainder Distribution

Specifies the method of redistributing the remainder.
Create Parcel From Remainder: Creates a new parcel from the remaining area.

Place Remainder in Last Parcel: Places the remaining area in the last parcel.

Redistribute Remainder: Redistributes the remaining area evenly to every parcel.

**Related procedures:**

■ Creating Parcels by Layout (page 815)

■ Editing Parcels by Layout (page 820)

■ Editing Subdivided Parcels (page 820)

# Parcel Properties Dialog Box

Use this dialog box to change the properties of a single parcel.

You can edit parcel name, description, object style, label style, analysis, and user-defined properties.

# Information Tab (Parcel Properties Dialog Box)

Use this tab to change a parcel, name, description, or style.

Name
Specifies the name of the parcel.

Description
Specifies the description of the parcel. Enter an optional description.

Object Style
Specifies the parcel style applied to the parcel.

Use Name Template In Parcel Style
Specifies whether the parcel name is based on the parcel style name template (page 1806).
Selected: The parcel name is (re)set based on the parcel style name template. The Name field is disabled for manual editing (the Name column is also disabled in List View (page 83)).
Cleared: Manually enter a parcel name in the Name field (You can also edit the Name column in the List View (page 83)).

**NOTE** This manually entered name is not automatically updated with subsequent changes to the parcel number.

Show Tooltips
Controls whether tooltips are displayed for the object in the drawing (not over toolbar icons).

**Related procedures:**

■ Parcel Properties (page 825)

## Composition Tab (Parcel Properties Dialog Box)

Use this tab to change a parcel area label style, or to view its area or perimeter.

Area Selection Label Style

Specifies the area selection label style that is applied to the parcel.

### Parcel Statistics

Area

Displays the area of the parcel.

Perimeter

Displays the perimeter of the parcel.

### Related procedures:

■ Editing Parcel Properties (page 825)

## Analysis Tab (Parcel Properties Dialog Box)

Use this tab to change parcel analysis type, point of beginning, or segment process-order, or to view analysis results.

### Analysis

NOTE Analysis results are displayed in the Result Area, which is the lower portion of the dialog box.

Inverse Analysis

Specifies that Inverse analysis type is used for the parcel.
Inverse analysis provides a sequential report of directions and distances, start and end coordinates, curve data for each parcel segment starting at a specified Point of Beginning (POB), and parcel area.

Mapcheck Analysis

Specifies that Mapcheck analysis type is used for the parcel.
Mapcheck analysis provides the same information as Inverse analysis, except that all start and end coordinates for each parcel segment are computed relative to the coordinates of the POB and the previous segment, using the labeled precision of the parcel segment's direction and distance/curve data. Therefore, error is introduced and accumulated so that the coordinates of the last segment will not equal that of the POB. This is termed 'error of closure'. Mapcheck reports check the plotted drawing for omissions of segment labels to avoid errors that may be introduced into legal documents, such as deed descriptions.

Enable Mapcheck Across Chord

This setting is available only if Mapcheck Analysis is selected.
If mapcheck across chord is enabled, the Mapcheck traverse is calculated for curve segments using their chord length. Otherwise, it is calculated using their curve length.

### Calculation Settings

Point Of Beginning

Specifies the parcel boundary's initial node (start point of its initial segment).

 Point of Beginning Selector

Selects a new point of beginning. Click the button and click a parcel node in the drawing.

Process Segment Order Counter Clockwise

Specifies that segments are processed in counter-clockwise order.

**Result Area**

(Not labeled) Displays analysis results in the lower portion of the dialog box.

**Related procedures:**

■ Parcel Properties (page 825)

# User Defined Properties (Parcel Properties Dialog Box)

Use this tab to review or change user defined parcel properties.

Parcel Number
   Specifies the number assigned to the parcel.

Parcel Address
   Specifies the address of the parcel.

Parcel Tax ID
   Specifies the Tax ID number assigned to the parcel.

**NOTE** The user-defined property classification cannot be defined here. It is set in the Site Parcel Properties dialog.

**Related procedures:**

■ Parcel Properties (page 825)

■ Editing Parcel Properties (page 825)

# Site Parcel Properties Dialog Box

Use this dialog box to change properties of a site parcel.

# Composition Tab (Site Parcel Properties Dialog Box)

Use this tab to change a site parcel's label style, to view its area or perimeter, or to change the display order of parcels that it contains, including the site parcel itself.

Site Parcel Style
   Specifies the style that is applied to the site parcel.

Site Area Label Style
   Specifies the area label style that is applied to the site parcel.
   Specifying <none> hides the site parcel's area label.

Parcel Style Display Order
   Specifies the display order of parcels within the site, including the site parcel itself, according to the styles that are assigned to them.
   The style highest in this list if first in the display order. Where parcels of two different styles share a common segment, the segment appears in the style that is higher in the display order.
   To change a style's list position, select it. Click an Up or Down Arrow. You can also drag a style up or down to a new position.

Parcel Area
   Displays the area of the site parcel.

Parcel Perimeter

Displays the perimeter of the site parcel.

User-defined property classification

Specifies the user-defined property classification used to group user-defined properties.

**Related procedures:**

- Using User-Defined Property Classifications with Parcels (page 853)

- Changing Parcel Display Order (page 827)

- Hiding or Showing Parcel Labels (page 842)

## Analysis Tab (Site Parcel Properties Dialog Box)

Use this tab to change a site parcel's analysis type, its point of beginning, its segment process-order, or to view analysis results.

### Analysis

**NOTE** Analysis results are displayed in the Result Area in the lower portion of the dialog box.

Inverse Analysis

Specifies that Inverse analysis type is used for the parcel.
Inverse analysis provides a sequential report of directions and distances, start and end coordinates, curve data for each parcel segment starting at a specified Point of Beginning (POB), and parcel area.

Mapcheck Analysis

Specifies that Mapcheck analysis type is used for the parcel.
Mapcheck analysis provides the same information as Inverse analysis, except that all start and end coordinates for each parcel segment are computed relative to the coordinates of the POB and the previous segment, using the labeled precision of the parcel segment's direction and distance/curve data. Therefore, error is introduced and accumulated so that the coordinates of the last segment will not equal that of the POB. This is termed 'error of closure'. Mapcheck reports check the plotted drawing for omissions of segment labels to avoid errors that may be introduced into legal documents, such as deed descriptions.

Enable Mapcheck Across Chord

Enables map check across chord. This setting is available only if Mapcheck Analysis is selected.
If mapcheck across chord is enabled, the Mapcheck traverse is calculated for curve segments using their chord length. Otherwise, it is calculated using their curve length.

### Calculation Settings

Point of Beginning

Specifies the site parcel boundary's initial node (start point of its initial segment).

 Point of Beginning Selector

Selects a new point of beginning. Click the button and click a site parcel node in the drawing.

Process Segment Order Counter Clockwise

If selected, segments are processed in counter-clockwise order.

### Result Area

(Not labeled) Displays analysis results in the lower portion of the dialog box.

# Export Parcel Analysis Dialog Box

Use this dialog box to export multiple inverse or mapcheck parcel analysis reports to a chosen location.

**NOTE** To perform a Mapcheck Analysis on parcel labels, click General menu ➤ Mapcheck Analysis. For more information, see Performing a Mapcheck Analysis (page 1608).

Destination File

Specifies the file name and the location to export the analysis report to. Enter the name and file path into the edit box or click to browse to a location. The edit box will default to the last used location.

## Analysis Type

Inverse Analysis

Specifies that Inverse analysis type is used for the parcel.
Inverse analysis provides a sequential report of directions and distances, start and end coordinates, curve data for each parcel segment starting at a specified Point of Beginning (POB), and parcel area.

Mapcheck Analysis

Specifies that Mapcheck analysis type is used for the parcel.
Mapcheck analysis provides the same information as Inverse analysis, except that all start and end coordinates for each parcel segment are computed relative to the coordinates of the POB and the previous segment, using the labeled precision of the parcel segment's direction and distance/curve data. Therefore, error is introduced and accumulated so that the coordinates of the last segment will not equal that of the POB. This is termed 'error of closure'. Mapcheck reports check the plotted drawing for omissions of segment labels to avoid errors that may be introduced into legal documents, such as deed descriptions.

Enable Mapcheck Across Chord

Enables map check across chord. This setting is available only if Mapcheck Analysis is selected.
If mapcheck across chord is enabled, the Mapcheck traverse is calculated for curve segments using their chord length. Otherwise, it is calculated using their curve length.

Process Segment Order Counter Clockwise

If selected, segments are processed in counter-clockwise order.

**Related procedures:**

■   Exporting a Parcel Inverse or Mapcheck Report (page 830)

# Renumber/Rename Parcels Dialog Box

Use this dialog box to renumber and/or rename parcels.

Parcel names using the parcel style name template (page 1806) (with the parcel number property) are updated automatically.

The default Starting Number is inherited from Parcel: Next Manual Area Counter on the Numbering tab of the Site Properties dialog box for the site you are working with. After you renumber a set of parcels, the site retains the next available number.

Site Name

Specifies the site in which you are renumbering parcels.

Renumber

Specifies whether to renumber the selected parcels. The names of the parcels may or may not be dynamically changed, depending on the other settings.

Starting Number

Specifies the next number that will be used for the selected parcel. If a duplicate number occurs, the current parcel's number and the duplicate parcel's number are swapped.

Increment Value

Specifies the difference between numbers in the sequence.

Use Name Template In Parcel Style

Specifies whether the names of the selected parcels are obtained from the parcel style name template. Selected: The parcel name is (re)set based on the parcel style name template.
Cleared: The parcel number will change and, depending on the current properties of the selected parcel, the parcel name may update.

Rename

Specifies whether the selected parcels will be renamed.

Specify The Parcel Name

Manually enter the parcel name. Note that this hard-coded name is no longer the "dynamic" name that updates if parcels are renumbered.

Click  to open the Name Template dialog box (page 1806). Select or enter values for the parcel name format. The parameters specified are returned and displayed in the Specify The Parcel Name field.

Use Name Template In Parcel Style

Specifies that the names of the selected parcels will be reset using the specified parcel style name template.

**Related procedures:**

■  Renumbering Parcels (page 850)

■  Numbering Parcel Segments (page 852)

# Create Right of Way Dialog Box

Use this dialog box to offset parcel boundaries from both sides of an alignment.

## Create Parcel Right Of Way

Offset From Alignment

Specifies the offset distance of each side of the right-of-way from the alignment.

## Cleanup At Parcel Boundaries

Fillet Radius At Parcel Boundary Intersections

Specifies the fillet radius or chamfer distance at boundary intersections.

Cleanup Method

None: Specifies that no cleanup is used at parcel boundary intersections.
Fillet: Specifies that a fillet is used at parcel boundary intersections. A fillet connects the parcel boundaries with an arc that is tangent to the boundaries and has a radius specified by Fillet Radius At Parcel Boundary Intersections.
Chamfer: Specifies that a chamfer is used at parcel boundary intersections. A chamfer connects the parcel boundaries with an angled line at a chamfer distance specified by Fillet Radius At Parcel Boundary Intersections.

## Cleanup At Alignment Intersections

Fillet Radius At Alignment Intersections

Specifies the fillet radius or chamfer distance at alignment intersections.

Cleanup Method

None: Specifies that no cleanup is used at alignment boundary intersections.

Fillet: Specifies that a fillet is used at alignment intersections. A fillet connects the alignment boundaries with an arc that is tangent to the alignments and has a radius specified by Fillet Radius At Alignment Intersections.

Chamfer: Specifies that a chamfer is used at alignment intersections. A chamfer connects the alignments with an angled line at a chamfer distance specified by Fillet Radius At Alignment Intersections.

**Related procedures:**

■ Creating a Right of Way (page 822)

# Parcel Move To/Copy To Site Dialog Boxes

Use these common dialog boxes to move or copy parcels from one site to another.

The contents of an entire site, including alignments, grading groups, or parcels, can be moved or copied together. For more information, see Move To Site dialog box (page 2327) and Copy To Site dialog box (page 2328).

**Related procedures:**

■ Move Objects to a Site (page 726)

■ Copy Objects to a Site (page 727)

# Pipe Networks Dialog Boxes

# 61

Use the following links to access information about the Pipe Networks dialog boxes.

## Create Pipe Network By Layout Dialog Box

Use this dialog box to enter the initial pipe network creation parameters such as a name, optional description, parts list, layer, and more.

Also, you can select a surface and/or an alignment to associate with the pipe network, as well as styles for structure and pipe labels.

Network Name

Specifies the name of the pipe network. Each pipe network must have a unique name.

Opens the Name Template (page 1806) dialog box, where you can modify the pipe network naming template.

Network Description

Specifies an optional description for the pipe network.

Network Parts List

Specifies the parts list associated with this pipe network.

Layers

Opens the Pipe Network Layers (page 2063) dialog box, where you can assign various views of the pipe network components to specific layers in the drawing.

Surface Name

Specifies the surface associated with this pipe network.

Alignment Name

Specifies the alignment associated with this pipe network.

### Structure Label Style

Style List

Displays the current style. Click the arrow to display the structure label styles in the drawing.

Style Selection

Specifies the style options. Create a new style, copy or edit the current style selection, or pick a style from the drawing.

 Style Detail

Opens the Style Detail dialog box, where you can preview the style and creation information.

**Pipe Label Style**

Style List

Displays the current style. Click the arrow to display the pipe label styles in the drawing.

Style Selection

Specifies the style options. Create a new style, copy or edit the current style selection, or pick a style from the drawing.

 Style Detail

Opens the Style Detail dialog box, where you can preview the style and creation information.

**Related procedures:**

■ Creating a Pipe Network Using the Layout Tools (page 1192)

# Create Pipe Network From Object Dialog Box

Use this dialog box to create a pipe network from a drawing entity such as a line, polyline, arc, or feature line.

Using this feature, you can select one of the following entity types in a drawing and create a pipe network from it: line, 2D or 3D polylines, 2D spline polyline, arc, feature line.

You are prompted to enter the initial pipe network creation parameters, including a pipe network name, description, parts list, layers, and more. Also, you can select a surface and/or an alignment to associate with the pipe network.

When using this feature, if the selected parts list has a mismatch with the selected catalog, the OK button is disabled, as well as the selector for the structure, where the structure types within the parts list have a mismatch with the currently selected catalog. An error message will also be displayed informing you that parts in the selected part list cannot be found in the current catalog. You are prompted to select a different part list or to select the correct catalog.

Network Name

Specifies the name of the pipe network. Each pipe network must have a unique name.

Opens the Name Template (page 1806) dialog box, where you can modify the pipe network naming template.

Network Description

Specifies an optional description for the pipe network.

Network Parts List

Specifies the parts list associated with this pipe network.

Pipe To Create

Specifies the part that will be used to represent pipes in this pipe network.

Structure To Create

Specifies the part that will be used to represent structures in this pipe network.

Layers

Opens the Pipe Network Layers (page 2063) dialog box, where you can assign various views of the pipe network components to specific layers in the drawing.

Surface Name

Specifies the surface associated with this pipe network.

Alignment Name

Specifies the alignment associated with this pipe network.

Erase Existing Entity

Specifies whether the entity (object) you selected will be erased automatically when you create the pipe network. Select the check box to erase the entity automatically when you create the pipe network.

NOTE This option is disabled when you select an object from an XREF.

Use Vertex Elevations

When this option is selected, the elevations of any vertexes along the selected entity are used to set the elevations of the pipes created in the network. For 3D entity types, this option determines if the 3D vertex elevations are honored by the pipes created. When selecting this option, rules are not applied, since they would likely be in conflict with the vertex elevations.

**Related procedures:**

■ Creating Pipe Networks from Objects (page 1194)

# Create Alignment From Network Dialog Box

Use this dialog box to create an alignment by selecting parts within a pipe network.

You can optionally create a profile and profile view as you create the new alignment.

Site

Specifies a site for the alignment. Either select a site from the Site list or click [icon] to select an object in the drawing. The alignment and the object you select in the drawing are associated with the same site.

NOTE The default Site selection is <None>, which places the alignment in the top-level Alignments collection in Prospector. See Alignment and Site Interaction (page 721) for more information.

Name

Specifies the name of the alignment. Each alignment style must have a unique name.

Description

Specifies an optional description for the alignment.

Starting Station

Specifies the start station for the alignment.

**Alignment Style**

Style List

Displays the current style. Click the arrow to display the alignment styles in the drawing.

Style Selection

Specifies the style options. You can create a new style, copy or edit the current style selection, or pick a style from drawing.

 Style Detail

> Opens the Style Detail dialog box. Preview the style and creation information.

Alignment Layer

> Displays the layer on which the alignment object will be created. To change the layer click the Object Layer icon and select a layer.

 Object Layer

> Opens the Object Layer dialog box. Click  to create a new layer on which the alignment will be drawn.

Alignment Label Set

> Lists the alignment Label Set styles in the drawing. Use the Selection icon to change the current style or create a new style. The Style Detail icon previews the current style.

Create Profile and Profile View

> Specifies whether a profile and a profile view are created for the alignment. If you select this check box, the Create Profile View dialog box (page 2145) is displayed.

**Related procedures:**

- Creating Alignments from Pipe Network Parts (page 1196)

- Creating Alignments (page 887)

# Edit Feature Settings - Pipe Network Dialog Box

Use this dialog box to view and change pipe network-related settings.

This topic documents settings in all pipe network-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

- Drawing-level ambient settings are identified by the  drawing icon.

- Pipe network feature settings are listed near the top of this dialog box, after the General property group, and are identified by the  pipe network icon.

- Pipe network command settings are identified by the  command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

##  Default Styles

Use these settings to establish the default styles assigned to pipe network components.

Interference Default Style

> Specifies the default style for interference in the pipe network. Click in the Value column, and click  to select a style in the Interference Default Style dialog box.

Structure Default Style

> Specifies the default style for structures in the pipe network.Click in the Value column, and click  to select a style in the Structure Default Style dialog box.

Pipe Default Style

Specifies the default style for pipes in the pipe network. Click in the Value column, and click ⊡ to select a style in the Pipe Default Style dialog box.

Interference Render Material

Specifies the default interference render material in the pipe network. Click in the Value column, and click ⊡ to select a style in the Interference Render Material dialog box.

Structure Plan Label Style

Specifies the default style for structure labels that are displayed in plan view. Click in the Value column, and click ⊡ to select a style in the Structure Plan Label Style dialog box.

Pipe Plan Label Style

Specifies the default style for pipe labels that are displayed in plan view. Click in the Value column, and click ⊡ to select a style in the Pipe Plan Label Style dialog box.

Structure Profile Label Style

Specifies the default style for structure labels that are displayed in a profile view. Click in the Value column, and click ⊡ to select a style in the Structure Profile Label Style dialog box.

Pipe Profile Label Style

Specifies the default style for pipe labels that are displayed in profile view. Click in the Value column, and click ⊡ to select a style in the Pipe Profile Label Style dialog box.

Structure Section Label Style

Specifies the default style for structure labels that are displayed in a section view. Click in the Value column, and click ⊡ to select a style in the Structure Section Label Style dialog box.

Pipe Section Label Style

Specifies the default style for pipe labels that are displayed in section view. Click in the Value column, and click ⊡ to select a style in the Pipe Section Label Style dialog box.

Render Material

Specifies the default render material in the pipe network. Click in the Value column, and click ⊡ to select a style in the Render Material dialog box.

Default Parts List

Specifies the default parts list for the pipe network. Click in the Value column, and click ⊡ to select a style in the Default Parts List dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

### 🏃 Default Name Format

Use these settings to specify the default name formats for pipe network components (pipe network, pipes, structures). Click in the Value column, and click ⊡ to make changes in the Name Template dialog box (page 1806).

### 🏃 Default Rules

Use these settings to establish the default rule set assigned to pipes and structures that are added to the pipe network.

Structure Default Rules

Specifies the default rule set assigned to structures. Click in the Value column, and click ⊡ to select a set in the Structure Default Rules dialog box.

Pipe Default Rules

Specifies the default rule set assigned to pipes. Click in the Value column, and click ⊡ to select a set in the Pipe Default Rules dialog box.

## Storm Sewers Migration Defaults

Use these settings to establish the defaults for part matching, and the default parts list, used when migrating pipe network data between the Storm Sewers Extension and AutoCAD Civil.

Part Matching Defaults

Specifies the defaults used for part matching when migrating pipe network data between the Storm Sewers Extension and AutoCAD Civil. Click in the Value column, and click ⊡ to display the Part Matchup Settings dialog box (page 2079) for importing and exporting. For more information, see Setting Part Matching Defaults for Migration (page 1276).

Parts List Used For Migration

Specifies the default parts list used when migrating pipe network data between the Storm Sewers Extension and AutoCAD Civil. Click in the Value column, and click ⊡ to select a parts list. For more information, see Setting the Default Parts List For Migration (page 1277).

## Default Profile Label Placement

Use these settings to establish the default placement of profile view labels associated with the pipe network.

Dimension Anchor Option for Pipes

Specifies the location of the dimension line anchor for profile view labels for pipes:

- Fixed

- Above

- Below

- Graph View Top

- Graph View Bottom

Dimension Anchor Elevation Value for Pipes

Specifies the default elevation of the dimension line anchor for profile view labels for pipes. Enter an elevation in the Value column or click ▦ and select an elevation in the drawing area.

Dimension Anchor Plot Height Value for Pipes

Specifies the default plot height of the dimension line anchor for profile view labels for pipes. Enter a height in the Value column.

Dimension Anchor Option for Structures

Specifies the location of the dimension line anchor for profile view labels for structures:

- Fixed

- Above

- Below

- Graph View Top

- Graph View Bottom

Dimension Anchor Elevation Value for Structures

Specifies the default elevation of the dimension line anchor for profile view labels for structures. Enter an elevation in the Value column or click  and select an elevation in the drawing area.

Dimension Anchor Plot Height Value for Structures

Specifies the default plot height of the dimension line anchor for profile view labels for structures. Enter a height in the Value column.

Structure Label Placement

Specifies the default location of structure labels:.

- At Top Of Structure

- At Middle Of Structure

- At Bottom Of Structure

## Default Section Label Placement

Use these settings to establish the default placement of section view labels associated with the pipe network.

Dimension Anchor Option for Pipes

Specifies the location of the dimension line anchor for section view labels for pipes:

- Fixed

- Above

- Below

- Graph View Top

- Graph View Bottom

Dimension Anchor Elevation Value for Pipes

Specifies the default elevation of the dimension line anchor for section view labels for pipes. Enter an elevation in the Value column or click  and select an elevation in the drawing area.

Dimension Anchor Plot Height Value for Pipes

Specifies the default plot height of the dimension line anchor for section view labels for pipes. Enter a height in the Value column.

Dimension Anchor Option for Structures

Specifies the location of the dimension line anchor for section view labels for structures:

- Fixed

- Above

- Below

- Graph View Top

- Graph View Bottom

Dimension Anchor Elevation Value for Structures

Specifies the default elevation of the dimension line anchor for section view labels for structures. Enter an elevation in the Value column or click  and select an elevation in the drawing area.

Dimension Anchor Plot Height Value for Structures

Specifies the default plot height of the dimension line anchor for section view labels for structures. Enter a height in the Value column.

Structure Label Placement

Specifies the default location of structure labels:

- At Top Of Structure

- At Middle Of Structure

- At Bottom Of Structure

Pipe Section Label Placement

Specifies the default location of pipe labels displayed in section views:

- At Top Of Structure

- At Middle Of Structure

- At Bottom Of Structure

## Table Creation

**NOTE** This property group is displayed when accessing the settings from the AddNetworkPipeTable and AddNetworkStructTable commands.

Use these settings to establish the defaults when you add a network pipe or structure table.

Table Style

Specifies the style for a table. Click in the Value column, and click ⋯ to select a style in the Table Style dialog box.

Split Table

Specifies whether a table is split into two or more sections after a specified maximum number of rows has been met.

Maximum Number of Rows

Specifies the maximum number of rows to include per section. If the number of data rows exceeds the specified maximum, the table is split into sections, and they are displayed either side by side (left to right), or stacked vertically.

Maximum Tables Per Stack

Specifies the maximum number of sections to include in each stack.

Table Spacing

Specifies the spacing between tables.

Tile Direction

Specifies the direction in which the table tiles (across or down).

## Label New Parts

**NOTE** This property group is displayed when accessing the settings from the CreateNetwork command.

Use these settings to establish the default labeling when you add parts to a network.

Pipe in Plan

Specifies whether a new pipe is labeled by default when placed in plan view.

**Pipe Profile**

Specifies whether a new pipe is labeled by default when placed in profile view.

**Structure in Plan**

Specifies whether a new structure is labeled by default when placed in plan view.

**Structure Profile**

Specifies whether a new structure is labeled by default when placed in profile view.

**Related procedures:**

■ Editing Pipe Network Settings (page 1201)

# Edit Feature Settings - Pipe Dialog Box

Use this dialog box to view and change standard drawing ambient settings for pipe objects.

The standard ambient settings are preceded with ⬜ . For feature-specific pipe object setting information, see Edit Feature Settings - Pipe Network Dialog Box (page 2026).

For more information about this dialog box, see Working with the Standard Settings Dialog Box Controls (page 62).

**Related procedures:**

■ Editing Pipe Network Settings (page 1201)

# Edit Feature Settings - Structure Dialog Box

Use this dialog box to view and change standard drawing ambient settings for structure objects.

The standard ambient settings are preceded with ⬜ . For feature-specific structure object setting information, see Edit Feature Settings - Pipe Network Dialog Box (page 2026).

For more information about this dialog box, see Working with the Standard Settings Dialog Box Controls (page 62).

**Related procedures:**

■ Editing Pipe Network Settings (page 1201)

# Network Layout Tools

Use this toolbar to create or edit a pipe network.

The names of the parts list, surface, and alignment referenced in the currently selected pipe network are displayed at the bottom of this toolbar.

⬛ **Pipe Network Properties**

Opens the Pipe Network Properties (page 2033) dialog box, where you can control defaults and properties of the pipe network, such as the referenced parts list, object references, label defaults, and more.

 Select Surface

Opens the Select Surface dialog box, where you can specify the surface referenced by any new parts to be added to the network. When a surface is selected, it is used to determine depths and elevations of pipe network parts, based on rules for the part. If there are no surfaces in the drawing, this button is not available. Changes made to this selection will not affect parts already created in the pipe network.

 Select Alignment

Opens the Select Alignment dialog box, where you can specify the alignment referenced by any new parts to be added to the network. If there are no alignments in the drawing, this button is not available. Changes made to this selection will not affect parts already created in the pipe network. The alignment provides station offset values for the pipe network parts, including the default alignment for labels.

 Parts List

Opens the Select Parts List dialog box, where you can specify the parts list referenced by the current pipe network. The parts list controls the set of pipes and structures that are available to add in the current pipe network.

Structure List

Specifies the type of structure currently selected for insertion into this pipe network.

Pipe List

Specifies the type of pipe currently selected for insertion into this pipe network.

 Drawing Commands

This drop-down button lets you specify whether to insert both pipes and structures, only pipes, or only structures.

 When Pipes And Structures mode is selected, a structure is inserted at the first selection point, followed by a pipe. Subsequent selection points continue to insert structures connected to pipes.

 When Pipes Only mode is selected, you are prompted to select the start and end points for each pipe you insert. You can only insert pipes in this mode.

 When Structures Only mode is selected, you are prompted to select the insertion points for each structure you insert. You can only insert structures in this mode.

---

**NOTE** The initial default command is Pipes and Structures. The initial prompt is `Specify the structure insertion point:` When reopening the toolbar, the default command is the last command that was used.

---

 Toggle Upslope/Downslope

Specifies whether the slope of the pipe network is upstream or downstream. This button acts as a toggle.

When  is displayed, the pipe network slope attribute is set to downslope. When is  displayed the slope attribute is set to upslope. This also ensures that pipe rules are processed correctly.

 Delete Pipe Network Object

Deletes the specified pipe network part from the drawing.

 Pipe Network Vistas

Opens the Panorama window (page 102). Lets you display and edit the pipe network data in vistas. There is a vista for pipe object data and a vista for structure object data. For more information, see Pipe Network Vistas (page 2064).

⇦ Undo

Reverses the last action.

# Pipe Network Properties Dialog Box

Use this dialog box to change the pipe network name, description, default settings, layers, labels, and settings for profile and section views.

You can change the style, parts list, surface, alignment, or layers of a selected pipe network. You can also change style and layers for how the pipe network is displayed in profile and section views.

## Information Tab (Pipe Network Properties Dialog Box)

Use this tab to view or change general information for the pipe network.

Name

Specifies the name of the current pipe network.

Description

Specifies the description for the current pipe network.

Show Tooltips

Specifies whether tooltips are displayed for the object in the drawing (not over toolbar icons).

## Layout Settings Tab (Pipe Network Properties Dialog Box)

Use this tab to view and edit the default parameters used for the current pipe network during layout (plan view) mode.

The parameters include labels, parts list, layers, and name templates.

### Labels

Structure Plan Label Style

Specifies the label style used for structures inserted into this pipe network during layout (plan view) mode.

Pipe Plan Label Style

Specifies the label style used for pipes inserted into this pipe network during layout (plan view) mode.

### Network Parts List

Parts List

Specifies a parts list for this pipe network. Use the parts list to select parts (pipes and structures) that can be inserted into the current pipe network. For more information, see Part Catalog and Parts Lists (page 1237).

### Default Object Reference

Surface Name

Displays the name of the surface that is referenced by this pipe network. The surface provides elevation data to the pipe network objects.

Alignment Name

Displays the name of the alignment that is referenced by this pipe network. The alignment provides station and offset data to the pipe network objects.

### Default Network Layers

Pipe Plan Layer

Specifies the default layer used when creating pipe objects within this pipe network. After the pipe object is created, you can change the layer using any of the standard AutoCAD layer features.

Structure Plan Layer

Specifies the default layer used when creating structure objects within this pipe network. After the structure object is created, you can change the layer using any of the standard AutoCAD layer features.

### Name Templates

Pipes

Specifies the object name template used when creating pipe objects within this pipe network.

Structures

Specifies the object name template used when creating structure objects within this pipe network.

## Profile Tab (Pipe Network Properties)

Use this tab to set default label styles and layers for the pipe network objects when they are displayed in a profile view.

### Labels

Structure Profile Label Style

Specifies the label style used to display the structures within this pipe network in a profile view.

Pipe Profile Label Style

Specifies the label style used to display the pipes within this pipe network in a profile view.

### Default Profile Layers

Pipe Profile Layer

Specifies the default layer used to display the pipes within this pipe network in a profile view.

Structure Profile Layer

Specifies the default layer used to display the structures within this pipe network in a profile view.

## Section Tab (Pipe Network Properties)

Use this tab to set the default layer for the pipe network objects when they are displayed in a section view.

### Default Section Layers

Network Section Layer

Specifies the default layer used to display this pipe network in a section view.

## Statistics Tab (Pipe Network Properties Dialog Box)

Use this tab to display pipe network statistics that are based on the current state of the pipe network.

### General

Displays the general statistics for the current pipe network.

Minimum Elevation

Displays the minimum elevation value found in the pipe network.

Maximum Elevation

Displays the maximum elevation value found in the pipe network.

**Pipes**

Total Number of Pipes

Displays the total number of pipes in this pipe network.

**Structures**

Total Number of Structures

Displays the total number of structures, including null structures, in this pipe network.

Inlet-Outlet Structure

Displays the total number of inlet/outlet structures in this pipe network.

Junction Structure

Displays the total number of junction structures in this pipe network.

Null Structures

Displays the total number of null structures in this pipe network.

**References**

Alignments

Displays the total number of alignments referenced in this pipe network.

Surfaces

Displays the total number of surfaces referenced in this pipe network.

# Network Parts List Dialog Box

Use this dialog box to create a new pipe network parts list, or to view or change the properties and/or contents of a parts list.

# Information Tab (Network Parts List Dialog Box)

Use this tab to view or change general information for the pipe network parts list.

Name

Specifies the name of the current parts list.

Description

Specifies the description for the current parts list.

# Pipes Tab (Network Parts List Dialog Box)

Use this tab to view or change the pipe sizes included in the parts list.

You can add new pipe sizes to the parts list or remove pipe sizes from the parts list. Each size selection matches a part size from a part family in the part catalog. Optional properties may also be set on the part size. The combined set of selected and optional properties is assigned to the pipe when it is inserted into the drawing.

Name

This tree view displays the name of the parts list at the top level, and then the names of the part families included in the parts list, and then the names of the part sizes included in each part family. Note when

a new size is added to the parts list, it is assigned a default unique name. The size name can be edited (renamed) to any unique name within the part family size list.

Style

Specifies the default style assigned to the pipe when it is inserted into the drawing. Select a part family and click the Select All Edit icon  to assign the selected style to all part sizes within that family.

Rules

Specifies the default rules assigned to the pipe when it is inserted into the drawing. Select a part family and click the Select All Edit icon  to assign the selected style to all part sizes within that family.

Render Material

Specifies the default render material assigned to the pipe when it is inserted into the drawing. Select a part family and click the Select All Edit icon  to assign the selected style to all part sizes within that family.

## Structures Tab (Network Parts List Dialog Box)

Use this tab to view or change the structure sizes included in the parts list.

You can add new structure sizes to the parts list or remove structure sizes from the parts list. Each size selection matches a part size from a part family in the part catalog. Optional properties may also be set on the part size. The combined set of selected and optional properties is assigned to the structure when it is inserted into the drawing.

Name

This tree view displays the name of the parts list at the top level, and then the names of the part families included in the parts list, and then the names of the part sizes included in each part family. Note when a new size is added to the parts list, it is assigned a default unique name. The size name can be edited (renamed) to any unique name within the part family size list.

Style

Specifies the default style assigned to the structure when it is inserted into the drawing. Select a part family and click the Select All Edit icon  to assign the selected style to all part sizes within that family.

Rules

Specifies the default rules assigned to the structure when it is inserted into the drawing. Select a part family and click the Select All Edit icon  to assign the selected style to all part sizes within that family.

Render Material

Specifies the default render material assigned to the structure when it is inserted into the drawing. Select a part family and click the Select All Edit icon  to assign the selected style to all part sizes within that family.

## Summary Tab (Network Parts List)

Use this tab to view information and statistics related to the part list.

### Information

Displays general information about the current parts list.

### Statistics

Number of Pipes

Displays the total number of pipes in this parts list.

Number of Structures

Displays the total number of structures in this parts list.

# Part Catalog Dialog Box

Use this dialog box to view the contents of the part catalog and to select the items you want to add to a parts list.

The tree view in the left pane displays the available part types in the part catalog. Parts are organized by type (for example, "Catch Basins"), and then by part family ("Concentric Catch Basin 1"). If you access the Part Catalog dialog box from the Pipes tab of the Network Parts List dialog box, only available pipe part families are displayed. Similarly, if you access the Part Catalog dialog box from the Structures tab of the Network Parts List dialog box, only available structure part families are displayed.

When a part family is selected in the left pane, a preview image of the part shape is displayed in the right pane.

**NOTE** Items that are already included in the current parts list are not displayed in the part catalog. Only items that are available to be added to the parts list are displayed in the catalog.

**Related procedures:**

■ Creating a Parts List (page 1238)

# Pipe Rule Set Dialog Box

Use this dialog box to view or edit the set of rules that can be assigned to pipes in a pipe network.

# Information Tab (Pipe Rule Set Dialog Box)

Use this tab to view or edit basic information about this pipe rules set.

You can view or edit the name and optional description values, and you can view information about when the rule set was created and last modified.

# Rules Tab (Pipe Rule Set Dialog Box)

Use this tab to view or edit the rules included in this set of pipe rules.

You can change values of existing rules, add rules, or delete rules. You can also change the order in which rules are processed by changing the order they appear on this dialog. For more information, see Part Rules (page 1247).

**NOTE** Rules are not applied to pipes or structures when importing pipe networks from either LandXML or from the Storm Sewers Extension.

**Add Rule**

Click this button to display the Add Rule dialog box (page 2069) where you can select a new rule to add to this rule set.

**Delete Rule**

You can remove a rule from the rule set by selecting the rule on this dialog box and clicking this button.

### Up and Down Arrow Buttons

⇧ ⇩ You can change the order in which rules are processed by changing the order they appear on this dialog. Rules are processed sequentially, starting from the rule displaying at the bottom of this dialog box, and ending with the rule displayed at the top of this dialog box.

### Cover And Slope

This rule ensures that a pipe slopes appropriately and warns when a pipe is placed too close to a ground surface. For more information, see Cover And Slope Rule (page 1251).

Maximum Cover

Specifies the maximum cover of soil over the length of the pipe, based on the surface being referenced by that pipe. If the maximum cover is exceeded, a rule violation occurs. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

Maximum Slope

Specifies the maximum slope of the pipe, expressed in percent. If the pipe slope is greater than the maximum, a rule violation occurs for that object.

Minimum Cover

Specifies the minimum cover of soil over the pipe, based on the surface being referenced by that pipe. During layout, a pipe will be created that attempts to maintain the minimum cover. This is also used to determine the initial elevations of the pipe. If the pipe is edited so that its cover is less than the minimum cover value, a rule violation occurs for that object.

Minimum Slope

Specifies the minimum slope of the pipe, expressed in percent. During layout, a pipe will be created according to its minimum slope rule value. If the pipe is edited so that its slope is less than the minimum, you can still edit the pipe as desired, breaking the minimum slope rule, but a rule violation occurs for that object.

### Cover Only

This rule is intended for laying out pipes in a pressure-based pipe network where pipe elevations are determined according to a specified depth below a terrain. This rule ensures that the minimum cover is met along the length of the pipe, and also validates that both the minimum and maximum cover values are not violated along any length of the pipe. For more information, see Cover Only Rule (page 1252).

Maximum Cover

This is the maximum cover of soil over the pipe, based on the surface being referenced by that pipe. If the pipe cover exceeds the maximum cover value, a rule violation occurs for that object. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

Minimum Cover

This rule represents the minimum cover of soil over the pipe, based on the surface being referenced by that pipe. During layout, a pipe will be created that attempts to maintain the minimum cover. If the pipe is edited so that its cover is less than the minimum cover value, a rule violation occurs for that object.

### Length Check

This rule governs the behavior that produces a warning condition on a pipe if the pipe length exceeds the value specified for the maximum pipe length, or is less than the value specified for the minimum pipe length. For more information, see Length Check Rule (page 1252).

Maximum Length

Specifies a maximum length for pipes. When this rule is in use, you can still draw pipes that exceed the defined maximum pipe length. However, the object will be displayed with a warning icon in the Prospector

list view. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

Minimum Length

Specifies a minimum length for pipes. When this rule is in use, you can still draw pipes that are shorter than the defined minimum pipe length. However, the object will be displayed with a warning icon in the Prospector list view. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is not met.

### Pipe To Pipe Match

This rule governs how a pipe elevation is determined in a pipe network that contains only pipes (no structures), and or when a pipe is inserted onto an existing pipe to break the pipe. For more information, see Pipe To Pipe Match Rule (page 1253).

Match Location

This parameter controls whether the inserted pipe holds to the pipe's invert, crown, or centerline elevation (location).

Drop Value

The drop value on a structure can determine a pipe's depth.

# Pipe Properties Dialog Box

Use this dialog box to view or change the properties of a pipe object.

You can change the name of the pipe object, description, style, render material, and more. You can also change part properties and rules.

When you add a pipe to a pipe network, much of the information about the pipe, such as its description and properties, is derived from the definition of the pipe in the part catalog. After the pipe is inserted into a drawing, you can make changes using this dialog box. When you make changes to the pipe, these changes apply only to the selected pipe in your drawing. The pipe definition in the part catalog is not affected by your modifications in the drawing.

For descriptions of part properties, see Part Properties (page 1235).

# Information Tab (Pipe Properties Dialog Box)

Use this tab to change the name, description, and style information for the pipe.

Name

Specifies the name of the current pipe.

Description

Specifies an optional description of the current pipe.

Object Styles

Specifies the pipe style. Select other styles from the list.

Style

Specifies the style options. Click to create a new style, copy or edit the current style selection, or pick a style from drawing. Click to open the Style Detail dialog box, where you can preview the style and creation information

Render Material

Specifies the default render material assigned to the pipe when it is inserted into the drawing. Click ![icon]
to select a render material from the drawing.

Show Tooltips

Controls whether or not tooltips are displayed for the object in the drawing.

# Part Properties Tab (Pipe Properties Dialog Box)

Use this tab to view or edit properties associated with this pipe.

This tab displays the properties associated with this pipe, along with their current values. Pipe properties
define a variety of characteristics of the pipe object, including its basic size and shape, and certain behaviors
such as flow direction and conditions under which the pipe part will automatically adjust its size.

Certain properties are specific to a type of pipe. For example, circular shaped pipes use the Inner Pipe Diameter
property while rectangular shaped pipes use the Inner Pipe Width and Inner Pipe Height properties.

Some properties are read-only and others are editable. To change an editable property, double-click on the
Value field and enter in a new value, or select one from the list. For more information, see Part Properties
(page 1235).

## General

These properties specify general characteristics of the pipe, such as the flow direction method, flow direction,
and the surface and alignment referenced.

Pipe Flow Direction Method

Specifies the method that is used to determine the flow for this pipe. Option are bi-directional, start to
end, end to start, or according to the current slope of the pipe.

Flow Direction

Specifies the current flow direction of the pipe, relative to the start and endpoint of the pipe. When you
begin drawing a pipe, the flow direction is based on the direction in which you draw the pipe.

Reference Surface

Specifies the surface of the pipe.

Reference Alignment

Specifies the alignment of the pipe.

## Geometry

These properties specify characteristics such as the names of the start and end structures, bearing, station
data, offsets, slope data, elevation data, and more.

Pipe Start Structure

Specifies the name of the structure connected to the start of the pipe.

Pipe End Structure

Specifies the name of the structure connected to the end of the pipe.

Bearing

Specifies pipe's bearing.

Pipe Start Station

Specifies pipe's start station.

Pipe End Station

Specifies pipe's end station.

**Start Offset**

Specifies the offset for the start of the pipe.

**End Offset**

Specifies the offset for the end of the pipe.

**Pipe Slope (Hold Start)**

Specifies the slope of the pipe away from the pipe's start point.

**Pipe Slope (Hold End)**

Specifies the slope of the pipe away from the pipe's end point.

**Pipe Slope**

Specifies the pipe's slope in absolute value.

**Start Invert Elevation**

Specifies the pipe's starting point elevation according to the pipe's invert.

**End Invert Elevation**

Specifies the pipe's ending point elevation according to the pipe's invert.

**Start Crown Elevation**

Specifies the pipe's starting point elevation according to the pipe's crown.

**End Crown Elevation**

Specifies the pipe's ending point elevation according to the pipe's crown.

**Pipe Start Easting**

Specifies the easting of the pipe's starting point.

**Pipe Start Northing**

Specifies the northing of the pipe's starting point.

**Pipe End Easting**

Specifies the easting of the pipe's ending point.

**Pipe End Northing**

Specifies the northing of the pipe's ending point.

**Start Centerline Elevation**

Specifies the pipe's starting point elevation according to the pipe's centerline.

**End Centerline Elevation**

Specifies the pipe's ending point elevation according to the pipe's centerline.

**Minimum Cover**

Specifies the minimum depth of cover along the entire length of pipe, from the top outside of the pipe to the reference surface.

**Maximum Cover**

Specifies the maximum depth of cover along the entire length of pipe, from the top outside of the pipe to the reference surface.

**2D Length - Center To Center**

Specifies the two-dimensional length of the pipe, measured from the center of the connected starting structure to the center of the connected ending structure.

**3D Length - Center To Center**

Specifies the three-dimensional length of the pipe, measured from the center of the connected starting structure to the center of the connected ending structure.

**2D Length - To Inside Edges**

Specifies the two-dimensional length of the pipe, measured from the inside edge of the connected starting structure to the inside edge of the connected ending structure.

**3D Length - To Inside Edges**

Specifies the three-dimensional length of the pipe, measured from the inside edge of the connected starting structure to the inside edge of the connected ending structure.

## Resize Behavior

This property specifies the pipe behavior that occurs when the pipe is automatically resized.

**On Resize, Hold**

Specifies if the pipe will hold its invert, crown, or centerline elevation when the pipe is automatically resized due to an edit.

## Part Data

These properties specify a variety of part characteristics, such as part type, part subtype, and the part size name as defined in the part catalog. Some of these properties specify the dimensions that define the part's basic shape and therefore are read-only.

**Part Type**

Specifies pipe's part type.

**Part Subtype**

Specifies pipe's subtype.

**Part Description**

Specifies pipe's description.

**Part Size Name**

Specifies the part size name.

**Cross Sectional Shape**

Specifies the pipe's cross sectional shape, such as circular, egg-shaped, elliptical, or rectangular.

**Wall Thickness**

Specifies the wall thickness for this pipe, measured from the inside edge of the pipe to the outside edge of the pipe.

**Material**

Specifies the material defined for this part. This optional property is used mainly for labeling purposes. It allows you to identify the type of material used to construct this part.

**Minimum Curve Radius**

Specifies the minimum curve radius for this part.

**Manning Coefficient**

This optional property specifies a Manning Coefficient value for a given part size.

**Hazen Williams Coefficient**

This optional property specifies a Hazen Williams Coefficient value for a given part size.

**Darcy Weisbach Factor**

This optional property specifies a Darcy Weisbach Factor value for a given part size.

**Inner Pipe Diameter**

Specifies the inner diameter for this pipe. This property is used for circular shaped pipes only.

Inner Pipe Width

Specifies the inner width for this pipe. This property is used for non-circular shaped pipes only, such as rectangular and egg-shaped.

Inner Pipe Height

Specifies the inner height for this pipe. This property is used for non-circular shaped pipes only, such as rectangular and egg-shaped.

### Hydraulic Properties

These properties specify the hydraulic property information related to the pipe. They are responsible for displaying the hydraulic grade line and energy grade line. Hydraulic grade lines and energy grade lines are displayed as a straight line through structures, connected between the HGL Up or EGL Up property from one pipe to the HGL Down or EGL Down property of the next pipe. For more information, see Adding Hydraulic Property Data to AutoCAD Civil Pipe Networks (page 1280). For information about creating label styles for displaying labels for these properties, see Labeling Hydraulic Properties in Pipe Networks (page 1270).

Hydraulic Grade Line Up

Specifies the elevation of the hydraulic grade line for pipe networks flowing in an upstream direction that contain hydraulic property data.

Hydraulic Grade Line Down

Specifies the elevation of the energy grade line for pipe networks flowing in a downstream direction that contain hydraulic property data.

Energy Grade Line Up

Specifies the elevation of the energy grade line for pipe networks flowing in an upstream direction that contain hydraulic property data.

Energy Grade Line Down

Specifies the elevation of the energy grade line for pipe networks flowing in a downstream direction that contain hydraulic property data.

Flow Rate

Specifies the flow rate for pipe networks that contain hydraulic property data.

Junction Loss

Specifies the junction loss for pipe networks that contain hydraulic property data.

Return Period

Specifies the return period for pipe networks that contain hydraulic property data.

## Rules Tab (Pipe Properties Dialog Box)

Use this tab to view or change the rule set or rule values associated with this pipe.

For more information, see Pipe Rules (page 1251) and Editing Part Rules (page 1258).

### Rule Set

This drop-down list lets you specify the rule set for the pipe.

### Use Values From Rule Set

This option lets you choose to override or accept the rule values as they are defined in the specified rule set. If you clear this check box, you can edit the rule values on this dialog box, and the pipe uses the rule values as they are specified on this dialog box. If this option is selected, the pipe uses the rule values as they are defined in the specified rule set, and those values display on this dialog box.

## Cover And Slope

This rule ensures that a pipe slopes appropriately and warns when a pipe is placed too close to a ground surface. For more information, see Cover And Slope Rule (page 1251).

Maximum Cover

> Specifies the maximum cover of soil over the length of the pipe, based on the surface being referenced by that pipe. If the maximum cover is exceeded, a rule violation occurs. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

Maximum Slope

> Specifies the maximum slope of the pipe, expressed in percent. If the pipe slope is greater than the maximum, a rule violation occurs for that object.

Minimum Cover

> Specifies the minimum cover of soil over the pipe, based on the surface being referenced by that pipe. During layout, a pipe will be created that attempts to maintain the minimum cover. This is also used to determine the initial elevations of the pipe. If the pipe is edited so that its cover is less than the minimum cover value, a rule violation occurs for that object.

Minimum Slope

> Specifies the minimum slope of the pipe, expressed in percent. During layout, a pipe will be created according to its minimum slope rule value. If the pipe is edited so that its slope is less than the minimum, you can still edit the pipe as desired, breaking the minimum slope rule, but a rule violation occurs for that object.

## Cover Only

This rule is intended for laying out pipes in a pressure-based pipe network where pipe elevations are determined according to a specified depth below a terrain. This rule ensures that the minimum cover is met along the length of the pipe, and also validates that both the minimum and maximum cover values are not violated along any length of the pipe. For more information, see Cover Only Rule (page 1252).

Maximum Pipe Cover

> This is the maximum cover of soil over the pipe, based on the surface being referenced by that pipe. If the pipe cover exceeds the maximum cover value, a rule violation occurs for that object. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

Minimum Pipe Cover

> This rule represents the minimum cover of soil over the pipe, based on the surface being referenced by that pipe. During layout, a pipe will be created that attempts to maintain the minimum cover. If the pipe is edited so that its cover is less than the minimum cover value, a rule violation occurs for that object.

## Length Check

This rule governs the behavior that produces a warning condition on a pipe if the pipe length exceeds the value specified for the maximum pipe length, or is less than the value specified for the minimum pipe length. For more information, see Length Check Rule (page 1252).

Maximum Pipe Length

> Specifies a maximum length for pipes. When this rule is in use, you can still draw pipes that exceed the defined maximum pipe length. However, the object will be displayed with a warning icon in the Prospector list view. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

Minimum Pipe Length

> Specifies a minimum length for pipes. When this rule is in use, you can still draw pipes that are shorter than the defined minimum pipe length. However, the object will be displayed with a warning icon in the

Prospector list view. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is not met.

**Pipe To Pipe Match**

This rule governs how a pipe elevation is determined in a pipe network that contains only pipes (no structures), and or when a pipe is inserted onto an existing pipe to break the pipe. For more information, see Pipe To Pipe Match Rule (page 1253).

Match Location

This parameter controls whether the inserted pipe holds to the pipe's invert, crown, or centerline elevation (location).

Drop Value

The drop value on a structure can determine a pipe's depth.

# Pipe Style Dialog Box

Use this dialog box to control the display of various pipe components in a pipe network.

You can edit styles to control how components like pipes walls, pipe ends, pipe centerlines, hatchings and crossings display in plan, profile, and section views.

Create different styles to use in the various phases of your project. For example, you can create a style to use specifically in the design phase, displaying pipe components in different colors, and create another style to use for plotting, displaying the components differently.

# Information Tab (Pipe Style Dialog Box)

Use this tab to change the pipe style name and description information, and to review details about the pipe style, such as when the style was most recently modified.

For more information, see Information Tab (Style Dialog Box) (page 1801).

# Plan Tab (Pipe Style Dialog Box)

Use this tab to define the appearance of the pipe in a 2D plan view.

**Pipe Wall Sizes**

Specifies the method that will be used to define and draw the dimensions of the pipe wall.

Use Part Dimensions

The inner and outer pipe wall dimensions are drawn according to the actual pipe dimensions.

User Defined

The inner and outer pipe wall dimensions are drawn according to user-specified values. The following size options are available:

■ Use Drawing Scale: When this option is selected, the value specified in the Units edit box (inches or millimeters, when the drawing linear unit is set to feet or meters, respectively) will be multiplied by the drawing scale to determine the width of the pipe walls displayed in the drawing. The user then enters the desired inner and outer wall dimensions in the text boxes below.

■ Use Size As Percentage Of Screen: When this option is selected, the value specified in the Units edit box is used as a percentage of the drawing screen size. The width of the pipe walls displayed in the drawing will be the displayed at the same percentage as the drawing screen size specified.

■ Use Size In Absolute Units: When this option is selected, the specified value that is entered in the Units edit box is an absolute value in the drawing linear units. The title text above this box displays Feet when the drawing units are set to feet, and Meters when the drawing units are set to meters.

## Pipe Hatch Options

Specifies which components of the pipe shape display a hatch pattern.

Hatch To Inner Walls

The hatch pattern is displayed only in the central area of the pipe, and to not hatch the pipe wall. When this option is selected, the pipe wall (which is the area between the inner wall and the outer wall of the pipe) is not hatched.

Hatch To Outer Walls

The hatch pattern is displayed to the entire area of the pipe, including the pipe wall. When this option is selected, the pipe wall (which is the area between the inner wall and the outer wall of the pipe) is hatched.

Hatch Walls Only

The hatch pattern is displayed only in the pipe walls. The pipe wall is the area between the pipe inner wall and the pipe outer wall.

## Pipe End Line Size

Specifies the method that will be used to define and draw the dimensions of the pipe ends.

Draw To Inner Walls

The pipe end line draws to the inner walls of the pipe.

Draw To Outer Walls

The pipe end line draws to the outer walls of the pipe.

User Defined

The pipe end line draws to a size specified by the user. The size options available are the same as the options available for the pipe wall dimensions.

## Pipe Centerline Options

Specifies the method that will be used to define and draw the dimensions of the pipe centerline.

By Lineweight

The pipe centerline is drawn according to the currently specified line weight of the pipe.

Specify Width

The pipe centerline is drawn according to user-specified values. The following width options are available:

■ Draw To Inner Walls: When this option is selected, the value specified in the edit box below (inches or millimeters, when the drawing linear unit is set to feet or meters, respectively) will be multiplied by the drawing scale to determine the width of the pipe centerline displayed in the drawing. The pipe centerline draws to the inner walls of the pipe, according to the value specified in the text box below.

■ Draw To Outer Walls: When this option is selected, the value specified in the edit box below (inches or millimeters, when the drawing linear unit is set to feet or meters, respectively) will be multiplied by the drawing scale to determine the width of the pipe centerline displayed in the drawing. The pipe centerline draws to the outer walls of the pipe, according to the value specified in the text box below.

■ Use Drawing Scale: When this option is selected, the value specified in the Units edit box (inches or millimeters, when the drawing linear unit is set to feet or meters, respectively) will be multiplied by the drawing scale to determine the width of the pipe walls displayed in the drawing. The user then enters the desired inner and outer wall dimensions in the text boxes below.

- Use Size As Percentage Of Screen: When this option is selected, the value specified in the Units edit box is used as a percentage of the drawing screen size. The width of the pipe walls displayed in the drawing will be the displayed at the same percentage as the drawing screen size specified.

- Use Size In Absolute Units: When this option is selected, the specified value that is entered in the Units edit box is an absolute value in the drawing linear units. The title text above this box displays Feet when the drawing units are set to feet, and Meters when the drawing units are set to meters

### Align Hatch To Pipe

When this option is selected, the angle of the hatch lines for the pipe align with the angle of the pipe.

### Clean Up Pipe To Pipe Connections

When this option is selected, the appearance of pipe to pipe connections in plan view is cleaned up. This option is available for multiple adjoining pipes that are connected to other pipes with null structures. This option must be selected for the clean up to occur, and the cleanup occurs only on the pipes that are connected to other pipes with null structures between them. For more information, see Pipe End Cleanup Option (page 1223). You can also set this option on the Profile tab of the Pipe Style dialog box for pipe to pipe connections displayed in profile views.

## Profile Tab (Pipe Style Dialog Box)

Use this tab to define the appearance of the pipe in a profile view.

### Pipe Wall Sizes

Specifies the method that will be used to define and draw the dimensions of the pipe wall.

Use Part Dimensions

The inner and outer pipe wall dimensions are drawn according to the actual pipe dimensions.

User Defined

The inner and outer pipe wall dimensions are drawn according to user-specified values. The following size options are available:

- Use Drawing Scale: Specifies that the value in the Units edit box (inches, or millimeters, when the drawing linear unit is set to Feet or Meters, respectively) will be multiplied by the drawing scale to determine the width of the pipe walls displayed in the drawing. Then the user enters the desired inner and outer wall dimensions in the text boxes below.

- Use Size As Percentage Of Screen: Specifies that the value in the Units edit box is a percentage of the drawing screen size. The width of the pipe walls displayed in the drawing will always be the percentage specified of the drawing screen size.

- Use Size In Absolute Units: Specifies that the value entered in the Units edit box is an absolute value of the drawing linear units. The static text of the Units edit box displays Feet when the drawing units are set to Feet, and Meters when the drawing units are set to Meters.

### Pipe Hatch Options

Specifies which components of the pipe shape display a hatch pattern.

Hatch To Inner Walls

The hatch pattern is displayed only in the central area of the pipe, and not in the pipe wall area of the pipe. When this option is selected, the pipe wall (which is the area between the inner wall and the outer wall of the pipe) is not hatched.

Hatch To Outer Walls

The hatch pattern is displayed in the entire area of the pipe, including the pipe wall area. When this option is selected, the pipe wall (which is the area between the inner wall and the outer wall of the pipe) is hatched.

Hatch Walls Only

The hatch pattern is displayed only in the pipe wall area. The pipe wall area is the area between the pipe inner wall and the pipe outer wall.

## Pipe End Line Size

Specifies the method that will be used to define and draw the dimensions of the pipe ends.

Draw To Inner Walls

The pipe end line draws to the inner walls of the pipe.

Draw To Outer Walls

The pipe end line draws to the outer walls of the pipe.

User Defined

The pipe end lines draw to a size specified by the user. The size options available are the same as the options available for the pipe wall dimensions.

## Crossing Pipe Hatch Options

Specifies which components of a pipe crossing display a hatch pattern.

Hatch To Inner Walls

The hatch pattern is displayed only to the inner walls of pipe crossings.

Hatch To Outer Walls

The hatch pattern is displayed all the way to the outer walls of pipe crossings.

Hatch Walls Only

The hatch pattern is displayed only within the pipe wall area of pipe crossings.

## Align Hatch To Pipe

When this option is selected, the angle of the hatch lines for the pipe align with the angle of the pipe.

## Clean Up Pipe To Pipe Connectons

When this option is selected, the appearance of pipe to pipe connections in profile view is cleaned up. This option is available for multiple adjoining pipes that are connected to other pipes with null structures. This option must be selected for the clean up to occur, and the cleanup occurs only on the pipes that are connected to other pipes with null structures between them. For more information, see Pipe End Cleanup Option (page 1223). You can also set this option on the Plan tab of the Pipe Style dialog box for pipe to pipe connections displayed in plan views. By default, this option is not checked.

# Section Tab (Pipe Style Dialog Box)

Use this tab to define the appearance of the pipe in a section view.

## Crossing Pipe Hatch Options

Specifies which components of a pipe crossing display a hatch pattern.

Hatch To Inner Walls

The hatch pattern is displayed only in the central area of the pipe, and does not hatch the pipe wall. When this option is selected, the pipe wall (which is the area between the inner wall and the outer wall of the pipe) is not hatched.

Hatch To Outer Walls

The hatch pattern is displayed the entire area of the pipe, including the pipe wall. When this option is selected, the pipe wall (which is the area between the inner wall and the outer wall of the pipe) is hatched.

Hatch Walls Only

The hatch pattern is displayed only in the pipe walls. The pipe wall is the area between the pipe inner wall and the pipe outer wall.

# Display Tab (Pipe Style Dialog Box)

Use this tab to change the display and visibility of pipe object components.

## View Direction

Some object styles can have unique display values and varying numbers of displayed components, depending on whether they are being displayed in Plan, Profile, Section, or Model views. You can create and set style characteristics for each supported view direction type using the View Direction list.

Plan

Specifies the display style settings when the pipe is displayed in plan view.

Model

Specifies the display style settings when the pipe is displayed in model view.

Profile

Specifies the display style settings when the pipe is displayed in a profile view.

Section

Specifies the display style settings when the pipe is displayed in a section view.

## Component Display

You can set the following display style characteristics for pipe components: Visibility, Layer, Color, Linetype, LT Scale, and Lineweight.

Pipe Centerline

The style for pipe centerlines.

Inside Pipe Walls

The style for the inside walls of pipes.

Outside Pipe Walls

The style for the outside walls of pipes.

Pipe End Line

The style for the ends of pipes.

Pipe Hatch

The hatch style for pipes.

Pipe Solid

The style for pipes displayed in 3D model view.

Crossing Pipe Inside Walls

The style for the inside wall of pipe crossings displayed in profile or section view.

Crossing Pipe Outside Walls

The style for the outside wall of pipe crossings displayed in profile or section view.

Crossing Pipe Hatch

The hatch style for pipe crossings displayed in profile or section view.

Hydraulic Grade Line

The style for displaying hydraulic grade lines for pipe networks that are displayed in profile views. For more information, see Viewing Hydraulic Data in Profile Views (page 1282).

Energy Grade Line

The style for displaying energy grade lines for pipe networks that are displayed in profile views. For more information, see Viewing Hydraulic Data in Profile Views (page 1282).

In certain views, you can specify hatch display styles for the fill areas of the following pipe components:

**Pipe Hatch**: The hatch pattern for pipe components displayed in plan or profile view.

**Crossing Pipe Hatch**: The hatch pattern for pipe crossings displayed in profile or section view.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Pipe Style Dialog Box)

Use this tab to review all the information about the current pipe style.

This information can be copied and pasted to the clipboard. For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Structure Rule Set Dialog Box

Use this tab to view or edit basic information about this structure rules set.

You can view or edit the name and optional description values, and you can view information about when the rule set was created and last modified.

## Information Tab (Structure Rule Set Dialog Box)

Use this tab to view or edit the basic information about this structure rules set, such as a name and an optional description for this set of structure rules.

## Rules Tab (Structure Rule Set Dialog Box)

Use this tab to view or edit the rules included in this set of structure rules.

You can change values of existing rules, add rules, and or delete rules. You can also change the order in which rules are processed by changing the order in which they appear on this dialog. For more information, see Part Rules (page 1247).

---

**NOTE** Rules are not applied to pipes or structures when importing pipe networks from either LandXML or from the Storm Sewers Extension.

---

**Add Rule**

Click this button to display the Add Rule dialog box (page 2069) where you can select a new rule to add to this rule set.

**Delete Rule**

You can remove a rule from the rule set by selecting the rule on this dialog box and clicking this button.

**Up and Down Arrow Buttons**

⇧ ⇩ You can change the order in which rules are processed by changing the order they appear on this dialog. Rules are processed sequentially, starting from the rule displaying at the bottom of this dialog box, and ending with the rule displayed at the top of this dialog box.

**Pipe Drop Across Structure**

This rule compares all pipes connected to a single structure and ensures that pipes enter and exit the structure at logical locations. For more information, see Pipe Drop Across Structure Rule (page 1253).

Drop Reference Location

  Determines the drop location by using the pipe's invert, crown, or centerline elevation.

Drop Value

  Specifies what the drop value is between the lowest incoming pipe and any outgoing pipe connected to the structure.

Maximum Drop Value

  Specifies the maximum drop value between the lowest incoming pipe and any outgoing pipe connected to the structure. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

**Maximum Pipe Size Check**

This rule checks to see if pipes entering a structure have a diameter or width that exceeds a specified maximum value. For more information, see Maximum Pipe Size Check Rule (page 1257).

Maximum Pipe Diameter or Width

  For circular pipes, this parameter measures the pipe diameter. For rectangular pipes, it measures width. If a pipe diameter or width exceeds the maximum value, a warning is issued on the structure. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

**Set Sump Depth**

This rule specifies the sump depth, or the vertical distance from the invert of the lowest pipe attached to the structure to the inside bottom of the Structure, see Set Sump Depth Rule (page 1258).

Sump Depth

  Determines the sump depth.

Drop Value

  Specifies what the drop value is between the lowest incoming pipe and any outgoing pipe connected to the structure.

Maximum Drop Value

  Specifies the maximum drop value between the lowest incoming pipe and any outgoing pipe connected to the structure. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

# Structure Properties Dialog Box

Use this dialog box to view or change the properties of a structure object.

You can change the name of the structure object, description, style, render material, and more. You can also change part properties and rules.

When you add pipe network containing structures to a drawing, much of the information about the structure, such as its description and properties, is derived from the definition of the structure as it exists in the part catalog.

After a structure is inserted into a drawing, you can make changes to the structure using this dialog box, if desired. When you make changes using this dialog box, the changes apply only to the current structure selected in your drawing, and have no impact on the information defined for that structure in the part catalog. For descriptions of part properties, see Part Properties (page 1235).

## Information Tab (Structure Properties Dialog Box)

Use this tab to change the name, description, and style information for the structure.

Name
  Specifies the name of the current pipe.

Description
  Specifies an optional description of the current pipe.

Object Styles
  Specifies the pipe style. Select other styles from the list.

Style
  Specifies the style options. Click to create a new style, copy or edit the current style selection, or pick a style from drawing. Click  to open the Style Detail dialog box, where you can preview the style and creation information.

Render Material
  Specifies the default render material assigned to the pipe when it is inserted into the drawing. Click  to select a render material from the drawing.

Show Tooltips
  Controls whether or not tooltips are displayed for the object in the drawing.

## Part Properties Tab (Structure Properties Dialog Box)

Use this tab to view or change properties associated with this structure.

This tab displays the properties associated with this structure, along with their current values. Structure properties define a variety of characteristics of the structure object, including its basic size and shape and elevation adjustment behavior.

Some properties are specific to a certain type of structure. For example, only junction structures use rim and sump behavior properties. Only inlet-outlet structures use properties that define headwalls such as Headwall Base Width.

Some properties are read-only and others are editable. To change an editable property, double-click on the Value field and enter a new value, or select one from the list. For more information, see Part Properties (page 1235)

### General

These properties specify general characteristics of the structure, such as the structure elevation at its insertion point, and the surface and alignment referenced.

Surface Elevation At Insertion Point
  Specifies the elevation at the structure's insertion point.

Reference Surface

Specifies the surface referenced by the structure.

Reference Alignment

Specifies the alignment referenced by the structure.

## Geometry

These properties specify characteristics such as the structure's rotation angle, offset, station data, and the number of pipes that are currently connected to the structure.

Structure Rotation Angle

Specifies the structure's rotation angle.

Structure Offset

Specifies the structure's offset.

Structure Northing

Specifies the structure's northing.

Structure Easting

Specifies the structure's easting.

Connected Pipes

Specifies the number of pipes currently connected to the structure.

## Insertion Rim Behavior

These properties are associated with junction structures only. They specify the structure's rim elevation and adjustment behavior.

Insertion Rim Elevation

Specifies the current elevation of the structure rim. This cannot be edited if Automatic Surface Adjustment property is set to True.

Automatic Surface Adjustment

Specifies whether or not to automatically adjust the rim elevation to the referenced surface, including the Surface Adjustment Value. When this property is set to True, grip editing the structure modifies the surface adjustment factor. When this property is set t o False, grip editing the structure modifies the rim elevation.

Surface Adjustment Value

If Automatic Surface Adjustment is set to True, the rim elevation is automatically adjusted by the surface elevation, plus the value specified here. If the structure is moved, resulting in the structure elevation changing, the structure automatically adjusts its elevation.

## Sump Behavior

These properties are associated with junction structures only. They specify the structure's behavior, elevation, and the depth of the structure's sump.

Sump Elevation

Specifies the elevation of the structure's sump, measured at the inside bottom of the structure. When this property is enabled, grip editing the structure modifies the sump elevation.

Sump Depth

Specifies the depth of the sump area, measured from the inside bottom of the structure to the lowest pipe invert of all pipes connected to the structure. When this property is enabled, grip editing the structure modifies the sump depth.

Control Sump By

Specifies if the sump depth is controlled by the depth based on the lowest pipe invert, or by a specific elevation value of the sump.

**Part Data**

These properties specify a variety of part characteristics, such as part type, part subtype, and the part size name as defined in the part catalog. Some of these properties define the part's basic shape and behavior, and therefore are read-only.

Part Type

Specifies structure's part type.

Part Subtype

Specifies structure's subtype.

Part Description

Specifies structure's description.

Part Size Name

Specifies the part size name.

Structure Shape

Specifies the basic primitive shape of the structure, as defined from the part catalog. For example, headwalls are typically defined in the part catalog as Bounding box shape, and manholes are typically defined as cylindrical shaped.

Vertical Pipe Clearance

Specifies the clearance required from the top outside of the highest pipe connected to the structure, to the rim. This is defined in the catalog and ensure that pipes enter the structure at an appropriate elevation. For example, it prevents a pipe from entering through the cone of structure.

Rim To Sump Height

Specifies the distance between the sump to the structure's rim. This property is for junction structures only.

Headwall Base Width

Specifies the width of the base of the headwall. This property is for inlet-outlet structures only.

Headwall Base Thickness

Specifies the thickness of the base of the headwall. This property is for inlet-outlet structures only.

Wall Thickness

Specifies the wall thickness for this structure, measured from the inside edge of the structure to the outside edge of the structure. This property is for junction structures only.

Floor Thickness

Specifies the thickness of the bottom of the structure. This property is for junction structures only.

Material

Specifies the material defined for this part. This optional property is used mainly for labeling purposes. It allows you to identify the type of material used to construct this part.

Frame

This optional property specifies the model or type of frame used for a structure.

Grate

This optional property specifies the model or type of grate used for a structure intended to be used as a catchbasin.

Cover

This optional property specifies the model or type of cover used for a structure intended to be used as a manhole.

Frame Height

Specifies the height of the structure's frame. This property is for junction structures only.

Frame Diameter

Specifies the diameter of the structure's frame. This property is for junction structures only.

Frame Length

Specifies the length of the structure's frame. This property is for junction structures only.

Frame Width

Specifies the width of the structure's frame. This property is for junction structures only.

Barrel Height

Specifies the height of the barrel section of the structure. This property is for two-tiered junction structures only.

Barrel Pipe Clearance

This property lets you determine how close to the structure's rim you can position a pipe. It is used for two-tiered junction structures only and specifies the clearance required above the top of the barrel section of the structure. It is similar to Vertical Pipe Clearance, but only describes the transition zone between the access cylinder and the larger barrel cylinder of a two-tiered structure.

Cone Height

Specifies the height of the cone shaped section of the structure. This property is for two-tiered junction structures only.

Slab Thickness

Specifies the thickness of the structure slab. This property is for junction structures only.

Inner Structure Diameter

Specifies the inner diameter for this structure. This property is for junction structures only.

Structure Height

Specifies the total height for this structure, measured from the bottom outside edge of the structure to the top outside edge of the structure.

Structure Diameter

Specifies the diameter for this structure, measured from the outside edges of the structure. Circular shaped structures typically use the diameter property while non-circular structures use width and length.

Structure Width

Specifies the width for this structure, measured from the outside edges of the structure. Non-circular shaped structures typically use the width and length properties while circular structures use diameter.

Structure Length

Specifies the length for this structure, measured from the outside edges of the structure. Non-circular shaped structures typically use the width and length properties while circular structures use diameter.

## Hydraulic Properties

These properties specify the hydraulic grade line, the energy grade line, and the junction loss values for pipe networks that contain this data.

Hydraulic grade lines and energy grade lines, when present, are displayed as a straight line through structures, connected between the HGL Up or EGL Up property from one pipe to the HGL Down or EGL Down property

of the next pipe. For more information, see Adding Hydraulic Property Data to AutoCAD Civil Pipe Networks (page 1280).

Hydraulic Grade Line
   Specifies the elevation of the hydraulic grade line for pipe networks that contain this data.

Energy Grade Line
   Specifies the elevation of the energy grade line for pipe networks that contain this data.

Known Capacity
   Specifies the known capacity for pipe networks that contain this data.

Bypass Target
   Specifies the bypass target for pipe networks that contain this data.

## Connected Pipes Tab (Structure Properties Dialog Box)

Use this tab to quickly make adjustments to pipes that are connected to a single structure.

The Connected Pipes tab lets you quickly view and edit properties that are important for pipes connected to structures. For example, you can use this tab to edit the following properties on pipes connected to the selected structure:

■ inner diameter

■ inner width

■ invert elevation

■ centerline elevation

■ crown elevation

You can use this tab to quickly perform a variety of edits to pipes that are connected to a structure. You can align the elevations on multiple pipes connected to the structure according to the invert, crown, or centerline elevation of a selected pipe.

For more information, see Matching Elevations on Connected Pipes (page 1219). The following information describes the properties that are displayed on the Connected Pipes tab.

Name
   Displays the name of the current structure and each pipe connected to it. Read-only.

Status
   Displays the current status of each pipe connected to the structure. Read-only.

Description
   Displays the description of each pipe connected to the structure. Read-only.

Inner Diameter
   Specifies the inner diameter for circular pipes. Editable.

Inner Width
   Specifies the inner width for non-circular (rectangular) pipes. Editable.

Inner Height
   Specifies the inner height for non-circular (rectangular) pipes. Editable.

Invert Elevation
   Specifies the invert elevation of the pipe. Editable.

Centerline Elevation
Specifies the centerline elevation of the pipe. Editable.

Crown Elevation
Specifies the crown elevation of the pipe. Editable.

Slope
Specifies the slope of the pipe coming out of the structure. Read-only.

In/Out
Displays the flow direction of the pipe, indicating if the pipe flows in to or out of the structure. Read-only.

From Structure
Displays the name of the structure at the other end of the pipe. Read-only.

# Rules Tab (Structure Properties Dialog Box)

Use this tab to view or change the rule set or rule values associated with this structure.

For more information, see Structure Rules (page 1253) and Editing Part Rules (page 1258).

## Rule Set

This drop-down list lets you specify the rule set for the structure.

## Use Values From Rule Set

This option lets you choose to override or accept the rule values as they are defined in the specified rule set. If you clear this check box, you can edit the rule values on this dialog box, and the structure uses the rule values as they are specified on this dialog box. If this option is selected, the structure uses the rule values as they are defined in the specified rule set, and those values display on this dialog box.

## Pipe Drop Across Structure

This rule compares all pipes connected to a single structure and ensures that pipes enter and exit the structure at logical locations. For more information, see Pipe Drop Across Structure Rule (page 1253).

Drop Reference Location
Determines the drop location by using the pipe's invert, crown, or centerline elevation.

Drop Value
Specifies what the drop value is between the lowest incoming pipe and any outgoing pipe connected to the structure.

Maximum Drop Value
Specifies the maximum drop value between the lowest incoming pipe and any outgoing pipe connected to the structure. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

## Maximum Pipe Size Check

This rules checks to see if pipes entering a structure have a diameter or width that exceeds a specified maximum value. For more information, see Maximum Pipe Size Check Rule (page 1257).

Maximum Pipe Diameter or Width
For circular pipes, this parameter measures the pipe diameter. For rectangular pipes, it measures width. If a pipe diameter or width exceeds the maximum value, a warning is issued on the structure. Note that this parameter provides validation only; it does not alter (move or resize) the part in the drawing in any way. It simply produces a rule violation on the part if the specified value is exceeded.

# Structure Style Dialog Box

Use this dialog box to control the display of each structure component in a pipe network.

You can edit styles to control how structure components like boundaries and hatchings display in model, plan, profile, and section views.

Create different styles to represent different types of structures. You can also create different styles to use in the various phases of your project. For example, you can create a style to use specifically in the design phase, displaying pipe network structures in different colors, and create another style to use for plotting, displaying the components differently.

## Information Tab (Structure Style Dialog Box)

Use this tab to change the structure style name and description information, and to review details about the structure style, such as when the style was most recently modified.

For more information, see Information Tab (Style Dialog Box) (page 1801).

## Model Tab (Structure Style Dialog Box)

Use this tab to define the appearance of the 3D object used to represent the structure in model view.

### Structure

Specifies the method that will be used to define and draw the dimensions of the structure in model view.

Use Catalog Defined 3D Part

The 3D object defined in the parts catalog is used when displaying the structure in 3D. For more information, see Part Catalog and Parts Lists (page 1237). This option is enabled by default.

Use Simple 3D Part

The structure is displayed with one of the following simple shape options:

- Cylinder: The cylinder shape is the default. The dimensions of the cylinder are determined by the boundary of the part. The preview image shows an elongated cylinder in isometric view.

- Cube: The dimensions of the cube are determined by the boundary of the part. The preview image shows an elongated cube in isometric view.

- Sphere: The dimensions of the sphere are determined by the boundary of the part. The preview image shows an elongated sphere in isometric view.

- Part Defined Shape: This will be either a cylinder, cube, or sphere as defined in the 3D model. Each part definition contains a simple shape and size. The parts display using their simple shape representation.

Preview

Displays an image which is a reasonable facsimile of the 3D shape with the current settings.

## Plan Tab (Structure Style Dialog Box)

Use this tab to define the appearance of the structure in 2D plan view.

### Structure

Specifies the method that will be used to define and draw the dimensions of the structure in 2D plan view.

**Use Outer Part Boundary**

The 2D plan view of the structure style is displayed as an outline of the 3D object specified on the Model tab. This option is enabled by default. A preview image is not available for this option.

**User Defined Part**

The structure style uses an AutoCAD block reference to display the structure. The Preview control displays the block listed in the Block Name drop-down list. The control lists all the blocks defined in the current drawing.

■ Block Name: Specifies the name of the drawing file to use as a structure symbol.

■ Select Drawing File Button: Click to select a drawing file to use as a structure symbol.

**Size Options**

When an AutoCAD block is selected above, the following size options are available:

■ Use Drawing Scale: When this option is selected, the specified value in the Units edit box (inches, or millimeters, when the drawing linear unit is set to Feet or Meters, respectively) is multiplied by the drawing scale to determine the size of the structure symbol displayed in the drawing. Use this setting when annotation symbols are used.

■ Use Size As Percentage Of Screen: When this option is selected, the specified value that is entered in the Units edit box is a percentage of the drawing screen size. The size of the structure symbol displayed in the drawing is always the percentage specified of the drawing screen size.

■ Use Size In Absolute Units: When this option is selected, the specified value that is entered in the Units edit box is an absolute value of the drawing linear units. The title text above this box displays Feet when the drawing units are set to feet, and Meters when the drawing units are set to meters.

■ Use Fixed Scale: When this option is selected the Fixed Scale group box is enabled. The structure symbol will be scaled by the Fixed Scale X, Y, and Z parameters.

■ Use Fixed Scale From Part Size: When this option is selected the Fixed Scale group box is enabled. The structure symbol will be scaled by the Fixed Scale X, Y, and Z parameters based on the object part size.

**Inch or Percent**

The type of units displayed above this box depends on what is selected in the Size options box.

■ Use Drawing Scale: When this option is selected, the title above this box displays as Inches when the drawing units are set to Feet, and Millimeters when the drawing units are set to Meters.

■ Use Fixed Scale: When this option is selected, the units box is disabled and the Fixed Scale X, Y, and Z boxes are enabled. The block size is based on the part size.

■ Use Size In Absolute Units: When this option is selected, the title above this box displays as Inches when the drawing units are set to Feet, and Millimeters when the drawing units are set to Meters.

■ Use Size As Percentage Of Screen: When this option is selected, the title above this box displays as Percent.

■ Use Fixed Scale From Part Size: When this option is selected, the units box is disabled and the Fixed Scale X, Y, and Z boxes are enabled. The block size is based on the part size. The default fixed scale factor for the block is 1 for X & Y.

**Enable Part Masking**

Specifies whether the pipe objects are masked by the plan structure object. This control is enabled by default.

**Preview**

When User Defined Part is selected, this area displays an image with the current setting.

# Profile Tab (Structure Style Dialog Box)

Use this tab to define the appearance of the 3D object used to represent the structure in profile view.

**Structure**

Specifies the method that will be used to define and draw the dimensions of the structure in profile view.

Display As Solid

The 3D object defined in the parts catalog is used when displaying the structure in 3D. For more information, Part Catalog and Parts Lists (page 1237). This option is enabled by default. A preview image is not available for this option.

Display As Boundary

Only the outer boundary of the structure, as defined in the parts catalog, is used when displaying the structure in a profile.

Display As Block

Specifies that the structure style uses an AutoCAD block reference to display the structure. The Preview control displays the block listed in the Block Name drop-down list. The control lists all the blocks defined in the current drawing.

- Block Name: Specifies the name of the drawing file to use as a structure symbol.

- Select Drawing File Button: Click to select a drawing file to use as a structure symbol.

Size Options

When an AutoCAD block is selected above, the following size options are available:

- Use Drawing Scale: When this option is selected, the specified value in the Units edit box (inches, or millimeters, when the drawing linear unit is set to Feet or Meters, respectively) is multiplied by the drawing scale to determine the size of the structure symbol displayed in the drawing. Use this setting when annotation symbols are used.

- Use Size As Percentage Of Screen: When this option is selected, the value specified in the Units edit box is a percentage of the drawing screen size. The size of the structure symbol displayed in the drawing is always the same percentage specified of the drawing screen size.

- Use Size In Absolute Units: When this option is selected, the specified value that is entered in the Units edit box is an absolute value of the drawing linear units. The title text above this box displays Feet when the drawing units are set to feet, and Meters when the drawing units are set to meters.

- Use Fixed Scale: When this option is selected the Fixed Scale group box is enabled. The structure symbol will be scaled by the Fixed Scale X, Y, and Z parameters.

- Use Fixed Scale From Part Size: When this option is selected the Fixed Scale group box is enabled. The structure symbol will be scaled by the Fixed Scale X, Y, and Z parameters based on the object part size.

Inch or Percent

The type of units displayed above this box depends on what is selected in the Size options box.

- Use Drawing Scale: When this option is selected, the title above this box displays as Inches when the drawing units are set to Feet, and Millimeters when the drawing units are set to Meters.

- Use Size Relative To Screen: When this option is selected, the title above this box displays as Percent.

- Use Size In Absolute Units: When this option is selected, the title above this box displays as Inches when the drawing units are set to Feet, and Millimeters when the drawing units are set to Meters.

- Use Fixed Scale: When this option is selected, the units box is disabled and the Fixed Scale X, Y, and Z boxes are enabled.

- Use Fixed Scale From Part Size: When this option is selected, the units box is disabled and the Fixed Scale X, Y, and Z boxes are enabled. The block size is based on the part size. The default fixed scale factor for the block is 1 for X & Y.

**Enable Part Masking**

Specifies whether the pipe objects are masked by the plan structure object. This control is enabled by default.

**Preview**

When User Defined Part is selected, this area displays an image with the current settings.

# Display Tab (Structure Style Dialog Box)

Use this tab to change the display and visibility of structure object components.

## View Direction

Some object styles can have unique display values and varying numbers of displayed components, depending on whether they are being displayed in Plan, Model, Profile, or Section views. You can create and set style characteristics for each supported view direction type using the View Direction list.

**Plan**

Specifies the display style settings when the structure is displayed in plan view.

**Model**

Specifies the display style settings when the structure is displayed in model view.

**Profile**

Specifies the display style settings when the structure is displayed in a profile view.

**Section**

Specifies the display style settings when the structure is displayed in a section view.

## Component Display

You can set the following display style characteristics for structure components: Visibility, Layer, Color, Linetype, LT Scale, and Lineweight.

**Structure**

The style for structures displayed in plan view.

**Structure Hatch**

The hatch pattern for structures.

**3D Solid**

The style for structures displayed in 3D model view.

**Structure Pipe Outlines**

The style for pipes that are displayed in profile or section views.

**Hydraulic Grade Line**

The style for displaying a hydraulic grade line for pipe networks that are displayed in profile views. For more information, see Viewing Hydraulic Data in Profile Views (page 1282).

**Energy Grade Line**

The style for displaying an energy grade line for pipe networks that are displayed in profile views. For more information, see Viewing Hydraulic Data in Profile Views (page 1282).

**Component Hatch Display**

In plan, profile, or section views, you can specify hatch display styles for the fill areas of the structure.

Structure Hatch

The hatch pattern for structures displayed in plan, profile, or section views.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Structure Style Dialog Box)

Use this tab to review all the information about the current structure style.

This information can be copied and pasted to the clipboard. For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Part Size Creator Dialog Box

Use this dialog box to select or edit sizes and parameters for parts you wish to create.

The sizes and values available through this dialog box are defined from the pipe network part catalog. In most cases, there is only a single value available, or a drop-down list of choices, where you can select a value.

Property

Each part property is matched to the part type and may be selected, or added as an optional property, to a part size depending on how it was published in the part catalog. Part properties are characterized by value, units, and source.

Value

Specifies the current value defined for the property.

Units

Specifies the current units defined for this property, if applicable.

Source

Specifies how the property was published in the part catalog. For example, if the value is selected from a list, the source will be identified as Fixed List. Source types can be:

- Fixed List: This is a read-only, selectable list of fixed sizes or items from the catalog part family. Select the size from the drop-down list or check the all-sizes option to bring in all size combinations.

- Range: This is an editable value. The part catalog defines a min/max range and the user can enter any value within that range for part creation.

- Table: Values are arranged and selected in table rows. This is only used for pipes. Size selection is enabled for pipe diameter or width.

- Constant: A constant is a read-only data type. This is a value explicitly defined in the part family and cannot be changed.

- Calculation: This is a read-only value that is obtained from a calculation based on any other parameter or parameter(s).

- Optional Property: Lets you add one of the optional properties from a fixed list of optional properties for each defined part. For example an optional property called "Material" can be added to the part. Once the property is added to the part, the optional property then appears in the Part Size Creator dialog box where you can set its value. Optional properties can be used for labeling purposes. For more information, see Assigning Optional Properties to a Part Size (page 1242).

Add All SIzes

This option is available only to properties with a Fixed List source type. Selecting this options adds all of the part sizes available in the current property. Select this option if you wish to add all of the size options available for this property. For example, if you choose to Add All Sizes for a property called "Structure Height" (Fixed List values = 1.0, 2.0, and 3.0) and a property called "Headwall Top Width" (Fixed List values = 4.0 and 5.0), then the following set of part sizes are automatically added:

- Structure Height 1.0, Headwall Top Width 4.0

- Structure Height 2.0, Headwall Top Width 4.0

- Structure Height 3.0, Headwall Top Width 4.0

- Structure Height 1.0, Headwall Top Width 5.0

- Structure Height 2.0, Headwall Top Width 5.0

- Structure Height 3.0, Headwall Top Width 5.0

For more information, see Assigning Optional Properties to a Part Size (page 1242).

# Pipe Network Layers Dialog Box

Use this dialog box to define the layers used when creating pipe network components in plan, profile, and section views.

The default object layers are defined from the root drawing settings on the Object Layers tab.

Pipe Plan Layer

Specifies the layer used when creating pipe network pipes in plan view.

Structure Plan Layer

Specifies the layer used when creating pipe network structures in plan view.

Pipe Profile Layer

Specifies the layer used when creating pipe network pipes in a profile view.

Structure Profile Layer

Specifies the layer used when creating pipe network structures in a profile plan view.

Pipe Network Section Layer

Specifies the layer used when creating the pipe network in a section view.

# Select Parts List Dialog Box

Use this dialog box to select a parts list to associate with a pipe network.

The parts list contains the pipes and structures that are available for use in the current pipe network. You can create new parts lists or edit existing ones.

# Pipe Network Catalog Settings Dialog Box

Use this dialog box to configure AutoCAD Civil to access the imperial or the metric pipe network parts catalog, or to access specific pipe and structure catalogs within the imperial or metric catalog folders.

The part catalog settings defined here enable pipe network parts lists to access the content for pipe and structure shapes.

Part catalogs are set for each drawing. When in a drawing, and you switch between drawings, the catalogs (both pipe and structure) will automatically be set to the unit it was last in that particular drawing (either imperial or metric). You can alternate between drawings that use imperial or metric units without changing any settings.

---

**NOTE** The default catalog unit is determined by the Drawing Units setting in the Drawing Settings dialog boxUnits and Zone tab. For new and previously existing drawings, use this setting on initialization to set the unit of measure. See the Specifying Drawing Settings (page 63) for more information.

---

Catalog Folder
    Specifies the folder that contains the current AutoCAD Civil pipe network parts catalogs.

Pipe Catalog
    Specifies the current AutoCAD Civil pipe catalog.

Structure Catalog
    Specifies the current AutoCAD Civil structure catalog.

# Pipe Network Vistas

Use the vistas displayed in the Panorama window to view and edit objects that are part of the selected pipe network.

Using the Panorama window, you can quickly display all data associated with pipe network parts in one of two vistas. There is a tab for Pipe objects and a tab for Structure objects. You can select an object in the vista and view or edit the pipe network property data.

This window is similar to a spreadsheet. Each row represents a pipe or structure object in a pipe network, and each column represents a property for that object. You can re-size, move, and copy columns. You can also copy all or some of the data from a vista and paste it into a spreadsheet. For more information, see The Panorama Window (page 102).

**Pipe Properties**

Status
    Displays a check mark icon when all design criteria (rules) have been met for this pipe object. Displays a
    warning icon  to indicate if there are rule violations associated with this pipe object. The number indicates how many rules are broken. See the Rules tab (page 2043) on the Pipe Properties dialog box to see which rules are broken. Hovering over the icon displays a tooltip disrobing the condition.

Name
    Specifies the name of the pipe object.

Description
    Specifies the description for the pipe object.

Style
    Specifies the style for the pipe object.

Rule Set
    Specifies the rule set associated with the selected pipe object.

Render Material
    Specifies the render material for the pipe object.

Shape
    Specifies the shape description as defined from the part catalog definition for this part.

**Inner Diameter**

Specifies the value for the inner diameter of the pipe shape.

**Inner Width**

Specifies the value for the inner width of the pipe shape.

**Inner Height**

Specifies the value for the inner height of the pipe shape.

**Reference Alignment**

Specifies the object name of the alignment that is referenced by this pipe object.

**Start Offset**

Specifies the offset of the starting point for the pipe object. This offset is obtained from the alignment referenced by this pipe object. Flow direction is not considered.

**Start Station**

Specifies the station of the starting point for the pipe object. This station is obtained from the alignment referenced by this pipe object. Flow direction is not considered.

**End Station**

Specifies the station of the ending point for the pipe object. This station is obtained from the alignment referenced by this pipe object. Flow direction is not considered.

**End Offset**

Specifies the offset of the ending point for the pipe object. This offset is obtained from the alignment referenced by this pipe object. Flow direction is not considered.

**Reference Surface**

Specifies the object name of the surface that is referenced by this pipe object.

**Slope (Hold Start)**

Specifies the slope of the pipe from the pipe's starting point. Flow direction is not considered.

**Slope (Hold End)**

Specifies the slope of the pipe from the pipe's ending point. Flow direction is not considered.

**Slope**

Specifies the slope of the pipe (upstream or downstream) based on the flow direction.

**Start Structure**

Specifies the name of the structure object the pipe object is connected to at the pipe start point, not considering flow direction.

**Start Northing**

Specifies the northing of the pipe start point, not considering flow direction.

**Start Easting**

Specifies the easting of the pipe start point, not considering flow direction.

**Start Invert Elevation**

Specifies the invert elevation of the pipe start point, not considering flow direction.

**Start Centerline Elevation**

Specifies the centerline elevation of the pipe start point, not considering flow direction.

**Start Crown Elevation**

Specifies the crown elevation of the pipe start point, not considering flow direction.

**End Structure**

Specifies the name of the structure object the pipe object is connected to at the pipe's end point, not considering flow direction.

**End Northing**

Specifies the northing of the pipe end point, not considering flow direction.

**End Easting**

Specifies the easting of the pipe start point, not considering flow direction.

**End Invert Elevation**

Specifies the invert elevation of the pipe end point, not considering flow direction.

**End Centerline Elevation**

Specifies the centerline elevation of the pipe end point, not considering flow direction.

**End Crown Elevation**

Specifies the crown elevation of the pipe end point, not considering flow direction.

**2D Length - Center to Center**

Specifies the two-dimensional length of the pipe, using the center of the first attached structure as the pipe start point, and using the center of the end attached structure as the pipe end point. Some scenarios may require or prefer that pipe length be measured in this way, from the center of the first attached structure to the center of the next attached structure.

**3D Length - Center to Center**

Specifies the three-dimensional length of the pipe, using the center of the first attached structure as the pipe start point, and using the center of the end attached structure as the pipe end point. Some scenarios may require or prefer that pipe length be measured in this way, from the center of the first attached structure to the center of the next attached structure.

**2D Length - To Inside Edges**

Specifies the two-dimensional length of the pipe, using the inside edge of the first attached structure as the pipe start point, and using the inside edge of the end attached structure as the pipe end point. Some scenarios performing hydraulic quantity calculations may require or prefer that pipe length be measured in this way, from the inside edge of the first attached structure to the inside edge of the next attached structure.

**3D Length - To Inside Edges**

Specifies the three-dimensional length of the pipe, using the inside edge of the first attached structure as the pipe start point, and using the inside edge of the end attached structure as the pipe end point. Some scenarios performing hydraulic quantity calculations may require or prefer that pipe length be measured in this way, from the inside edge of the first attached structure to the inside edge of the next attached structure.

**Bearing**

Specifies the horizontal bearing for straight pipes, and chord bearing for curved pipes.

**Start Direction**

Specifies the bearing of the start point for curved pipes, not considering flow direction.

**End Direction**

Specifies the bearing of the end point for curved pipes, not considering flow direction.

**Radius**

Specifies the horizontal radius for curved pipes.

**Flow Direction**

Specifies the flow direction relative to how the pipe was drawn end to start or start to end. The flow is always assumed to be downstream unless Flow Method forces the flow otherwise.

**Flow Method**

Specifies whether the flow direction of a pipe is set by slope, start to end, or end to start. This property is used to force the flow direction of a pipe based on start and end points.

**Minimum Cover**

Specifies the minimum distance of cover for the pipe, measured from the top outside of the pipe to the referenced surface elevation.

**Maximum Cover**

Specifies the maximum distance of cover for the pipe, measured from the top outside of the pipe to the referenced surface elevation.

**Chord Length**

Specifies the horizontal chord length of a curved pipe, measured from pipe end to pipe end.

**Radius Point Northing**

Specifies the northing of the radius point of a curved pipe.

**Radius Point Easting**

Specifies the easting of the radius point of a curved pipe.

**HGL Up\Down**

Specifies the HGL Up and Down elevation values for the selected pipe object. For more information, see Adding Hydraulic Property Data to AutoCAD Civil Pipe Networks (page 1280).

**EGL Up\Down**

Specifies the EGL Up and Down elevation values for the selected pipe object. For more information, see Adding Hydraulic Property Data to AutoCAD Civil Pipe Networks (page 1280).

**Structure Properties**

**Status**

Displays a check mark icon when all design criteria (rules) have been met for this structure object. Displays a warning icon ![icon] to indicate if there are rule violations associated with this structure object. The number indicates how many rules are broken. See the Rules tab (page 2057) on the Structure Properties dialog box to see which rules are broken. Hovering over the icon displays a tooltip disrobing the condition.

**Name**

Specifies the name of the structure object.

**Description**

Specifies the description for the structure object.

**Style**

Specifies the style for the structure object.

**Rule Set**

Specifies the rule set associated with the selected structure object.

**Render Material**

Specifies the render material for the structure object.

**Type**

Specifies the type description as defined in the part catalog definition for this part. Valid choices are Junction, Inlet/Outlet, or Null.

Inner Diameter

Specifies the value for the inner diameter of the structure shape.

Inner Length

Specifies the value for the inner length of the structure shape.

Inner Width

Specifies the value for the inner width of the structure shape.

Inner Height

Specifies the value for the inner height of the structure shape.

Rotation Angle

Specifies the AutoCAD rotation angle of the structure object in the drawing.

Reference Alignment

Specifies the object name of the alignment that is referenced by this structure object.

Station

Specifies the station of the insertion point for the structure object. This station is obtained from the alignment referenced by this structure object.

Reference Surface

Specifies the object name of the surface that is referenced by this structure object.

Insertion Northing

Specifies the northing of the structure insertion point.

Insertion Easting

Specifies the easting of the structure insertion point.

Insertion Rim Elevation

Specifies the rim elevation of the structure insertion point. Typically, this applies to the rim for a junction structure.

Connected Pipes

Specifies the number of pipes connected to this structure.

Hydraulic Grade Line

Specifies the elevation of the hydraulic grade line for the selected structure object. For more information, see Adding Hydraulic Property Data to AutoCAD Civil Pipe Networks (page 1280).

Energy Grade Line

Specifies the elevation of the energy grade line for the selected structure object. For more information, see Adding Hydraulic Property Data to AutoCAD Civil Pipe Networks (page 1280).

**Related procedures:**

■ Editing Pipe Networks Using the Pipe Network Vistas (page 1204)

■ The Panorama Window (page 102)

■ Part Properties (page 1235)

# Swap Part Size Dialog Box

Use this dialog box to select the part size that will be used to replace the currently selected pipe network part.

Expand the desired part family, select a part size, then click OK.

You can swap a part with a part that is the same type (pipe to pipe or structure to structure), but is from a different part family and/or part size.

For example, a pipe can only be swapped with another pipe; a junction structure can only be swapped with another junction structure; an inlet/outlet structure can only be swapped with another inlet/outlet structure; and a null structure can only be swapped with a junction structure. You cannot swap a pipe with a structure, and vice versa. Only parts that are available to be swapped display in the Swap Part Size dialog box.

If you want to replace a part with a different part type, you must delete the part, and then add the new one.

Note that when swapping parts, connection elevations are maintained. For example, pipe invert elevations remain the same if a pipe is swapped with another pipe, or if a structure with one or more pipes attached to it is swapped with another structure.

**Related procedures:**

■ Swapping Pipe Network Parts (page 1214)

# Add Rule Dialog Box

Use this dialog box to add a rule to a part.

You can also view the parameter values and the name and location of the VBA macro project and macro name files associated with each rule. Click on the Parameter and or Value column names to sort the items in ascending or descending order.

Category
Specifies the category the currently selected rule, displayed in the Rule Name field, belongs to. Click to select a rule category.

Rule Name
Specifies the name of the rule currently selected. Only rules that belong to the currently selected Category are displayed in the drop down list. Click to select a rule.

Macro Project
Specifies the name of the VBA project containing the macro used for processing this rule.

Macro Name
Specifies the name of the macro used for processing this rule.

Rule Parameters
Displays the rule parameter values that are used by the VBA script to process the currently selected rule. On this dialog box, these values are read-only. You can click on the Parameter and or Value column names to sort the items in ascending or descending order. You can also right-click in a column or row to display a shortcut menu from which you can select options.

**Default Name Format**

Use these settings to specify the default name formats for pipe network components (pipe network, pipes, structures). Click ⬚ to open the Name Template dialog box, where you can specify the template. For more information, see Name Template Dialog Box (page 1806).

**Default Rules**

Use these settings to establish the default rule set assigned to pipes and structures that are added to the pipe network. Click ⬚ to open the Structure Default Rules dialog box, where you can specify the default rule set assigned to pipes and structures.

**Related procedures:**

■ Editing Part Rules (page 1258)

# Create Interference Check Dialog Box

Use this dialog box to create an interference check, defining a name for the interference check, an optional description, pipe networks, layer, and styles.

You can enable or change proximity check criteria for the interference check by clicking the 3D Proximity Check Criteria button.

Name

Specifies the name of the interference check. Each interference check must have a unique name.

Opens the Name Template (page 1806) dialog box, where you can modify the interference check naming template.

Description

Specifies an optional description for the interference check.

Network 1

Specifies the first pipe network that will be tested in this interference check.

Network 2

Specifies the second pipe network that will be tested in this interference check.

Layer

Opens the Pipe Network Layers (page 1985) dialog box, where you can assign the layer for displaying interference check results.

**Interference Style**

Style List

Displays the current style for interferences. Click the arrow to display the interference styles available in the drawing.

Style Selection

Specifies the style options. Create a new style, copy or edit the current style selection, or pick a style from the drawing.

**Render Material**

Material List

Displays the currently used render material. Click the arrow to display the render material available in the drawing.

Render Material

Click to select a render material from the drawing.

3D Proximity Check Criteria

Click this button to display the Criteria (page 2071) dialog box. The Criteria dialog box lets you choose to run the interference check using a specified distance or a specified scale factor.

**Related procedures:**

■ Checking for Interferences (page 1226)

# Criteria Dialog Box

Use this dialog box to enable or disable proximity checking, and to specify a distance or scale factor for the proximity check.

For more information, see Proximity Checking Criteria (page 1228).

**Apply 3D Proximity Check**

This option is available for checking a single pipe network, or for comparing two pipe networks to determine if any parts from one network are too close to parts from another network.

When this option is selected, the interference check looks for and detects the proximity check conditions specified on this dialog box. When this option is not selected, the interference check does not check for the proximity conditions specified on this dialog box, and the proximity checking options are not available (grayed out). Whether proximity checking is enabled or disabled, the interference check still checks for parts that physically collide.

Use Distance

When this option is selected, you can enter a distance. When the interference check is run, any pipe network parts within the specified distance away from each other (on any side) are marked as an interference.

Use Scale Factor

When this option is selected, you can enter a value that is used as a scale factor. When you enter a scale factor value, AutoCAD Civil calculates the limits of the part (the pipe or the structure) multiplied by the scale factor value that is specified. For example, if the pipe diameter is 600mm, and you specify a scale factor value of 2, AutoCAD Civil identifies any interferences within a distance of 1200mm (or the pipe diameter, which is 600, multiplied by the scale factor value, which is two). When the interference check is run, any pipe network parts within that distance away from each other (on any side) are marked as an interference.

# Interference Check Properties Dialog Box

Use this dialog box to view or change the information associated with an interference check.

You can change properties such as style, layer on which the interference check object is placed, or the interference checking criteria.

# Information Tab (Interference Check Properties Dialog Box)

Use this tab to view or change the name, description, style information, and layer of an interference check.

Name

Specifies the name of the current interference check.

Description

Specifies an optional description for the current interference check.

**Interference Defaults**

Style

Specifies the current style option. Select other styles from the list or click to create a new style, copy or

edit the current style selection, or pick a style from drawing. Click  to open the Style Detail dialog box, where you can preview the style and creation information

Render Material

Specifies the default render material assigned to the interference check when the interference check is inserted into the drawing. Click  to select a render material from the drawing.

Layer

Specifies the drawing layer on which the interference check results are placed. Click  to open the Object Layer Dialog Box (page 1985) dialog box to select a different layer.

Show Tooltips

Controls whether tooltips are displayed for the interference check object(s) in the drawing.

## Criteria Tab (Interference Check Properties Dialog Box)

Use this tab to view or change the conditions set for an interference check.

### Apply 3D Proximity Check

This option is available for checking a single pipe network, or for comparing two pipe networks to determine if any parts from one network are too close to parts from another network.

When this option is selected, the interference check looks for and detects the proximity check conditions specified on this dialog box. When this option is not selected, the interference check does not check for the proximity conditions specified on this dialog box, and the proximity checking options are not available (grayed out).

For more information, see Proximity Checking Criteria (page 1228).

Use Distance

When this option is selected, you can enter a distance. When the interference check is run, any pipe network part that is less than the specified distance away from any other part in the specified network(s), in any direction, is marked as an interference.

Use Scale Factor

When this option is selected, you can enter a value that is used as a scale factor. When you enter a scale factor value, AutoCAD Civil calculates the limits of the part (the pipe or the structure) multiplied by the scale factor value that is specified. For example, if the pipe diameter is 600mm, and you specify a scale factor value of 2, AutoCAD Civil identifies any interferences within a distance of 1200mm (or the pipe diameter, which is 600, multiplied by the scale factor value, which is two). When the interference check is run, any pipe network parts within that distance away from each other (on any side) are marked as an interference.

## Statistics Tab (Interference Check Properties Dialog Box)

Use this tab to view statistical information on the current interference check.

### Comparison

Displays the names of the pipe networks used in the current interference check.

Network 1

Displays the name of the first pipe network used in the interference check.

Network 2

Displays the name of the second pipe network, if there is one, used in the interference check.

### Statistics

Displays general information for the current interference check, such as the number of interference instances found and if the interference check is still current (valid) or out of date (obsolete).

Number of Interferences

Displays the total number of pipe network parts that have met the specified interference criteria. Each pipe network part that meets any interference criteria is considered to be an interference.

Status

Displays the current state of the interference check. Current means that the interferences found still exist, and that no changes have been made to and of the pipe network parts included in the interference check. A status of out of date means that one or more of the parts included in the interference check have changed.

**NOTE** If any pipe network part included in the interference check has changed in any way, the interference check becomes out of date. Even changing the description of a pipe network part that is not in interference, but is part of the pipe network that was checked causes the interference check to become out of date.

# Interference Properties Dialog Box

Use this dialog box to view or change information on an interference object.

You can change properties such as name, description, and or style of an interference object.

## Information Tab (Interference Properties Dialog Box)

Use this tab to view or change the name, description, and or style information of an interference.

Name

Specifies the interference name for the current interference.

Description

Specifies an optional description of the current interference.

### Object Styles

Style

Specifies the current style option. Select other styles from the list or click to create a new style, copy or edit the current style selection, or pick a style from drawing. Click to open the Style Detail dialog box, where you can preview the style and creation information

Render Material

Specifies the default render material assigned to the interference when the interference is inserted into the drawing. Click to select a render material from the drawing.

Show Tooltips

Controls whether or not tooltips are displayed for the interference in the drawing.

## Statistics Tab (Interference Properties Dialog Box)

Use this tab to view statistical information, including specific location information, and part names of the parts involved in the interference.

### General

Displays general statistics for the two parts comprising the interference.

Network Part1 / Network1

Displays the object name for the first pipe or structure comprising the interference. This field also displays the name of the pipe network the pipe or structure belongs to.

Network Part2 / Network2

Displays the object name for the second pipe or structure comprising the interference. This field also displays the name of the pipe network the pipe or structure belongs to.

Interference Location(X, Y, Z)

Displays the X, Y, and Z location information for the interference.

Interference Check

Displays the name of the interference check this interference belongs to.

# Interference Style Dialog Box

Use this dialog box to control the display of interferences in a pipe network.

Create different styles for various types of interferences. For example, create one interference style that displays overlapping parts in red, and another that displays parts that are too close to one another in green.

In addition to color and layer settings, you can also choose

## Information Tab (Interference Style Dialog Box)

Use this tab to change the interference style name and description information, and to review details about the interference style, such as when the style was most recently modified.

For more information, see Information Tab (Style Dialog Box) (page 1801).

## View OptionsTab (Interference Style Dialog Box)

Use this tab to define the appearance of interferences in plan and model views.

### Symbol Options

Specifies the marker style that will be used to visually identify interferences in 2D plan view.

Marker Style

When this option is selected, a 2D marker is used to visually identify interferences in plan view.

### Solid Options

Specifies the method that will be used to visually identify interferences in model view.

Show True Interference Solid

When this option is selected, interferences appear as a solid of the true collision of the network parts. This includes solids that are created when using the proximity check options.

Show as Sphere

This is the default option. When this option is selected, interferences are identified in the drawing by a sphere that is inserted into the drawing at the location of the interference. This option can be useful for identifying interferences that are otherwise difficult to see, due to being obscured by other drawing entities. The size of the sphere can be defined by specifying the following size (diameter) options:

■ Diameter by True Solid Extents: When this option is selected, the sphere is inserted at the centroid of the interference solid, with a size equal to the extents of the true interference solid. This option may be useful to visually represent (symbolize) the severity of the collision between parts.

■ User Specified Diameter: The size of the sphere is determined by the value entered in the box. When Use Size in Absolute Units is selected, the value entered in the box is calculated in feet or meters, depending on drawing settings. When Use Drawing Units is selected, the value is calculated in inches or millimeters, depending on drawing settings.

## Display Tab (Interference Style Dialog Box)

Use this tab to change the display and visibility of an interference.

You can specify display styles for the following interference components:

**Plan 2D Symbol**: The style for the symbol that unidentified interferences displayed in 2D plan view. For example, if a rectangle is chosen as the symbol for identifying interferences in plan view, this component lets you set the display style for the rectangle.

**Model 3D Solid**: The style for interferences displayed in as solids in 3D model view.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Interference Style Dialog Box)

Use this tab to review all the information about the current interference style.

This information can be copied and pasted to the clipboard. For more information, see Summary Tab (Style Dialog Box) (page 1803).

## Match Elevation Dialog Box

Use this dialog box to set pipe elevations to consistent, matching values in cases where multiple pipes connect to a single structure.

This feature lets you quickly set pipe elevations in cases where multiple pipes connect to a single structure. This provides a method for quickly and accurately matching multiple pipe elevations to the crown, centerline, or invert elevation of a selected pipe. You can also add a drop value that lets you adjust that elevation value further, if desired.

For more information, see Matching Elevations on Connected Pipes (page 1219).

Drop Amount
> This value is added to the elevation of the pipe that is selected on this dialog box. By default, this value is zero. It gives you the ability to adjust the elevation you are matching to by a specified value.

## Pipe Table Creation Dialog Box

Use this dialog box to create a pipe table in a drawing.

Most of the controls in this dialog box are generic table creation controls. For a description of these controls, see Table Creation Dialog Box (page 2441).

Use the following controls to specify the points to be included in the pipe table:

By Network
> Specifies a pipe network to add to the pipe table.

Multiple Selection
> Selects the pipe networks to be added to the pipe table.

**Related procedures:**

- Adding Pipe Tables (page 1271)

# Structure Table Creation Dialog Box

Use this dialog box to create a structure table in a drawing.

Most of the controls in this dialog box are generic table creation controls. For a description of these controls, see Table Creation Dialog Box (page 2441).

Use the following controls to specify the structures to be included in the structure table:

**By Network**

Specifies a network. The structures within the selected network are added to the structure table.

**Multiple Selection**

Selects the multiple network structures to be added to the structure table. You can add structures from differing networks.

**Related procedures:**

■ Adding Structure Tables (page 1272)

# Table Cell Components Dialog Box

Use this dialog box to manage the text components within a given cell within a structure table.

This dialog box is accessed by double-clicking a cell in the Structure Table in the Table Style dialog box.

Component Name

Displays a list of existing table components defined for the table style. Select a component from this list to edit its properties.

Create Component

Creates a new table component. Select a component type from this list to create a new text component, or text-for-each component. The possible components are **Structure**, **Structure all pipes**, **Structure in flow pipes**, and **Structure out flow pipes**.

Copy Component

Copies the selected component.

Delete Component

Deletes the selected component.

Component Row Order

Displays the Component Row Order (page 2077)dialog box.

From the Create Component list, click to create a new text component.

**General**

Name

Specifies the name of the text component.
The default name, such as "Text.1," is the component name with a numeric increment. If the text component exists in a parent table style, then the name cannot be edited.

Visibility

Specifies whether the text component is visible in the label style.

# Component Row Order Dialog Box

Use this dialog box to determine the order of the text components within a structure table cell.

Use the Top and Bottom arrows to arrange the component row order.

## Component

Name

Displays the name of the text component.

# Rename Pipe Network Parts Dialog Box

Use this dialog box to rename connected parts (pipes and structures) in a pipe network.

You can select one or more connected parts in a pipe network and automatically rename them. You can enter a new name to be applied, or select a name template. Optionally, you can select a starting number to renumber the parts.

**NOTE** When using this command, if the first part you select is not connected to another pipe or structure, you can only rename that single part.

Rename Structures

Select this option to rename the selected structure(s).

## Structure Name Template

Name

Specifies the name that will be used for the selected structure(s).

Opens the Name Template (page 1806) dialog box, where you can modify the naming template that will be used for the selected structure(s).

Starting Number

This optional field lets you specify a starting number that will be used to number the selected structure(s).

Rename Pipes

Select this option to rename the selected pipe(s).

## Pipe Name Template

Name

Specifies the name that will be used for the selected pipe(s).

Opens the Name Template (page 1806) dialog box, where you can modify the naming template that will be used for the selected pipe(s).

Starting Number

This optional field lets you specify a starting number that will be used to number the selected pipe(s).

**Name Conflict Options**

You must select one of the following naming conflict options:

Skip Number

When this option is selected, if a name and number combination is already being used by a pipe network part in the drawing, then the number will be incremented until that name\number combination is available as a name for the selected part.

Rename Existing Parts

When this option is selected, if a name and number combination is already being used by a pipe network part in the drawing, then that part will be renamed so that the selected part can use that desired name instead. The original pipe network part will be renamed using the next available name and number combination available.

# Export to Storm Sewers Dialog Box

Use this dialog box to select the pipe network data in the drawing to export to an .stm file format.

This dialog box is used for exporting AutoCAD Civil pipe network data to an .stm file so that it can be used by the Hydraflow Storm Sewers Extension. For more information, see Exporting Pipe Network Data to an .stm File (page 1279).

**NOTE** You cannot open .stm files that were exported from AutoCAD Civil, or that were saved in the Storm Sewers Extension for Civil 3D 2010, in the Storm Sewers Extension for Civil 3D 2009, or earlier versions of the Storm Sewers Extension.

Specify Objects To Be Exported

Lists the AutoCAD Civil pipe networks that exist in the current drawing. Expand the collections to display all of the subcomponents.
Select or clear the check box to the left of each item select the items that you want to export to an .stm file format.

**NOTE** The check boxes have a tri-state display. If only some items are selected under a collection, the check box is shaded ☑. If all the items are selected, the check box is selected ☑. If all the items below the collection are cleared, the check box for the collection is cleared ☐.

Pick From Drawing

Specifies pipe networks to export by selecting from the drawing.

**NOTE** If you access this dialog box by right-clicking a collection in the Prospector tree and selecting Export to Storm Sewers, the Pick From Drawing button is not available.

OK

When you click OK, the Export Storm Sewers to File dialog box is displayed where you can select a location to save the .stm file.

**Related procedures:**

■ Exporting Pipe Network Data to an .stm File (page 1279)

# Part Matchup Settings Dialog Box

Use this dialog box to specify the part types that will be used when importing and exporting pipe networks between AutoCAD Civil and the Storm Sewers Extension.

## Import Tab (Part Matchup Settings Dialog Box)

Use this tab to view or change the AutoCAD Civil part types that will be matched up to Storm Sewers part types when importing pipe network data from a Storm Sewers Extension .stm file into AutoCAD Civil.

The list of available Storm Sewers part types is displayed in the first column. In the second column, click in a cell, and then click ⊡ to display the AutoCAD Civil Part Catalog dialog box. Select a part type and click OK.

**Related procedures:**

■ Setting Part Matching Defaults for Migration (page 1276)

■ Part Catalog Dialog Box (page 2037)

Importing Circular Structures

This section lets you specify the AutoCAD Civil part types that will be used when importing circular structures from a Storm Sewers Extension .stm file.

Importing Rectangular Structures

This section lets you specify the AutoCAD Civil part types that will be used when importing rectangular structures from a Storm Sewers Extension .stm file.

Miscellaneous Part Types

This section displays the AutoCAD Civil part types that will be used for importing Storm Sewer parts that do not have a part type specified. Storm Sewers parts that do not have a part type specified are by default matched up to null structures when imported into AutoCAD Civil.

Importing Pipes

This section lets you specify the AutoCAD Civil part types that will be used when importing pipes from a Storm Sewers Extension .stm file.

## Export Tab (Part Matchup Settings Dialog Box)

Use this tab to view or change the AutoCAD Civil part types that will be matched up to Storm Sewers part types when exporting pipe network data from AutoCAD Civil to an .stm file.

The list of availableAutoCAD Civil part types is displayed in the first column. In the second column, click in a cell to select the Storm Sewers part type, and click OK.

**Related procedures:**

■ Setting Part Matching Defaults for Migration (page 1276)

■ Part Catalog Dialog Box (page 2037)

Exporting Structures

This section lets you specify the Storm Sewers part types that will be used when exporting structures from AutoCAD Civil to an .stm file.

### Exporting Pipes

This section lets you specify the Storm Sewers part types that will be used when exporting pipes from AutoCAD Civil to an .stm file.

# 62

# Plan Production Tools Dialog Boxes

The following topics describe the plan production tools dialog boxes.

## Edit Feature Settings - View Frame Group Dialog Box

Use this dialog box to view and change view frame group-specific settings.

This topic documents settings in all view frame group-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

■ Drawing-level ambient settings are identified by the  drawing icon.

■ View frame group feature settings are listed near the top of this dialog box, after the General property group, and are identified by the  view frame group icon.

■ View frame group command settings are identified by the  command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

### Default Styles

Use these settings to specify the default styles assigned to view frame group components.

Match Line Style

Specifies the default style for match lines. Click in the Value column, and click ⋯ to select a style in the Match Line Style dialog box.

View Frame Style

Specifies the default style for view frames. Click in the Value column, and click ⋯ to select a style in the View Frame Style dialog box.

**2081**

**Match Line Left Label Location**

Specifies the default location for labels that are displayed on the left side of a match line. Click in the value field to select a location from the list.

**Match Line Right Label Location**

Specifies the default location for labels that are displayed on the right side of a match line. Click in the value field to select a location from the list.

**View Frame Label Location**

Specifies the default location on the view frame for view frame labels. Click in the value field to select a location from the list.

**View Frame Label Style**

Specifies the default style for view frame labels. Click in the Value column, and click [...] to select a style in the View Frame Label Style dialog box.

**Match Line Label Style Left**

Specifies the default style for labels that are displayed on the left side of a match line. Click in the Value column, and click [...] to select a style in the Match Line Label Style Left dialog box.

**Match Line Label Style Right**

Specifies the default style for labels that are displayed on the right side of a match line. Click in the Value column, and click [...] to select a style in the Match Line Label Style Right dialog box.

**Profile View Style**

Specifies the default profile view style. Click in the Value column, and click [...] to select a style in the Profile View Style dialog box.

**Profile View Band Set**

Specifies the default style for profile view band sets. Click in the Value column, and click [...] to select a style in the Profile View Band Set dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

## Default Name Format

Use these settings to specify the default name formats for view frame group components (view frame groups, view frames, match lines, layouts, and sheet files). Click in the Value column, and click [...] to select a style in the Name Template dialog box (page 1806).

## Sheet Creation

**NOTE** This property group is displayed when accessing the settings from the CreateSheets command.

Use these settings to specify the default styles assigned to sheet creation.

**Sheet Creation Method**

Specifies the default method for creating new sheets:

- A specified number per new drawing

- All in a new drawing

- All in the current drawing

Number of Layouts per Drawing
Specifies the number of layouts per new drawing.

Align North Arrow
Specifies whether the selected North arrow block is aligned to North.

North Arrow Block Name
Specifies the name of the selected North arrow, as entered in the cell.

Sheet Set Use
Specifies whether a you create a New sheet set for any new sheets, or whether you Add To Existing sheet sets.

Existing Sheet Set
Specifies the sheet set file to which you add a new sheet, if you select Add To Existing for Sheet Set Use.

Add to Vault
Specifies whether newly created sheet set files are added to Vault.

Align Profile and Plan View
Specifies whether profile and plan views are aligned:

- At Start Station

- At Center

- At End Station

## View Frame Creation

**NOTE** This property group is displayed when accessing the settings from the CreateViewFrames command.

Use these settings to specify the default styles assigned to view framecreation.

Alignment Station Range
Specifies whether creation of view frames is Automatic for the entire alignment, or for a User Specified range.

Sheet Type
Specifies type of sheet to be created:

- Plan And Profile

- Plan Only

- Profile Only

View Frame Orientation
Specifies whether view frames orient Along Alignment or Rotate To North orientation.

Enable First View Frame Offset
Specifies whether the first view frame is offset.

First View Frame Offset Distance
Specifies the distance by which the first view frame is offset. Enter a distance in the Value column or click
and select a distance in the drawing area.

Insert Match Line
Specifies whether match lines can be inserted.

Match Line Snap Station

Specifies whether match lines snap down to a rounded station value.

Match Line Snap Station Value

Specifies a whole number, multiples of which are the station values.

Match Line Repositioning

Specifies whether match lines can be repositioned after placement.

Match Line Repositioning Value

Specifies the distance by which match lines can be repositioned after placement. Enter a distance in the Value column or click  and select a distance in the drawing area.

# Edit Feature Settings - View Frame Dialog Box

Use this dialog box to view and change standard drawing ambient settings for all view frame objects.

The standard drawing ambient settings are preceded with . For feature-specific settings for View Frame Style and the View Frame Name Template, see Edit Feature Settings - View Frame Group Dialog Box (page 2081).

For more information about this dialog box, see Working with the Standard Settings Dialog Box Controls (page 62).

# Edit Feature Settings - Match Line Dialog Box

Use this dialog box to view and change standard drawing ambient settings for all match line objects.

The standard drawing ambient settings are preceded with . For feature-specific settings for Match Line Style and the Match Line Name Template, see Edit Feature Settings - View Frame Group Dialog Box (page 2081).

For more information about this dialog box, see Working with the Standard Settings Dialog Box Controls (page 62).

# Create View Frames Wizard

Use this wizard to create a set of view frames that will be automatically placed along a selected alignment.

Using this wizard quickly leads you through the process of creating view frames along an alignment. The view frames created will be automatically associated with a view frame group. When you finish using this wizard, the view frame and view frame group objects are displayed in the drawing and in the Prospector tree. If you chose to insert match lines, the match line objects are also displayed in the drawing and in the Prospector tree.

For more information, see Creating View Frames (page 1703).

# Alignment Page (Create View Frames Wizard)

Use this page of the wizard to select the alignment and station range for creating view frames.

### Alignment

Select an alignment name in the list, or click  and select an alignment in the drawing area.

### Station Range

Specify a station range for the alignment that is currently selected in the Alignment field above.

Automatic

   Selects the entire alignment.

User specified

   When this option is selected, you may enter a value or click ⬚ to select a location in the drawing area.

If the Create View Frames button is unavailable (grayed out), it may be for one of the following reasons:

■   There are no templates available or selected.

■   There are no valid layouts in the selected template. For example, there are no appropriate viewports in the selected template.

**Related procedures:**

■   Creating View Frames (page 1703)

## Sheets Page (Create View Frames Wizard)

Use this page of the wizard to select the type of sheets to create, a template for the sheets, and to determine how view frame are aligned.

### Sheet Settings

Select the type of sheet to generate:

Plan And Profile

   This is the default choice. The sheets that will be created will contain both a plan view and a profile view.

Plan Only

   The sheets that will be created will contain plan views, but no profile views.

Profile Only

   The sheets that will be created will contain profile views, but no plan views.

Template For Sheet

   You must select the template to be used by the sheet. Browse to a template (.dwt) or enter a valid path to
   specify the template to be used. When you click ⬚
   to browse to a template, the Select Layout as Sheet Template (page 2100) dialog box is displayed.
   If the Create View Frames button is disabled on this page of the wizard, it may be because a template has not yet been selected in this field.

   **NOTE** If you select a template that does not contain appropriately defined viewports, a message is displayed on the Select Layout As Sheet Template dialog box indicating that no layouts contain the necessary viewports for the selected sheet type. For more information, see Configuring Viewports for Plan Production (page 1700).

### View Frame Placement

Specifies the orientation and placement of the view frame.

Along Alignment

   When this option is selected, the view frames will be aligned following along the alignment. Typically, this is the preferred method for making the most efficient use of paper when plotting.

Rotate To North

When this option is selected, the view frames will be rotated according to the north orientation in the drawing.

Set The First View Frame Before The Start Of The Alignment By

This option allows you to set a distance by which the first view frame is offset from the location on the alignment where it begins. Entering a distance value here adds a margin so that the start location of your view frame does not hide important drawing data that you want to display. If you leave this field blank, some drawing data near the start of the first view frame may be too close to the start of the view frame.

**Related procedures:**

■  Creating View Frames (page 1703)

## View Frame Group Page (Create View Frames Wizard)

Use this page of the wizard to specify criteria for creating the view frame group object.

### View Frame Group

Name

Specifies the name for the view frame group.

Opens the Name Template (page 1806) dialog box, where you can modify the view frame group naming template.

Description

Enter an optional text description identifying the view frame group.

### View Frame

View Frame Layer

Displays the layer on which the view frame will be created.

Opens the Object Layer dialog box, where you can select a different layer for the view frame.

Name

Specifies the name of the view frame.

**NOTE** To name the view frame, either click on its default name and enter a new name, or use the naming template.

Opens the Name Template (page 1806) dialog box, where you can modify the view frame naming template.

View Frame Style

Displays the style that is used to display certain components of the view frame, such as layer, line style, line weight, color, and so on.

Click to select the style of a view frame in the drawing.

View Frame Label Style

Displays the style that is used to display labels on view frames. For more information, see Understanding Labels (page 1466).

Click to select the label style of a view frame in the drawing.

Label Location

Specifies the location where the label will be placed on the view frame. For example, selecting Top Left places the label starting at the top left side of the view frame.

**Related procedures:**

■ Creating View Frames (page 1703)

## Match Lines Page (Create View Frames Wizard)

Use this page of the wizard to configure a variety of choices that determine how and if match lines will be placed on the view frames.

Insert Match Lines

Match lines are only displayed in Model space and in plan views. They are not displayed in profile views. If you have selected to create plan and profile or profile only sheets, this option is automatically selected and you cannot clear (edit) it.

When this option is selected, match lines will be inserted on the view frames in plan views. If you do not want match lines on the view frames, clear this check box.

### Positioning

Use these options to adjust where match lines are placed, and how they may be moved after creation, so that they do not obstruct data that you want to display.

Snap Station Value Down To The Nearest

Clear this option to use a rounding value (calculation) for the match line positioning based on derived stations. Select this option to use the rounding calculation value that is entered. The rounding calculation always rounds down. For example, if the calculated station for a match line is 48+37.69, then a rounding of 100 would place the match line on 48+00.

| When Snap Station Value Down To The Nearest is set to ... | the station will round to |
| --- | --- |
| 100 | 18+00 |
| 50 | 18+50 |
| 10 | 18+60 |
| 1 | 18+65 |
| 27+45.3 to 50 | 27+00 to the next lowest multiple of 50 |

**NOTE** This option will not accept values that cause the match lines to be placed in undesirable locations, such as before the previous match line or before the beginning of the alignment. If a rounding calculation would result in the match line being placed in an undesirable location, then the rounding calculation is ignored and the match lines are placed at calculated station.

Allow Additional Distance For Repositioning (Increases View Overlap)

This option gives you the ability to increase the distance that you can move match lines in plan view after they have been created. When you increase this margin, or additional distance, the overlap area of

the match lines increases. This option can also be used to force an overlap of frames in plan sheets only when, on a straight line alignment for example, adjacent edges of two view frames might be coincident, and therefore not provide enough room on either side of the match line for labeling and notes.

**Match Line**

Layer

Displays the layer that the match line will be created on.

Opens the Object Layer dialog box, where you can select a different layer for the match line.

Name

Specifies the name of the match line.

**NOTE** To name the match line, either click on its default name and enter a new name, or use the naming template.

Opens the Name Template (page 1806) dialog box, where you can modify the match line naming template.

Match Line Style

Displays the style that is used to display the match line and the match line mask area. For more information, see Match Line Style Dialog Box (page 2099) and/or Editing the Match Line Mask Area (page 1715).

Click to select the style of a match line in the drawing.

**Labels**

Left Label Style

Displays the style that is used to display the match line label that is on the left side of the match line.

Click to select the label style of a match line in the drawing.

Left Label Location

Specifies the location for the label that is placed on the left side of a match line. For example, selecting End places the left side match line label at the end of the match line.

Right Label Style

Displays the style that is used to display the match line label that is on the right side of the match line.

Click to select the label style of a match line in the drawing.

Right Label Location

Specifies the location for the label that is placed on the right side of a match line. For example, selecting End places the right side match line label at the end of the match line.

**Related procedures:**

■ Creating View Frames (page 1703)

## Profile Views Page (Create View Frames Wizard)

Use this page of the wizard to select the profile view style and band set that will be used for the profile views displayed in the viewports (sheets).

It is important to understand that the profile view style and band set for the profile view cannot be changed later when you are using the Create Sheets wizard to create sheets. For more information, see Understanding Profile View Options (page 1724).

Profile View Style

Specifies the style that is used to display the profile views in the viewports (sheets).

Band Set

Specifies the band set that is used to display the profile views in the viewports (sheets). You can copy an existing band set.

**Related procedures:**

■ Creating View Frames (page 1703)

## Create Sheets Wizard

Use this wizard to automatically create sheets from a view frame group.

Using this wizard quickly leads you through the process of creating sheets from a selected view frame group. The sheets created display the data that is inside each view frame within the view frame group. When you finish using this wizard, you may want to then use the Sheet Set Manager to create, organize, and manage sheet sets.

**See also:**

■ Creating Sheets (page 1719)

## View Frame Group and Layouts Page (Create Sheets Wizard)

Use this page of the wizard to select the view frame group and output settings for layout creation.

### View Frame Group

Specifies the view frame group used to create the sheets. Click  to select a view frame group in the drawing.

View Frame Range

Specifies which view frames to include in the sheets.

■ **All**: This is the default setting. Select this option to create sheets for every view frame in the view frame group.

■ **Selection**: When this is selected, the Choose View Frames button is available, and you can click it to select one or more view frames from the list in the Select View Frame dialog box.

### Layout Creation

These options determine how the layouts will be created.

Number Of Layouts Per New Drawing

This option may be an appropriate choice if you plan to have several people working on individual sheets. When this option is selected, and you enter 1 for the value, you get one new layout (sheet) created in each new drawing. The total number of sheets and drawings would depend on the length of the alignment selected and other criteria, such as the size of the viewports in the referenced template.

If you select this option and enter a value greater than one, three for example, three new layouts would be created in each new drawing. The total number of sheets and drawings would depend on the length of the alignment selected and other criteria, such as the size of the viewports in the referenced template. You can enter an integer from 1 to 255.

All Layouts in One New Drawing

This option may be an appropriate choice if having each individual layout in a separate drawing is not necessary for you, and if you have less than 10 sheets. You may place all the layouts in one newly created drawing. The total number of sheets would depend on the length of the alignment selected and other criteria, such as the size of the viewports in the referenced template. For optimal results, it is recommended that you create no more than 10 sheets per drawing. Therefore, this option may not be the best choice if you have more than 10 sheets.

All Layouts in The Current Drawing

If you are only generating less than 10 sheets, you may want to generate the layouts in the current drawing. The total number of sheets would depend on the length of the alignment selected and other criteria, such as the size of the viewports in the referenced template. For optimal results, it is recommended that you create no more than 10 sheets per drawing. Therefore, this option may not be the best choice if you have more than 10 sheets.

Layout Name

Specifies the name of the layout(s) that will be created.

Opens the Name Template (page 1806) dialog box, where you can modify the naming template for the layouts.

Choose The North Arrow Block To Align In Layouts

All blocks that exist in the currently selected template are displayed in the drop-down list. If you select a block from this list, that block will be aligned to the north on the sheet(s). Typically, this option is used for aligning a north arrow block in the layouts.

**Related procedures:**

■ Creating Sheets (page 1719)

# Sheet Set Page (Create Sheets Wizard)

Use this page of the wizard to specify creation criteria for the sheet set, such as names and locations for the sheet set, the sheet set file (*.dst*), and the sheet file.

Add Files To Vault

If you are currently logged in to a Vault, this field is available and automatically selected, and the following files, which are related to the sheet set creation, will be checked in to the Vault:

■ Sheet files created from this wizard session

■ Sheet set files created from this wizard session

This field is not available if you are not currently logged in to a Vault, or if Autodesk Vault is not installed.

Log in to Vault...

This button is not available (grayed out) if you are already logged in to a Vault, or if Vault is not installed on the machine. Clicking this button displays the Vault Log In dialog box which prompts you to log in to a Vault server and a Vault database. If you wish to use Vault to manage the files created during this wizard session, you must be logged in to Vault.

### Sheet Set

Use these options either to create a new sheet set or add to an existing sheet set. You can also specify the storage location of the sheet set file associated with the new or existing sheet set.

New Sheet Set

> Creates a new sheet set using the name of the view frame group displayed in the text box.

Add To Existing Sheet Set

> Creates sheets adds them to an existing sheet set. Click [...] to select a sheet set.

Sheet Set File (.DST) Storage Location

> Specifies the location where the sheet set file created or used during this session is located. Click [...] to select a location. If you selected Add to Existing Sheet Set, this field displays the location of the sheet set file for the sheet set that you selected in that field.

### Sheets

These options determine how the sheet files will be named and stored. If you have chosen to save all sheets in the current drawing (the All Layouts In The Current Drawing choice on the Create Sheets wizard View Frame Group and Layouts page), these fields are not available (read only, grayed out).

Sheet Files Storage Location

> Specifies the location where the sheet files created during this session will be located. Click [...] to select a location.
> If you are logged in to a project in Vault, by default this path displays the root folder for the project. If you are not logged in to a project in Vault, by default this path is set to the directory containing the working (current) drawing.

Sheet File Name

> Specifies the name of the sheet file(s) that will be created.

> 

> Opens the Name Template (page 1806) dialog box, where you can modify the naming template for the sheet files.

### Related procedures:

■ Creating Sheets (page 1719)

## Profile Views Page (Create Sheets Wizard)

Use this page of the wizard to view the profile view style and band set selected during view frame creation. While you cannot change the profile view style or the band set chosen, you can configure certain other profile view options.

If you want to change the profile view style or band set, click Cancel on the Create Sheets wizard, return to the Create View Frames wizard, change the profile view style and/or the band set there, recreate the view frames, and then use the Create Sheets wizard. Optionally, you can launch the Profile View Wizard from this page by choosing Choose Settings, and then clicking Profile View Wizard.... This lets you change a variety of profile view options. For more information, see Understanding Profile View Options (page 1724).

If you have chosen an output that does not include profiles, this page of the Create Sheets wizard is skipped (not displayed), and the Data References page of the Create Sheets wizard is displayed.

### Profile View Settings

Profile View Style To Be Used

This read-only field displays the profile view style that was chosen during frame view creation. This is the profile view style that will be added to each profile view.

Band Set To Be Used

This read-only field displays the band set that was chosen during frame view creation. This is the band set that will be used to generate these sheets.

### Other Profile View Options

Use these options to change certain settings on the profile views that will be used to create these sheets. For more information, see Understanding Profile View Options (page 1724). If you do not want to change any profile view settings, click Next.

Get Other Settings From An Existing Profile View

Select this option if you want to use the settings from another profile view in the current drawing. Select

a profile view in the list or click  to select a profile view in the drawing.

Choose Settings

Select this option if you want to use the Create Multiple Profile Views wizard to select options from multiple profile views. When this option is selected, the Profile View Wizard... button is available.

Profile View Wizard...

Click the Profile View Wizard... button to open the Create Multiple Profile View wizard. At this point in the Create Sheets wizard, you can use the Create Multiple Profile Views wizard to create multiple profile views if desired. If you use this option, multiple profile views will be created and placed in model space in the file containing the sheets. At the end of the Create Multiple Profile Views wizard session, you are returned to the Profile Views page of the Create Sheets wizard.

### Align Views

When creating plan and profile sheets, you can choose how to align the data that is displayed in the plan and profile views. If you are creating plan only or profile only sheets, these options are not available. These options are useful on projects that require the data displayed in sheets to be aligned according to certain project requirements (such as aligned left, center, or right).

Align Profile And Plan View At Start

The left side (start station) match line in the plan view aligns with the left side (start) of the profile view.

Align Profile And Plan View At Center

The center of the plan view aligns with the center point of the profile view.

Align Profile And Plan View At End

The right side (end station) match line in the plan view aligns with the right side (end) of the profile view.

**Related procedures:**

■ Creating Sheets (page 1719)

## Data References Page (Create Sheets Wizard)

Use this page of the wizard to select the data that you want referenced in your sheets.

In the collections that are displayed, items that are required for creating the sheets, such as the selected alignments and profiles, are already selected. You cannot edit these items because you cannot clear the check mark. All other items that are available are expanded in the tree. Select the items in the tree that you want to include in your sheets.

If you have chosen to have the sheets saved in the current file, (in other words, if you have chosen All Layouts In The Current Drawing on the View Frame Group And Layouts page of the Create Sheets wizard), then the Data References page of the Create Sheets wizard is skipped (not displayed).

 Pick From Drawing

Click to select the objects in the drawing.

Copy Pipe Network Labels To Destination Drawings

Selecting this option copies any pipe network labels to the destination drawing(s). If no pipe networks exist, this option is not available.

**Related procedures:**

■ Creating Sheets (page 1719)

# View Frame Properties Dialog Box

Use this dialog box to view the properties of a view frame, such as the view frame name, description, and style.

The View Frame Properties dialog box also lists the view frame group, which template was used, and whether a sheet has been created from the view frame.

**See also:**

■ Editing View Frames (page 1711)

## Information Tab (View Frame Properties Dialog Box)

Use this tab to view or change general information for the view frame using the following settings:

Name

Specifies the name of the current view frame.

Description

Specifies an optional description for the current view frame.

Object Style

Specifies the default view frame style used to display view frames. Select a style in the list or use the standard style selection tools. For more information about the standard style selection tools, see the Select Style (page 1805) dialog box.

Show Tooltips

Specifies whether tooltips are displayed for the object in the drawing (not over toolbar icons).

## View Frame Tab (View Frame Properties Dialog Box)

Use this tab to view the parameters of the current view frame, including the alignment name, view frame group, view frame number, orientation, and station values.

Alignment

This read-only field displays the alignment that was used to create the view frame group.

View Frame Group

This read-only field displays the name of the view frame group this view frame belongs to.

## View Frame Number

This read-only field indicates the order in which this view frame is displayed in the sequence of view frames in this view frame group. For example, the first view frame displayed in the view frame group has a view frame number of 1. If there are a total of eight view frames in the view frame group, the last view frame in the group would have a view frame number of 8. Note that the view frame number is not related to the number counter that may be included in the view frame naming template.

## View Frame Orientation

Displays the orientation of the view frame; either Rotate To North or Along Alignment, depending on which option was selected in the View Frame Placement section of the Sheets page (Create View Frames wizard).

## Start Station

Displays the station value at which the match line associated with this view frame begins.

## End Station

Displays the station value at which the match line associated with this view frame ends.

# Sheet Tab (View Frame Properties Dialog Box)

Use this tab to view the sheet settings of the current view frame.

## Sheet

This read-only field displays the path, filename, and layout name for the sheet file containing the layout (sheet), if it has been generated. Otherwise it displays No Sheet Created.

## Type

This read-only field displays the type of sheet (Plan And Profile, Plan Only, or Profile Only).

## Sheet Set

This read-only field displays the path where the sheet set file associated with this view frame is stored, if it has been generated. Otherwise it displays No Sheet Created.

## Template Source

This read-only field displays the path, filename, and layout name for the sheet file/layout that was used for the sheet creation.

# Match Line Properties Dialog Box

Use this dialog box to view or change the properties of a match line, such as the match line style, name, and description.

The Match Line Properties dialog box also lists the match line number and which alignment station it is associated with.

**See also:**

■   Editing Match Lines (page 1715)

# Information Tab (Match Line Properties Dialog Box)

Use this tab to view or change general information for the match line.

## Name

Specifies the name of the current match line.

Description

Specifies an optional description for the current match line.

Object Style

Specifies the default match line style used to display the match line and the match line mask area (page 1715). Select a style in the list or use the standard selection tools. For more information about the standard style selection tools, see the Select Style (page 1805) dialog box. For more information about the match line style components, see Match Line Style Dialog Box (page 2099).

Show Tooltips

Specifies whether tooltips are displayed for the object in the drawing (not over toolbar icons).

## Match Line Tab (Match Line Properties Dialog Box)

Use this tab to view the parameters of the current match line, including the alignment name, match line number, the station value where the match line is located, and the name of the view frame group that this match line is associated with.

Alignment

Specifies the alignment that this match line is associated with.

Match Line Number

This read-only field indicates the order in which this match line is displayed in the sequence of match lines in this view frame group. For example, the first match line displayed in the view frame group has a match line number of 1. If there are a total of eight match lines in the view frame group, the last match line in the group would have a match line number of 8. Note that the match line number is not related to the number counter that may be included in the match line naming template.

Station

This read-only field displays the station value where this match line is located.

View Frame Group

This read-only field displays the name of the view frame group that this match line is associated with.

## View Frame Group Properties Dialog Box

Use this dialog box to view or change the properties of a view frame group.

These are the default settings that are used when new view frames are added to a view frame group.

## Information Tab (View Frame Group Properties Dialog Box)

Use this tab to view or change general information for the view frame group object.

Name

Specifies the name of the current view frame group.

Description

Specifies an optional description for the current view frame group.

Show Tooltips

Specifies whether tooltips are displayed for the object in the drawing (not over toolbar icons).

**Related procedures:**

■ Creating View Frames (page 1703)

# View Frames Tab (View Frame Group Properties Dialog Box)

Use this tab to view and edit the parameters of the view frames associated with the current view frame group.

These are the default settings that are used when new view frames are added to a view frame group using the InsertViewFrame command.

**View Frame Group Defaults**

View Frame Style

Displays the style that is used to display the view frame.

Click to select the style of a view frame in the drawing.

View Frame Layer

Displays the layer that the view frame will be created on.

Click to open the Object Layer dialog box, where you can select a different layer for the view frame.

Name

Specifies the name of the view frame.

**NOTE** To name the view frame, either click on its default name and enter a new name, or use the naming template.

Click to open the Name Template (page 1806) dialog box, where you can modify the view frame naming template.

The view frames table contains the following columns:

Number

This read-only field displays the number assigned to each view frame in this view frame group.

Name

Specifies the name of the view frame. You can change the name by clicking in the field.

Description

Specifies an optional description of the view frame. You can change the description by clicking in the field.

Begin Station

This read-only field displays the station along the alignment where this view frame begins. If the alignment that was used to create this view frame is unavailable or has been deleted, Not Available is displayed.

End Station

This read-only field displays the station along the alignment where this view frame ends. If the alignment that was used to create this view frame is unavailable or has been deleted, Not Available is displayed.

End Station

This read-only field displays the station along the alignment where this view frame ends. If the alignment that was used to create this view frame is unavailable or has been deleted, Not Available is displayed.

Layer

Specifies the layer of the view frame. You can change the layer by clicking in the field.

**Style**

Specifies the style of the view frame. You can change the style by clicking in the field.

**Layout Path**

This read-only field displays the path and filename of the layouts that are used by the view frames in this view frame group. If it was not generated, then No Sheet Generated is displayed.

# Match Lines Tab (View Frame Group Properties Dialog Box)

Use this tab to view and edit the parameters of the match lines associated with the current view frame group.

These are the default settings that are used when new match lines are added to a view frame group using the InsertViewFrame command.

## View Frame Group Defaults

**Match Line Style**

Displays the style that is used to display the match line and the match line mask area. Editing the Match Line Mask Area (page 1715)

Click to select the style of a match line in the drawing.

**Match Line Layer**

Displays the layer that the match line will be created on.

Click to open the Object Layer dialog box, where you can select a different layer for the match line.

**Name**

Specifies the default name template used for new match lines.

> **NOTE** To name the match line, click on its default name and enter a new name or use the naming template.

Click to open the Name Template (page 1806) dialog box, where you can modify the match line naming template.

The match lines table contains the following columns:

**Number**

This read-only fields displays the number assigned to each match line in this view frame group.

**Name**

Specifies the name of the match line. You can change the name by clicking in the field.

**Description**

Specifies an optional description of the match line. You can change the description by clicking in the field.

**Station**

This read-only field displays the station along the alignment where this match line is placed. If the alignment that was used to create this view frame group is unavailable or has been deleted, Not Available is displayed.

**Layer**

Specifies the layer of the match line. You can change the layer by clicking in the field.

Style

Specifies the style of the match line. You can change the style by clicking in the field.

Sheet Left

This read-only field displays the filename and sheet name of the sheet that is on the left side of the match line.

Sheet Right

This read-only field displays the filename and the sheet name of the sheet that is on the right side of the match line.

# Profile Views Tab (View Frame Group Properties Dialog Box)

Use this tab to view the parameters of the profile view(s) that may be associated with the current view frame group.

### Profile View Style

Profile View Style To Be Used

This read-only field shows you the style that will be used to display the profile view(s) associated with this view frame group.

### Band Set

Band Set Style To Be Used

This read-only field shows you the style that will be used to display the band sets for profile view(s) associated with this view frame group.

# View Frame Style Dialog Box

Use this dialog box to make it easier to locate and work with view frames by changing their display.

The view frame style controls the appearance of view frames.

**See also:**

■ View Frame Styles and Display (page 1695)

# Information Tab (View Frame Style Dialog Box)

Use this tab to change the view frame style name and description information, and to review details about the style, such as when it was most recently modified.

For more information, see Information Tab (Style Dialog Box) (page 1801).

# Display Tab (View Frame Style Dialog Box)

Use this tab to change the display and visibility of view frames.

### View Direction

Some object styles can have unique display values and varying numbers of displayed components, depending on whether they are being displayed in Plan, Profile, Section, or Model views. You can create and set style characteristics for each supported view direction type using the View Direction list.

Plan

Specifies the display style settings when the view frame is displayed in plan view. For view frames, only Plan View Direction is supported.

### Component Display

View Frame Border

This is the closed polyline entity that represents the extents of a view frame. You can set the following style characteristics for this component: Visibility, Layer, Color, Linetype, LT Scale, and Lineweight.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (View Frame Style Dialog Box)

Use this tab to review all the information about the current view frame style.

You can copy and paste this information to the clipboard. For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Match Line Style Dialog Box

Use this dialog box to make it easier to work with match lines by changing their display characteristics.

The match line style controls the appearance of the match line and the match line mask area.

**See also:**

- Match Lines Styles and Display (page 1697)
- Editing the Match Line Mask Area (page 1715)

## Information Tab (Match Line Style Dialog Box)

Use this tab to view or change the match line style name and description information, and to review details about the style, such as when it was most recently modified.

For more information, see Information Tab (Style Dialog Box) (page 1801).

## Display Tab (Match Line Style Dialog Box)

Use this tab to view or change the display and visibility of match lines and the match line mask area.

### View Direction

Plan

Some object styles have unique display values and varying numbers of displayed components, depending on whether Plan, Profile, Section, or Model is selected for View Direction. For match lines, only Plan View Direction is supported.

### Component Display

Lines

Specifies the style for match lines. Match lines are only displayed in plan views, not profile views. You can set the following style characteristics for match lines: Visibility, Layer, Color, Linetype, LT Scale, Lineweight, and Plot Style.

Match Line Mask

Specifies the style for the match line mask areas. Match line mask areas are only displayed in plan view and in paper space. The the match line mask area is the area outside of match lines, between the outside of the match line, and the inside of the view frame boundary.

**Component Hatch Display**

Match Line Mask

Specifies the hatch pattern for the match line mask areas, which are only displayed in plan views, not profile views. You can define a pattern, angle and scale for hatching in this closed polyline area. For more information, see The Match Line Object (page 1696) and Editing the Match Line Mask Area (page 1715).

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Match Line Style Dialog Box)

Use this tab to review all the information about the current match line style.

You can copy and paste this information to the clipboard. For more information, see Summary Tab (Style Dialog Box) (page 1803).

## Select Layout as Sheet Template Dialog Box

Use this dialog box to select the template to use when you create a view frame group using the Create View Frames wizard.

The choices you make in this dialog box define the folder path, drawing template (DWT) file, and a layout name that will be used for creating the new sheets. You must choose a template that has viewports defined appropriately. For example, if you want to choose a template that contains viewports for both plan and profile views, you must select a template that contains viewports with Viewport Types that are defined as "plan" and "profile".

If you try to select a template that does not have appropriately defined viewports for the sheet type you selected on the Sheets page of the Create View Frames wizard (Plan Only, Profile Only, or Plan and Profile), AutoCAD Civil detects this and displays the following message: No layouts contain the necessary viewports for this sheet type.

For more information, see Configuring Viewports for Plan Production (page 1700).

Drawing Template File Name

Specifies the drawing template file path and name that will be used for creating the new sheets. Click ⋯ to select a valid template for the sheet(s) that will be created later when using the Create Sheets wizard.

Select A Layout To Create New Sheets

Lists and specifies the name of the layout in the drawing template file to be used for the new sheet(s) that will be created later when using the Create Sheets wizard.

**Related procedures:**

## Edit Match Line Group Labels Dialog Box

Use this dialog box to change label styles and locations for all match lines in a view frame group.

Left Match Line Label Style

Specifies the style for the labels that are displayed on the left side of a match line. You can choose a label style from the list.

Right Match Line Label Style

Specifies the style for the labels that are displayed on the right side of a match line. You can choose a label style from the list.

 Style Selection

Specifies the label style options. You can create a new label style, copy or edit the current style selection, or pick a style from the drawing.

 Style Detail

Opens the Style Detail dialog box. Preview the style and creation information.

Left Label Location

Specifies the location for labels that are displayed on the left side of a match line. Click in the value field to select a location from the list.

■ Start: Places the left match line label at the start of the match line, near the top of the view frame.

■ End: Places the left match line label at the end of the match line, near the bottom of the view frame.

■ Middle: Places the left match line label at the middle of the match line.

■ Alignment Intersection: Places the left match line label where the alignment intersects the match line.

Right Label Location

Specifies the location for labels that are displayed on the right side of a match line. Click in the value field to select a location from the list.

■ Start: Places the right match line label at the start of the match line, near the top of the view frame.

■ End: Places the right match line label at the end of the match line, near the bottom of the view frame.

■ Middle: Places the right match line label at the middle of the match line.

■ Alignment Intersection: Places the right match line label where the alignment intersects the match line.

**Related procedures:**

■ Labeling Match Lines (page 1718)

# Edit Match Line Labels Dialog Box

Use this dialog box to change label styles and locations for a match line.

Match Line Label Style

Specifies the style for the labels that are displayed on a match line. You can choose a label style from the list.

 Style Selection

Specifies the label style options. You can create a new label style, copy or edit the current style selection, or pick a style from the drawing.

 Style Detail

Opens the Style Detail dialog box. Preview the style and creation information.

Label Location

Specifies the location for labels that are displayed on a match line. Click in the value field to select a location from the list.

- Start: Places the match line label at the start of the match line, near the top of the view frame.

- End: Places the match line label at the end of the match line, near the bottom of the view frame.

- Middle: Places the match line label at the middle of the match line.

- Alignment Intersection: Places the match line label where the alignment intersects the match line.

**Related procedures:**

- Labeling Match Lines (page 1718)

# Edit View Frame Labels Dialog Box

Use this dialog box to change label styles and locations for a view frame.

View Frame Label Style

Specifies the style for the labels that are displayed on a view frame. You can choose a label style from the list.

 Style Selection

Specifies the label style options. You can create a new label style, copy or edit the current style selection, or pick a style from the drawing.

 Style Detail

Opens the Style Detail dialog box. Preview the style and creation information.

Label Location

Specifies the location for labels that are displayed on a view frame. Click in the value field to select a location from the list. For example, choosing Top Left places the view frame labels at the top left side of the view frame.

**Related procedures:**

- Labeling View Frames (page 1713)

# Points Dialog Boxes

# 63

Use the following links to access information about the Points dialog boxes.

## Edit Feature Settings - Point Dialog Box

Use this dialog box to view and change point-related settings.

This topic documents settings in all point-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

- Drawing-level ambient settings are identified by the ▭ drawing icon.

- Point feature settings are listed near the top of this dialog box, after the General property group, and are identified by the ✛ point icon.

- Point command settings are identified by the ☑ command icon.

You can also change the settings at the command level in the Create Points dialog box.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

### ✛ Default Styles

Use these settings to establish the default styles assigned to points and points labels.

---

**IMPORTANT** By default, in the Create Points dialog box - Points Creation section the Disable Description Keys value is set to false and the controls in the Default Styles section are not available. To enable the Default Styles controls, set the Disable Description Keys value to true.

---

Point Style

Specifies the default point style. Click in the Value column, and click ⋯ to select a style in the Point Style dialog box.

Point Label Style

Specifies the default point label style. Click in the Value column, and click ![...] to select a style in the Point Label Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

## ⊕ Default Name Format

Use these settings to specify the default name formats for new points and point groups. Click in the Value column, and click ![...] to make changes in the Name Template dialog box (page 1806).

## ⊕ Update Points

Use this setting to specify whether you can change local copies of project points without checking them out.

---

**WARNING** If you edit local copies of project points in a drawing without checking them out, you cannot check the points in to the project. Your changes exist only in the drawing in which you made them.

---

Allow Checked-In Points To Be Modified

Specifies whether you can change checked in points when you are working offline.

For more information, see Editing the Update Points Settings (page 412).

## ☑ Point Identity

Use these settings to assign defaults for point number identity.

Next Point Number

Specifies the next available point number.

Use Sequential Numbering

Specifies whether points are automatically numbered in sequence as they are created.

- False: Prompts you to assign point numbers as you create points.

- True: Automatically numbers points in sequence, starting with the number specified in Next Point Number

Point Number Offset

Specifies the offset added to imported point numbers when If Point Numbers Are Supplied is set to Add An Offset. Enter an offset.

Sequence Point Numbers From

Specifies the starting point number for imported points when If Point Numbers Need To Be Assigned is set to Sequence From. Enter a starting point number.

If Point Numbers Are Supplied

Specifies how to handle point numbers that are included in the point data being imported:

- Use: Uses the point numbers in the point data file to create points during import.

- Ignore: Does not use the point numbers in the point data file to create points during import. Points are numbered according to the If Point Numbers Need To Be Assigned setting.

- Add an Offset: Adds a fixed value, the value specified in Point Number Offset, to each point number in the point data file. For example, if you specify 200 for Point Number Offset, then points with numbers 1, 2, and 3 in the point data file are numbered 201, 202, and 203 when imported.

Force Names

Specifies if null point names are allowed.:

■ False: Point names are not automatically assigned to a point when it is created or imported.

■ True: Point names are always assigned to a point when it is created or imported.

If Point Numbers Already Exist

Specifies how to handle point numbers that already exist when the same point number is present in the data being imported:

■ Renumber: Assigns new point numbers to any imported points whose point numbers already exist. Points are numbered according to the If Point Numbers Need To Be Assigned setting.

■ Merge: Merges the point data of the existing point with the point data of the imported point. Point properties, such as elevation or raw description, that are specified in the point data file overwrite the point properties existing in the drawing. Point properties that are not specified in the point data file are preserved in the drawing.

■ Overwrite: Overwrites all point properties using the values in the point data file. No data is preserved; point properties that are not specified in the point data file are blank in the drawing.

■ Notify: Notifies you that a point number collision has occurred. Opens the Duplicate Point Number (page 2134) dialog box where you can specify how to resolve the collision.

NOTE For more information about how the Merge and Overwrite options work, see Editing the Point Identity Settings (page 413).

If Point Names Already Exist

Specifies how to handle point names that already exist when the same point name is present in the data being imported:

■ Use Name Template: Uses the name specified in the Point Name Template.

■ Counter: Increments a counter to the current point name.

■ Notify: Notifies you that a point name collision has occurred. Opens the Duplicate Point Name (page 2135) dialog box where you can specify how to resolve the collision.

If Point Numbers Need To Be Assigned

Specifies how new point numbers are assigned, when required, during import:

■ Use Next Point Number: Points are created using the next available point number.

■ Sequence From: Points are created beginning with the point number specified in Sequence Point Numbers From. Additional points are created with point numbers specified by incrementing the starting point number. For example, if you specify 300 for Sequence Point Numbers From, the first point is created with point number 300, the second point is created with point number 301, and the next point is created with point number 302.

## Table Creation

NOTE This property group is displayed when accessing the settings from the AddPointTable command.

Use these settings to establish the defaults when you add a point table.

Table Style

Specifies the style for a table. Click in the Value column, and click  to select a style in the  Table Style dialog box.

Split Table

Specifies whether a table is split into two or more sections after a specified maximum number of rows has been met.

Maximum Number of Rows

Specifies the maximum number of rows to include per section. If the number of data rows exceeds the specified maximum, the table is split into sections, and they are displayed either side by side (left to right), or stacked vertically.

Maximum Tables Per Stack

Specifies the maximum number of sections to include in each stack.

Table Spacing

Specifies the spacing between tables.

Tile Direction

Specifies the direction in which the table tiles (across or down).

## Default Layer

**NOTE** This property group is displayed when accessing the settings from the ConvertPointsToSdskPoints and CreatePoints commands.

Use this setting to establish default layer information when you create points.

Layer

Specifies a default layer. Click in the Value column, and click [...] to select or create a layer in the Layer Selection dialog box (page 1986).

## Points Creation

**NOTE** This property group is displayed when accessing the settings from the CreatePoints command.

Use these settings to establish default information for creating points.

Local Coordinates

Specifies the order and format used to display local coordinates on the command line during point creation:

- Easting - Northing

- Northing - Easting

- X - Y

- Y - X

Grid Coordinates

Specifies the order in which grid coordinates are displayed on the command line during point creation:

- Grid Easting - Grid Northing

- Grid Northing - Grid Easting

Geographic Coordinates

Specifies the order in which geographic coordinates are displayed on the command line during point creation:

- Latitude - Longitude

- Longitude - Latitude

**Prompt For Elevations**

Specifies how elevations are assigned point creation:

- Automatic: Creates points using the elevation value specified in Default Elevation.

- Manual: Prompts you to enter an elevation at the command line when a point is created.

- None: Creates points without elevations.

> **NOTE** If you are prompted for an elevation while creating a point and you want to create a point without an elevation, enter a period (.) at the prompt

**Prompt For Point Names**

Specifies how point names are entered during point creation:

- Automatic: Point names will automatically be assigned based on the point name template.

- Manual: Prompts for a point name at the command line when a point is created.

- None: Creates points without point names.

**Prompt For Descriptions**

Specifies how descriptions are assigned during point creation:

- Automatic: Creates points using the description specified in Default Description.

- Automatic-Object: Creates point description from the object.

  > **NOTE** Use the Automatic - Object option with commands from the Creating Points Based on Horizontal Alignments (page 459) list. When you specify this option the Alignment name and Station display in the Raw Description column in the Point Editor window.

- Manual: Prompts for a description at the command line when a point is created.

- None: Creates points without descriptions.

> **NOTE** If you are prompted for a description while creating a point and you want to create a point without a description, enter a period (.) at the prompt.

**Default Elevation**

Specifies the elevation automatically assigned by the point creation commands when the Prompt For Elevations setting is set to Automatic. Enter an elevation in the Value column or click ![icon] and select an elevation in the drawing area.

**Default Description**

Specifies the description that is automatically assigned by the point creation commands when Prompt For Descriptions is set to Automatic.

**Match On Description Parameters ($1, $2, Etc.)**

Specifies whether parameters are used in description key matching to rotate and scale the point symbol. For more information, see Controlling Whether Raw Description Values Are Interpreted as Parameters During Point Creation (page 539).

**Disable Description Keys**

Specifies whether description key matching occurs during point creation. For more information, see Activating Description Key Matching (page 539).

> **NOTE** If you change this setting, then the Disable Description Keys check box on the Create Points dialog box is also changed to the same state.

Echo Coordinates To Command Line

Specifies whether coordinates are displayed on the command line when creating points.

**Related procedures:**

■ Point Settings (page 410)

# Point Group Properties Dialog Box

Use this dialog box to change the properties of a point group.

## Information Tab (Point Group Properties Dialog Box)

Use this tab to view or change general information for the point group.

Name

Specifies the point group name. Change the number and the increment display in the Point Feature Settings. For more information, see Working with the Standard Settings Dialog Box Controls (page 62).

Description

Specifies a description for the point group.

Default Styles

Point Style

Specifies the default point style used to display a point in the point group, if no other style takes precedence. For more information, see Point Group Default Styles (page 523).

**NOTE** Changing the default point style updates the point style on the Overrides tab.

Point Label Style

Specifies the default point label style used to display a point in the point group, if no other style takes precedence. For more information, see Point Group Default Styles (page 523).

**NOTE** Changing the default point label style updates the point label style on the Overrides tab.

Object Locked

Specifies whether changes can be made to the point group in the drawing. Select the check box to lock the point group and prevent changes. For more information, see Locking and Unlocking Point Groups (page 528).

Show Tooltips

Controls whether tooltips are displayed for the object in the drawing (not over toolbar icons).

For more information about how point group styles are used to display a point, see Controlling the Appearance of Points in a Drawing (page 425).

**Related procedures:**

■ Creating Point Groups (page 529)

## Point Groups Tab (Point Group Properties Dialog Box)

Use this tab to include points in a point group by specifying one or more other point groups.

Point Group

Lists all point groups in the drawing. Select the check box next to the name of any point group you want to include in the current point group.

Description

Lists point group descriptions.

Information specified on this tab also appears on the Query Builder tab.

---

**NOTE** If an included point group is out-of-date, any point group that includes it is also out-of-date. For more information, see Out-of-Date Point Groups (page 524).

---

**Related procedures:**

■ Creating Point Groups (page 529)

## Raw Desc Matching Tab (Point Group Properties Dialog Box)

Use this tab to include points in a point group using raw description matching based on available description key codes.

This tab lists the description key codes for all the description keys in the drawing. When you select the check box next to a description key code, any point with a raw description that matches that code is included in the point group.

Code

Lists description key codes for all the description keys in the drawing. Select the check box next to the name of the description key codes you want to match.

Format

Specifies the format for the description key whose code is listed.

For more information about description keys, see Understanding Description Keys (page 537).

Information specified on this tab also appears on the Query Builder tab.

---

**NOTE** You can include or exclude a point from a point group based on its raw or full description. For more information, see Include Tab (Point Group Properties Dialog Box) (page 2109) and Exclude Tab (Point Group Properties Dialog Box) (page 2110).

---

**Related procedures:**

■ Creating Point Groups (page 529)

## Include Tab (Point Group Properties Dialog Box)

Use this tab to include points in a point group by point number, description, name, elevation, or by selection.

With Numbers Matching

Includes a point in the point group based on its point number or by selection:

■ Enter point numbers or ranges of point numbers separated by commas. Specify a range of point numbers by separating the beginning and ending numbers with a hyphen (for example, 100-105).

■ Click Selection Set In Drawing and select points from the drawing using standard AutoCAD selection techniques.

■ Click Project Points In Window and define a window by specifying two points in the drawing. The project northing and easting coordinates of the window corners are used to determine which project points are contained in the window. All points in the project to which the drawing is attached, and which fall within the window, are included in the point group.

**With Elevations Matching**

Includes a point in the point group based on its elevation. Enter any combination of the following, separated by commas:

■ An individual elevation

■ A greater than sign (>) followed by an elevation. Includes all points with an elevation above the specified value

■ A less than sign (<) followed by an elevation. Includes all points with an elevation below the specified value

■ An elevation range, which is specified by separating the beginning and ending numbers with a hyphen (for example, 1-100). Includes all points with an elevation that falls within the range

For example, <-100,1-100,110.01,>200 would include all points whose elevations meet one of the following criteria: less than -100, equal to or between 1 and 100, equal to 110.01, or greater than 200.

**With Names Matching**

Includes a point in the point group based on its name. Enter one or more point names separated by commas.

**With Raw Descriptions Matching**

Includes a point in the point group based on its raw description. Enter one or more raw descriptions separated by commas, for example IP**\***,GB**\***,TREE,STA.
The asterisk (**\***) is a wild card that matches any string. For example, the code IP**\*** will match all raw descriptions that begin with IP, so the raw description IPS matches the description IP**\***.

**With Full Descriptions Matching**

Includes a point in the point group based on its full description. Enter one or more full descriptions separated by commas, for example IP**\***,GB**\***,TREE,STA.
The asterisk (**\***) is a wild card that matches any string. For example, the code IP**\*** will match all full descriptions that begin with IP, so the full description IPS matches the description IP**\***.

**Include All Points**

Includes all points in the drawing in the point group. When the check box is selected, all other options on the tab are disabled.

Information specified on this tab appears on the Query Builder tab.

**Related procedures:**

■ Creating Point Groups (page 529)

# Exclude Tab (Point Group Properties Dialog Box)

Use this tab to exclude points from a point group by point number, description, name, elevation, or by selection.

#### With Numbers Matching

Excludes a point from the point group based on its point number or by selection. Select the check box and do one of the following:

■ Enter point numbers or ranges of point numbers separated by commas. Specify a range of point numbers by separating the beginning and ending numbers with a hyphen (for example, 100-105).

■ Click Selection Set In Drawing and select points from the drawing using standard AutoCAD selection techniques.

■ Click Project Points In Window and define a window by specifying two points in the drawing. The northing and easting coordinates of the window corners are used to determine which project points are contained in the window. All points in the project to which the drawing is attached that are within the window are excluded from the point group.

#### With Elevations Matching

Excludes a point from the point group based on its elevation. Enter any combination of the following, separated by commas:

■ An individual elevation

■ A greater than sign (>) followed by an elevation. Excludes all points with an elevation above the specified value

■ A less than sign (<) followed by an elevation. Excludes all points with an elevation below the specified value

■ An elevation range, which is specified by separating the beginning and ending numbers with a hyphen (for example, 1-100). Excludes all points with an elevation that falls within the range

For example, <-100,1-100,110.01,>200 would exclude all points whose elevations meet one of the following criteria: less than -100, equal to or between 1 and 100, equal to 110.01, or greater than 200.

#### With Names Matching

Excludes a point from the point group based on its name. Enter one or more point names separated by commas.

#### With Raw Descriptions Matching

Excludes a point from the point group based on its raw description. Enter one or more raw descriptions separated by commas, for example IP**,**GB**,**TREE,STA.
The asterisk (**) is a wild card that matches any string. For example, the code IP** will match all raw descriptions that begin with IP, so a raw description IPS matches the description IP**.

#### With Full Descriptions Matching

Excludes a point from the point group based on its full description. Enter one or more full descriptions separated by commas, for example IP**,**GB**,**TREE,STA.
The asterisk (**) is a wild card that matches any string. For example, the code IP** will match all full descriptions that begin with IP, so a full description IPS matches the description IP**.

Information specified on this tab appears on the Query Builder tab.

**Related procedures:**

■ Creating Point Groups (page 529)

## Query Builder Tab (Point Group Properties Dialog Box)

Use this tab to define point groups by using a query, which is a set of complex parameters or conditions.

A query consists of one or more expressions. Each row on the Query Builder tab contains an expression. You combine expressions using the set operators AND, OR, and NOT. You can also use parentheses to group expressions. For more information, see Understanding Point Group Queries (page 533).

When you first display the Query Builder tab, the starting query reflects the current contents of the following tabs: Raw Desc Matching, Include, Exclude, and Point Group.

This tab is read only until you select the Modify Query check box. To modify a cell in the query builder grid, click once in the cell to activate the row, then click again to activate the cell. To create a new row, right-click in the Query Builder and click Insert Row. To delete a row, click the row and press Delete.

---

**NOTE** After you select the Modify Query check box, the Raw Desc Matching, Point Groups, Include, and Exclude tabs become inactive. If you want to use these tabs, you must clear the Modify Query check box. For more information, see Creating Point Groups (page 529).

---

Use Case-Sensitive Matching
Specifies whether raw description matching and full description matching are case-sensitive, not only on this tab, but also on the Raw Desc Matching, Include, and Exclude tabs.

Modify Query
Controls whether the query builder tab is active.
Select this check box to edit the current query, which is derived from the contents of the Point Groups, Raw Desc Matching, Include, and Exclude tabs. These tabs become inactive, and their contents are lost, if you click Apply on the active Query Builder tab.
Clear this check box to activate the Point Groups, Raw Desc Matching, and Exclude tabs. If you click any of the activated tabs, the current query in the Query Builder is lost.

Set Operator
Specifies the set operator for an expression. Activate the cell and select AND, OR, or NOT. For more information, see Understanding Point Group Queries (page 533).

(
Turns opening parenthesis on or off. Activate the cell and click in it. For more information about using parentheses to combine expressions, see Understanding Point Group Queries (page 533).

Property
Specifies the property for the expression:

■ Name

■ Raw Description

■ Full Description

■ Point Number

■ Point Elevation

■ Point Group

Operator
Defines the relationship between Property and Value. The operators displayed in the list depend on the property you specified for the expression. Valid values include:

■ = (equal)

■ != (not equal)

■ > (greater than)

■ < (less than)

- \>= (greater than or equal)

- <= (less than or equal)

Value

Specifies the value for the property. Activate the cell and enter the value. Valid values depend on the property, as follows:

- Name: Enter a point name.

- Raw Description: Enter a raw description. You can use wild cards.

- Full Description: Enter a full description. You can use wild cards.

- Point Number: Enter an individual point number or a point range. A range is two point numbers separated by a hyphen, such as 10-21.

- Point Elevation: Enter an individual elevation or a range. A range is two elevations separated by a hyphen, such as 1001-1050.

- Point Group: Enter a point group name.

)

Turns closing parenthesis on or off. Activate the cell and click. For more information about using parentheses to combine expressions, see Understanding Point Group Queries (page 533).

Reset

Resets the current query to the starting query. Any changes you made since you entered the query builder are lost.

Apply

Applies the current query to the point group and updates the Point List and Summary tabs.

**Related procedures:**

- Creating Point Groups (page 529)

## Overrides Tab (Point Group Properties Dialog Box)

Use this tab to override some properties for the points in a point group.

Override values specified in this dialog box are displayed in the drawing, the point group item view, and on the Point List tab of the Point Group Properties dialog box. However, the point itself is not changed. The point group display order can affect the override values displayed in labels for raw description and elevation. It can also affect both the style and label style that is used to display a point in a drawing. For more information, see Using Point Groups to Override Point Properties (page 523).

Raw Description

Overrides the raw description for points in the point group. Under Property, select the check box. Under Override, either click ⊞ and enter the raw description override value, click ⊞ to attach an external data reference, or click ⊞ then click in the row to specify a user-defined property from the list. For more information, see Using External Data References (page 508) and User-Defined Property Classifications (page 416).

Point Elevation

Overrides the elevation for points in the point group.

Point Style

Overrides the point style for points in the point group. Under Property, select the check box. Click in the Override column to open the Point Style dialog box where you can specify a style.

**NOTE** Changing the override point style updates the point style on the Information tab.

Point Label Style

Overrides the point label style for points in the point group. Under Property, select the check box. Click in the Override column to open the Point Label Style dialog box where you can specify a style.

**NOTE** Changing the override point label style updates the point label style on the Information tab.

**Related procedures:**

■ Creating Point Groups (page 529)

## Point List Tab (Point Group Properties Dialog Box)

This tab displays a read only list of the points in the point group.

Change the order in which the headings are displayed by dragging a heading left or right. Adjust the width of a column by dragging the separator between two column headings left or right.

**Related procedures:**

■ Creating Point Groups (page 529)

## Summary Tab (Point Group Properties Dialog Box)

Use this tab to display information about the point groups properties.

Some information on this tab can be copied to a file for editing or printing using standard Windows cut-and-paste techniques.

Property

Lists point group information by category. Expand or collapse the categories to view the information.

Value

Lists the value for each property.

Query Statement

Lists the point group query. Use the Query Builder tab to modify the query.

**Related procedures:**

■ Creating Point Groups (page 529)

# Point Style Dialog Box

This dialog box defines a point style, which controls the way a point symbol is displayed in a drawing.

## Information Tab (Point Style Dialog Box)

Use this tab to change the point style name and description information, and to review details, such as when the style was most recently modified.

For more information, see Information Tab (Style Dialog Box) (page 1801).

**Related procedures:**

■ Creating a Point Style (page 420)

# Marker Tab (Point Style Dialog Box)

Use this tab to specify the appearance of the point symbol in the drawing.

## Use AutoCAD Point For Marker

Use AutoCAD Point For Marker

Displays the point using the current AutoCAD point symbol, which is specified by the AutoCAD PDMODE and PDSIZE system variables.

## Use Custom Marker

Use Custom Marker

Displays the point using the specified symbol.

Custom Marker Style

Specifies the symbol to be displayed. Click one of the five symbols on the left to use as a base symbol. Optionally, click the sixth symbol, the seventh symbol, or both, to superimpose over the base symbol. The specified symbol combination is displayed in the Preview window.

## Use AutoCAD Block Symbol For Marker

Use AutoCAD Block Symbol For Marker

Displays the point using a reference to the selected AutoCAD block. The block is scaled using the options specified under Size.
Lists available block definitions in the drawing. Do one of the following:

■ Click a block name to specify the block to be used for the point symbol. The block displays in the Preview window.

■ Right-click in the block list window. Click Browse to select a block located in another folder.

The specified block displays in the Preview window.

## Marker Rotation Angle

Marker Rotation Angle

Specifies the rotation angle for the symbol. Applies to all three symbol types (AutoCAD Point, Custom

Marker, and AutoCAD Block). Enter a value or click ⌖ to specify an angle.

Orientation Reference

Specifies the Marker Rotation Angle:

■ World Coordinate System: Indicates that the marker rotation angle is relative to the world coordinate system.

■ Object: Indicates that the marker rotation angle is relative to an object it is attached to.

■ View: Indicates that the marker rotation angle is relative to the current AutoCAD view direction.

### Size

Options

Specifies symbol scaling:

- Use Drawing Scale: Determines the size of the marker by multiplying the specified value by the drawing scale. Enter the scale factor.

- Use Fixed Scale: Activates the Fixed Scale options.

- Use Size in Absolute Units: The marker size is an absolute value based on the displayed units. Enter the value.

- Use Size Relative to Screen: The size of the marker is a percentage of the drawing screen size. Enter the percentage.

Fixed Scale

Specifies independent fixed scale values when Options is set to Use Fixed Scale. Enter values for X, Y, or Z.

### Preview

Preview

Displays a preview of the specified symbol. Right-click in the Preview window to access commands that you can use to change the Preview window display.

**Related procedures:**

- Creating a Point Style (page 420)

# 3D Geometry Tab (Point Style Dialog Box)

Use this tab to specify the appearance of the point symbol in 3D views.

### 3D Geometry

Point Display Mode

Specifies how the point symbol will be displayed in 3D views:

- Use Point Elevation: Displays the point using its actual elevation value.

- Flatten Points To Elevation: Specifies the elevation that the point is projected (flattened) to. Enter a value for Point Elevation.

- Exaggerate Points By Scale Factor: Exaggerates the elevation of the point by a specified scale factor. Enter a value for Scale Factor.

Point Elevation

Specifies the elevation to which a point is projected when Point Display Mode is set to Flatten Points To Elevation.

Scale Factor

Specifies the scale factor when Point Display Mode is set to Exaggerate Points By Scale Factor.

**Related procedures:**

- Creating a Point Style (page 420)

## Display Tab (Point Style Dialog Box)

Use this tab to change the display and visibility of point components.

View Direction

Specify the context for which you are setting the point display attributes:

■ Plan – the printed drawing

■ Model – the on-screen design environment

■ Profile – projection into a profile view (marker only)

■ Section – projection into a section view (marker only)

Point components include:

■ Marker: The symbol displayed at the point location.

■ Label: The point label, which is specified by the point label style.

For more information, see Display Tab (Style Dialog Box) (page 1801).

**Related procedures:**

■ Creating a Point Style (page 420)

## Summary Tab (Point Style Dialog Box)

Use this tab to display information about a particular point style. You can copy and paste this information to the clipboard.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

**Related procedures:**

■ Creating a Point Style (page 420)

# Create Points Dialog Box

Use this dialog box to create points using a variety of options, including importing point data from a file.

You can expand the Create Points dialog box to display and edit the point creations settings. For more information, see Point Settings (page 410) and Edit Feature Settings - Point Dialog Box (page 2103)

**NOTE** If you specify Save Command Changes To Settings at the Drawing Settings, and enter a different value for Save Command Changes To Settings at the feature level or the command level, an icon displays in the Child Override column of the Drawing Settings to indicate a setting change at a lower level. For more information, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856).

≫ Expand

Expands the Create Points dialog box to display point settings.

≪ Collapse

Collapses the Create Points dialog box so that only the command lists display.

Point Creation Lists

Specifies point creation commands. Select a point creation command from the following lists:

- Miscellaneous: For more information, see Creating Points Using Miscellaneous Methods (page 428).

- Intersection: For more information, see Creating Points at Intersections (page 440).

- Alignment: For more information, see Creating Points Based on Horizontal Alignments (page 459).

- Surface: For more information, see Creating Points Based on Surface Elevations (page 469).

- Interpolation: For more information, see Creating Points by Interpolation (page 474).

- Slope: For more information, see Creating Points Based on Slope (page 483).

- Import Points Category: For more information, see Creating Points by Importing Point Data (page 487).

**Related procedures:**

- Creating Points (page 427)

# Point Groups Dialog Box

Use this dialog box to change the display order for point groups in a drawing and to update out-of-date point groups.

Also, use this dialog box to select a point group when needed, for example to add a point group to a surface definition or to specify a point group when creating a point table.

A point group is out-of-date when  is displayed next to a point group name.

 Show Differences

Displays the Point Group Changes (page 2119) dialog box.

 Update Point Groups

Updates all out-of-date point groups.

Name

Lists the point groups in the order they are drawn. Select a point group to change its position in the display order or to add it to a surface definition. For more information about point group display order, see Changing the Point Group Display Order (page 526).

Description

Lists point group descriptions.

 Up Arrow

Moves the selected point group up in the display order.

 Down Arrow

Moves the selected point group down in the display order.

# Point Group Changes Dialog Box

Use this dialog box to review and update out-of-date point groups.

![icon] Update Point Groups

Updates all out-of-date point groups by applying the changes specified in the Name, Add/Remove, and List columns.

Name

Lists the names of the out-of-date point groups.

Add/Remove

Specifies which of the following actions must be taken to bring the point group up to date:

■ Add: Points in the List column must be added to the point group to bring it up to date.

■ Remove: Points in the List column must be removed from the point group to bring it up to date.

List

Lists the point numbers that must be added to or removed from the point group to bring it up to date.

# Point File Formats Dialog Box

Use this dialog box to manage point import/export formats.

Format List

Specifies the name of the format you want to work with. Click a point file format to select it.

New

Creates a new format.

Copy

Creates a copy of the selected format.

Modify

Edits the selected format. This option is active only when the selected format can be changed.

View

Displays the properties of the selected format. This option is active only when the selected format cannot be changed.

Delete

Deletes the selected format.

# Point File Formats - Select Format Type Dialog Box

Use this dialog box to specify the type of point file format to create.

User Point File

Creates a point file format that describes the contents of an ASCII (text) point data file.

User Point Database

Creates a point file format that describes the content of a Microsoft® Access (*.mdb*) point data file.

**Related procedures:**

■ Understanding Point File Formats (page 496)

# Point File Format Dialog Box

Use this dialog box to view or edit the properties of a user point file format, which is used to import points from or export points to an ASCII (text) file.

### File Information

Format Name

Specifies the name of the point file format. This name appears in the Point File Formats list in the Settings tree. Enter a name.

Default File Extension

Specifies the default file extension of the point data file when you import or export points using this format.
Enter a file extension or select one of the following:

■ .auf: Autodesk Uploadable File, comma delimited. Required values in the file are Point Number, Northing, Easting, Elevation, and Description (in that order).

■ .csv: Comma Separated Value file; ASCII (text) file comma-delimited.

■ .nez: Northing, Easting, and Elevation data

■ .pnt: Point file.

■ .prn: Formatted text, space delimited.

■ .txt: Delimited ASCII (text) file.

■ .xyz: Coordinates *X*, *Y*, and *Z*.

Comment Tag

Specifies how descriptive text is designated in the point data file. Enter the symbol that precedes a comment in the point data file. For example, if you specify # for the comment tag, any line in the point data file that begins with #, such as #Autodesk Point Data, is ignored during import.
The comment tag indicates where the comment begins. A comment always ends at the end of the line.

### Coordinate Zone Transform

For more information, see Point File Format Coordinate Zone Transformation Property (page 497).

Coordinate Zone Transform

Indicates that the format references a coordinate zone.

Select Zone

Opens the Select Coordinate Zone dialog box.

### Format Options

For more information, see Point File Formatting Options (page 498).

Columnated
Specifies that the point data in the point data file is arranged in columns.

Delimited By
Specifies that the point data in the file is separated by the indicated character. Enter the character.

Read No More Than
Specifies the maximum number of points that can be read from a file (during import) or written to a file (during export), beginning at the top of the file. The limit does not include comment lines or errors in the text file. If you specify a limit of 100, then 100 points are imported or exported.

Sample Every
Samples point data at a specified interval. For example, if you specify a sample interval of 100, then every 100th point is imported or exported.

### Format Column Names

Column Headings or <unused>
Opens the Point File Formats - Select Column Name (page 2122) dialog box. Click an <unused> column heading to assign a column name to the column.

**NOTE** Drag a column heading horizontally to quickly change the column order.

### Reference File Column Names

Column Headings
Displays a point data file so that you can reference its contents as you build the format. (See Load and Parse.)

### Options

Load
Opens the Select Source File dialog box where you can load and view a point data file for reference.

Parse
Displays the loaded file in the dialog box using the point file format you are creating.

**Related procedures:**

■ Creating Point File Formats (page 500)

# User Point Database Format Dialog Box

Use this dialog box to view or edit the properties of a user point database format, which is used to import points from or export points to a Microsoft® Access database *(.mdb)* file.

### File Information

Format Name
Specifies the name of the user point database format. This name appears in the Point File Formats list in the Settings tree. Enter a name.

Table Name
Specifies which table within the Microsoft Access file contains point data. Used when a Microsoft Access point database contains multiple tables.

In the Table Name list, click the table in the Microsoft Access file that you want to use. If you do not see any table names listed, then click the Load button to load the *.mdb* file or enter the name of the table you want to use.

### Coordinate Zone Transform

For more information, see Point File Format Coordinate Zone Transformation Property (page 497).

Coordinate Zone Transform

Indicates that the format references a coordinate zone.

Select Zone

Opens the Select Coordinate Zone dialog box.

### Format Column Names

Column Headings or <unused>

Opens the Point File Formats - Select Column Name (page 2122) dialog box. Click an <unused> column heading to assign a column name to the column.

**NOTE** Drag a column heading horizontally to quickly change the column order.

### Options

Load

Opens the Select Source File dialog box where you can load and view a Microsoft® Access file for reference.

**Related procedures:**

■ Creating a User Point Database Format (page 501)

# Point File Formats - Select Column Name Dialog Box

Use this dialog box to specify a column to be included in a point file format.

After you chose a column name, the dialog box displays additional edit boxes that are consistent with the type of data the column contains.

Column Name

Specifies the name of the column to be included in the point file format. For more information, see Point File Format Column Name Property (page 497).

■ <unused>: Designates a column in the point data file that is empty or that contains data you do not want imported or exported.

■ Easting

■ Northing

■ Point Elevation

**NOTE** The elevation value in a point data file can be adjusted during import or export. For more information, see Adjusting Elevation During Import and Transfer (page 499).

■ Point Number

■ Name

■ Raw Description

■ Full Description

**NOTE** You cannot import the full description; you can only export it.

- Grid Northing

- Grid Easting

- Longitude

- Degrees-Longitude

- Minutes-Longitude

- Seconds-Longitude

- Hemisphere-Longitude

- DECDEG Longitude

- DASHED Longitude

**NOTE** A DASHED longitude value is expressed with dashes, such as 73-13-12.67.

- Latitude

- Degrees-Latitude

- Minutes-Latitude

- Seconds-Latitude

- Hemisphere-Latitude

- DECDEG Latitude

- DASHED Latitude

**NOTE** A DASHED latitude value is expressed with dashes, such as 73-13-12.67.

- Thickness: For more information, see Adjusting Elevation During Import and Transfer (page 499).

- User Defined: Specifies a custom column format. Create as many custom columns as you need. Specify a name for the column, a data type, and an invalid indicator value. You should use this option when you need to copy columns from the source file to the destination file during a Transfer Points command .

- Z+: Specifies a positive elevation adjustment. For more information, see Adjusting Elevation During Import and Transfer (page 499).

- Z-: Specifies a negative elevation adjustment. For more information, see Adjusting Elevation During Import and Transfer (page 499).

- Convergence: Contains calculated convergence angles during point export. For more information, see Calculating Convergence Angles During Export (page 499).

- Scale Factor: Contains calculated scale factors for export. For more information, see Calculating Scale Factors During Export (page 499).

- Intensity: Specifies the color intensity of points in a point cloud.

- **RGB-Red**: Specifies the value of red in the RGB color space for points in a point cloud.

- RGB-Green: Specifies the value of green in the RGB color space for points in a point cloud.

- RGB-Blue: Specifies the value of blue in the RGB color space for points in a point cloud.

- Classification: Specifies the LiDAR LAS format Classification value, such as Bare Earth, Low/Medium/High Vegetation, or Infrastructure. For details, see The American Society Photogrammetry and Remote Sensing (ASPRS) LAS Specification.

- \<user-defined\>: Displays the name of a user-defined property. If you are importing point data from and ASCII file that contains user defined columns, you must create a user defined classification for each column. For more information, see Importing Point Data from an ASCII File Containing User Defined Columns (page 504).

**Invalid Indicator**

(Displayed only after you click a column name.) Specifies a value that causes this column to be ignored when detected in the point data file. Enter a value, for example, 999999.

**Precision**

(Displayed only after you click a column name that requires a decimal value.) Enter the number of decimal precision places for the column, up to 12.

**Thickness Name**

(Displayed only after you click the Thickness column name.) Enter a name for the thickness.

**User Defined Column Name**

(Displayed only after you click the User Defined column name.) Enter a heading name for the user-defined column.

**Data Type**

(Displayed only after you click the User Defined column name.) Select the type of data the column contains:

- Double: Contains a double precision floating point value. Use Double for numbers that contain decimal points, including elevations, northings, eastings, grid northings, grid eastings, latitudes, and longitudes.

- Long: Contains a long integer value. Use Long for point numbers.

- String: Contains an alphanumeric value. Use String for point descriptions and point names.

**Related procedures:**

- Creating Point File Formats (page 500)

# Import Points Dialog Box

Use this dialog box to specify options before you import points from an ASCII (text) file or a Microsoft® Access database (*.mdb*) file.

**Format**

Specifies the format determining how the point data is arranged in the file from which the points will be imported.

 Point Format

Opens the Point File Formats (page 2120) dialog box. Select a point file format, edit a point file format, or create a new point file format to use when importing the point data.

**Source File**

Specifies the name of the point data file that contains the points to be imported. Enter a file name, including the full path name.

⊕ File Selector

Opens the Select Source File dialog box. Browse to the folder where the point data file to be imported is located. Select the file name, and click Open.

## Add Points to Point Group

Add Points to Point Group

Specifies whether the imported points are added to a point group:

- Selected: Adds the imported points to the specified point group and to the _All Points point group.

- Cleared: Adds the imported points only to the _All Points point group.

Add Points To Point Group

Specifies the point group to which imported points are added when is selected.

⟨⊕⟩

Opens the Point File Formats - Create Group (page 2125)dialog box. Specify a point group name.

## Advanced Options

Do Elevation Adjustment If Possible

Specifies that elevation adjustments are performed during import. The point file format must contain Z+, Z-, or Thickness columns. For more information, see Adjusting Elevation During Import and Transfer (page 499).

Do Coordinate Transformation If Possible

Specifies that coordinate transformations should occur during import. The point file format must have a coordinate zone assigned to it, and the current drawing must have coordinate zone and transformation information defined. The points that are imported are transformed to match the zone of the current drawing.

Do Coordinate Data Expansion If Possible

Specifies that coordinate data properties of the points, such as degrees, minutes, seconds, and hemisphere for latitude and longitude, should be calculated if possible. These values are calculated from known coordinate data information contained in the point data file, such as grid northing and grid easting.

**Related procedures:**

- Importing Point Data (page 503)

# Point File Formats - Create Group Dialog Box

Use this dialog box while importing points to either create a point group that includes all the imported points or to add the imported points to an existing point group.

Point Group

Specifies the name of the point group to which the points are added. If the point group does not exist, it is created.

**Related procedures:**

- Creating Point Groups (page 529)

# Export Points Dialog Box

Use this dialog box to specify options before you export points to an ASCII (text) file or a Microsoft Access database (*.mdb*) file.

Format

Specifies the format describing how the point data will be arranged in the exported file.

⊞ Point Format

Opens the Point File Formats (page 2120) dialog box. Select a point file format, edit a point file format, or create a new point file format to use when importing the point data.

Destination File

Specifies the name of the file to which the exported points will be written. Enter a file name, including the full path name.

⊞ File Selector

Opens the Select Destination File dialog box. Browse to the folder where the exported point data file will be located. Enter a file name, and click Save.

## Limit to Points in Point Group

Limit To Points In Point Group

Specifies whether or not a point group is used to specify the points to be exported:

■ Selected: Only the points in the specified point group are exported.

■ Cleared: All points are exported.

Point Group

Specifies the name of the point group that contains the points to be exported when Limit To Points In Point Group is selected.

## Advanced Options

Do Coordinate Transformation If Possible

Specifies that coordinate transformations should occur during export. The point file format must have a coordinate zone assigned to it and the drawing you are exporting points from must have coordinate zone and transformation information defined. The points that are exported are transformed to match the zone assigned to the point file format.

Do Coordinate Data Expansion If Possible

Specifies that missing coordinate data properties of the points being exported, such as degrees, minutes, seconds, and hemisphere for latitude and longitude, are calculated if possible. These values are calculated from known coordinate data information, such as grid northing and grid easting.

**Related procedures:**

■ Exporting Point Data (page 505)

# Transfer Points Dialog Box

Use this dialog box to specify options before you transfer points from a source point data file (either text or *.mdb*) to a destination point data file (either text or *.mdb*).

**Source**

Format

    Specifies the format describing how the point data is arranged in the source file.

➕ Source

    Specifies the name of the point data file from which the point data is read. Enter a file name, including the full path name.

File Selector

    Opens the Select Source File dialog box. Browse to the folder where the source point data file is located. Select the file name, and click Open.

**Destination**

Format

    Specifies the format describing how the point data will be arranged in the destination file.

Destination

    Specifies the name of the file to which the point data is written. Enter a file name, including the full path name.

🔍 File Selector

    Opens the Select Destination File dialog box. Browse to the folder where the point data file will be located. Enter a file name, and click Save.

**Advanced Options**

Do Elevation Adjustment If Possible

    Specifies that elevation adjustments are performed during import. The format must contain Z+, Z-, or Thickness columns. For more information, see Adjusting Elevation During Import and Transfer (page 499).

Do Coordinate Transformation If Possible

    Specifies that coordinate transformations should occur during transfer. Both source and destination point file formats must have coordinate zones assigned to them. The point data in the source file is transformed during transfer to match the zone specified in the destination file point file format.

Do Coordinate Data Expansion If Possible

    Specifies that missing coordinate data properties of the points in the source file, such as degrees, minutes, seconds, and hemisphere for latitude and longitude, should be calculated, if possible, and transferred to the destination file. These values are calculated from known coordinate data information such as grid northing and grid easting in the source file.

**Additional Options**

Manage

    Opens the Point File Formats (page 2119) dialog box. Create, copy, or change a format.

**Related procedures:**

■   Transferring and Converting Point Data (page 506)

# Description Key Set Dialog Box

Use this dialog box to specify the name and description of a description key set.

Name

    Specifies the name of the description key set. Enter a name.

Description

Specifies a description for the description key set. Enter a description.

**Related procedures:**

■ Creating a New Description Key Set (page 547)

# Description Key Sets Search Order Dialog Box

Use this dialog box to specify the order in which description key sets are searched during description key matching.

The description key sets are listed in the order in which they are searched. The description key set at the top of the list is searched first.

Name

Lists the name of the description key set. Click the name to select the description key set.

Description

Lists the description of the description key set.

⬆ Up Arrow

Moves the selected description key set up in the search order.

⬇ Down Arrow

Moves the selected description key set down in the search order.

**Related procedures:**

■ Changing the Description Key Sets Search Order (page 548)

# Description Key Editor

Use this dialog box to edit description key properties.

You can also edit description keys in the Prospector item view. However, because the DescKey Editor is a separate window, it provides more viewing area and greater flexibility.

**Code and Format**

These properties are required in every description key.

Code

Specifies what points match this description key during description key matching. Click in the cell and then enter a code. For more information, see Description Key Code (page 540).

Format

Specifies the format used to translate the raw description into the full description. Click in the cell and enter a format. Enter $* if you want the full description to be the same as the raw description. For more information, see Description Key Format (page 542).

**Styles and Layer**

For more information about how point style, point label style, and point layer are used to display a point, see Controlling the Appearance of Points in a Drawing (page 425).

Point Style

Specifies the point style to be referenced by a point that is created using the description key.

To specify a point style:

- Select the Point Style check box.

- Click in the cell to open the Point Style (page 2114) dialog box. Select a point style.

---

**NOTE** Scale and rotation values in the point style are overridden by description key scale and rotation overrides.

---

Point Label Style

Specifies the point label style to be referenced by a point that is created using the description key.
To specify a point label style:

- Select the Point Label Style check box.

- Click in the cell to open the Point Label Style (page 1805) dialog box. Select a point label style.

Layer

Specifies the layer for the point.
To specify a layer:

- Select the Layer check box.

- Click in the cell to open the Layer Selection dialog box. Select a layer.

## Scale Override Properties

Use the Scale Override properties of a description key to specify how the point symbol is scaled when a point is created using the description key.

Scale values specified in this part of the description key take precedence over any scale values specified in the point style referenced by the description key. If scale parameters have been set, hold your cursor over

□ in the Code column, to display a tooltip with the scale parameters and values.

Select Apply To X-Y or Apply To Z before you specify a scale using Scale Parameter, Fixed Scale Factor, or Use Drawing Scale properties.

Scale Parameter

Specifies the position (1-9) in the raw description of the parameter that contains the value used to scale the point symbol when the description key is matched.
To specify a scale parameter:

- Select the Scale Parameter check box.

- Click in the cell and select a parameter.

For more information, see Specifying Point Symbol Scaling and Rotation Using Description Key Parameters (page 544).

Fixed Scale Factor

Specifies a fixed scale, used to scale the point symbol when the description key is matched.
To specify a fixed scale factor:

- Select the Fixed Scale Factor check box.

- Click in the cell and enter a scale factor.

Use Drawing Scale

Specifies that the drawing scale is used to scale the point symbol when the description key is matched.
Click in the cell then select Yes to use the drawing scale.

Apply To X-Y

Specifies that description key scaling is applied to the *X-Y* axis of a point when the description key is matched. Click in the cell then select Yes to specify *X-Y* scaling.

Apply To Z

Specifies that description key scaling is applied to the Z axis of a point when the description key is matched. Click in the cell then select Yes to specify Z scaling.

### Rotation Override Properties

Use the Rotation properties of a description key to specify how the point symbol is rotated when a point is created using the description key.

Rotation values specified in this part of the description key take precedence over any rotation values specified in the point style that is referenced by the description key.

If rotation parameters have been set, hold your cursor over in the Code column to display a tooltip with the rotation parameters and values.

Rotate Parameter

Specifies the position (1-9) in the raw description of the parameter containing the value used to rotate the point symbol when the description key is matched.
To specify a rotation parameter:

■ Select the Rotation Parameter check box.

■ Click in the cell then select a parameter.

For more information, see Specifying Point Symbol Scaling and Rotation Using Description Key Parameters (page 544).

Fixed Rotation

Specifies a fixed rotation used to rotate the point symbol when the description key is matched.
To specify a fixed rotation factor:

■ Select the Fixed Rotation check box.

■ Click in the cell and enter a rotation value.

Rotation Direction

Specifies whether the values specified for the Rotate Parameter property or the Fixed Rotation property are clockwise angles or counterclockwise angles.

### Related procedures:

■ Editing Description Keys (page 556)

## Point Editor

Use the window to edit drawing point properties.

Each row in the Point Editor contains the properties for a single point. To edit a point property value, click in the cell containing the property to activate it. If a cell is shaded, you cannot change the value.

**NOTE** You can also edit drawing points in the Prospector item view. However, because the Point Editor is a separate window, it provides more viewing area and greater flexibility.

These drawing point properties are displayed in the Point Editor and in the drawing Points collection list view:

**Point Number**

Specifies the point number. Point numbers must be unique. Enter an integer.

**Easting**

Specifies a local easting value for the point. If the transformation settings are enabled for the drawing when you edit this value, the corresponding values for grid easting and latitude are automatically updated. Enter a value with up to 12 digits of precision.

**Northing**

Specifies a local northing value for the point. If the transformation settings are enabled for the drawing when you edit this value, the corresponding values for grid northing and longitude are automatically updated. Enter a northing value with up to 12 digits of precision.

**Point Elevation**

Specifies an elevation for the point. Enter an elevation value.

**Name**

Specifies an optional point name, which must be unique within a drawing or a project.

**NOTE** Point names are not case sensitive.

**Raw Description**

Specifies a raw description for the point, which is often the description entered by the surveyor in the field. Enter alphanumeric characters. Any character, including a blank, can be used.

**Full Description**

Specifies an expanded description that is created from the raw description using the description format. If a point does not have a description format, the full description is the same as the raw description. You cannot edit this field directly. The value can be set initially using description key matching. For more information, see Description Keys (page 537). You can update the full description of a single point either by changing the points description format or by changing the points raw description. For more information, see Description Key Format (page 542).

**Description Format**

Specifies a format that translates the points raw description into a full description. If a point does not have a description format, the full description is the same as the raw description. For more information, see Description Key Format (page 542).

**Grid Easting  Grid Northing**

Displays the calculated grid easting and grid northing values for the point, relative to the coordinate zone and the transformation settings specified for the drawing.

**Longitude  Latitude**

Displays the latitude and longitude for a point, relative to the coordinate zone and the transformation settings specified for the drawing.

**Scale Factor**

Displays the scale factor value of a point, relative to the coordinate zone and the transformation settings specified for the drawing.

**Convergence**

Displays the convergence value of a point, relative to the coordinate zone and the transformation settings specified for the drawing.

**Point Style**

Specifies the point style for the point. Click in the cell to specify a new point style or remove a point style.

If this field is empty, the point displays using a point style specified by a point group. Also, the point style specified in this field might not be used to display the point in the drawing. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

**Point Label Style**

Specifies the point label style for the point. Click in a cell to specify a new point label style or remove the point label style.

If this field is empty, the point uses a point label style specified by a point group. Also, the point label style specified in this field might not be used to display the point in the drawing. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

**Point Layer**

Specifies the layer for the point. Click in the cell to display the Layer Selection dialog box.

If this field is empty, the point displays using a layer specified by a point group. For more information, see Controlling the Appearance of Points in a Drawing (page 425).

**Project Version**

For project points, specifies the version number of the local copy of the point in the drawing.

**X-Y Scale**

Specifies the X-Y scale factor for the point symbol. This value can be set initially using description key matching. For more information, see Description Keys (page 537).

**Z Scale**

Specifies the Z scale factor for the point symbol. This value can be set initially using description key matching. For more information, see Description Keys (page 537).

**Rotation**

Specifies the rotation value for the point symbol. This value can be set initially using description key

matching. For more information, see Description Keys (page 537). Enter a value or click ⬉ and pick two points in the drawing to specify the rotation angle.

These point properties are displayed in a project Points collection list view for a project point:

**Point Number, Easting, Northing, Point Elevation, Name, Raw Description**

See the preceding text for descriptions of these properties.

**Version**

Displays the most recent project version for the point.

**Modified By**

Displays the login name of the person who last modified the point.

**Modified Date**

Displays the date when the point was last modified.

**Current State**

Displays the current state of the point with respect to the project.

**Current State By**

Displays the project member who set the points current state.

**Current State Date**

Displays the date the state of the point was last changed.

**Checked-Out Drawing**

If the point is checked out, displays the drawing it is checked out to.

Checked-Out Host

    If the point is checked out, displays the computer it is checked out to.

**Related procedures:**

■   Editing Points Using the Point Editor (page 488)

# Geodetic Calculator Dialog Box

Use this dialog box to calculate geodetic information relative to the zone and the transformation values specified in the drawing settings.

To use the calculator, enter values for known coordinate properties, and the remaining coordinate values are calculated.

---

**NOTE** If transformation settings for a drawing are not enabled, the Select Point, Local Northing, Local Easting, and Local Elevation options are not active.

---

Specify Point

    Specifies local northing and easting values using a drawing point. Click a point in the drawing.

Create Point

    Creates a point with the specifications you enter in the value column. After you enter or edit values, you can click this icon to create a new point. At the command line you are prompted to enter a point description and elevation.

Zone Description

    Displays read-only information about the zone specified in the drawing.

Point Number

    Specifies a starting point number from which local northing and easting values are read. Grid Northing, Grid Easting, Latitude, and Longitude are calculated using the drawing zone. Enter a point number.

Latitude

    Specifies latitude. Enter a latitude value using the format specified for the Lat Long drawing ambient setting.
    Changing this property updates the fields for Grid Northing, Grid Easting, Local Northing, Local Easting, Scale Factor, and Convergence.

Longitude

    Specifies longitude. Enter a longitude value using the format specified for the Lat Long drawing ambient setting.
    Changing this property updates the fields for Grid Northing, Grid Easting, Local Northing, Local Easting, Scale Factor, and Convergence.

Grid Northing

    Specifies grid northing. Enter a grid northing value.
    Changing this property updates the fields for Latitude, Longitude, Local Northing, Local Easting, Scale Factor, and Convergence.

Grid Easting

    Specifies grid easting. Enter a grid easting value.
    Changing this property updates the fields for Latitude, Longitude, Local Northing, Local Easting, Scale Factor, and Convergence.

Local Northing

Specifies local northing. Enter a local northing value.
Changing this property updates the fields for Latitude, Longitude, Grid Northing, Grid Easting, Scale Factor, and Convergence fields to be updated.

Local Easting

Specifies local easting. Enter a local easting value.
Changing this property updates the fields for Latitude, Longitude, Grid Northing, Grid Easting, Scale Factor, and Convergence.

Local Elevation

Specifies the local elevation for the specified point number.

Scale Factor

Displays the scale factor for the specified coordinate values. This read-only value is updated when coordinates are recalculated.

Convergence

Displays the convergence for the specified coordinate values using the format specified for the Lat Long drawing ambient setting. This read-only value is updated when coordinates are recalculated.

Sea Level Corrections Applied

Specifies whether sea level corrections are applied in Drawing Settings.

Grid Scale Factor Applied

Specifies whether the grid scale factor is applied in Drawing Settings.

**Related procedures:**

■  Geodetic Calculator (page 515)

# Duplicate Point Number Dialog Box

Use this dialog box to handle point number conflicts arising from trying to create a point with the same point number as an existing point.

In the following descriptions, source point is the point that the command is attempting to create, and destination point is the existing point.

### Duplicate Point Number Resolution

IMPORTANT  For duplicate Survey point numbers, Overwrite and Ignore are the only Resolution options. Selecting the Ignore option leaves the COGO point values intact. Options for Add An Offset From and Sequence From are not available.

Resolution

Specifies how the point number conflict is resolved:

■  Add An Offset: Adds the offset specified for the Add An Offset From option to the source point number. For example, if you enter an offset of 200, source points with numbers 1, 2, and 3 are re-numbered 201, 202, and 203.

■  Merge: Overwrites point data that exists in the destination point with data that exists in the source point and preserves data in the destination point that is not supplied by the source point.

■  Overwrite: Overwrites the destination point.

■  Sequence From: Begins renumbering the source points using the point number specified in the Sequence From option.

■ Use Next Point Number: Assigns the next unused point number to the point.

Add An Offset From

Specifies the offset to be added to the source point number when the Resolution is set to Add An Offset. Enter an integer.

Sequence From

Specifies the starting sequence number for renumbering the source points when the Resolution is set to Sequence From. Enter an integer.

Apply To All Duplicate Point Numbers

Specifies that the Resolution setting is applied to any additional duplicate point numbers encountered by the command. If a duplicate point number occurs that cannot be resolved based on the Resolution setting, this dialog box displays again.

# Duplicate Point Name Dialog Box

Use this dialog box to handle point name conflicts arising from trying to create a point with the same point name as an existing point.

In the following descriptions, source point is the point that the command is attempting to create, and destination point is the existing point.

### Duplicate Point Name Resolution

Resolution

Specifies how the point name conflict is resolved:

■ Counter: adds a numerical suffix to the current point name. A new point is created. The second instance of the duplicate point name would be <point name> (1).

■ Specify: Displays the Point Name edit box to specify a name for the imported point.

■ Use Name Template: Creates a new point and assigns the point name based on the point name template.

Point Name

Specify a point name if you select Specify as the Resolution.

Apply To All Duplicate Point Numbers

Select to apply the resolution to all duplicate point names. If you select Specify as the Resolution type, this check box is not available.

# Point Table Creation Dialog Box

Use this dialog box to create a point table in a drawing.

Most of the controls in this dialog box are generic table creation controls. For a description of these controls, see Table Creation Dialog Box (page 2441).

Use the following controls to specify the points to be included in the point table:

⊡ Point Group Selector

Displays the Point Groups (page 2118) dialog box. Specifies a point group. The points in the point groups point list are added to the point table.

▣ Point Selector

Selects the points to be added to the point table.

**Related procedures:**

■ Point Tables (page 422)

# Create External Data Reference Dialog Box

Use this dialog box to create an external data reference (XDRef) or change the properties of an existing XDRef.

Name

Specifies the file name for the XDRef.

Description

Specifies an optional description.

Database

Specifies the name and the path for the external database file *(.mdb file)*.

Password Protected Database

Specifies that a password must be entered if this is selected.

Table

Specifies the column data for the XDRef.

Index Column

Specifies the index column containing the integers that correspond to the point numbers within the point group that you are overriding.

Value Column

Specifies the column that contains the values that override the point group values when you specify this XDRef as the override.

**Related procedures:**

■ Using External Data References (page 508)

# Create Blocks from COGO Points Dialog Box

Use this dialog box to specify a selection of COGO points to use in creating an AutoCAD BLOCK for each Civil point.

**Select COGO Points**

Spatial Filter

Specifies a filter.

■ None: Uses only those points contained in the point group that is specified under Point Groups.

■ Current Display: Uses the current display to define the spatial selection of points in the drawing.

■ Define Window: Uses a crossing window in the drawing to define the spatial selection of points.

Point Groups

Click 🔲 to open the Point Groups dialog box, which lists all point groups in the drawing. Specify the point group(s) you want to include in the block creation.

**Block Output**

Block Creation

■ Use Existing Block: to use this option the block must contain at least three attribute definitions exactly named ELEV, POINT, and DESC. If there are no blocks in the drawing with these exact attributes, this option is not available.

■ Make New Block: specifies a new block and block name. If a block has two or more instances of the same attribute, each instance is filled with the same value.

Block Layer

Specifies the layer the block is placed on.

**Related procedures:**

■ Creating Blocks from COGO Points (page 513)

# Convert Land Desktop Points Dialog Box

Use this dialog box to enter the point settings for the Land Desktop points you are converting.

For a description of the point settings, see Edit Feature Settings - Point Dialog Box (page 2103).

# Profiles Dialog Boxes

# 64

The following topics provide information about the AutoCAD Civil Profiles dialog boxes.

## Band Set Dialog Box

Use this dialog box to create a set of data band styles for profile views.

Use a band set to apply the same set of data bands to many profile views.

**See also:**

- Profile View Band Styles (page 1038)
- Editing Profile Views (page 1113)

## Information Tab (Band Set Dialog Box)

Use this tab to change the name and description for a band set, and to review details such as latest modification date.

Name
  Specifies the name of the band set.

Description
  Specifies a description of the band set.

Created By
  Displays the Windows login name of the person who created the band set.

Date Created
  Displays the date and time the band set was created.

Last Modified By
  Displays the Windows login name of the person who last modified the band set.

Date Modified
  Displays the date and time the band set was last modified.

# Bands Tab (Band Set Dialog Box)

Use this tab to specify which data bands are included in the set, along with their styles and positions relative to the profile view grid.

Band Type

Specifies which type of data band to add to the set: Profile Data, Vertical Geometry, Horizontal Geometry, Superelevation, Sectional Data, or Pipe Data.

Select Band Style

Specifies a style for the band. To edit a style or create a new one, click  and select from the list of operations. For more information, see Select Style dialog box (page 1805). To examine the details of an existing style, select the style by name in the list and click . For more information, see Style Detail dialog box (page 1804).

Add >>

Adds the specified data band type to the style set. Before clicking this button, ensure that the settings are correct for data band type, style, and location.

## List of Bands

Location

Specifies either the top or bottom of the profile view. The table below this field shows the current location of the bands in the current band style set.

Band Type

Specifies the data band type.

Style

Specifies the style for the band type.

Description

Specifies optional description of the band type

Gap

Specifies the distance between the current data band and the adjacent profile view grid or data band. For bands below the profile view grid, the gap is measured from the top of the current band to the bottom of the band or grid above it. For bands above the profile view grid, the gap is measured from the bottom of the current band to the top of the band or grid below it.

Geometry Points

For Profile Data bands, specifies the alignment and profile geometry points to label in the data band. Click  to open the Geometry Points to Label in Band dialog box (page 2162).

Label Start Station

Specifies whether the start end of the band is labeled.

Label End Station

Specifies whether the end of the band is labeled.

Label Origin

Specifies whether the profile view origin is labeled with its station and elevation values.

Weeding

Used only for labels at vertical geometry points on profile data bands. Vertical geometry points or grade breaks that are closer than the weeding factor are removed, making it easier to read the remaining labels. Enter a positive number to specify a label exclusion distance.

Stagger Labels

Specifies the location of the label staggering line: No staggering, Stagger both sides, Stagger to right, or Stagger to left.

Stagger Line Height

Specifies the height of the label stagger line.

Band Position Controls

Changes the position of data bands in the set and deletes unwanted bands.

⬆ Moves selected data bands up.

⬇ Moves selected data bands down.

✖ Deletes selected bands.

Match major/minor increments to vertical grid intervals

Specifies if the profile data band major/minor interval distances for profile views matches the profile view style's major/minor grid spacing intervals. Select the checkbox to match major/minor increments to vertical grid intervals. If this checkbox is selected, the major/minor interval fields are unavailable.

# Copy Profile Data Dialog Box

Use this dialog box to copy all or part of an existing profile.

Copying a profile can be useful when you want to design a profile that runs parallel to another profile in the vertical plane. For example, you can create a ditch profile that follows the shape of a centerline, but is at a lower elevation.

## Source Profile Information

Name

Displays the name of the copied profile

Style

Displays a description for the copied profile.

## PVI Range

Select one of the following options:

All

Copies the entire profile.

Station Range

Copies a series of PVIs between two station values. Default values for the station range are the beginning and end of the profile. If a station equation is in effect, use the station equation values to specify a range

## Destination Profile Options

These options determine how the copy is used: either to create a profile or to overwrite an existing profile.

Overwrite Existing Profile

Replaces an existing profile with the specified source profile. If you select this option, use the drop-down list to specify the profile to be overwritten. To copy all styles, descriptions, and other attributes from the source profile to the specified destination profile, select the Overwrite All Properties check box. Otherwise, only the linear data is overwritten.

Create New Profile

Copies the current profile, subject to any limitations specified in the PVI Range section. The name of the new profile is created according to the current naming template, like the name of any new profile. The new profile is superimposed on the source profile in the profile view. To work on one of these profiles without affecting the other, select it by name on the Prospector tab or in a dialog box. Control the visibility of individual profiles in the Profile View Properties dialog box (page 2179)

**Related procedures:**

■ Copying a Profile (page 1057)

# Create Profile Band Style Dialog Box

Click the type of profile view band style you want to create, then click OK.

After selecting the band style, the Profile View Band Style dialog box (page 2164) is displayed for you to create the style.

**Related procedures:**

■ Profile View Band Styles (page 1038)

# Create Profile - Draw New Dialog Box

Use this dialog box to configure the settings for a new layout profile.

After using this dialog box, click OK to open the Profile Layout Tools dialog box (page 2170) and prepare drawing tools. Draw the profile on the profile view grid by selecting PVIs (points of vertical intersection).

**Related procedures:**

■ Creating Layout Profiles (page 1048)

# General Tab (Create Profile - Draw New Dialog Box)

Use this tab to enter basic information about the profile, including style, layer, and label set.

Alignment

Specifies the horizontal alignment along which to create the profile.

Name

Specifies the name of the profile. Each profile must have a unique name.

Description

Specifies an optional description of the profile.

**Profile Style**

Profile Style List

Displays the current style. Click the arrow to select another profile style in the drawing.

Style Selection

Specifies the style options. Create a style, copy or edit the current style selection, or pick a style from drawing.

 Style Detail

Opens the Style Detail dialog box. Preview the style and creation information.

### Profile Layer

Profile Layer List

Displays the layer on which the profile object is created.

 Object Layer

Opens the Object Layer dialog box (page 1985), in which you can select or create a layer on which the profile is drawn.

### Profile Label Set

Profile Label Set List

Displays the default profile label set. You can either accept the default label set, or use the list to select a different one from the drawing.

 Label Set Selection

Edits or copies the current label set, or creates a label set. The Style Detail icon previews the current style.

 Style Detail

Opens the Style Detail dialog box. Preview the label set and creation information.

# Design Criteria Tab (Create Profile - Draw New Dialog Box)

Use this tab to specify the profile design criteria settings, including the design criteria file and design check set.

Alignment

Specifies the horizontal alignment along which to create the profile.

Name

Specifies the name of the profile. Each profile must have a unique name.

Description

Specifies an optional description of the profile.

### Use Criteria-Based Design

Specifies whether to apply design criteria to the profile. If this check box is cleared, then the Use Design Criteria File and Use Design Check Set options are not available.

### Use Design Criteria File

Use Design Criteria File

Specifies whether to associate a design criteria file with the profile. If this check box is cleared, then the design criteria file selector and Default Criteria table are not available.
For more information, see Profile Standards in the Design Criteria File (page 1045).

Design Criteria File Selector

Specifies the design criteria file to associate with the profile. The design criteria file that is applied to the parent alignment is displayed by default. Click  to select another design criteria file.

Default Criteria Table

Displays the profile standards formulas that are defined in the selected design criteria file. Click the Value column to change a criteria table.

### Use Design Check Set

Use Design Check Set Check Box

Specifies whether to associate a design check set with the profile. If this check box is cleared, then the Design Check Set list is not available.

For more information, see Profile Design Check Sets (page 1046).

Design Check Set List

Displays the default design check set. You can either accept the default design check set, or use the list to select a different one from the drawing.

 Design Check Set Selection

Edits or copies the current design check set, or creates a design check set.

# Create Profile from Surface Dialog Box

Use this dialog box to create profiles from existing surfaces, including profiles at offsets to parent alignments.

Each profile created here must be associated with a horizontal alignment and one or more surfaces.

Alignment

Specifies the horizontal alignment along which to create the profile. Select an alignment by name, or click to select an alignment in the drawing.

Select Surfaces

Lists all surfaces in the current drawing. Select surfaces by name, or click  to select surfaces in the drawing. To select multiple surfaces, hold down the Shift key while clicking with the mouse.

Station Range

Specifies the range of stations along the parent alignment that are included in the profile. Default values represent the full length of the alignment. To set a different length, enter station values numerically, or click  to select stations in the drawing.

Sample Offsets

Specifies whether to create offset profiles. Select this option if you want offsets. Enter numeric values for the offset distances. Enter positive numbers for right offsets, negative numbers for left offsets, and commas to separate the values (for example, 10,-10,25). Click Add to add each set of profiles to the profile list.

## Profile List

Lists the profiles that have been created for the specified alignment and surfaces. You cannot edit profiles that were created in a previous session. You can edit Profiles created in the current session.

Name

Specifies the name of the profile. Default name strings are generated as defined in Profile Settings dialog box (page 2156). Existing profiles for the parent alignment are also displayed in this list as unavailable entries.

Description

Specifies optional description of the profile.

Type

Specifies whether the profile represents surface or design layout.

Data Source

For surface profile, displays the name of the surface represented in the profile. For superimposed profiles, displays the name of the superimposed profile. For corridor profiles, specifies the name of the source corridor. Not used for layout profiles.

Offset

Specifies the offset distance from the centerline of the parent horizontal alignment: 0 for a centerline profile, a positive number for a right offset, a negative number for a left offset.

Update Mode

For surface profiles only. Specifies whether the profile is dynamic or static.
**Dynamic**: The profile automatically updates to reflect changes in the surface elevation and the route traced by the parent horizontal alignment.

**Static**: The profile shows surface elevations at the time of its creation. It does not update to reflect changes that occur later.

Layer

Specifies the drawing layer on which the profile is placed.

Style

Specifies the style used by the profile.

Station Start/End

Specifies the first and last station numbers for the profile. The station numbers represent distances along the parent horizontal alignment.

Elevation Minimum/Maximum

Specifies the highest and lowest elevation values that occur along the profile.

Remove

Removes a selected profile from the profile list. Any profiles removed in this way are unavailable for drawing in a profile view.

Draw in Profile View

Opens the Create Profile View dialog box (page 2145), configured to draw the current profiles.

OK

Saves the profile data and closes the Create Profile from Surface dialog box. If one or more profile views are created along the alignment, the profiles you created are added to the views.

Cancel

Cancels the creation of profiles.

**Related procedures:**

■ Creating Surface Profiles (page 1047)

■ Understanding the Profile Object (page 1019)

# Create Profile View Wizard

Use this wizard to create single or multiple profile views.

Some controls on this wizard are disabled when it is used with the plan production tools (page 1691).

**Related procedures:**

■ Creating Profile Views (page 1108)

■ Understanding Plan Production Tools (page 1691)

# General Page (Create Profile View Wizard)

Use this page to specify basic information about the profile view, including the parent alignment and the profile view name, description, style, and layer.

**NOTE** The controls on this page are not available when multiple profile views are created as part of the plan production process.

Select Alignment

Specifies the name of the parent horizontal alignment for the profile that appears in the profile view. Select a name from the list or click to pick an alignment from the drawing.

Profile View Name

Specifies an editable, system-generated name. The name must remain unique within the drawing.

Description

Specifies an optional description of the profile.

Profile View Style

Specifies the style for the profile view. Provides standard controls you use to review or change the style.

Profile View Layer

Specifies the drawing layer for the profile view. To review or change layer data, click ⬗ .

Show Offset Profiles By Vertically Stacking Profile Views

Specifies to create stacked profile views (page 2483) views. Selecting this option causes the Stacked Profile page (page 2147) to become available.

# Station Range Page (Create Profile View Wizard)

Use this page to specify the station range to which the profile view is drawn.

**NOTE** This page is disabled when multiple profile views are created as part of the plan production process.

Automatic

Specifies the full station range for the horizontal alignment.

User Specified Range

Limits the station range in the profile view. Either enter numeric station values in the Start and End fields, or click ⬗ to select the range on the alignment in the drawing.

Length of Each View

Specifies a length for each profile view segment in a multiple profile view.

# Profile View Height Page (Create Profile View Wizard)

Use this page to specify the profile view height and any split profile view settings.

**Profile View Height**

Automatic

Specifies the full height of the highest profile. Includes a buffer region above the maximum and below the minimum elevations.

User Specified

Specifies the height to which the profile view is drawn. If a profile extends beyond the user-specified value, it is either split according to the Split Profile View settings or clipped.

Profile View Datum By

Specifies how to place the datum for all profiles within the profile view.

- **Minimum Elevation**—All profile datum values are based on the lowest datum value of all profiles in the profile view. This option works well for profiles that have relatively high variation in elevation.

- **Mean Elevation**—Profile datum values are based on the mean value of all profiles drawn in the profile view. Profiles are drawn in the center of the profile view, which places an equal amount of space above and below the profile in the profile view. This option is useful in profiles that have relatively little variation in elevation.

## Split Profile View

**NOTE** The Split Profile View settings are enabled only if the Profile View Height is set to User Specified.

Split Profile View

Specifies that if the height of the profile extends beyond the User-Specified height value of the profile view, the profile view splits.

First Split View Style

Specifies the profile view style to use for the first split profile view segment. Use the standard controls to edit the style or create a new one.

Intermediate Split View Style

Specifies the profile view style to use for the all split profile view segments between the first and last segments. Use the standard controls to edit the style or create a new one.

Split Station

Specifies the horizontal location to split the profile view: previous major grid, previous minor grid, or exact station.

Datum Option

Specifies the vertical location to split the profile view: previous major grid, previous minor grid, or exact elevation.

Last Split View Style

Specifies the profile view style to use for the last split profile view segment. Use the standard controls to edit the style or create a new one.

# Stacked Profile Page (Create Profile View Wizard)

Use this page to specify the settings for stacked profile views (page 2483) views.

**NOTE** This page is not available if the Show Offset Profiles By Stacking Views check box on the General page (page 2146) is cleared.

Number of Stacked Views

Specifies the total number of profile views to create. This unitless value can be any integer from 2 to 9. The graphic on the right-hand side of the page changes to reflect the number selected.

Gap Between Views

Specifies the amount of spacing (in plotted units) to leave between stacked profile views. A negative value in this field causes the stacked profile views to overlap.

Top View Style
    Specifies the profile view style to use for the top-most profile view.

Middle View Style
    Specifies the profile view style of all profile views between the top-most and bottom-most profile views.

Bottom View Style
    Specifies the profile view style to use for the bottom-most profile view.

Preview (unlabled)
    Displays the number of profile views specified in the Number of Stacked Views field.

# Profile Display Options Page (Create Profile View Wizard)

Use this page to view and change settings for all the profiles associated with the specified alignment.

## Select Stacked View To Specify Options For

**NOTE** This control is not available if the Show Offset Profiles By Stacking Views check box on the General page (page 2146) is cleared.

Displays a list of the stacked profile views. The number of profile views in this list depends on the Number Of Stacked Views specified on the Stacked Profile page (page 2147). Select a profile view from the list, and then use the Specify Profile Display Options table to specify the settings for that stacked profile view.

## Specify Profile Display Options

Change column widths in the table to make it easier to see the contents of cells. Use the following controls to modify profiles in the view.

 Select All Profiles
    Selects the Draw check box for all profiles listed in the table.

 Deselect All Profiles
    Clears the Draw check box for all profiles listed in the table.

Name
    Specifies the name of the profile.

Draw
    By default, specifies that all profiles are drawn in the profile view. To omit a profile from the profile view, clear its check box.

Clip Grid
    Specifies which profile controls the horizontal and vertical extents of the profile view grid. This setting works only if the profile view style Grid Options are set to clip the grid. For further information, see Grid Tab (Profile View Style Dialog Box) (page 2186).

Split At
    Specifies which profile to favor when splitting a profile view containing multiple profiles.
    For example, a profile view often contains both existing ground and finished ground profiles. Selecting Split At for the finished ground profile ensures that split occurs at the finished ground profile elevation.

Description
    Specifies an optional description of the profile.

Type

Specifies whether the profile is a surface profile , layout profile , superimposed profile , or corridor profile .

Data Source

For surface profile, displays the name of the surface represented in the profile. For superimposed profiles, displays the name of the superimposed profile. For corridor profiles, specifies the name of the source corridor. Not used for layout profile.

Offset

Specifies the offset distance from the centerline of the parent horizontal alignment: either 0 for a centerline profile, a positive number for a right offset, a negative number for a left offset.

Update Mode

For surface profiles only, specifies whether the profile is dynamic or static.
**Dynamic**: The profile automatically updates to reflect changes in the surface elevation and the route traced by the parent horizontal alignment.

**Static**: The profile shows surface elevations at the time of its creation. It does not update to reflect changes that occur later.

Layer

Specifies the drawing layer on which the profile is placed.

Style

Specifies the style used by the profile. If you change the style here, it changes the profile properties and the style is retained as the specified style when creating additional profile views. Use the standard controls to edit the style or create a new one.

Override Style

Specifies whether the profile style is overridden (changed) for the current profile view. You can override the style by clicking the check box and selecting a different style. If you do, the style change applies only to the current profile view. It does not change the style in the profile properties.

Labels

Click to open the Pick Profile Label Set dialog box where you can edit the profile labels.

Station Start/End

Specifies the first and last station numbers for the profile. The station numbers represent distances along the parent horizontal alignment.

Elevation Low/High

Specifies the highest and lowest elevation values that occur along the profile.

Alignment

Specifies either the parent alignment of current profile view or the parent alignment of any superimposed profiles.

## Pipe Network Display Page (Create Profile View Wizard)

Use this page to specify which pipe networks or parts to include in the profile view.

**NOTE** This page is not available if there are no pipe networks present in the drawing.

### Select Stacked View To Specify Options For

**NOTE** This control is not available if the Show Offset Profiles By Stacking Views check box on the General page (page 2146) is cleared.

Displays a list of the stacked profile views. The number of profile views in this list depends on the Number Of Stacked Views specified on the Stacked Profile page (page 2147). Select a profile view from the list, and then use the Select Pipe Networks To Draw In Profile View table to specify the pipe network display settings for that stacked profile view.

### Select Parts From Screen

Select pipe networks or parts by clicking in the drawing window. Click then follow the prompts at the command line.

### Select Pipe Networks to Draw in Profile View

Use this list to select pipe networks or parts from the drawing. By default, this list is populated with all pipe networks in the current drawing but none of the parts are selected.

Select All Networks
   Selects the Select check box for all pipe networks and parts listed in the table.

Deselect All Networks
   Clears the Select check box for all pipe networks and parts listed in the table.

Name
   Specifies the name of the pipe network and its parts.

Select
   Specifies whether a network or part is drawn in the profile view. Check box displays one of three states:

   Not Selected. If a part is not selected, it is not drawn. If a pipe network is not selected, none of its parts are drawn.

   Selected. If a part is selected, it is drawn. If a pipe network is selected, all of its parts are drawn.

   Partially selected. If a pipe network is partially selected, only its selected parts are drawn. Parts cannot be partially selected.

Show Only Parts Selected
   Specifies whether to display only the pipes and structures that are selected to draw in the profile view.

## Data Bands Page (Create Profile View Wizard)

Use this page to specify the properties of the data bands associated with the profile view.

Select Band Set
   Specifies the set of band styles for the profile view. Provides standard controls you use to review or change the set.

   **NOTE** This control is disabled when multiple profile views are created as part of the plan production process.

### List of Bands

Location
   Specifies either the top or bottom of the profile view. The table below this field shows current location of the bands in the current band style set.

**Band Type**

Specifies the data band type: Profile Data, Vertical Geometry, Horizontal Geometry, Superelevation, Sectional Data, or Pipe Data.

**Style**

Specifies the style for the band type.

**Profile 1/Profile 2**

Specifies which profile or profiles supply the data for the band. For example, if two separate profiles are listed in Profile 1 and Profile 2 columns, then each station displayed in the band shows the elevation information for both profiles.

**Alignment**

Specifies either the parent alignment of current profile view or the parent alignment of any superimposed profiles.

**Geometry Points**

Specifies the geometry points to label. Click [...] to open the Geometry Points to Label in Band dialog box (page 2162).

**Data Source**

Specifies the source of the data displayed in the band. The options displayed depend on the type of data band:

Pipe Data Band: Select a pipe network in the drawing file.

Sectional Data Band: Select a sample line group that is associated with the alignment in the profile view

This column is available only for pipe and sectional data bands.

**Material**

Specifies a material or list of materials for which data is displayed in a sectional data band. The options are generated using the properties of sample line groups that are associated with the alignment in the profile view.

# Hatch Options Page (Create Profile View Wizard)

Use this page to add hatch areas to show cut and fill regions in a profile view.

### Add Areas to Hatch

**Cut Area**

Click to add hatching to the profile view in areas where terrain must be cut to create the design profile.

**Fill Area**

Click to add hatching to the profile view in areas where terrain must be filled to create the design profile.

**Multiple Boundaries**

Click to add hatching to the profile view in areas where multiple boundaries are used to define a hatch region.

**From Criteria**

Click to add hatching to the profile view in areas where quantity takeoff criteria are used to define a hatch region.

**Hatch Table**

Hatch Area

Specifies the upper and lower boundaries for each hatch area. Use the buttons along the top of the table to manage these boundaries. Use the + and – buttons to expand and collapse the list of boundaries for each hatch area heading.

 Collapse All

Collapse the display of boundaries to show only the top-level headings.

 Expand All

Expand the display to show all boundaries.

Add Upper Boundary

Add an upper boundary to the selected hatch area.

Add Lower Boundary

Add a lower boundary to the selected hatch area.

 Delete

Delete the selected boundary.

Profile

Specifies the surface or layout profile that defines each hatch area boundary. Where only a single surface and single layout profile exist in the profile view, the profiles are automatically assigned to boundaries. Click the arrow beside the profile name to select a different profile.

Shape Style

Specifies the shape style applied to the hatch area. Click the name to select another style or modify the style properties. These styles are found on the Toolspace Settings tab ➤ General ➤ Multipurpose Styles ➤ Shape Styles.

## Multiple Plot Options Page (Create Profile View Wizard)

Use this page to specify the layout of the plotted profile view segments.

**NOTE** This page is disabled if you are creating a single profile view.

**Draw Order**

By Rows

Specifies to draw profile view segments in a row. After the number of views in the Maximum in a Row field has been reached, a new row is started.

By Columns

Specifies to draw profile view segments in a column. After the number of views in the Maximum in a Column field has been reached, a new column is started.

Maximum in a Row (or Column)

Specifies the maximum number of profile view segments to draw in a single row or column. After this value is reached, a new row or column is started.

Start Corner

Specifies the direction in which to draw the profile view segments:

**Lower Left**: Draw profile view segments in rows starting from the lower left. When the Maximum in a Row value is reached, a new row is started above.

**Upper Left**: Draw profile view segments in rows starting from the upper left. When the Maximum in a Row value is reached, a new row is started below.

**Lower Right**: Draw profile view segments in rows starting from the lower right. When the Maximum in a Row value is reached, a new row is started to the left.

**Upper Right**: Draw profile view segments in rows starting from the upper right. When the Maximum in a Row value is reached, a new row is started to the left.

### Gap Between Adjacent Profile Views

Row

Specifies amount of spacing (in plotted units) to leave between adjacent rows of profile view segments.

Column

Specifies amount of spacing (in plotted units) to leave between adjacent columns of profile view segments.

# Create Quick Profiles Dialog Box

Use this dialog box to create a temporary profile to view elevation information along a line, polyline, feature or lot line, survey figure, or surface.

### Surfaces to Sample

Select All Surfaces

Specifies whether to sample all surfaces in the drawing in the quick profile. This option is cleared when you clear any of the surfaces in the list.

Surface

The name of a surface in the drawing. This field is read only.

Select

Select the check box to sample the surface in the quick profile.

Profile Style

Specifies the style used to display the surface in the quick profile. To change the style, click in the Profile Style column to open the Pick Profile Style dialog box. Select a style in the list or use the standard controls to create a style, copy or edit the current style selection, or pick a style from the drawing.

Profile View Style

Specifies the style of the profile view. Select a style in the list or use the standard controls to create a style, copy or edit the current style selection, or pick a style from the drawing.

Draw 3D Entity Profile

Specifies whether the elevation data for the selected 3D object is displayed in the quick profile. Used only when the object you selected is a 3D object such as a 3D line or polyline.

3D Entity Profile Style

Specifies the style used to display the 3D object elevation data in the quick profile. Select a style in the list or use the standard controls to create a style, copy or edit the current style selection, or pick a style from the drawing.

**Related procedures:**

■  Creating a Quick Profile (page 1058)

# Curb Return Profile Properties Dialog Box

Use this dialog box to view or change the properties of a curb return profile, such as its name, style, and station data.

These properties apply to layout, surface, superimposed, and corridor profiles.

**See also:**

■  Profile Properties (page 1024)

## Information Tab (Curb Return Profile Properties Dialog Box)

Use this tab to view or change primary information about a curb return profile.

Name
Specifies the name of the profile. The application generates a default value, or you can enter a name.

Description
Specifies an optional description of the profile.

Object Style
Specifies the name of the style used by the profile. Use the buttons to preview or edit the style.

Show Tooltips
Specifies whether tooltips are displayed for the object in the drawing (not over toolbar icons).

## Profile Data Tab (Curb Return Profile Properties Dialog Box)

Use this tab to view structural data about a curb return profile.

Name
Specifies the name of the profile.

Description
Specifies an optional description for the profile.

Type
Specifies whether the profile is a surface profile ⌣ , layout profile ⌣ , superimposed profile, or corridor profile ⌣ .

Data Source
This column is not used for curb return profiles.

Offset
This column is set to 0.00 for curb return profiles.

Update Mode
This column is not used for curb return profiles.

Layer
Specifies the drawing layer on which the profile is placed.

Style
Specifies the style used by the profile.

Station Start/End
Specifies the first and last station numbers for the profile. The station numbers represent locations on the curb return alignment.

Elevation Minimum/Maximum
Specifies the highest and lowest elevation values that occur along the profile.

Alignment
Specifies the name of the curb return alignment for the profile.

## Design Criteria Tab (Curb Return Profile Properties Dialog Box)

Use this tab to apply or change the profile design criteria.

### Use Criteria-Based Design

Specifies whether to apply design criteria to the profile. If this check box is cleared, then the Use Design Criteria File and Use Design Check Set options are not available.

### Use Design Criteria File

Use Design Criteria File
Specifies whether to associate a design criteria file with the profile. If this check box is cleared, then the design criteria file selector and Default Criteria table are not available.
For more information, see Profile Standards in the Design Criteria File (page 1045).

Design Criteria File Selector
Specifies the design criteria file to associate with the profile. The design criteria file that is applied to the parent alignment is displayed by default. Click ![button] to select another design criteria file.

Default Criteria Table
Displays the profile standards formulas that are defined in the selected design criteria file. Click the Value column to change a criteria table.

### Use Design Check Set

Use Design Check Set
Specifies whether to associate a design check set with the profile. If this check box is cleared, then the Design Check Set list is not available.
For more information, see Profile Design Check Sets (page 1046).

Design Check Set List
Displays the default design check set. You can either accept the default design check set, or use the list to select a different one from the drawing.

![icon] Design Check Set Selection
Edits or copies the current design check set, or creates a design check set.

## Offset Edge Profiles Tab (Curb Return Profile Properties Dialog Box)

Use this tab to view data about the other profiles attached to a curb return profile.

### Incoming Edge Information

Incoming Alignment
Specifies the alignment to which the start of the curb return alignment is attached.

Incoming Profile

    Specifies the profile to which the start of the curb return alignment is attached.

Incoming Profile Type

    Specifies the profile type as either dynamic cross slope, with a numeric slope value, or static.

**Outgoing Edge Information**

Outgoing Alignment

    Specifies the alignment to which the end of the curb return alignment is attached.

Outgoing Profile

    Specifies the profile to which the end of the curb return alignment is attached.

Outgoing Profile Type

    Specifies the profile type as either dynamic cross slope, with a numeric slope value, or static.

# Edit Feature Settings - Profile Dialog Box

Use this dialog box to view and change profile-related settings.

This topic documents settings in all profile-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

- Drawing-level ambient settings are identified by the ⬜ drawing icon.

- Profile feature settings are listed near the top of this dialog box, after the General property group, and are identified by the ⌄ profile icon.

- Profile command settings are identified by the ⬛ command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

## ⌄ Default Styles

Use these settings to specify the default styles assigned to profiles and their labels.

Profile Label Set

    Specifies the default profile label style set. Click in the Value column, and click […] to select a style in the Profile Label Set dialog box.

Profile Style

    Specifies the default profile style. Click in the Value column, and click […] to select a style in the Profile Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

## ⬛ Default Name Format

Use these settings to specify the default name formats for profiles, offset profiles, superimposed profiles, and 3D entity profiles. Click in the Value column, and click […] to make changes in the Name Template dialog box (page 1806).

## ⌄ Profile Creation

Use these settings to specify the default values for vertical curve sub-entities. For all linear settings such as length, height, or radius, enter a number in the Value column or click and select a distance in the drawing area.

Default Vertical Curve Type
    Specifies the default vertical curve type for a new profile:

- Circular Curve

- Symmetric Parabola

- Asymmetric Parabola

Parabolic Sag Curve Length And K-Value
    Specifies whether curve length or K value is the primary constraint on a parabolic sag curve.

Parabolic Crest Curve Length And K-Value
    Specifies whether curve length or K value is the primary constraint on a parabolic crest curve.

Parabolic Crest Curve Length
    Specifies the default length for a parabolic crest curve.

Parabolic Crest Curve K-Value
    Specifies the default K-value for a parabolic crest curve.

Parabolic Sag Curve Length
    Specifies the default length for a parabolic sag curve.

Parabolic Sag Curve K-Value
    Specifies the default K-value for a parabolic sag curve.

Circular Crest Curve Length And Radius
    Specifies whether curve length or radius is the primary constraint on a circular crest curve.

Circular Sag Curve Length And Radius
    Specifies whether curve length or radius is the primary constraint on a circular sag curve:

Circular Crest Curve Length
    Specifies the default length for a circular crest curve.

Circular Crest Curve Radius
    Specifies the default radius for a circular crest curve.

Passing Eye Height
    Specifies the default passing eye height.

Circular Sag Curve Length
    Specifies the default length for a circular sag curve.

Passing Object Height
    Specifies the default passing object height.

Circular Sag Curve Radius
    Specifies the default radius for a circular sag curve.

Stopping Eye Height
    Specifies the default stopping eye height.

Asymmetrical Crest Curve Length 1

Specifies the default length for the first part of the asymmetrical crest curve.

Stopping Object Height

Specifies the default stopping object height.

Asymmetrical Crest Curve Length 2

Specifies the default length for the second part of the asymmetrical crest curve.

Headlight Angle

Specifies the default headlight angle.

Asymmetrical Sag Curve Length 1

Specifies the default length for the first part of the asymmetrical sag curve.

Headlight Height

Specifies the default headlight height.

Asymmetrical Sag Curve Length 2

Specifies the default length for the second part of the asymmetrical sag curve.

## Criteria-Based Design Options

Use these settings to specify the default design criteria.

For more information, see Criteria-Based Profile Design (page 1044).

**NOTE** The design criteria values of the parent alignment take precedence over the default design criteria values of the profile. If the parent alignment does not use design criteria values, then the criteria-based design options in the profile are used.

Use Design Criteria File Option

Specifies whether to associate a design criteria file with the profile.
The first XML file found in the *<install directory>\Data\Corridor Design Standards\<units>* is used by default. You can select another design criteria file by using either the Create Profile - Draw New dialog box (page 2142) during profile creation, or the Profile Properties dialog box (page 2175) after the profile is created.

Use Design Checks Option

Specifies whether to associate a design check set with the profile.

Default Design Check Set

Specifies the default design check set. Click in the Value column, and click [⋯] to select a set in the Default Design Check Set dialog box.
You can select another design check set by using either the Create Profile - Draw New dialog box (page 2142) during profile creation, or the Profile Properties dialog box (page 2175) after the profile is created.

**NOTE** This setting is not available if the Use Design Checks Option is set to False.

## Curve Tessellation Option

**NOTE** This property group is displayed when accessing the settings from the CreateProfileLayout command.

Use these settings to specify the default behavior when curve entities are used as an input option for best fit arc, line, and parabola creation.

Tessellate Curve

Specifies whether to tesselate curve segments if they are included as an input option.

Mid-ordinate Tolerance

Specifies the mid-ordinate tolerance based on a distance across the tessellated curve segments. Enter a length in the Value column or click and select two points along a curve.

## Regression Graph Option

**NOTE** This property group is displayed when accessing the settings from the CreateProfileLayout command.

Use this setting to specify the default behavior for regression analysis graphs in best fit arc, line, and parabola creation.

Spline Fit For Regression Analysis Graph

Specifies whether the regression graph displays splines on the green line that represents the best fit entity.

## Quick Profile Options

**NOTE** This property group is displayed when accessing the settings from the CreateQuickProfile command.

Use these settings to specify the default settings for quick profile creation.

Select All Surfaces

Specifies whether to generate profiles of all surfaces in the drawing file in the quick profile.

Create Profile of 3D Entities

Specifies whether to include elevation data for the selected 3D entity in the quick profile.

## Superimpose Profile

**NOTE** This property group is displayed when accessing the settings from the SuperimposeProfile command.

Use these settings to specify the default values for the mid-ordinate distances that the system uses when tessellating (approximating) the shape of curves in superimposed profiles.

Horizontal Mid-ordinate Distance

Specifies the horizontal mid-ordinate distance for tessellated curve segments. Enter a distance in the Value column or click and select a distance in the drawing.

Vertical Mid-ordinate Distance

Specifies the vertical mid-ordinate distance for tessellated curve segments. Enter a length in the Value column or click and select a distance in the drawing.

These settings are used in the Superimpose Profile Options dialog box (page 2193).

**Related procedures:**

■ Profile Settings (page 1025)

■ Creating Profiles (page 1046)

# Edit Feature Settings - Profile View Dialog Box

Use this dialog box to view and change profile view-related settings.

This topic documents settings in all profile view-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

■ Drawing-level ambient settings are identified by the drawing icon.

- Profile view feature settings are listed near the top of this dialog box, after the General property group, and are identified by the ![profile view icon] profile view icon.

- Profile view command settings are identified by the ![command icon] command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

## ![icon] Default Styles

Use these settings to specify default styles assigned to profile views and their labels.

Marker Style
> Specifies the default style for markers associated with manually placed profile view labels for station and elevation or depth. Click in the Value column, and click ![...] to select a style in the Marker Style dialog box.

Profile View Style
> Specifies the default profile view style. Click in the Value column, and click ![...] to select a style in the Profile View Style dialog box.

Profile Label Set
> Specifies the default style for profile label sets. Click in the Value column, and click ![...] to select a style in the Profile Label Set dialog box.

First Split View Style
> Specifies the default style for the first split profile segment. Click in the Value column, and click ![...] to select a style in the First SplitView Style dialog box.

Intermediate Split View Style
> Specifies the default style for the intermediate split profile view segments. Click in the Value column, and click ![...] to select a style in the Intermediate SplitView Style dialog box.

Last Split View Style
> Specifies the default style for the last split profile view segment. Click in the Value column, and click ![...] to select a style in the Last SplitView Style dialog box.

Top Stack View Style
> Specifies the default profile view style of the top-most profile view in the stack. Click in the Value column, and click ![...] to select a style in the Top StackView Style dialog box.

Middle Stack View Style
> Specifies the default profile view style of all profile views between the top-most and bottom-most profile views. Click in the Value column, and click ![...] to select a style in the Middle StackView Style dialog box.

Bottom Stack View Style
> Specifies the default profile view style of the bottom-most profile view in the stack. Click in the Value column, and click ![...] to select a style in the Bottom StackView Style dialog box.

Profile Label Set

Specifies the default profile label set. Click in the Value column, and click ![icon] to select a set in the Profile Label Set dialog box.

Profile Station and Elevation Label Style

Specifies the default style for profile station and elevation labels. Click in the Value column, and click ![icon] to select a style in the Profile Station and Elevation Label Style dialog box.

Profile Depth Label Style

Specifies the default style for profile depth labels. Click in the Value column, and click ![icon] to select a style in the Profile Depth Label Style dialog box.

Projection Label Style

Specifies the default style for labels on projected objects. Click in the Value column, and click ![icon] to select a style in the Profile Projection Label Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

## Default Name Format

Use this setting to specify the default name format for profile views. Click in the Value column, and click ![icon] to make changes in the Name Template dialog box (page 1806).

## Profile View Creation

Use these settings to specify default parameters for the creation of profile views.

Specify Profile Station Range
   Specifies whether to allow the user to set range of stations to be displayed in the profile view.

Specify Profile Elevation Range
   Specifies whether to allow the user to set a minimum and maximum height to be displayed in the profile view.

Pipe Network Parts
   Specifies whether to Display Only Selected or to Display All pipe network parts in the profile view.

## Split Profile View Options

Use these settings to specify default parameters for splitting profile views.

**NOTE** If the Split Profile Views option is set to No, then the remaining Split Profile View Options are not available.

Split Profile Views
   Specifies whether to split a profile view that exceeds the maximum profile view height setting.

Split Station Option
   Specifies the default split station rounding setting.

Split Datum Option
   Specifies the default datum elevation rounding setting.

## Stacked Profile View Options

Use these settings to specify default parameters for stackng profile views.

**NOTE** If the Stacked Views option is set to No, then the remaining Stacked Profile View Options are not available.

Stacked Views

Specifies whether to create stacked profile views by default.

Number of Stacked Views

Specifies the default total number of profile views to create. This unitless value can be any integer from 2 to 9.

Gap Between Views

Specifies the default amount of spacing (in plotted units) to leave between stacked profile views. Enter a distance in the Value column or click and select a distance in the drawing. A negative value in this field causes the stacked profile views to overlap.

 **Multiple Profile View Creation**

NOTE  This property group is displayed when accessing the settings from the  CreateMultipleProfileView command.

Use these settings to specify defaults for creating multiple profile views.

Default Profile VIew Length

Specifies the default length for profile views. Enter a length in the Value column or click and select a length in the drawing area.

Default Profile VIew Height

Specifies the default height for profile views. Enter a height in the Value column or click  and select a height in the drawing area.

Plot Pattern

Specifies whether profile views are by default plotted by rows or columns.

Profile Views In Row Or Column

Specifies the default number of profile views in a row or column.

Start Corner

Specifies the default corner in which the first of the multiple profile views will be plotted. (Lower Left, Lower Right, Upper Left, Upper Right)

Column Spacing

Specifies the default gap between individual profile views in a column. Enter a distance in the Value column or click  and select a distance in the drawing area.

Row Spacing

Specifies the default gap between individual profile views in a row. Enter a distance in the Value column or click  and select a distance in the drawing area.

**Related procedures:**

■  Profile View Settings (page 1026)

# Geometry Points to Label in Band Dialog Box

Use this dialog box to specify the horizontal and vertical geometry points that you want to label in the profile view data band.

**See also:**

■  Creating Profile Views (page 1108)

## Alignment Points

Use this tab to specify which alignment geometry points you want to label in the data band.

### Select Geometry Points To Label

 **Select All**

Selects all check boxes in the Label column.

 **Deselect All**

Clears all check boxes in the Label column.

Geometry Point Column

Identifies the available geometric details.

> **NOTE** The Abbreviations tab (page 1855) in the Drawing Settings dialog box also lists these geometry points.

Label Column

Specifies whether to label a geometry point.

## Profile Points

Use this tab to specify which profile geometry points you want to label in the data band.

### Select Geometry Points To Label

 **Select All**

Selects all check boxes in the Label column.

 **Deselect All**

Clears all check boxes in the Label column.

Geometry Point Column

Identifies the available geometric details.

> **NOTE** The Abbreviations tab (page 1855) in the Drawing Settings dialog box also lists these geometry points.

Label Column

Specifies whether to label a geometry point.

# Import Quantity Takeoff Criteria Dialog Box

Use this dialog box to specify profile view hatch areas based on quantity takeoff criteria.

Pick quantity takeoff criteria to import

Select a criteria from the list. Criteria defined for the drawing are specified on the Toolspace Settings tab ➤ Quantity Takeoff ➤ Quantity Takeoff Criteria. Standard buttons are provided to create or edit a style. For more information, see Select Style dialog box (page 1805).

**Hatch Boundary Table**

Area Boundary Name
Specifies the boundaries defined for the quantity takeoff criteria.

Profile
Specifies the profile in the profile view that is assigned to the boundary.

**Related procedures:**

■ Adding Hatch Areas to a Profile View (page 1116)

# Insert PVIs Dialog Box

Use this dialog box to record data about points of vertical intersection (PVIs) that you want to add to a layout profile.

After you select the vertical curve type (or None), the table grid shows the data columns that apply to that type.

The dialog box is designed to support rapid entry of PVI data from the numeric keypad. In the table grid, after you enter the first station number, press Enter to move to the next cell, and continue in this manner.

**Related procedures:**

■ Editing PVIs (page 1093)

# Profile Data Band Style Dialog Box

Use this dialog box to create band styles that annotate profile and alignment data on the profile views.

Create separate band styles for profile data (station and elevation), vertical geometry, horizontal geometry, superelevation, pipe data, and sectional data. The procedures are similar for each type.

**See also:**

■ Profile View Band Styles (page 1038)
■ Editing Profile Views (page 1113)

# Information Tab (Profile Data Band Style Dialog Box)

Use this tab to change the name and description of a band style or review details, such as when the style was most recently modified.

Name
Specifies the name of the band set.

Description
Specifies an optional description of the band set.

Created By
Displays the Windows login name of the person who created the band set.

Date Created
Displays the date and time the band set was created.

Last Modified By
    Displays the Windows login name of the person who last modified the band set.

Date Modified
    Displays the date and time the band set was last modified.

# Band Details Tab (Profile Data Band Style Dialog Box)

Use this tab to design the format and contents of the band style.

## Title Text

Click the Compose Label button to change attributes of the band title, using the Label Style Composer dialog box (page 1942).

## Layout

Band Height
    Specifies the vertical dimension of the band in plotted units, which can affect readability of the contents.

Text Box Width
    Specifies the width (in plotted units) of the box that contains the band title.

Offset From Band
    Specifies the distance between the title box and the left side of the data band.

Text Box Position
    Specifies the location of the title text box with respect to the band: Left of Band or Right of Band.

## Labels and Ticks

At
    Specifies the location type to be labeled, which varies according to the band style:
    **Profile Data Bands Style:** major station, minor station, horizontal geometry point (HGP), vertical geometry point (VGP), station equation, or incremental distance.

    **Vertical Geometry Bands Style:** uphill tangent, downhill tangent, crest curve, or sag curve.

    **Horizontal Geometry Bands Style:** tangent, curve, or spiral.

    **Superelevation Data Bands Style:** normal crown, level crown, reverse crown, full super, shoulder critical points, or slope transition region.

    **Sectional Data Bands Style:** sample line station, incremental section data.

    **Pipe Data Bands Style:** structure, pipe.

    Several label styles can appear in the same data band, but each one must be composed separately. Each appears in the preview as it is created.

Full Band Height Ticks
    Select if you want a line across the band for each tick.

Small Ticks At
    Select if you want smaller ticks. Select the tick location (Top, Middle, or Bottom of the band), and specify the tick size in drawing units.

Compose Label
    Click to review or change the label text, using the Label Style Composer dialog box (page 1942).

Schematic Line Option
    For horizontal geometry data bands, specify the information for schematic lines to draw: Geometry, Radius, or Curvature.

## Display Tab (Profile Data Band Style Dialog Box)

Use this tab to manage the display of profile view band style components.

Each type of band style has a slightly different set of display components, but they are all managed in the same way. For more information about the Component display section of this tab, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Profile Data Band Style Dialog Box)

Use this tab to review and adjust settings for the profile view band style.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Profile Entities Vista

Use this vista to view and edit numeric data about curves and tangents at a PVI or for a specific sub-entity in a profile.

If ⟋ PVI Based is selected in the Profile Layout Tools (page 2170), the vista displays PVI data. If ⟋ Entity Based is selected, the vista displays entity data.

Use the Profile Entities vista to navigate through all entities that make up the profile. You can select an entity in the Profile Entities vista and then edit it in the Profile Layout Parameters dialog box (page 2168). Attributes in the Profile Entities vista and Profile Layout Parameters window are automatically updated as the profile is edited.

If design criteria has been applied to the profile, a ⚠ warning symbol is displayed next to sub-entities that violate the specified design criteria. For more information, see Viewing and Correcting Profile Design Criteria Violations (page 1103).

The display can be filtered to show a selected range of entities along a profile. See Selecting Profile Sub-entities (page 1092) for more information.

The Profile Entities vista is like a spreadsheet. Each row represents a profile entity and each column represents an attribute for that entity. You can resize, move, and copy columns.

The first column (No.) is pinned and always displayed. It does not move when you use the scroll bar.

Two column configurations are available: default and criteria-based design. To switch between the configurations, or to create your own configuration, right-click a column heading, and click Customize Columns.

This window remains open when you grip edit the profile or enter another command. The window closes when you either delete the currently selected profile, click the X button, or click 🖳 Profile Grid View on the Profile Layout Tools.

**Related procedures:**

■ Vertical Curve Design (page 1068)

■ Criteria-Based Profile Design (page 1044)

■ Selecting Profile Sub-entities (page 1092)

■ Editing Profile Curve and Tangent Parameter Values (page 1098)

# Profile Label Set Dialog Box

Use this dialog box to manage the labels for a particular profile in a profile view. A set of labels created here can be saved and used for other profiles.

Type
Specifies the type of label to be added to the profile in the profile view: either major stations, minor stations, horizontal geometry points, lines, grade breaks, sag curves, or crest curves.

Profile <Label Type> Label Style
Specifies the style for the labels. Standard buttons are provided to create or edit a label style.

Add >>
Adds the specified label type to the set in the table below. These labels are displayed along the profile line in the profile view.

✖
Deletes the selected label type from the table, and also removes it from the profile.

## Label Table

Type
Specifies the type of profile label.

Style
Specifies the label style.

Increment
Specifies the distance between labels of this type; used only for station labels.

Check
Specifies whether the labels are applied from the beginning of the profile or start at a specified station.
**Selected**: The label type is applied from the beginning of the profile.
**Cleared**: The label type is applied to the part of the profile that begins at the station recorded in the Start Station column.

Start Station
Specifies the station where the label type begins.

Check
Specifies whether the labels are applied to the end of the profile or finish at a specified station.
**Selected**: The label type is applied as far as the end of the profile.
**Cleared**: The label type is applied to a part of the profile that ends at the station recorded in the End Station column.

End Station
Specifies the station where the label type ends.

Dim Anchor Opt
This option is for crest and sag curve labels only. Specifies the location of the dimension line that marks the length of the vertical curve. Uses the distance specified in Dim Anchor Val. Select one of the following:
**Distance Above**: Places the line a specific distance above the curve.
**Distance Below**: Places the line a specific distance below the curve.
**Fixed Elevation**: Places the line at a fixed elevation on the profile view.
**Graph View Top**: Places the line anchor at the top of the profile view grid. This option creates a vertical graph line above the curve label. To display the full extent of the line, set Dim Anchor Val to 0.

**Graph View Bottom**: Anchors the line to the bottom of the profile view grid. This option creates a vertical graph line below the curve label. To display the full extent of the line, set Dim Anchor Val to 0.

Dim Anchor Val

Specifies the vertical distance or elevation used with the setting in Dim Anchor Opt.

Weeding

For grade break labels only. Remove overlapping labels making it easier to read the remaining labels. Enter a positive number to specify a label exclusion distance. From a given grade break, if another break occurs within the specified distance, it is not labeled.

Geometry Points To Label

For Horizontal Geometry Points label types, specifies the alignment geometry points to label. Click [...] to open the Alignment Geometry Points dialog box (page 1739).

Stagger Labels

Specifies the location of the label staggering line: No staggering, Stagger both sides, Stagger to right, or Stagger to left.

---

**NOTE** The staggering options are available for the following labels: Profile (Grade Breaks, Major/Minor Station, Horizontal Geometry), and Section (Major/Minor Offsets and Grade Break).

---

Stagger Line 1 Height

Specifies the height of the first label stagger line.

Stagger Line 2 Height

Specifies the height of the second label stagger line.

**Related procedures:**

■ Profile Labels and Label Styles (page 1033)

■ Staggering Profile and Section Labels (page 1527)

# Profile Layout Parameters Dialog Box

Use this dialog box to analyze and modify profile data in a layout profile.

When the Profile Entities Vista (page 2166) is open, click any table row of PVI or sub-entity data. The data populates the Profile Layout Parameters dialog box in a vertical layout that you may find more convenient for analysis.

If ⬧ PVI Based is selected in the Profile Layout Tools (page 2170), the Profile Layout Parameters dialog box displays PVI data. If ⬧ Entity Based is selected, the Profile Layout Parameters dialog box displays entity data.

You can edit available parameters. You cannot edit parameters that are unavailable (shaded).

If the profile uses design criteria, then the Profile Layout Parameters dialog box contains up to three panels that can be collapsed by clicking ⬧ . If design criteria has not been associated with the profile, then only the Layout Parameters panel is available. If a sub-entity violates the specified design criteria, a ⚠ warning symbol is displayed next to sub-entities that violate the specified design criteria. For more information, see Viewing and Correcting Profile Design Criteria Violations (page 1103).

You cannot dock the Profile Layout Parameters dialog box, but you can pin or resize it.

This window remains open when you grip edit the profile or enter another command. The window closes when you either delete the currently selected profile, click the X button in the upper right-hand corner of the window, or click  on the Profile Layout Tools (page 2170) toolbar.

**Design Speed**

Specifies the design speed of the current sub-entity. The design speed is set in the properties of the parent alignment.

**NOTE** If multiple speeds are assigned to a sub-entity, then the highest speed is used to look up constraint values from the design criteria file and to validate the design checks. This ensures the safest design for that sub-entity.

**Design Criteria Panel**

The following parameters are displayed only if design criteria has been associated with the profile.

Use the Design Criteria panel to apply design criteria that is different from the default values that have been set for the profile. To change a criterion value, click the Value cell in the appropriate row.

A  warning symbol in the Property column indicates that the sub-entity design violates the criteria set in the design criteria file. You can find the specific parameter that has been violated by examining the Layout Parameters panel.

Minimum K For Stopping Sight Distance

Specifies the minimum K value for stopping sight distance at the specified design speed.

Minimum K For Passing Sight Distance

Specifies the minimum K value for passing sight distance at the specified design speed.

Minimum K For Headlight Sight Distance

Specifies the minimum K value for headlight sight distance at the specified design speed.

**Layout Parameters**

Use this panel to examine and change the general layout parameters of the selected sub-entity.

Click  Show More to expand the number of parameters that appears in the window. The default, collapsed view displays editable and other important parameters. Use the horizontal and vertical scroll bars when the list is longer or wider than the window.

When a design criteria file has been associated with a profile, the Constraints column displays the value to which a given parameter is limited. The selected design criteria file defines the constrained values. When a parameter value violates the range displayed in the Constraints column, a  warning symbol appears next to the parameter name.

**NOTE** The constraint definition for each profile entity determines the parameters that are displayed in the Layout Parameters panel.

**Design Checks**

The Design Checks panel displays the name and contents of the design check set that is associated with the profile.

When the sub-entity design violates a design check, a  warning symbol appears next to the affected design check.

**NOTE** The Design Checks panel is available only for profiles that use a design check set.

**Related procedures:**

■ Vertical Curve Design (page 1068)

■ Editing Profile Curve and Tangent Parameter Values (page 1098)

■ Criteria-Based Profile Design (page 1044)

# Profile Layout Tools

Use the tools in this toolbar to draw and edit profiles and to analyze vertical tangents and curves.

These tools are most useful for editing profiles by adding tangents and curves, or moving PVIs.

For dynamic surface profiles, most tools in this toolbar are not available. Use the Profile Entities Vista (page 2166) to display profile data. Similarly, many of the tools are unavailable for use with locked PVIs, including the endpoints of curb return profiles.

The name of the currently selected profile is displayed at the top of the toolbar. When you click an icon, the current command is displayed at the bottom of the toolbar. The toolbar remains open if you grip edit the profile or enter another command. The toolbar closes if you either delete the currently selected profile or click the X button in the upper right-hand corner of the toolbar.

### Layout Profile Creation

These three buttons control how a layout profile is drawn on a profile view.

Draw Tangents

Adds a series of fixed tangents between specified points.

Draw Tangents With Curves

Adds a series of fixed tangents between specified points, with free curves automatically added at the points of vertical intersection.

Curve Settings

Specifies the curve parameters to use with the Draw Tangents with Curves command.

To change the default curve settings, go to the Profile Creation section of the Edit Feature Settings - Profile (page 2156) dialog box.

### PVI Edit Operations

Use these three buttons to graphically modify the PVIs in a layout profile.

Insert PVI

Breaks a tangent into two adjacent tangents by creating a point of vertical intersection (PVI) at a specified location on the profile view.

Click above or below an existing tangent to specify the new PVI location.

Delete PVI

Creates a single tangent from two adjacent tangents by removing a point of vertical intersection (PVI) from a profile.

If two tangents meet at the PVI, they are replaced by a single tangent between two adjacent PVIs.

Move PVI

Moves a profile point of vertical intersection (PVI) to a new location on a profile view.

The tangents connected to the PVI remain attached. You can also use editing grips to move a PVI.

## Tangent Creation Operations

Use these three buttons to add tangents to a layout profile.

Fixed Tangent (Two Points)

Adds a fixed tangent between two specified points.

Fixed Tangent - Best Fit

Adds the most probable fixed tangent through a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen.

Floating Tangent (Through Point)

Adds a floating tangent from an existing entity to a specified pass-through point.

Float Tangent - Best Fit

Adds the most probable floating tangent from a point on an existing entity through a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen. Tangency is maintained to the attached entity, regardless of how the entity is edited.

Free Tangent (Between Two Parabola)

Adds a free tangent between two parabolic curves.

## Curve Creation Operations

Use these buttons to add a curve to a profile. You can create curves by selecting entities to attach to, specifying parameters, or selecting a PVI where you want to add a curve. Parameters can be specified numerically or graphically.

For example, to numerically specify a pass-through point, enter the point coordinates. To graphically specify the point, select a point in the drawing window.

To graphically specify a curve length, K value, or radius, use the cursor to pick two points on the screen the correct distance apart. For parabolic and circular curves, you see a preview of the curve as you move the cursor. For asymmetrical curves, you do not see the preview until you begin to specify the second length.

Fixed Vertical Curve (Three Points)

Adds a fixed curve through three specified points.

Fixed Vertical Curve (Two Points, Parameter)

Adds a fixed sag or crest curve, with a specified K value or minimum radius, through two specified points.

Fixed Vertical Curve (Entity End, Through Point)

Adds a fixed curve from the end of an existing entity to a specified pass-through point.

Fixed Vertical Curve (Two Points, Grade at Start Point)

Adds a fixed curve that is defined by two specified pass-through points and a specified grade at the start point.

Fixed Vertical Curve (Two Points, Grade at End Point)

Adds a fixed curve that is defined by two specified pass-through points and a grade at the end point.

**Fixed Vertical Curve - Best Fit**

Adds the most probable fixed vertical curve through a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen.

**Floating Vertical Curve (Through Point, Parameter)**

Adds a floating curve, which is defined by either a K value or minimum radius, between an existing entity and a specified pass-through point.

**Floating Vertical Curve (Through Point, Grade)**

Adds a floating curve, which is defined by a specified pass-though point and grade, to an existing entity.

**Floating Vertical Curve - Best Fit**

Adds the most probable floating vertical curve from an existing entity through a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen. Tangency is maintained to the attached entity, regardless of how the entity is edited.

**Free Vertical Curve (Parameter)**

Adds a free curve, which is defined by a specified curve length, radius, or K value, between two entities.

**Free Vertical Parabola (PVI Based)**

Adds a free vertical parabola, which is defined by a specified curve length, pass-through point, or K value, to an existing point of vertical intersection (PVI).

**Free Asymmetrical Parabola (PVI Based)**

Adds a free asymmetrical parabola, which is defined by specified before and after PVI curve lengths, to an existing point of vertical intersection (PVI).

**NOTE** If the first length you specify is too large for the asymmetric curve, you cannot enter the length for the second curve. The length of the first curve must be less than the station distance between the PVI you select and the station value of the previous PVI (or end station of the previous curve).

**Free Circular Curve (PVI Based)**

Adds a free circular curve, which is defined by a specified radius or pass-through point, to an existing point of vertical intersection (PVI).

**Free Vertical Curve - Best Fit**

Adds the most probable free vertical curve between two existing entities, and through a series of AutoCAD Civil points, AutoCAD points, existing entities, or clicks on screen. Tangency is maintained to the attached entities, regardless of how the entities are edited.

## Convert AutoCAD Line and Spline

This button enables you to convert an AutoCAD line or spline to a profile sub-entity.

**Convert AutoCAD Line and Spline**

Creates a fixed tangent or three-point vertical curve entity from an AutoCAD line or spline.

## PVI Operations

These buttons control various operations with PVIs when the Profile Grid View dialog box is active. If the profile is dynamic, only the Copy Profile button is available.

**Insert PVIs – Tabular**

Creates points of vertical intersection (PVIs) at multiple locations simultaneously.

**Raise/Lower PVIs**

Changes the vertical position of a series of points of vertical intersection (PVIs) simultaneously.

**Copy Profile**

Copies all or a part of a layout profile or static surface profile.

## Selection Operations

**PVI Based**

Edits the profile PVI parameter values in tabular format.

**Entity Based**

Edits the profile entity parameter values in tabular format.

**Select PVI**

Displays a selected PVI's parameter values in the Profile Layout Parameters dialog box. If you do not see this button, click ⟋ to change to a PVI-based view.

**Select Entity**

Displays a selected profile subentity's parameter values in the Profile Layout Parameters dialog box. If you do not see this button, click ⟋ to change to an entity-based view.

## Delete Entities

This button enables you to delete a tangent or curve.

**Delete Entity**

Deletes a specified tangent or curve. If you do not see this button, click ⟋ to change to an entity-based view.

## Data Analysis

**Edit Best Fit Data For All Entities**

Toggles the display of a horizontal table of regression data for all entities in the profile that were created by best fit.

**Profile Layout Parameters**

Toggles the display of a vertical table of numeric data about a single, selected profile subentity or PVI.

**Profile Grid View**

Toggles the display of a horizontal table of numeric data about multiple, selected profile sub-entities or PVIs.

**Undo**

Reverses the last AutoCAD Civil or AutoCAD command.

 Redo

Reverses the last AutoCAD Civil or AutoCAD undo operation. Redo is limited to one operation.

**Related procedures:**

■ Understanding the Profile Object (page 1019)

■ Creating Profiles (page 1046)

■ Editing Layout Profiles (page 1091)

# Profile Properties Dialog Box

Use this dialog box to view or change the properties of a profile, such as its name, style, and station data.

These properties apply to layout, surface, superimposed, and corridor profiles.

**See also:**

■ Profile Properties (page 1024)

## Information Tab (Profile Properties Dialog Box)

Use this tab to view or change primary information about a profile. These properties apply to layout, surface, superimposed, and corridor profiles.

Name

Specifies the name of the profile. The application generates a default value, or you can enter a name.

Description

Specifies an optional description of the profile.

Object Style

Specifies the name of the style used by the profile. Use the buttons to preview or edit the style.

Show Tooltips

Specifies whether tooltips are displayed for the object in the drawing (not over toolbar icons).

## Profile Data Tab (Profile Properties Dialog Box)

Use this tab to view structural data about a profile. These properties apply to layout, surface, superimposed, and corridor profiles.

Name

Specifies the name of the profile.

Description

Specifies an optional description for the profile.

Type

Specifies whether the profile is a surface profile , layout profile , superimposed profile, or corridor profile .

Data Source

For surface profile, displays the name of the surface represented in the profile. For superimposed profiles, displays the name of the superimposed profile. For corridor profiles, specifies the name of the source corridor. Not used for layout profiles.

Offset

Specifies the offset distance from the centerline of the parent horizontal alignment: either 0 for a centerline profile, a positive number for a right offset, a negative number for a left offset.

Update Mode

For surface profiles only. Specifies whether the profile updates automatically to reflect changes in surface elevation.

- **Dynamic**: The profile automatically updates to reflect changes in the surface elevation or the geometry of the parent horizontal alignment.

- **Static**: The profile shows surface elevations at the time of its creation. It does not update to reflect changes that occur later.

Layer

Specifies the drawing layer on which the profile is placed.

Style

Specifies the style used by the profile.

Station Start/End

Specifies the first and last station numbers for the profile. The station numbers represent distances along the parent horizontal alignment.

Elevation Minimum/Maximum

Specifies the highest and lowest elevation values that occur along the profile.

Alignment

For superimposed profiles only. Specifies the horizontal alignment for the profile.

## Parent Horizontal Alignment

Name

Specifies the name of the horizontal alignment associated with this profile.

Stationing

Specifies the start and end station values for the horizontal alignment.

# Design Criteria Tab (Profile Properties Dialog Box)

Use this tab to apply or change the profile design criteria.

## Use Criteria-Based Design

Specifies whether to apply design criteria to the profile. If this check box is cleared, then the Use Design Criteria File and Use Design Check Set options are not available.

## Use Design Criteria File

Use Design Criteria File

Specifies whether to associate a design criteria file with the profile. If this check box is cleared, then the design criteria file selector and Default Criteria table are not available.

For more information, see Profile Standards in the Design Criteria File (page 1045).

Design Criteria File Selector

Specifies the design criteria file to associate with the profile. The design criteria file that is applied to the parent alignment is displayed by default. Click [···] to select another design criteria file.

Default Criteria Table

Displays the profile standards formulas that are defined in the selected design criteria file. Click the Value column to change a criteria table.

**Use Design Check Set**

Use Design Check Set

Specifies whether to associate a design check set with the profile. If this check box is cleared, then the Design Check Set list is not available.
For more information, see Profile Design Check Sets (page 1046).

Design Check Set List

Displays the default design check set. You can either accept the default design check set, or use the list to select a different one from the drawing.

Design Check Set Selection

Edits or copies the current design check set, or creates a design check set.

# Profile Style Dialog Box

Use this dialog box to define profile styles that control the display and behavior of profiles.

**See also:**

■ Profile Styles (page 1027)

# Information Tab (Profile Style Dialog Box)

Use this tab to change the style name and description and to review details such as when the style was most recently modified.

For more information, see Information Tab (Style Dialog Box) (page 1801).

# Design Tab (Profile Style Dialog Box)

Use this tab to set the representation of 3D curves.

**3D Chain Visualization**

Curve Tessellation Distance

Specifies the distance between elevation samples in the three-dimensional display of alignment data. Enter a small number to see a smooth 3D curve, or a large number to see a rougher approximation.

# Markers Tab (Profile Style Dialog Box)

Use this tab to specify the appearance of markers for locations on the profile.

**Profile Points**

Name

Displays the name of the point on the profile.

Marker Style

Specifies the style for the point marker on the profile. Click to open the Select Marker Style dialog box where you can select a style or <None>.

## Arrowhead

Type

Specifies the arrowhead style for the profile direction arrow. Select a style from the list or select User Arrow to select an AutoCAD block.

Fit Options

Specifies how the arrow is drawn when the profile segment is shorter than the arrowhead. The arrow may be reduced to a size 80 per cent of the segment length, not displayed, or displayed at its normal size. Select Shrink, Omit, or Always Draw.

Size Options

Specifies the method used to determine the size of the arrowhead:
**Use Drawing Scale**: Determines size of the arrowhead by multiplying the specified value by the drawing scale. Enter the scale factor.

**Use Fixed Scale**: Activates the Fixed Scale options.

**Use Size in Absolute Units**: Specifies that the arrowhead size is an absolute value based on the displayed units. Enter the value.

**Use Size Relative to Screen**: Specifies that the size of the arrowhead is a percentage of the drawing screen size. Enter the percentage.

Size

Specifies the size of the arrowhead in the units specified in Size Options.

Fixed Scale

Specifies independent fixed scale values when Size Options is set to Use Fixed Scale. Enter values for X, Y, and Z.

# Display Tab (Profile Style Dialog Box)

Use this tab to set the visibility and format of profile components, such as lines, curves, and arrows.

Profile components include:

**Line**: Solved lines with true tangent lengths that are part of the profile geometry.

**Circular Curve**: Solved, circular curves that are true curve lengths within the profile.

**Symmetrical Parabola**: Solved, symmetrical parabola that are true curve lengths within the profile.

**Asymmetrical Parabola**: Solved, asymmetrical parabola that are true curve lengths within the profile.

**Arrow**: Shows the direction of the profile entities, either solved or unsolved.

**Line Extensions**: Line segments that extend beyond the solved portion of a line to a pass-through point or another constraint.

**Parabolic Curve Extensions**: Parabolic curve segments that extend beyond the solved portion of a parabolic curve to a pass-through point or another constraint.

**Warning Symbol**: Markers that identify entities that violate the rules specified in the design criteria file. This component only applies to profiles that use design criteria.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Profile Style Dialog Box)

Use this tab to review and adjust settings for the profile style.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Profile View Properties Dialog Box

Use this dialog box to view or change the properties of a profile view, including annotation, projected objects, and hatching.

**See also:**

■ Profile View Properties (page 1024)

## Information Tab (Profile View Properties Dialog Box)

Use this tab to view or change primary reference information about a profile view.

Name

Specifies the name of the profile view. Default value is PV - (n), where n is an integer that increments as profile views are created in the drawing.

Description

Specifies an optional description of the profile view.

Object Style

Specifies the style used by the profile view. Click the down arrow to select a style by name. Use the buttons to preview or edit the style.

**NOTE** If the profile view is split, this setting is ignored. Set split profile view styles on the Elevations tab (page 2179).

Show Tool tips

Controls whether tool tips are displayed for the object in the drawing (not over toolbar icons).

## Stations Tab (Profile View Properties Dialog Box)

Use this tab to view and change the horizontal range of the profile view.

### Alignment Name

Specifies the name of the alignment from which the profile view was created.

### Station Range

Automatic

Specifies the first and last stations of the parent horizontal alignment.

User Specified Range

Specify a station range if you want the profile view to show less than the full length of the horizontal alignment. Enter numeric station values or click  and pick points along the alignment in the drawing. If you specify the station range, the profile view length remains constant. If the alignment length is modified, the profile length does not adjust.

# Elevations Tab (Profile View Properties Dialog Box)

Use this tab to view and change the vertical range and split settings of the profile view.

See The Profile View Object (page 1021) for more information about split profile views.

### Elevation Range

Automatic Height

Specifies the elevation range for all profiles associated with the parent horizontal alignment, regardless of whether they are drawn in the profile view. The system refers to these values to set the default elevation range for the profile view.

User Specified Height

Specify an elevation range if you want the profile view to show other than the full height of the horizontal alignment.
If the current profile view style includes a padding (buffer) setting, it is applied to expand the elevation range. The padding is set on the Grid tab (page 2186) of the Profile View Style dialog box.
Selecting User-Specified Height enables the Split Profile View controls.

### Split Profile View

Selecting Split Profile View enables the Automatic and Manual controls.

Manual

Splits the profile view at user-specified locations and allows using a different style for each split segment.
**No:** Sequential number of split segments.

**Split Station:** Starting station value of each split location. The split station of segment number 1 is the starting station of the profile view and is not editable. Enter a specific value or click to select a location on the profile view.

**Adjusted Datum:** Vertical split location. Enter a specific value or click  to select a location on the profile view.

**Profile View Style:** Style selection of each profile view segment.

 Add a split location.

 Delete a split location.

Automatic

Splits the profile view to fit it within the user-specified height, rounding to specified station and datum locations.
**Station Rounding**: Specifies where to round the horizontal split location (Previous Major Grid, Previous Minor Grid, or Exact Elevation)

**Datum Rounding**: Specifies where to round the vertical split location (Previous Major Grid, Previous Minor Grid, or Exact Elevation)

**NOTE** Switching from manual to automatic clears all user-specified split settings.

# Profiles Tab (Profile View Properties Dialog Box)

Use this tab to view and change properties of the individual profiles in a profile view. Change column widths in the table to make it easier to see the contents of cells.

Name

Displays the name of the profile.

**Draw**

Specifies whether the profile is drawn in the profile view. After selecting or clearing check boxes here, click Apply to see the changes.

**Clip Grid**

Specifies which profile controls the size of the profile view grid.

**Split At**

Specifies which profile to favor when splitting a profile view containing multiple profiles.
For example, a profile view often contains both existing ground and finished ground profiles. Selecting Split At for the finished ground profile ensures that split occurs at the finished ground profile elevation.

**Description**

Specifies an optional description of the profile.

**Type**

Specifies whether the profile is a surface profile ⟋, layout profile ⋎ , superimposed profile ⋈, or corridor profile ⋎ .

**Data Source**

For surface profile, displays the name of the surface represented in the profile. For superimposed profiles, displays the name of the superimposed profile. For corridor profiles, specifies the name of the source corridor. Not used for layout profiles.

**Offset**

Displays the profile offset distance from the centerline of the parent horizontal alignment: either 0 for a centerline profile, a positive number for a right offset, or a negative number for a left offset.

**Update Mode**

For surface profiles only. Specifies whether the profile is dynamic or static.
**Dynamic**: The profile automatically updates to reflect changes in the surface elevation or the geometry of the parent horizontal alignment.

**Static**: The profile shows surface elevations at the time of its creation. It does not update to reflect changes that occur later.

**Layer**

Specifies the drawing layer on which the profile is placed.

**Style**

Specifies the style used by the profile. Click to open the Pick Profile Style dialog box where you can select a style.

**Override Style**

Specifies an override style for the display of the profile. This style is used only in the current profile view. Any other profile view that is plotting the profile would use the style as specified by the Style column value. Click the check box to open the Pick Profile Style dialog box where you can select a style.

**Labels**

Click to open the Profile Labels dialog box where you can edit the profile labels.

**Station Start/End**

Specifies the first and last station numbers for the profile. The station numbers represent distances along the parent horizontal alignment.

**Elevation Minimum/Maximum**

Specifies the highest and lowest elevation values that occur along the profile.

Alignment

For superimposed profiles only. Specifies the horizontal alignment for the profile.

# Bands Tab (Profile View Properties Dialog Box)

Use this tab to manage the data band sets for the profile view.

Band Type

Specifies which type of data band to add to the set: Profile Data, Vertical Geometry, Horizontal Geometry, Superelevation, Sectional Data, or Pipe Data.

Select Band Style

Specifies a style for the band. Standard buttons are provided to create or edit a style. For more information, see Select Style dialog box (page 1805).

Add >>

Adds the specified band type to the set for this profile view. Before clicking this button, ensure that the settings are correct for data band type, style, and location.

## List of Bands

Location

Specifies either the top or bottom of the profile view. The table below this field shows current location of the bands in the current band style set.

Band Type

Specifies the data band type: Profile Data, Vertical Geometry, Horizontal Geometry, Superelevation, Sectional Data, or Pipe Data.

Style

Specifies the style for the band type.

Description

Specifies optional descriptive notes about the band type

Gap

Specifies the distance between the current data band and the adjacent profile view grid or data band.

Geometry Points

For Profile Data bands, specifies the alignment and profile geometry points to label in the data band. Click [...] to open the Geometry Points to Label in Band dialog box (page 2162).

Label Start Station

Specifies whether the starting station of the band is labeled.

Label End Station

Specifies whether the ending station of the band is labeled.

Alignment

Specifies either the parent alignment of current profile view or the parent alignment of any superimposed profiles.

Profile1/Profile2

Specifies which profile or profiles supply the data for the band. For example, if two separate profiles are listed in Profile 1 and Profile 2 columns, then each station displayed in the band shows the elevation information for both profiles.

## Data Source

Specifies the source of the data displayed in the band. The options displayed depend on the type of data band:

Pipe Data Band: Select a pipe network in the drawing file.

Sectional Data Band: Select a sample line group that is associated with the alignment in the profile view

This column is available only for pipe and sectional data bands.

## Material

Specifies a material or list of materials for which data is displayed in a sectional data band. The options are generated using the properties of sample line groups that are associated with the alignment in the profile view.

## Weeding

Used only for labels at vertical geometry points on profile data bands. Vertical geometry points or grade breaks that are closer than the weeding factor are removed, making it easier to read the remaining labels. Enter a positive number to specify a label exclusion distance.

## Stagger Labels

Specifies the location of the label staggering line: No staggering, Stagger both sides, Stagger to right, or Stagger to left. This option is only enabled for profile or section data band styles.

## Stagger Line Height

Specifies the height of the label stagger line.

## Band Position Controls

Changes the position of data bands in the set and deletes unwanted bands.

⇧ Move selected data bands up.

⇩ Move selected data bands down.

✖ Delete selected bands.

## Import Band Set

Opens the Band Set dialog box (page 2139). Select an existing band set to add to the band set for the current profile view.

## Save As Band Set

Opens the Band Set dialog box, where you can save the current band set for use with other profile views.

## Match major/minor increments to vertical grid intervals

Specifies if the profile data band major/minor interval distances for profile views matches the profile view style's major/minor grid spacing intervals. Select the checkbox to match major/minor increments to vertical grid intervals. If this checkbox is selected, the major/minor interval fields in the List of Bands table are unavailable.

**Related procedures:**

■ Adding Data Bands to a Profile View (page 1115)

# Hatch Tab (Profile View Properties Dialog Box)

Use this page to add hatch areas to show cut and fill regions in a profile view.

### Add Areas to Hatch

## Cut Area

Click to add hatching to the profile view in areas where terrain must be cut to create the design profile.

Fill Area

Click to add hatching to the profile view in areas where terrain must be filled to create the design profile.

Multiple Boundaries

Click to add hatching to the profile view in areas where multiple boundaries are used to define a hatch region.

From Criteria

Click to add hatching to the profile view in areas where quantity takeoff criteria are used to define a hatch region.

**Hatch Table**

Hatch Area

Specifies the upper and lower boundaries for each hatch area. Use the buttons along the top of the table to manage these boundaries. Use the + and – buttons to expand and collapse the list of boundaries for each hatch area heading.

Collapse All

Click to collapse the display of boundaries to show only the top-level headings.

Expand All

Click to expand the display to show all boundaries.

Add Upper Boundary

Click to add an upper boundary to the selected hatch area.

Add Lower Boundary

Click to add a lower boundary to the selected hatch area.

Delete

Click to delete the selected boundary.

Profile

Specifies the surface or layout profile that defines each hatch area boundary. Where only a single surface and single layout profile exist in the profile view, the profiles are automatically assigned to boundaries. Click the arrow beside the profile name to select a different profile.

Shape Style

Specifies the shape style applied to the hatch area. Click the name to select another style or modify the style properties. These styles are found on the Toolspace Settings tab ➤ General ➤ Multipurpose Styles ➤ Shape Styles.

**Related procedures:**

■ Adding Hatch Areas to a Profile View (page 1116)

# Projections Tab (Profile View Properties Dialog Box)

Use this tab to show or hide projected objects in a profile view.

Name

Specifies the names and categories of objects that are available for display in the current profile view. Click to add or remove objects in the profile view.

Style

Specifies the display style of each projected object. Click a single entry to change it, or click <set all> for a category to select a style for all objects in that category.

Elevation Options

Specifies whether the elevation of the projected object is determined by its elevation in plan view (Use Object) or manually controlled in the profile view. Click a single entry to change it, or click <set all> for a category to select an option for all objects in that category.

Elevation Value

Specifies the actual elevation of the projected object. Click <set all> for a category to select an elevation for all objects in that category.

Pick Objects

Click to select objects in the drawing and add them to the profile view.

**Related procedures:**

■ Adding Projected Objects to a Profile View (page 1119)

## Pipe Networks Tab (Profile View Properties Dialog Box)

Use this tab to view and change properties of pipe network parts (pipes and structures) in a profile view. You can change the column widths in the table to make it easier to see the contents of cells.

**NOTE** This tab is displayed only if there are one or more pipe networks in the drawing.

The properties table has the following columns:

Name

Displays the name of the pipe network and associated pipe and structure objects.

Draw

Specifies whether to display the pipe or structure in the profile view. Selected items are displayed in the profile view.

**NOTE** Only checked items can have their Layer, Style, and Style Override modified.

Description

Displays an optional description of the pipe or structure.

Layer

Specifies the drawing layer on which the pipe or structure profile is placed. Click to display Layer Selection dialog box from which you can modify the layer.

Style

Specifies the style used by the pipe or structure. Click to display the Pick Style For Pipe dialog box from which you can modify the style.

Style Override

Specifies whether to override the style for the selected pipe or structure for this profile view. This style is used only in the current profile view. Any other profile view that is plotting the pipe or structure would use the style as specified by the Style column value. Click to select a style in the Pick Style For Pipe dialog box.

Show Only Parts Drawn In The Profile View

Specifies whether to display only the pipes and structures that are selected to draw in the profile view.

**Related procedures:**

- [Displaying Pipe Networks in Profile Views](#) (page 1220)

- [Profile View Properties](#) (page 1024)

# Profile View Style Dialog Box

Use this dialog box to define profile view styles that control the format for titles, axis annotation, and other elements of a profile view.

**See also:**

- [Profile View Styles](#) (page 1029)

# Information Tab (Profile View Style Dialog Box)

Use this tab to record basic information about the profile view style.

Name

Specifies the name of the profile view style.

Description

Specifies an optional description of the profile view style.

Created By

Displays the Windows login name of the person who created the profile view style.

Date Created

Displays the date and time the profile view style was created.

Last Modified By

Displays the Windows login name of the person who last modified the profile view style.

Date Modified

Displays the date and time the profile view style was last modified.

# Graph Tab (Profile View Style Dialog Box)

Use this tab to set the vertical scale and direction of the profile view.

## Vertical Scale

Use the controls in this area to specify how much to increase the elevation values for greater visibility in the profile view. Specify the profile view vertical scale in either of the following ways:

- By Vertical Exaggeration — Enter a value in the Vertical Exaggeration field. The Vertical Scale value is calculated automatically.
  The Current Horizontal Scale (HS) factor of the drawing is divided by the Vertical Scale value (VS) to obtain the profile view Vertical Exaggeration value (VX).

$$\frac{HS}{VS} = VX$$

For example, if the Current Horizontal Scale is 50, and you want the profile view Vertical Scale to be 1"=10′, then set the Vertical Exaggeration to 5.

$$\frac{50}{10} = 5$$

■ By Vertical Scale — Select a scale from the Vertical Scale list. Alternatively, enter a custom value in the Custom field. The Vertical Exaggeration value is calculated automatically.

Vertical Scale

The profile view vertical scale. Select a vertical scale from the list, or enter a custom scale in the Custom Scale field.
Vertical Scale (VS) = Current Horizontal Scale (HS) divided by Vertical Exaggeration (VX)

$$VS = \frac{HS}{VX}$$

Custom Scale

Specifies the current Vertical Scale factor. Enter a value in this field to specify a scale factor that is not provided in the Vertical Scale list.

Current Horizontal Scale

The overall drawing Scale specified in the Drawing Settings dialog box (page 1851). This field is not editable. The horizontal scale must be changed in the Drawing Settings dialog box.

Vertical Exaggeration

Specifies by how much the elevation values increase in the profile view for greater visibility. Enter either 1 for no increase in scale or a larger number to increase the scale. The elevation values are multiplied by this value, so a larger number increases the amount of exaggeration in the profile view.

**Profile View Direction**

 Specifies the direction of the profile in the profile view grid:

■ **Left To Right**: The profile is drawn with 0 or the lowest station number on the left the highest station number on the right.

■ **Right To Left**: The profile is drawn with the highest station number on the left and 0 or lowest station number on the right.

## Grid Tab (Profile View Style Dialog Box)

Use this tab to specify clipping, padding, and axis offset options on the profile view grid.

**Grid Options**

 Clip Vertical Grid

Specifies that vertical grid lines are only drawn below the profile line. If Clip to Highest Profile is not selected, the vertical lines are drawn only below the profile line that has Clip Grid selected on the Profiles tab in the Profile View Properties dialog box (page 2179).
**Clip to Highest Profile(s)**: Specifies that vertical profile view grid lines are drawn to the highest of all displayed profiles.

**Omit Grid in Padding Areas**: Specifies that vertical profile view grid lines are not drawn in the padding areas.

 Clip Horizontal Grid

Specifies that horizontal grid lines are only drawn below the profile line. If Clip to Highest Profile is not selected, the horizontal lines are drawn only below the profile line that has Clip Grid selected on the Profiles tab in the Profile View Properties dialog box (page 2179).

**Clip to Highest Profile(s)**: Specifies that vertical profile view grid lines are drawn to the highest of all displayed profiles.

**Omit Grid in Padding Areas**: Specifies that horizontal profile view grid lines are not drawn in the padding areas.

## Grid Padding

 Grid Padding (Major Grids)

Specifies the distance (in major grid blocks) to add to the extents of the profile view in relation to the profiles it contains.

Above Maximum Elevation

Specifies the number of grid blocks that the profile view extends above the maximum profile elevation. A positive value enables the graph to be taller than the extents of the profile drawn in the profile view.

Below Datum

Specifies the number of grid blocks that the profile view extends below the datum or minimum profile elevation. A positive value enables the graph to extend below the extents of the profile drawn in profile view.

To Left

Specifies the number of major grids to place before the left-most station value of the alignment. A positive value enables the graph to be wider than the extents of the profile drawn in the profile view.

To Right

Specifies the number of major grids to place after the right-most station value of the alignment. A positive value enables the graph to be wider than the extents of the profile drawn in the profile view.

**NOTE** The To Left and To Right settings are not applied if the Station Range is set to User Specified. Set the Station Range option in the Profile View Properties dialog box (page 2178).

## Axis Offset

**NOTE** The axis offset distance is specified in plotted units, which is based on the Drawing Units and Scale settings. Set the Drawing Units and Scale on the Units and Zone tab of the Drawing Settings dialog box (page 1851).

 Axis Offset (Plotted Units)

Specifies the distance (in plotted units) to offset the profile view horizontal and vertical axes from the grid extents (including padding). A positive value creates a blank area between the axis and the grid.

Above Maximum Elevation

   Specifies the distance to offset the horizontal axis above the vertical extent.

Below Datum

   Specifies the distance to offset the horizontal axis below the vertical extent.

To Left

   Specifies the distance to offset the horizontal axis to the left of the horizontal extent.

To Right

   Specifies the distance to offset the horizontal axis to the right of the horizontal extent.

# Title Annotation Tab (Profile View Style Dialog Box)

Use this tab to specify settings for the graph view and axis titles.

## Graph View Title

Text Style

   Specifies the text style for the profile view title.

Text Height

   Specifies the current text height in drawing units.

Title Content

   Specifies the text elements used to compose the title, such as horizontal alignment (HA) name and station

   range. To change title format or content, click ![icon] to open the [Text Component Editor dialog box](#) (page 1961).

## Title Position

These controls specify the position of the profile view title. Use Location and Justification settings for basic positioning, then X and Y offsets for more precise placement, if necessary.

Location

   Specifies the location of the title in relation to the profile view grid: either top, bottom, left, or right.

Justification

   Specifies the justification (alignment) of the title. If Location is top or bottom, justification values are left, right, or center. If Location is right or left, justification values are top, middle, or bottom.

X Offset

   Specifies a horizontal offset from the position set by the Location and Justification values. Enter a positive number to move the title right or a negative number to move it left.

Y Offset

   Specifies a vertical offset from the position set by Location and Justification values. Enter a positive number to move up the title or a negative number to move it down.

Border Around The Title

   Specifies whether a border line is drawn around the title block.

Gap

   Specifies the distance between the title and its border.

## Axis Title Text

Separate titles can be displayed at each of the axes. Use the radio buttons around the graphic to select the axis title to edit. Configure title settings and click Apply. Repeat that process with each axis title.

**NOTE** The Axis Title selections do not control axis title visibility. Visibility controls for all profile view components are located on the Display tab (page 2192).

 Axis Title Text

Specifies which axis title is controlled by the text editing tools.

Title Text

Specifies the title text for the horizontal axis. To change the title content, click  to open the Text Component Editor dialog box (page 1961).

Location

Specifies the location of the title on the axis: either Left, Center, or Right. For more precise control, use the X and Y Offsets.

Text Style

Specifies a text style for use in the horizontal axis title.

Text Height

Specifies the title text height (in plotted units).

Rotation

Specifies the angle for the title. Enter a positive or negative value. The angle direction is always counterclockwise. If the value is zero (0), the title is not rotated.

X Offset

Specifies a horizontal offset from the Location setting. Enter a positive number to move the title right or a negative number to move it left.

Y Offset

Specifies a vertical offset from the Location setting. Enter a positive number to move up the title or a negative number to move it down.

## Horizontal Axes Tab (Profile View Style Dialog Box)

Use this tab to specify the settings for the tick marks on the horizontal axes of the profile view.

 Select Axis to Control

Specifies the axis for which you adjust the Major and Minor Tick Details.

**NOTE** The bottom axis controls the major and minor grid spacing.

Top

Adjust Major and Minor Tick Details along the top axis.

Bottom

Adjust Major and Minor Tick Details along the bottom axis.

Tick and Label Start Station

Specifies whether ticks and labels are placed at the start station on the horizontal axes.

**Major Tick Details**

Interval

Specifies the spacing of major ticks on the horizontal axis, using the actual ground units.

Tick Size

Specifies the height of the tick on the horizontal axis in plotted units.

Tick Justification

Specifies the position of the tick relative to the axis: top, bottom, or center.

Text Height

Specifies the height of text (in plotted units) used to label major ticks on the horizontal axis.

Tick Label Text

Specifies a label property for the tick. To change the text format or content, click ![icon] to display the Text Component Editor dialog box (page 1961).

Text Style

Specifies the style of the tick label text.

Rotation

Specifies the angle for the tick label. Enter a positive or negative value. The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

Specifies a horizontal offset for the tick label from the bottom of the tick.

Y Offset

Specifies a vertical offset for the tick label from the bottom of the tick.

**Minor Tick Details**

Interval

Specifies the spacing of minor ticks on the horizontal axis, using the actual ground units.

Tick Size

Specifies the height of the tick on the horizontal axis in plotted units.

Tick Justification

Specifies the position of the tick relative to the axis: top, bottom, or center.

Text Height

Specifies the height of text (in plotted units) used to label minor ticks on the horizontal axis.

Tick Label Text

Specifies a label property for the tick. To change the text format or content, click ![icon] to display the Text Component Editor dialog box (page 1961).

Text Style

Specifies the style of the tick label text.

Rotation

Specifies the angle for the tick label. Enter a positive or negative value. The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

Specifies a horizontal offset for the tick label from the bottom of the tick.

Y Offset

  Specifies a vertical offset for the tick label from the bottom of the tick.

# Vertical Axes Tab (Profile View Style Dialog Box)

Use this tab to specify the settings for the tick marks on the vertical axes of the profile view.

 Select Axis to Control

Specifies the axis to adjust the Major and Minor Tick Details.

**NOTE** The left axis controls the major and minor grid spacing.

Left

  Adjust Major and Minor Tick Details along the left axis.

Right

  Adjust Major and Minor Tick Details along the right axis.

Tick and Label Start Station

  Specifies whether ticks and labels are placed at the start station on the vertical axes.

## Major Tick Details

Interval

  Specifies the spacing of major ticks on the horizontal axis, using the actual ground units.

Tick Size

  Specifies the height of the tick on the horizontal axis in plotted units.

Tick Justification

  Specifies the position of the tick relative to the axis being annotated: left, right, or center.

Text Height

  Specifies the height of text (in plotted units) used to label major ticks on the vertical axis.

Tick Label Text

  Specifies a property with which the tick is labeled. To change the text format or content, click  to display the Text Component Editor dialog box (page 1961).

Text Style

  Specifies the style of the tick label text.

Rotation

  Specifies the angle for the tick label. Enter a positive or negative value. The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

  Specifies a horizontal offset for the tick label from the bottom of the tick.

Y Offset

  Specifies a vertical offset for the tick label from the bottom of the tick.

**Minor Tick Details**

Interval
Specifies the spacing of minor ticks on the vertical axis, using the actual ground units.

Tick Size
Specifies the height of the tick on the vertical axis in plotted units.

Tick Justification
Specifies the position of the tick relative to the axis being annotated: left, right, or center.

Text Height
Specifies the height of text (in plotted units) used to label minor ticks on the vertical axis.

Tick Label Text
Specifies a property with which the tick is labeled. To change the text format or content, click ![icon] to display the Text Component Editor dialog box (page 1961).

Text Style
Specifies the style of the tick label text.

Rotation
Specifies the angle for the tick label. Enter a positive or negative value. The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset
Specifies a horizontal offset for the tick label from the bottom of the tick.

Y Offset
Specifies a vertical offset for the tick label from the bottom of the tick.

## Display Tab (Profile View Style Dialog Box)

Use this tab to manage the display of profile view components in 2D and 3D.

For more information about the Component Display section of this tab, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Profile View Style Dialog Box)

Use this tab to review and adjust settings for the profile view style.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Project Objects to Profile View Dialog Box

Use this dialog box to specify objects in the current drawing to be projected into a profile view.

To highlight an object in the drawing, select its row in this table.

Name
Displays the objects that can be projected, divided into categories. Select the ones you want to project.

Style
Specifies the current style for each object. You can change the style used to project an object. Select <set all> at the category level to change all objects in that category in one operation.

Elevation Options

Specifies how the elevation of each object is determined. Longitudinal objects, such as feature lines and 3D polylines, have multiple elevation values; their elevation options can differ from those for point objects.

- Use Object: Elevation is read from the object properties.

- Surface: The object is set to the elevation of a selected surface.

- Manual: You can specify the elevation. This option cannot be used with longitudinal objects.

- Profile: The object is set to the elevation of a selected profile.

- <set all>: Used at the category level to specify the elevation option for all projected objects in the category.

Elevation Value

Specifies the elevation of each projected object. You can change the value here for point objects if the elevation option is manual.

Label Style

Specifies the style of label applied to the projected object. Select <none> to display no label. Select <set all> at the category level to set a label style for all projected objects in the category.

Pick Objects

Click to select objects in the drawing and add them to the profile view.

**Related procedures:**

- Adding Projected Objects to a Profile View (page 1119)

## Raise/Lower PVI Elevations Dialog Box

Use this dialog box to change the elevation of an entire profile either for layout profiles or static surface profiles, or a range of stations.

In the Elevation Change field, enter either a positive number to raise the PVIs, or a negative number to lower them. In the PVI Range area, choose one of the following options:

- **All**: To raise or lower the entire profile

- **Station Range**: To raise or lower a subset of PVIs, specified by start and end station values

Default values for the station range are the beginning and end of the profile. If a station equation is in effect, use the station equation values to specify a range.

**Related procedures:**

- Editing PVIs (page 1093)

## Superimpose Profile Options Dialog Box

Use this dialog box to specify the station range of a superimposed profile and the accuracy of curve approximation.

**See also:**

- Creating a Superimposed Profile (page 1054)

## Limits Tab (Superimpose Profile Options Dialog Box)

Use this tab to specify the start and end stations for a superimposed profile.

Specify the station range either by numeric entry or by clicking a station along the parent horizontal alignment.

---

**NOTE** If you want the superimposed profile's station range to remain fixed, then select the Select Start and Select End check boxes. Selecting these options prevents the superimposed profile from reacting to changes in the station range of the source alignment. If the Select Start and Select End boxes are not selected, then the start and end of the superimposed profile is locked to the start and end of the source alignment. If the start or end of the source alignment is then changed, the superimposed profile updates dynamically.

---

## Accuracy Tab (Superimpose Profile Options Dialog Box)

Use this tab to specify the accuracy of curves in the superimposed profile.

Specify the mid-ordinate distances used for approximating horizontal and vertical curves. A small value results in the use of many short line segments to represent a curve. A large value results in longer segments and a coarser curve, with a shorter drawing time.

# Vertical Curve Settings Dialog Box

Use this dialog box to specify the type of curve to be placed between tangents in a profile.

Curves of the type defined here are used if you select the ⛏ Draw Tangents With Curves button on the Profile Layout Tools dialog box (page 2170).

After you select which of the three vertical curve types to use, specify the related parameters for crest curves and sag curves as follows:

■ **Parabolic**: Specify either curve length or K value.

■ **Circular**: Specify either curve length or radius.

■ **Asymmetric**: Specify separate lengths for the parabola in (Length1) and the parabola out (Length2).

Click OK to save the settings.

**Related procedures:**

■ Vertical Curve Design (page 1068)

■ Creating Layout Profiles (page 1048)

# Project Management Dialog Boxes

<div style="text-align: right; font-size: 3em; font-weight: bold;">65</div>

The following topics provide information about the Project Management dialog boxes.

## Add Points To Project Dialog Box

Use this dialog box to create project points from drawing points by adding them to a project.

Point List

Lists the drawing points to be added to the project.

Comment

Specifies a comment to be associated with the point database for this operation. This comment can be viewed in the Autodesk Vault tool by a system administrator.

Check In Options

Specifies additional actions to take after the project points are created.

■ Check In: Creates project points, and then relinquishes your control over the created points, making them available for someone else to edit.

■ Check In And Keep Checked Out: Creates project points and then checks them out to you.

■ Check In And Protect: Creates project points and then protects them, preventing others from editing them.

**Related procedures:**

■ [Adding Points to a Project](#) (page 168)

## Add To Project Wizard

Use this wizard to add a drawing to a project.

This wizard leads you through the steps of adding a drawing to a project.

■ Select the project to which you will add a drawing.

■ Specify the location of the drawing within the project.

- Specify which dependent files will be added to the project, and whether DWF files will be created for those files.

- Specify which drawing objects will be shared across the project.

**Related procedures:**

- [Adding a Drawing to a Project](#) (page 156)

## Select Project Page (Add To Project Wizard)

Use this page to select the project to which you will add a drawing.

The available projects are listed. The active project is the default selection. If you want to select a different project, click it in the list.

Click Next to move to the next page.

## Select Drawing Location Page (Add To Project Wizard)

Use this page to specify the location of the drawing within the project.

The selected project is shown, along with any existing subfolders.

Folder List

Click a subfolder to specify the location of the drawing. Optionally, click  to create a new folder within the project under the currently selected folder.

Click Next to move to the next page.

## File Dependencies Page (Add To Project Wizard)

Use this page to review any dependent files to be added to the project along with the drawing, and to specify the creation of DWF files.

DWF files display the drawing's preview in Prospector and in the Autodesk Vault tool.

Keeps Files Checked Out
Specifies that the files will be added to the project, but the drawing will remain checked out to the working folder, available for revisions. The file remains open in the current AutoCAD Civil session.

Project Files
Specifies which files to add to the project. If you do not want to add a dependent file, clear its check box.

Create DWF
Specifies whether to create a DWF file.

Enter Version Comments
Specifies an optional description of the file you are adding to the project.

Click Next to move to the next page.

## Share Data Page (Add To Project Wizard)

Use this page to specify which objects in the drawing to share across the project.

A shared object is available for use by others. It is listed in the project's Prospector tree and can be referenced by other project drawings.

**NOTE** You should only share objects that are required by others.

Object

Lists the objects in the drawing that can be shared with others. Select the objects that you want to share. If you select an object collection such as Alignments, all objects in the collection are selected.

Status

Displays an error message if an object cannot be shared.

Description

Specifies an optional description of the shared object.

Click Finish to complete the process of adding the drawing to a project.

**Related procedures:**

■ Adding a Drawing to a Project (page 156)

# Check In Drawing Wizard

This wizard leads you through the steps of checking a drawing in to a project.

■ Specify which dependent files will be checked in to the project, and whether DWF files will be created for those files.

■ Specify which drawing objects will be shared across the project.

## File Dependencies Page (Check In Drawing Wizard)

Use this page to choose the dependent files to be checked in to the project along with the drawing.

Keeps Files Checked Out

Specifies that the files will be checked in and the versions will be updated, but the drawing will remain checked out to the working folder and available for revisions.

Project Files

Specifies which files will be checked in to the project. If you do not want to check in a dependent file, clear its check box.

Create DWF

Specifies whether to create a DWF file for the drawing.

Enter Version Comments

Specifies an optional description of the files you are checking in to the project.

Click Next to move to the next dialog box.

## Share Data Page (Check In Drawing Wizard)

Use this page to review the set of objects in the drawing that will be shared, allowing others to reference them in drawings.

If the drawing contains objects that have already been shared, they are not listed.

Object

Lists the objects in the drawing that can be shared with others. Select the objects that you want to share. If you select an object collection such as Alignments, all objects in the collection are selected.

Status

Displays an error message if an object cannot be shared.

Description

Displays a description of the shared object, which you can change.

Click Finish to complete the process of checking in the drawing.

**Related procedures:**

■ Checking a Drawing in to a Project (page 158)

# Check In Points Dialog Box

Use this dialog box to update project points with changes that you have made.

You must check the points in from the same drawing that you checked them out from.

Point list

Lists the project points to be checked in to the project.

Comment

Specifies a comment to be associated with the point database for this operation. This comment can be viewed in the Autodesk Vault tool by a system administrator.

Check In Options

Specifies additional actions to be taken after the points are checked in.

■ Check In: Updates the project points, and then relinquishes your control over them, making them available for someone else to edit.

■ Check In And Keep Checked Out: Updates the project points and keeps them checked out to you.

■ Check In And Protect: Updates the points and then protects them, preventing others from editing them.

**Related procedures:**

■ Checking In Points (page 170)

# Check Out Drawing Dialog Box

Use this dialog box to check out a project drawing.

Include File Dependencies

Specifies whether dependent files should be checked out with the project drawing.

Get Latest Version

Specifies whether local copies of files are overwritten.
Selected: The latest versions in the project database are checked out, overwriting the related files in the working folder.
Cleared: Files in the working folder are not overwritten, but the latest versions in the project database are checked out. Use this option if you have made changes to the local files and you want to check them in to the database as the latest project version.

**IMPORTANT** If you clear this check box with the intention of checking in files from the working folder, make sure that no one else has revised the project versions of the files since you last checked them out. Such changes would be lost when you check in your working version. If needed, a prior version can be restored by an administrator using the Autodesk Vault tool.

File List

Specifies the files and the dependent files, if applicable, that you want to check out.

Enter Version Comments

Specifies an optional description of the file version you are checking out of the project.

**Related procedures:**

■  Checking a Drawing out from a Project (page 157)

■  Checking Out Project Object Source Drawings (page 165)

# Check Out Points Dialog Box

Use this dialog box to check out project points to the active drawing.

Point List

Lists the project points to be checked out.

**Related procedures:**

■  Checking Out Points (page 169)

# Create Alignment Reference Dialog Box

Use this dialog box to create a data reference to an alignment.

Source Alignment

Specifies the alignment from which to create the reference. Click to change the alignment or to display all available alignments.

Site

Specifies a site for the alignment reference. Either select a site from the Site list or click  to select an object in the drawing. The alignment and the object you select in the drawing are associated with the same site.

**NOTE** Accepting the default <None> selection places the alignment in the top-level Alignments collection in Prospector. See Alignment and Site Interaction (page 721) for more information.

Name

Specifies a system-generated name for the alignment reference. To edit the name, click  .

Description

Specifies an optional description of the alignment reference.

Alignment Style

Displays the current style. Click the arrow to display the alignment styles in the drawing.  specifies the style options. Create a new style, copy or edit the current style selection, or pick a style from drawing.  opens the Style Detail dialog box. Preview the style and creation information.

Alignment Layer

Displays the layer on which the alignment reference will be created. To change the layer click  and select a layer.

Alignment Label Set

Lists the alignment label sets in the drawing. You can select a label set from the list. After you select the label set, use the Selection icon to edit the current label set, copy the current label set, or create a new label set. The Style Detail icon previews the current style.

**Related procedures:**

■ Creating an Alignment Reference (page 893)

# Create Data Shortcuts

Use this dialog box to share objects from the current drawing.

Object Table

Select the objects that you want to reference in other drawings.

Hide Already Published Objects

Click to hide all objects in the table that are already shared.

Pick In Drawing

Click to select objects in the drawing rather than in the table.

**Related procedures:**

■ Creating Data Shortcuts (page 131)

# Create Pipe Network Reference Dialog Box

Use this dialog box to create a data reference to a pipe network.

Source Pipe Network

Specifies the pipe network data shortcut from which to create the reference. Click to change the data shortcut or display all available pipe network data shortcuts.

Network Name

Specifies a system-generated name for the pipe network reference. To edit the name, click  .

Network Description

Specifies an optional description of the pipe network reference.

Network Parts List

Specifies the parts list associated with this pipe network reference.

Layers

Displays the layer on which the pipe network reference will be created. To change the layer click ⊗ and select a layer.

Override Reference Surface

If you select this option, each referenced part references the surface specified here.

Override Reference Alignment

If you select this option, each referenced part references the alignment specified here.

---

**NOTE** If neither Override Reference option is selected, each part from the source drawing matches the same-named object (surface or alignment) in the reference drawing. When specific parts reference surfaces or alignments that cannot be found in the reference drawing, the following warning appears in event viewer: **Reference <Object> not found in reference drawing**. In this case, these network parts are created with a value of <none> for the missing reference object.

---

Include Source Labels

If you select this option, labels or label sets are copied with the reference object as they exist in the source drawing and the label style options are grayed out. Otherwise, the label style options are active and the label styles will be created when the referenced parts are added to the drawing.

---

**NOTE** Spanning pipe labels are created in the reference drawing matching their data from the source drawing. They reference the same parts as were specified when the spanning label was created.

---

Structure Label Style and Pipe Label Style

These fields display the current styles for structure and pipe labels. Click the arrow to display the structure and pipe label styles in the drawing. 📝 specifies the style options. Create a new style, copy or edit the current style selection, or pick a style from drawing. 🔍 opens the Style Detail dialog box. Preview the style and creation information.

**Related procedures:**

■   Creating a Pipe Network Reference (page 1199)

# Create Profile Reference Dialog Box

Use this dialog box to create a data reference to a profile.

Source Profile

Specifies the profile to reference. Click to change the profile or to display all available profiles.

Source Alignment

Displays the alignment data shortcut along which to create the profile data shortcut.

---

**NOTE** If the Source Alignment field is set to <None>, you must create an alignment reference before continuing with the profile reference creation. See Creating an Alignment Reference (page 893).

---

Name

Specifies a system-generated name for the profile. To edit the default naming scheme, click 🔖 .

Description

Specifies an optional description of the profile.

Profile Style

Specifies the current style for the profile. Use the standard controls to edit the style or create a new one.

Profile Layer

Displays the drawing layer on which the profile will be drawn. To change the layer, click ⬟ .

Profile Label Set

Specifies the name of the current profile label set. Use standard controls to review or change the set.

**Related procedures:**

■ Creating a Profile by Reference (page 1055)

# Create Surface Reference Dialog Box

Use this dialog box to create a data reference to a surface.

Source Surface

Specifies the complete path to the surface in the project folder.

Surface Layer

Displays the layer on which the surface will be created.

⬟

Click to open the Object Layer dialog box where you can select a different layer for the surface.

The Properties Table section of the dialog box displays varying properties depending on the type of surface selected.

## Information

Name

Specifies the name of the surface.

**NOTE** To name the surface, click its default name and enter a new name, or click the Name Template button and use the Name Template. For more information, see Name Template Dialog Box (page 1806).

Description

Specifies a description of the surface.

Style

Specifies the style for the surface. Click ⋯ to open the Select Surface Style (page 1801) dialog box where you can select a different style.

Render Material

Specifies the render material (page 1577). Click ⋯ to select a render material.

## Grid Parameters

This property group is displayed when a grid surface is selected.

Grid X Spacing

Specifies the X distance between the grid lines. When selected, you can click ▦ to digitize the spacing in the drawing area.

Grid Y Spacing

Specifies the Y distance between the grid lines. When selected, you can click ▦ to digitize the spacing in the drawing area.

Orientation

Specifies the direction for the grid in the X and Y directions. When selected, you can click  to pick two points in the drawing to define the orientation direction.

## Volume Surfaces

Base Surface

Specifies the base surface from which the volume surface is generated. Enter the surface name or click  to open the Select Base Surface (page 1810) dialog box where you can select the surface from the list.

Comparison Surface

Specifies the comparison surface from which the volume surface is generated. Enter the surface name or click  to open the Select Comparison Surface (page 1810) dialog box where you can select the surface from the list.

**Related procedures:**

■ Creating a Surface Reference (page 609)

# Create View Frame Group Reference Dialog Box

Use this dialog box to create a data reference to a view frame group.

## View Frame Group

Source View Frame Group

Specifies the view frame group from which to create the reference. Click to change the group or to display all available view frame groups.

Name

Specifies a system-generated name for the view frame group reference. To edit the name, click  .

Description

Specifies an optional description of the view frame group reference.

## View Frame

View Frame Style

Displays the style used to display the view frames in this view frame group reference.

View Frame Label Style

Displays the style used to display labels on the view frames used in this view frame group reference. For more information, see Understanding Labels (page 1466).

View Frame Layer

Displays the layer on which the view frames used in this view frame group reference will be created. To change the layer click  and select a layer.

## Match Line

Match Line Style

Displays the style used to display match lines and match line mask areas in this view frame group reference.

Match Line Left Label Style

Displays the style used for the labels that are on the left side of a match line in this view frame group reference. For more information, see Understanding Labels (page 1466).

Match Line Right Label Style

Displays the style used for the labels that are on the right side of a match line in this view frame group reference. For more information, see Understanding Labels (page 1466).

Match Line Layer

Displays the layer on which the match lines used in this view frame group reference will be created. To change the layer click ⬟ and select a layer.

Alignment

Specifies the alignment this view frame group reference is associated with.

**Related procedures:**

■ Creating a View Frame Group Reference (page 1709)

# Databases Dialog Box

Use this dialog box to review the list of available databases on a specified Vault server and select the one to log in to.

# Delete Points From Project Dialog Box

Use this dialog box to delete points from a project.

You must check out a point before you can delete it.

Point list

Lists the project points to be deleted.

**Related procedures:**

■ Deleting Project Points (page 172)

# Get Latest Version Dialog Box

Use this dialog box to get a read-only local copy of a project file.

Include File Dependencies

Specifies whether dependent files should be displayed when they exist.

File List

Lists the available files and related project files. Select the files and dependent files you want.

**Related procedures:**

■ Getting the Latest Version of a Drawing (page 159)

■ Getting the Latest Version of Project Objects (page 163)

# Get Points From Project Dialog Box

Use this dialog box to create a read-only local copy of project points in the active drawing.

Point list

Lists the project points to be copied into the active drawing.

**Related procedures:**

■ Copying Project Points into a Drawing (page 171)

# Log In Dialog Box

Use this dialog box to log in to a Vault server and a Vault database.

User Name
 Specifies the user name for logging in to the database. This name must be known to the Vault server.

Password
 Specifies the password associated with the user name.

Server
 Specifies the Vault server to log in to. The list shows all Vault servers that the user has accessed.

Database
 Specifies the database on the Vault server to access. To see the list of available databases, click ⬚ .

Automatically Log In Next Session
 Specifies whether the user is automatically logged in to the above-specified server and database when the next AutoCAD Civil session starts.

**Related procedures:**

■ Logging in to a Vault Server (page 149)

# New Data Shortcut Folder

Use this dialog box to create a new folder for a project that uses data shortcuts.

Working Folder
 Specifies the parent folder in which the project folder will be created. Default value is C:\Civil Projects.

Name
 Enter a name for the new project folder.

Description
 Optionally enter a text description of the project.

Use Project Template
 Select if you want to use a template (standard set of subfolders) for the new project. This option is recommended.

Project Templates Folder
 Displays the available project templates in the current folder. Default value is C:\Civil Project Templates.
 Click ⬚ to browse to a different template folder.

Project Template
 Select the template you want to use for the new project. Default value is _Sample Project.

**Related procedures:**

■ Creating a New Shortcuts Folder (page 129)

# New Folder Dialog Box

Use this dialog box to specify the name of a new folder you are creating within the project folder.

Enter a name and click OK to continue.

# New Project Dialog Box

Use this dialog box to specify the name, description and template when creating a new Vault project.

Name
  Specifies the project name.

Description
  Specifies a description of the project.

## Project Template

Use Project Template
  Select if you want to use a template (standard set of subfolders) for the new project. This option is recommended.

Project Templates Folder

  Specifies the location for your project template. folder. Click  to browse to the folder.

Project Template
  Specifies the name of the project template.

Created By
  Displays the name of the user who created the project.

Date Created
  Displays the date and time the project was created.

**Related procedures:**

■  Creating Projects (page 150)

# Project Properties Dialog Box

Use this dialog box to review the properties of a Vault project.

Name
  Specifies the project name.

Description
  Specifies a description of the project.

Created By
  Displays the name of the user who created the project.

Date Created
  Displays the date and time the project was created.

**Related procedures:**

■  Creating Projects (page 150)

# Properties - Civil Projects Dialog Box

Use this dialog box to review or change the Vault database or the working folder.

Vault Database
   Specifies the database that you are logged in to.

Working Folder
   Specifies the current location for your local copies of files. Click [...] to browse to another folder.

Project Templates Folder
   Specifies the location for your project template folder. Click [...] to browse to the folder.

Current User Name
   Displays the user name for the current session.

**Related procedures:**

■  Changing the Working Folder (page 150)

# Protect Points Dialog Box

Use this dialog box to prevent others from editing project points.

Point list
   Lists the project points to be protected.

**Related procedures:**

■  Protecting Project Points (page 171)

# Reset Points To Checked In Dialog Box

Use this dialog box if you are a system administrator and need to reset checked-out points.

Point list
   Lists the project points to be reset.

**Related procedures:**

■  Resetting Project Points Set by Others (page 174)

# Select Projects To Display Dialog Box

Use this dialog box to select the projects to display in the Prospector tree and the Add to Project (page 2196) dialog box.

The dialog box contains a list of all the projects available in the Vault database you are logged in to. Project names with a selected check box will be displayed in the Projects collection in the Master View of the Prospector tree.

When an active project has been set, the name of the active project is not displayed in the list.

   Selects all projects in the list.

Clears all projects in the list.

Selects multiple project names. Use Ctrl+click or Shift+click to select multiple project names, then click this button to select their check boxes.

Clears multiple project names. Use Ctrl+click or Shift+click to select multiple project names, then click this button to clear their check boxes.

Name

Lists all the projects available in the database. Click the column heading to sort the projects alphabetically by name.

**Related procedures:**

■ Selecting Projects to Display (page 152)

## Set Data Shortcuts Folder

Use this dialog box to select a different project folder as a source of data shortcuts.

Typically you select a different project folder when you want to associate the current drawing with that project.

Folder List

Click a table row, then click OK to select the associated project folder. You can click the Name or Description heading to sort the table entries alphabetically.

Folder Name

Displays the currently selected project folder.

**Related procedures:**

■ Setting the Data Shortcuts Folder (page 130)

## Sync To Project Dialog Box

Use this dialog box to update out-of-date local copies of project objects and project points contained in a drawing.

Object

Lists the local objects in the drawing that are older than the latest project version. Select all objects that you want to synchronize. If you select or clear an object collection, such as Alignments, the action affects all objects in the collection.

Specifies that the object is a reference to a project object.

Specifies that the object is not synchronized with the project data.

**Related procedures:**

■ Synchronizing Drawing Data with Project Data (page 161)

# Undo Check Out Dialog Box

Use this dialog box to reset a checked-out drawing and related files to a checked-in state.

This operation is useful if you decide to make no changes to a checked-out drawing, or if you make some changes but do not want to update the master version of the file with the changes.

Include File Dependencies
  Specifies whether related files are reset to a checked-in state.

File List
  Lists the available files and related project files. Select the files and dependent files, if applicable, that you want to reset to a checked-in state.

Version Comments
  Displays any comment that was added when the drawing was checked out.

**Related procedures:**

■ Resetting a Checked out Drawing (page 160)

■ Resetting a Checked Out Source Drawing (page 165)

# Undo Check Out Points Dialog Box

Use this dialog box to reset your checked-out points to a checked-in state.

Point list
  Lists the project points to be checked in.

**Related procedures:**

■ Resetting Points You Checked Out (page 173)

# Unprotect Points Dialog Box

Use this dialog box to allow others to edit protected project points.

Only the person who protected a project point can unprotect it.

Point list
  Lists the project points to be unprotected.

**Related procedures:**

■ Unprotecting Project Points (page 172)

# Reports Dialog Boxes

# 66

Use the following links to access information about the AutoCAD Civil Reports dialog boxes.

## Toolbox Editor Vista

Use this panorama vista to add custom reports or other custom tools to the Toolbox.

**Expand All Categories**

Expands all categories.

**Collapse All Categories**

Collapses all open categories.

**Add Root Item**

Inserts a new collection at the same level as the Reports Manager.

**Tree Items**

Right-click a tree item to display commands to add and remove categories and tools.

**Properties & Values**

Specifies the values for categories in tools.

For example, if you are adding a new report, you need to specify the Report Type (VBA, COM, .NET, or XSL), the file to use, and the macro to run.

You can optionally specify a help file and help topic to display.

**Reload**

Clears any changes you have made in the current session and reloads the data.

**Save**

Saves any changes you have made but keeps the window open for further edits.

**Dismiss**

Closes the Toolbox Editor vista.

# Edit Report Settings Dialog Box

Use this dialog box to edit settings for all report types.

⊡▼ Expand All Categories

Expands all categories in the dialog box.

⊡▲ Collapse All Categories

Collapses all open categories in the dialog box.

Categories and Settings

Use the +/- boxes to display or hide the settings in the category. Use the Value column to specify a value for a setting.

# Create Reports - PI Station Report

Use this dialog box to select the alignments and specify station ranges for the PI Station report.

This report lists tangent information for a range of alignment stations. No curve data is reported.

### List of Alignments

Include

Specifies the alignments to include in the report. Select a check box to include the alignment.

Name & Description

Displays the name and description of the alignments in the drawing.

Station Start & Station End

Displays the start and end stations for a selected alignment
You can edit these values by highlighting an alignment in the list and adjusting the Report Settings (see below).

### Report Settings

Start Station & End Station

Displays the start and end stations for a highlighted alignment. Click an alignment name in the list to highlight it.
You can edit these values to change the range of stations included in the report. You can enter formatted or unformatted values, such as 2+50.95 or 250.95.

Save Report To

Specifies the name and location of the resulting report.

Create Report

Generates the report and saves it to the specified location.

Done

Closes the dialog box and discards changes to station ranges.

# Create Reports - Incremental Station Report

Use this dialog box to select the alignments and specify station ranges for the Incremental Station report.

This report lists northing, easting, and tangent information for a range of alignment stations, based on a specified station increment.

**List of Alignments**

Include

Specifies the alignments to include in the report. Select a check box to include the alignment.

Name & Description

Displays the name and description of the alignments in the drawing.

Station Start & Station End

Displays the start and end stations for a selected alignment
You can edit these values by highlighting an alignment in the list and adjusting the Report Settings (see below).

**Report Settings**

Start Station & End Station

Displays the start and end stations for a highlighted alignment. Click an alignment name in the list to highlight it.
You can edit these values to change the range of stations included in the report. You can enter formatted or unformatted values, such as 2+50.95 or 250.95.

Station Increment

Specifies the station increment to use. For example, specify 50 to report at increments of 50 feet or meters along the alignment.

---

**NOTE** The increment is applied to all alignments. Station 0+00 is always included in the report. Odd stations are not included if they do not match the station increment. For example, if the increment is 50, and the alignment starts at station -10+00, the report will begin at station 0+00. However, if the alignment begins at station -60+00, the report will begin at station -50+00.

---

Save Report To

Specifies the name and location of the resulting report.

Create Report

Generates the report and saves it to the specified location.

Done

Closes the dialog box and discards changes to station ranges.

# Create Reports - Stakeout Alignment Report

Use this dialog box to select the alignments and specify station ranges for an Alignment Stakeout report.

This report lists angle, distance, northing, and easting from the occupied point to each alignment station.

**List of Alignments**

Include

Specifies the alignments to include in the report. Select a check box to include the alignment.

Name & Description

Displays the name and description of the alignments in the drawing.

Station Start & Station End

Displays the start and end stations for a selected alignment
You can edit these values by highlighting an alignment in the list and adjusting the Report Settings (see below).

**Stakeout Options**

Point Occupied

Specifies the point from which the angles to the alignment are calculated. You can enter a point number

or click  to select a point in the drawing.

Backsight Point

Specifies the backsight point. The backsight point and occupied point cannot be the same point.

Select Angle Type

Specifies the stakeout angle type to use.

- **Turned +**: Turned angle right

- **Turned -**: Turned angle left

- **Deflect +**: Deflection angle right

- **Deflect -**: Deflection angle left

- **Direction**: Uses azimuths or bearings

backsight point      occupied point

turned angle right

occupied point      backsight point

turned angle left

occupied point

backsight point

deflected angle right

occupied point

backsight point

deflected angle left

## Report Settings

Start Station & End Station

Displays the start and end stations for a highlighted alignment. Click an alignment name in the list to highlight it.

You can edit these values to change the range of stations included in the report. You can enter formatted or unformatted values, such as 2+50.95 or 250.95.

Station Increment

Specifies the station increment to use. For example, specify 50 to report at increments of 50 feet or meters along the alignment.

**NOTE** The increment is applied to all alignments. Station 0+00 is always included in the report. Odd stations are not included if they do not match the station increment. For example, if the increment is 50, and the alignment starts at station -10+00, the report will begin at station 0+00. However, if the alignment begins at station -60+00, the report will begin at station -50+00.

Offset

Specifies a distance from the alignment the stakeout report will use in calculations. Enter a negative number to indicate a left offset.

Save Report To

Specifies the name and location of the resulting report.

Create Report

Generates the report and saves it to the specified location.

Done

Closes the dialog box and discards changes to station ranges.

# Create Reports - Alignment Design Criteria Verification

Use this dialog box to compare alignment parameters with specified design criteria.

This report lists displays each entity's parameters, and whether the entity clears or violates the specified design criteria and design checks.

For more information, see Criteria-Based Alignment Design (page 866).

### List of Alignments

Include

Specifies the alignments to include in the report. Select a check box to include the alignment.

Name & Description

Displays the name and description of the alignments in the drawing.

Station Start & Station End

Displays the start and end stations for a selected alignment.
You can edit these values by highlighting an alignment in the list and adjusting the Report Settings (see below).

### Report Settings

Start Station & End Station

Displays the start and end stations for a highlighted alignment. Click an alignment name in the list to highlight it.
You can edit these values to change the range of stations included in the report. You can enter formatted or unformatted values, such as 2+50.95 or 250.95.

Save Report To

Specifies the name and location of the resulting report.

Create Report

Generates the report and saves it to the specified location.

Done

Closes the dialog box and discards changes to station ranges.

# Create Reports - Profile Design Criteria Verification

Use this dialog box to compare profile parameters with specified design criteria.

This report lists displays each entity's parameters, and whether the entity clears or violates the specified design criteria and design checks.

For more information, see Criteria-Based Profile Design (page 1044).

**List of Profiles**

Include

Specifies the profiles to include in the report. Select a check box to include the profile.

Name & Description

Displays the name and description of the profiles in the drawing.

Station Start & Station End

Displays the start and end stations for a selected profile.
You can edit these values by highlighting a profile in the list and adjusting the Report Settings (see below).

Alignment

Displays the name of each profile's parent alignment.

**Report Settings**

Start Station & End Station

Displays the start and end stations for a highlighted profile. Click a profile name in the list to highlight it.
You can edit these values to change the range of stations included in the report. You can enter formatted or unformatted values, such as 2+50.95 or 250.95.

Save Report To

Specifies the name and location of the resulting report.

Create Report

Generates the report and saves it to the specified location.

Done

Closes the dialog box and discards changes to station ranges.

# Create Reports - PVI Station and Curve Report

Use this dialog box to select the profiles and specify station ranges for a profile PVI station and curve report.

This report lists station, elevation, and grade out for each PVI in an profile. Vertical curve information is included for finished ground profiles.

**List of Profiles**

Include

Specifies the profiles to include in the report. Select a check box to include the profile.

Name & Description

Displays the name and description of the profiles in the drawing.

Station Start & Station End

Displays the start and end stations for a selected profile.
You can edit these values by highlighting a profile in the list and adjusting the Report Settings (see below).

Alignment

Displays the horizontal alignment that the profile is associated with.

**Report Settings**

Start Station & End Station

Displays the start and end stations for a highlighted profile. Click a profile name in the list to highlight it.

You can edit these values to change the range of stations included in the report. You can enter formatted or unformatted values, such as 2+50.95 or 250.95.

Save Report To

Specifies the name and location of the resulting report.

Create Report

Generates the report and saves it to the specified location.

# Create Reports - Profile Incremental Station Report

Use this dialog box to select the profiles and specify station ranges for a profile incremental station report.

This report lists PVI stations and elevations of the selected profile at regular intervals, at critical geometry points, and crest and sag curve points.

## List of Profiles

Include

Specifies the profiles to include in the report. Select a check box to include the profile.

Name & Description

Displays the name and description of the profiles in the drawing.

Station Start & Station End

Displays the start and end stations for a selected profile.
You can edit these values by highlighting a profile in the list and adjusting the Report Settings (see below).

Alignment

Displays the horizontal alignment that the profile is associated with.

## Report Settings

Start Station & End Station

Displays the start and end stations for a highlighted profile. Click a profile name in the list to highlight it.
You can edit these values to change the range of stations included in the report. You can enter formatted or unformatted values, such as 2+50.95 or 250.95.

Station Increment

Specifies the station increment to use. For example, specify 50 to report at increments of 50 feet or meters along the profile.

**NOTE** The start and end stations are always included in the report. The increment starts at the beginning station, even if it is an odd value. The increment is applied to all profiles.

Save Report To

Specifies the name and location of the resulting report.

Create Report

Generates the report and saves it to the specified location.

Done

Closes the dialog box and discards changes to station ranges.

# Create Reports - Vertical Curve Report

Use this dialog box to select the profiles and specify station ranges for a profile vertical curve report.

**List of Profiles**

Include

Specifies the profiles to include in the report. Select a check box to include the profile.

Name & Description

Displays the name and description of the profiles in the drawing.

Station Start & Station End

Displays the start and end stations for a selected profile.
You can edit these values by highlighting a profile in the list and adjusting the Report Settings (see below).

Alignment

Displays the horizontal alignment that the profile is associated with.

**Report Settings**

Start Station & End Station

Displays the start and end stations for a highlighted profile. Click a profile name in the list to highlight it.
You can edit these values to change the range of stations included in the report. You can enter formatted or unformatted values, such as 2+50.95 or 250.95.

Save Report To

Specifies the name and location of the resulting report.

Create Report

Generates the report and saves it to the specified location.

Done

Closes the dialog box and discards changes to station ranges.

# Create Reports - Slope Stake Report

Use this dialog box to select the corridors and specify sample line groups for a cross section slope stake report. This report identifies the points of slope change for a selected corridor link.

## Select Report Components

Select Corridor

Specifies the corridors to include in the report. Only corridors that are based on alignments with defined sample line groups are displayed.

Select a corridor from the list or click  to select a corridor from the drawing.

Select Alignment

Specifies the alignment to include in the report. Only the alignments contained in the selected corridor are displayed.

Select Sample Line Group

Specifies the sample line group to include in the report. Only the sample line groups for the selected alignment are displayed.

Select Corridor Link

Specifies which corridor link to use in the report. A link is defined as a single straight-line segment between endpoints on a subassembly.

Add

Adds the selected corridor, alignment, and sample line group to the List of Corridors to include in the report.

## List of Corridors

Include

Lists the corridors to include in the report.

**NOTE** When a corridor is highlighted, the start and end stations are editable. See Report Settings below.

Alignment & Sample Line Group

Lists the alignment and sample line group that you selected.

Station Start & Station End

Displays the start and end stations for the selected sample line group.
You can edit these values using the Report Settings (see below).

Delete

Removes the corridor from the list.

## Report Settings

Start Station & End Station

Displays the start and end stations for a highlighted sample line group. Click a sample line group name in the list to highlight it.
You can edit these values to change the range of stations included in the report. You can enter formatted or unformatted values, such as 2+50.95 or 250.95.

Save Report To

Specifies the name and location of the resulting report.

Create Report

Generates the report and saves it to the specified location.

Done

Closes the dialog box and discards changes to station ranges.

## Report Results

The slope stake report has data formatted in columns. The end columns contain information about the last two offsets in the corridor. The other columns contain information about the point codes.

End Column Descriptions

- **Row 1**: Reports either cut (C) or fill (F) which is determined by the elevational difference between the last two offsets reported.

- **Row 2**: Reports the distance difference between the last two offsets reported.

- **Row 3**: Reports the slope value from the second-to-last offset point to the last offset point.

   For example:
   C 8.47
   @33.87
   S 1:4.00

Report Column Descriptions

- **Row 1**: Reports the point code.

- **Row 2**: Reports the offset value relative to 0+00.

- **Row 3**: Reports the elevation value at that offset.

- **Row 4**: Reports the slope from that point headed toward the next point (away from 0+00).

For example:
Daylight
-110.369
629.991
1:-4.00

**NOTE** For slope values greater than 2:1, the value is reported as 1:X. For slope values less than 2:1, the value is reported as X%.

# Create Reports - Map Check Report

Use this dialog box to select the parcels or survey figures to include in a map check report. This report displays the directions and distances, start and end coordinates, curve data, perimeter, and area, and calculates the error of closure.

## List of Objects

Parcels

Select this option to report on parcels in the drawing. When you select this option, the parcels in the current drawing are listed in the table below.

Survey Figures

Select this option to report on survey figures.

**NOTE** The Survey database in the drawing must be open to report on figures.

Include

Select the individual parcels or figures to include in the report by selecting the check boxes. Use this option to select an individual parcel to change the Point of Beginning (see below).

Select All

Selects all parcels or figures for the report.

Deselect All

Clears the current selection of parcels or figures.

## Analysis

**NOTE** All options in the Analysis section are available for parcel reports only and are unavailable if you select the Survey Figures option.

Point Of Beginning

If only one parcel is selected in the list above, its Point of Beginning X,Y values are displayed here. You can click the icon to specify a different point of beginning to use in the report.

**NOTE** The Point of Beginning (POB) X,Y values are not displayed if more than one parcel is selected in the list above. If you change the POB for one parcel, the change is not saved if you select another parcel in the list. Changes are not saved to the parcel in the drawing.

Process Segment Order Counterclockwise

■ **Selected**: Segments are processed in counter-clockwise order.

■ **Cleared**: Segments are processed in clockwise order.

Enable Mapcheck Across Chord

■ **Selected**: The mapcheck traverse is calculated for curve segments using their chord length.

■ **Cleared**: The mapcheck traverse is calculated for curve segments using their curve length.

Truncate Area (Square Unit)

- **Selected**: The area values output are limited to the specified number of decimal places in the Parcel Area Precision settings without rounding. For example, if the area of a parcel is 43,559.989 square feet and the Area precision is set to 2, then the value will be truncated to 43,559. 98 (it will not be rounded up).

- **Cleared**: The area values output are rounded based on the Parcel Area Rounding settings.

### Settings

Parcel Settings

Displays read-only settings for parcels, as specified in the Parcel settings (page 824).

Figure Settings

Displays read-only settings for survey figures, as specified in the Survey settings (page 225).

### Report Settings

Save Report To

Specifies the name and location of the resulting report.

# Create Reports - Parcel Volume Report

Use this dialog box to select the surface and parcels for a parcel volume report. This report calculates the volume of an area bounded by the selected parcels and is based on an existing volume surface.

### List of Parcels

Parcel

Specifies the parcels to use in the report. Select the check boxes next to the parcels to include.

### Report Settings

Volume Surface

Specifies the volume surface to use in the report. For more information about creating a volume surface, see Calculating Surface Volumes (page 690).

Fill Correction

Specifies the contraction or shrinkage of the fill material. The fill factor can be used to compute the additional material volume requirements.
A factor of 1.00 applies no adjustment to the raw volume.

Cut Correction

Specifies the expansion or swell of the cut material. The volume of material generally expands after removing it. Therefore, the cut factor is usually set to greater than 1, which indicates swell or expansion of the material. For example, a 1.2 cut factor would mean that for every 1 cubic meter of material removed, 1.2 cubic meters of volume would need to be accounted for transport.

Elevation Tolerance

Specifies the difference in elevation that must exist between the two surfaces of the volume surface in order for the volume to be included in the report. The surfaces are compared at each grid node. If the difference in elevation is less than the tolerance value, then it is considered to be zero volume.

**NOTE** This control is available only if the selected Volume Surface is a grid surface.

Save Report To

Specifies the name, file type, and location of the resulting report. Click the folder icon to specify a file type and location.

Create Report
    Generates the report and saves it to the specified location.

Done
    Closes the dialog box.

# Create Reports - Station Offset to Points Report

Use this dialog box to select the points and alignment to use for creating a station offset to points report. This report lists the station and offset of the points relative to the selected alignment.

## List of Points

Select All
    Selects all the points in the drawing. When a point is selected the Include box is checked.

Deselect All
    Deselects all the points in the drawing.

Include
    When selected, includes the point in the report.

## Report Settings

Select Alignment

Specifies the alignment to include in the report. Select an alignment from the list or click  to select an alignment from the drawing.

Save Report To
    Specifies the name and location of the resulting report.

Create Report
    Generates the report and saves it to the specified location.

Done
    Closes the dialog box and discards changes to station ranges.

# Create Reports - HEC-RAS Geographical Data Report

Use this dialog box to select a sample line group and to define reaches to include in a HEC-RAS geographical data report. This report describes the properties of a stream profile and its reaches and includes the cross sectional data along the entire profile.

### Prerequisites

To run this report, the main river must be defined as a horizontal alignment, and sample lines must be cut at all critical points along the river (alignment). To create sample lines, a surface is required.

You must define alignment PIs at stream junctions so you can define reaches for the report. For more information about adding PIs to an alignment, see Alignment Layout Tools (page 1747).

Reaches are defined by selecting station values that represent the beginning and end of the reach.

### Select Sample Line Group

Select Alignment
    Specifies the alignment (river) to include in the report. Only those alignments that have valid sample line groups are listed.

Select Sample Line Group

Specifies the sample line group to include in the report. Only the sample line groups for the selected alignment are displayed.

**Define Reach**

Name

Specifies the name for the reach.

Reach Begin Point

Specifies the beginning point for the reach. The list displays the station values of each PI along the alignment. See Prerequisites (page 2223) above for information on how to add points.

Reach End Point

Specifies the end point for the reach.

Add

Adds the reach to the List Of Reaches to be included in the report.

**List Of Reaches**

Reaches

Each defined reach is displayed in this list. Select a reach and click the Delete button to remove it from the report.

Save Report To

Specifies the name and location of the resulting report.

Create Report

Generates the report and saves it to the specified location.

Done

Closes the dialog box and discards changes to station ranges.

# Create Reports - LandXML Reports

Double-click a LandXML report to launch the Export To LandXML dialog box (page 1983) and then select the data to include in the report.

Each report type filters out irrelevant data when the report is created. If you are creating a points report, for example, only the points that are selected are used in the report. You can clear the selection of other objects in the Export To LandXML dialog box, but that is not necessary.

# Create Reports - Corridor Feature Line Report

Use this dialog box to select a corridor, an alignment, and the feature lines to include in a corridor feature line report. This report displays northing, easting, and elevation coordinates at the specified station interval for the feature lines. It also includes the coordinates of the roadway crown at those stations.

Select Corridor

Specifies the corridor to use in the report.

Select Alignment

Specifies the alignment to use in the report.

Sample Line Group

Specifies the sample line group to include in the report. This list is not available if Corridor Points is selected.

Type selector

■ **Corridor Points**: Reports northing, easting, and elevation coordinates at the specified station interval for the selected feature lines and at the roadway crown.

■ **Corridor Links**: Reports offset, elevations and point code information at each grade break of the selected links.

■ **Surfaces**: Reports a series of data for each station for the selected surface sections.

List of Feature Lines/List of Corridor Links/List of Surfaces

This list changes depending on whether you choose to report the data based on Corridor Points, Corridor Links, or Surfaces. Select individual items, or use the buttons on the right to select all items in the list or to clear the entire selection.

Start Station

Specifies the start station for the report. This station is used for all selected items.

End Station

Specifies the end station for the report. This station is used for all selected items.

Station Interval

Specifies the station interval to use.

Save Report To

Specifies the location and file type for the report. Click the button and specify the folder and file type.

Create Report

Creates the report in the location specified and displays the report results.

When you click Create Report, you may be prompted to add stations to the corridor if the station interval you specified is different than the existing corridor sampling. If you click OK, the command applies the Station Interval setting to the corridor, which can result in increasing the frequency that data is reported. If you click Cancel, only the stations that are common based on the specified interval and the assembly insertion locations are presented in the report.

Increasing the frequency that data is reported is similar to using the Frequency To Apply Assemblies dialog box to add more stations to the corridor. For more information, see To add stations to a region (page 1338). Additional station interval lines are added to the corridor in the drawing when you increase the frequency. You can control the display properties of these lines by changing the Link Style on the Codes tab of the Corridor Properties dialog box. For more information, see Codes Tab (Corridor Properties Dialog Box) (page 1817).

# Create Reports - Lane Slope Report

Use this dialog box to select a sample line group to include in a lane slope report. This report displays the station values for the sample lines associated with the selected corridor and the X,Y coordinates of the sample line at the intersection of the alignment. The report also displays the elevation values of the existing ground and finished ground profiles at those X,Y points and the left and right slopes of the lanes defined between the alignment and the edge of pavement.

List of Sample Line Groups

Specifies the sample line group to include in the report.

Start Station

Specifies the start station for the report. The Start Station and End Station fields are enabled only if one of the sample line groups is selected in the list.

End Station

Specifies the end station for the report. The Start Station and End Station fields are enabled only if one of the sample line groups is selected in the list.

Save Report To

Specifies the location and file type for the report. Click the button and specify the folder and file type.

Create Report

Creates the report in the location specified and displays the report results.

# Create Reports - Daylight Line Report

Use this dialog box to select a sample line group to include in a daylight line report. This report includes the X,Y, and elevation data for the daylight points at the ends of the sample lines. The report also includes the widths of the sample lines to the left and right of the alignment.

List of Sample Line Groups

Specifies the sample line group to include in the report.

Start Station

Specifies the start station for the report. The Start Station and End Station fields are enabled only if one of the sample line groups is selected in the list.

End Station

Specifies the end station for the report. The Start Station and End Station fields are enabled only if one of the sample line groups is selected in the list.

Save Report To

Specifies the location and file type for the report. Click the button and specify the folder and file type.

Create Report

Creates the report in the location specified and displays the report results.

# Create Reports - Incremental Station Elevation Difference Report

Use this dialog box to select a profile to include in an incremental station elevation difference report. This report compares an existing ground profile with a design profile and lists the station, existing ground elevation, design elevation, and the elevational differences between PVIs.

List of Design Profiles

Specifies the design (layout) profile. You must select one. Only dynamic profiles are included in the list. When you click on the design profile, the Start Station and End Station fields become active so you can specify the station range for the report.

List of Existing Profiles

Specifies the existing ground profile. You must select one.

Start Station

Specifies the start station for the report. The Start Station and End Station fields are enabled only if one of the design profiles is selected in the list.

End Station

Specifies the end station for the report. The Start Station and End Station fields are enabled only if one of the design profiles is selected in the list.

Station Interval

Specifies the station interval to use when the Regular Interval option is selected.

**Regular Interval**

Specifies that regular station intervals are included in the report. The interval is based on the Station Interval setting.

**Horizontal Tangent Points**

Specifies that tangent points in the horizontal alignment design are included in the report. For example, PT or PC points.

**Vertical Tangent Points**

Specifies that tangent points in the vertical profile design are included in the report. For example, the start vertical tangent point.

**Existing Ground Points**

Specifies that existing ground grade break points are included in the report.

**Save Report To**

Specifies the location and file type for the report. Click the button and specify the folder and file type.

**Create Report**

Creates the report in the location specified and displays the report results.

# Sections Dialog Boxes

# 67

The following topics provide information about the Sample Line, Section, and Section View dialog boxes.

## Corridor Section Properties Dialog Box

Use this dialog box to edit properties of the selected corridor section, such as its name, section data, and code set styles.

**See also:**

■ Editing Corridor Section Properties (page 1151)

## Information Tab (Corridor Section Properties Dialog Box)

Use this tab to edit primary information about the selected corridor section.

Name

Specifies the name of the corridor section. The default format is <SLG>-n - <SL>-n - <corridor>(n). <SLG> is the parent sample line group name, <SL> is the sample line name, and <corridor> is the name of the corridor on which the corridor section is drawn.
n is an integer greater than or equal to one, which increments as each feature is created in the drawing.

Description

Specifies the optional description of the corridor section.

Object Style

Specifies the name of the style used by the corridor section.

**NOTE** Corridor section object styles are the same as code set styles.

Creates, copies, or edits a style using the Code Set Style dialog box (page 1783). Click the down arrow to display the style selection menu:

■ **Create New**: Creates a new style.

■ **Copy Current Selection**: Copies the current style.

■ **Edit Current Selection**: Edits the current style.

Displays details about an existing style. Select the style by name in the list. Click to open the Style Detail dialog box (page 1804). Preview the style and creation information.

Show Tooltips

Controls whether tooltips are displayed for the object in the drawing (not over toolbar icons).

## Section Data Tab (Corridor Section Properties Dialog Box)

Use this tab to edit properties of the selected corridor section object.

Description

Specifies the optional description of the current corridor section.

Type

Displays a , which indicates that the section was extracted from a corridor.

Data Source

Displays the name of the data source from which the current corridor section was sampled.

Update Mode

Specifies the type of update mode for the corridor section. Select Dynamic to specify that the corridor section data updates dynamically if the position of the sample line associated with the corridor section changes or the data source (surface or corridor) geometry changes.

Layer

Specifies the drawing layer that contains the current corridor section associated with the selected sample line group. Click in the Layer column to open the Layer Selection dialog box (page 1986). Select a layer in the Layers table.

Style

Specifies the name of the style of the corridor section. Click in this column to open the Select Style dialog box (page 1805). Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection.

Station

Displays the station value of the sample line along which the corridor section is sampled.

Left Offset

Displays the left offset value of the current section.

Right Offset

Displays the right offset value of the current section.

Minimum Elevation

Displays the minimum elevation of the section associated with the selected sample line group.

Maximum Elevation

Displays the maximum elevation of the section associated with the selected sample line group.

## Codes Tab (Corridor Section Properties Dialog Box)

Use this tab to display codes and code set style information of the selected corridor section object.

**NOTE** The codes displayed in this tab are as collected from the current corridor section's subassemblies. The Description, Style, and Label Style are as assigned through the associated code set style. To change the display or label styles for any of the codes, edit the object style associated with the current corridor section in the Information tab (page 2229).

Use code set styles to control the visual appearance of a set of codes (link, point, and shape codes) associated with a current corridor section.

Name

Displays an expandable tree with a collection for each type of code: Link, Point, and Shape. Expand the collections to display the individual codes.

Description

Displays the description of each code.

Style

Displays the style assigned to each code.

Label Style

Displays the label style assigned to each code or <none> if no label style is assigned.

Render Material

Displays the render material assigned to each code or <none> if no render material is assigned.

Material Area Fill Style

Displays the Material Area Fill style assigned to each code or <none> if no fill style is assigned.

# Create/Edit Sample Line Group Dialog Box

Use this dialog box to create and edit a sample line group.

**NOTE** Sample lines must be part of one, and only one, sample line group. If a sample line group already exists, the dialog box changes from create mode to edit mode.

Name

Specifies the name of the sample line group. The default format is <SLG>-<[Next Counter]>.
<SLG> is the sample line group name.
<[Next Counter]> is an integer greater than or equal to one, which increments as sample line groups are created in the drawing. This naming convention is based on the name template.
Enter a name or edit a default naming convention in the Name Template dialog box.

Opens the Name Template dialog box (page 1806). Edit the default sample line group naming convention.

Description

Specifies the optional description of the sample line group.

Alignment

Displays the parent alignment under which the sample line group belongs.

Sample Line Style

Specifies the sample line style. To edit a style or create a new one, click  . Select a style from the list of operations. For more information, see Select Style dialog box (page 1805) and Section Data Band Style dialog box (page 2267).

To examine the details of an existing style, select the style name in the list. Click  .
For more information, see the Style Detail dialog box (page 1804).

Sample Line Label Style

Specifies the sample line label style. Standard buttons are also provided to create or edit a label style.

Sample Line Layer

Specifies the drawing layer for the sample line. Standard buttons are also provided to review or change the style.

**Select Data Sources To Sample**

Type

Displays the type of data source from which the section is sampled such as , which indicates a TIN surface; , which indicates a corridor; , which indicates a corridor surface; or  which indicates a pipe network.

Data Source

Displays the name of the data source.

Sample

Specifies a data source from which to sample elevations. A new section object is created for each data source selected. The section object is located at each sample line in the current sample line group.

Style

Specifies the style to apply for each section. Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

**NOTE** If the data source is a corridor, then the style list is for a code set style.

Section Layer

Specifies the drawing layer for the section. Standard buttons are also provided to review or change the style.

Update Mode

Specifies the type of update mode for the section. Select Dynamic to specify that the section data updates dynamically if the position of the sample line associated with the section changes or the data source (surface or corridor) geometry changes.

**Related procedures:**

■ Creating Sample Lines (page 1142)

# Create Multiple Section Views Wizard

Use this wizard to create multiple section views.

The multiple section views are created from existing sections, which represent sectional data at the stations along the alignment. You can also display data bands above or below each of the multiple section views.

After configuring the settings in this wizard, click Create Section Views. Specify the location of the lower left corner of the multiple section views grid.

**NOTE** Some controls on this wizard are not available when requisite objects are not present. For example, the Section Views Tables page of this wizard is not available if there is no materials list for the drawing. For information about how to create a material list, see Generating Material Lists (page 1163).

**Related procedures:**

■ Creating/Editing Section Views (page 1153)

# General Page (Create Multiple Section Views Wizard)

Use this page to specify basic information about the section views, including the parent alignment and sample line group name, range of stations, description, style, and layer.

Select Alignment

Specifies the name of the parent horizontal alignment. Select a name from the list or click  to pick an alignment from the drawing.

Sample Line Group Name

Specifies the sample line group from which the section views are created. Select a sample line group from the list or click  to pick a sample line group from the drawing.

Automatic

Specifies that the offset range is set automatically. The start and end stations of the specified sample line group are displayed in the fields next to the selection.

User Specified

Specifies that the station range is set by the user. Specify start and end stations for the multiple station views in the fields next to the selection.

Section View Name

Specifies an editable, system-generated name. The name must remain unique within the drawing.

Description

Specifies an optional description of the section views.

Section View Layer

Specifies the drawing layer for the section views. To review or change layer data, click  .

Section View Style

Specifies the style of the section views. Use standard buttons to review or change the style.

Group Plot Style

Specifies the group plot style for the section views. Use standard buttons to review or change the style.

# Offset Range Page (Create Multiple Section Views Wizard)

Use this page to specify the offset range to which the section views are drawn.

Automatic

Specifies that the offset range is set automatically. The lengths of the left and right swath widths are displayed in the fields next to the selection.

User Specified

Specifies that the offset range is set by the user. Specify the length of the left and right swath widths in the fields next to the selection.

Left

Specifies the offset length of the left swath width.

Right

Specifies the offset length of the right swath width.

# Elevation Range Page (Create Multiple Section Views Wizard)

Use this page to specify the elevation properties of the selected section view.

### Elevation Range

Automatic

Specifies that the elevation range is set automatically. The minimum and maximum heights are displayed in the fields next to the selection.

User Specified

Specifies that the elevation range is set by the user. Specify how the elevation is applied by selecting a Section Views Height Option.

Height

Specifies the height of the elevation.

### Section Views Height Option

From Lowest Elevations Of All Sections

Specifies that the elevation is set from the lowest elevation of each section.

From Mean Elevations Of All Sections

Specifies that the elevation is set from the mean elevation of each section.

Follow A Section

Specifies that the elevation is set from a particular section. Select the section from the Select Section list.

# Section Display Options Page (Create Multiple Section Views Wizard)

Use this page to specify section display options.

### Select Sections To Draw

Name

Displays the names of the sections.

Draw

Specifies whether the sections are drawn in the section views. Select the check box to draw the sections in the section views.

Clip Grid

Specifies whether the grid lines in the current section views are clipped to the sections (horizontal and/or vertical depending on the section view style definition). Select the radio button to clip the grid lines in the section views to one of the named sections.

Change Labels

Specifies the style set from which the section labels will be drawn. Click in this column to open the Select Style dialog box (page 1805).

Style

Specifies the section style. Click in this column to open the Select Section Style dialog box.

Override Style

Specifies the style for the sections. Select the check box to open the Select Section Style dialog box.

# Data Bands Page (Create Multiple Section Views Wizard)

Use this page to specify the properties of the data bands associated with the section view.

Select Band Set

Specifies the set of band styles for the section views. Provides standard controls that you use to review or change the set.

**List of Bands**

Location

Specifies either the top or bottom of the section views. The table below this field shows the current location of the bands in the current band style set.

Band Type

Specifies the data band type, either Section Data or Section Segment.

Style

Specifies the style for the band type.

Surface 1

Specifies a surface sampled by the sample line that supplies the data for the band, including any corridor surface.

Surface 2

Specifies an additional surface sampled by the sample line that supplies the data for the band, including any corridor surface. Not used for Section Segment type data bands.

## Section View Tables Page (Create Multiple Section View Wizard)

Use this page to set volume table properties for the section view.

**NOTE** This page is not available if there is no material list for the drawing. For information on how to create a material list, see Generating Material Lists (page 1163).

Use the following controls to specify the volume table types to draw:

Type

Specifies the type of the volume table(s).

Select Table Style

Specifies the style of the volume table(s). Use the standard to create or edit a label style.

Add >>

Adds a volume table to the list.

**List Of Volume Tables**

Table Type

Displays the current table type.

Style

Specifies the name of the table style that was added using the Select Table Style list. To change the style, click in this column to open the Select Style dialog box (page 1805). Select a band style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Material List

Specifies the material list for the volume table.

Materials

Click 🔲 to specify the materials for the volume table.

Layer

Specifies the drawing layer that contains the sampled source.

Split

Specifies whether the layer is split.

Gap

Specifies the distance, in plotted units, between the current data band and the previous data band (or the nearest section view axis). Enter a positive gap value in plotted units.

Reactivity Mode

Specifies the type of update mode for the section. Select Dynamic to specify that the section data updates dynamically when either the position of the sample line associated with the section changes or the data source (surface, corridor, or pipe) geometry changes.

### Position Of Table(s) Relative To Section Views

Section View Anchor

Specifies the section view anchor (Top/Middle/Bottom, Left/Center/Right).

Table Anchor

Specifies the location of the table anchor (Top/Middle/Bottom, Left/Center/Right).

Table Layout

Specifies whether the layout of the tables is horizontal or vertical, in relation to the section view.

X Offset

Specifies the distance, in plotted units, to move the title away from the position set by the table anchor. Enter a positive number to move the title right, or a negative number to move it left.

Y Offset

Specifies the distance, in plotted units, to move the title away from the position set by the table anchor. Enter a positive number to move the title up, or a negative number to move it down.

# Create Sample Lines - By Station Range Dialog Box

Use this dialog box to create sample lines along an alignment for a specified range of stations.

### General

Alignment

Displays the name of the currently selected alignment associated with the range of stations.

### Station Range

From Alignment Start

Specifies whether the station range starts at the beginning of the alignment (that is, at the station located at the beginning of the alignment):

- **True**: Begins the station range at the start of the alignment.

- **False**: Specifies the beginning station in the range. Enter or pick a beginning station.

Start Station

Specifies the beginning station in the range. Enter a station value directly or click 🔖 to pick from the drawing. Available if From Alignment Start is False.

To Alignment End

Specifies whether the station range ends at the end of the alignment (that is, at the final station along the alignment):

■ **True**: Ends the station range at the end of the alignment.

■ **False**: Specifies the ending station in the range. Enter or pick an editing station.

End Station

Specifies the end station in the range. Enter a station value directly or click ⬚ to pick from the drawing. Available if To Alignment End is False.

## Left Swath Width

Snap To An Alignment

Specifies that the sample line snaps the swath widths to an offset alignment at each station:

■ **True**: Snaps the widths to an offset alignment at each station.

■ **False**: Does not snap the widths.

Alignment

Specifies the currently selected alignment. Available if Snap To Alignment is True.

NOTE Although all alignments in the current drawing are listed, do not select the parent alignment. The resulting length will be zero.

Width

Specifies the swath width to the left of the alignment, using the actual ground units. Enter a positive value in ground units. Available if Snap To Alignment is False.

## Right Swath Width

Snap To An Alignment

Specifies that the sample line snaps the swath widths to an offset alignment at each station:

■ **True**: Snaps the widths to an offset alignment at each station.

■ **False**: Does not snap the widths.

Alignment

Specifies the currently selected alignment. Available if Snap To Alignment is True.

NOTE Although all alignments in the current drawing are listed, do not select the parent alignment. The resulting length will be zero.

Width

Specifies the swath width to the right of the alignment, using the actual ground units. Enter a positive value in ground units. Available if Snap To Alignment is False.

## Sampling Increments

Use Sampling Increments

Specifies whether sample lines are created at incremental stations along the alignment:

■ **True**: Changes the default sample increments for either tangents, curves, or spirals. For example, you may want to decrease the values for curves and/or spirals.

■ **False**: Sample lines are not created at stations along the alignment.

Increment Along Tangents

Specifies the sample increment distance along tangents, using the actual ground units. Enter a positive value in ground units.

Increment Along Curves

Specifies the sample increment distance along curves, using the actual ground units. Enter a positive value in ground units.

Increment Along Spirals

Specifies the sample increment distance along spirals, using the actual ground units. Enter a positive value in ground units.

---

**NOTE** Changing sampling increments can affect performance on rebuild. A shorter increment means more sampling stations, and thus a larger drawing.

---

**Additional Sample Controls**

At Range Start

Specifies whether a sample line is created at the beginning of the specified range.

At Range End

Specifies whether a sample line is created at the end of the specified range.

At Horizontal Geometry Points

Specifies whether additional sample lines are created at horizontal geometry points, such as, at the start of a spiral, or at a spiral-curve point.

At Superelevation Critical Stations

Specifies whether additional sample lines are created at superelevation critical stations.

**Related procedures:**

■ Creating Sample Lines (page 1142)

■ Editing Sample Line Group Properties (page 1149)

# Create Sample Lines - From Corridor Stations Dialog Box

Use this dialog box to create sample lines along an alignment for specified corridor stations.

**General**

Alignment

Displays the name of the currently selected alignment associated with the range of stations.

**Station Range**

From Alignment Start

Specifies whether the station range starts at the beginning of the alignment (that is, at the station located at the beginning of the alignment):

■ **True**: Begins the station range at the start of the alignment.

■ **False**: Specifies the beginning station in the range. Enter or pick a beginning station.

Start Station

Specifies the beginning station in the range. Enter a station value directly or click ⟊ to pick from the drawing. Available if From Alignment Start is False.

To Alignment End

Specifies whether the station range ends at the end of the alignment (that is, at the final station along the alignment):

■ **True**: Ends the station range at the end of the alignment.

■ **False**: Specifies the ending station in the range. Enter or pick an ending station.

End Station

Specifies the end station in the range. Enter a station value directly or click  to pick from the drawing. Available if To Alignment End is False.

### Left Swath Width

Snap To An Alignment

Specifies that the sample line snaps the swath widths to an offset alignment at each station:

■ **True**: Snaps the widths to an offset alignment at each station.

■ **False**: Does not snap the widths.

Alignment

Specifies the currently selected alignment. Available if Snap To Alignment is True.

**NOTE** Although all alignments in the current drawing are listed, do not select the parent alignment. The resulting length will be zero.

Width

Specifies the swath width to the left of the alignment, using the actual ground units. Enter a positive value in ground units. Available if Snap To Alignment is False.

### Right Swath Width

Snap To An Alignment

Specifies that the sample line snaps the swath widths to an offset alignment at each station:

■ **True**: Snaps the widths to an offset alignment at each station.

■ **False**: Does not snap the widths.

Alignment

Specifies the currently selected alignment. Available if Snap To Alignment is True.

**NOTE** Although all alignments in the current drawing are listed, do not select the parent alignment. The resulting length will be zero.

Width

Specifies the swath width to the right of the alignment, using the actual ground units. Enter a positive value in ground units. Available if Snap To Alignment is False.

**Related procedures:**

■ Creating Sample Lines (page 1142)

■ Editing Sample Line Group Properties (page 1149)

# Create Section View Wizard

Use this wizard to create section views.

**NOTE** Some controls on this wizard are not available when requisite objects are not present. For example, the Section Views Tables page of this wizard is not available if there is no materials list for the drawing. For information about how to create a material list, see Generating Material Lists (page 1163).

**Related procedures:**

■   Creating/Editing Section Views (page 1153)

## General Page (Create Section View Wizard)

Use this page to specify basic information about the section view, including the parent alignment and sample line group name, sample line, station, description, style, and layer.

Select Alignment

Specifies the name of the parent horizontal alignment. Select a name from the list or click  to pick an alignment from the drawing.

Sample Line Group Name

Specifies the parent sample line group of the sample line from which the section view is created. Select a name from the list or click  to pick an alignment from the drawing.

Sample Line

Specifies the sample line from which the section view is created. Select a name from the list or click  to pick an alignment from the drawing. Specifying a sample line also changes the Station value.

Station

Specifies the station value of the sample line from which the section view is created. Specifying a station also changes the Sample Line value.

Section View Name

Specifies an editable, system-generated name. The name must remain unique within the drawing.

Description

Specifies an optional description of the section view.

Section View Layer

Specifies the drawing layer for the section view. To review or change layer data, click  .

Section View Style

Specifies the style for the section view. Provides standard controls you use to review or change the style.

## Offset Range Page (Create Section View Wizard)

Use this page to specify the offset range to which the section view is drawn.

Automatic

Specifies that the offset range is set automatically. The lengths of the left and right swath widths are displayed in the fields next to the selection.

User Specified

Specifies that the offset range is set by the user. Specify the lengths of the left and right swath widths in the fields next to the selection.

Left

Specifies the offset length of the left swath width.

Right

Specifies the offset length of the right swath width.

## Elevation Range Page (Create Section View Wizard)

Use this tab to specify the elevation properties of the section view.

### Elevation Range

Automatic

Specifies that the elevation range is set automatically. The minimum and maximum heights are displayed in the fields next to the selection.

User Specified

Specifies that the elevation range is set by the user. Specify minimum and maximum heights in the fields next to the selection.

Minimum

Specifies the minimum height of the elevation.

Maximum

Specifies the maximum height of the elevation.

## Section Display Options Page (Create Section View Wizard)

Use this page to specify section display options.

### Select Sections To Draw

Name

Displays the name of the section.

Draw

Specifies whether the section is drawn in the section view. Select the check box to draw the section in the section view.

Clip Grid

Specifies whether the grid lines in the section view are clipped to the section (horizontal and/or vertical depending on the section view style definition). Click the radio button to clip the grid lines in the section view to one of the named sections.

Change Labels

Specifies the style set from which the section labels will be drawn. Click in this column to open the Select Style dialog box (page 1805)

Style

Specifies the section style. Click in this column to open the Select Section Style dialog box.

Override Style

Specifies the style for a section. Select the check box to open the Select Section Style dialog box.

## Data Bands Page (Create Section View Wizard)

Use this page to specify the properties of the data bands associated with the section view.

Select Band Set

Specifies the set of band styles for the section view. Provides standard controls that you use to review or change the set.

### List of Bands

Location

Specifies either the top or bottom of the section view. The table below this field shows the location of the bands in the band style set.

Band Type

Specifies the data band type, either Section Data or Section Segment.

Style

Specifies the style for the band type.

Surface 1

Specifies a surface sampled by the sample line that supplies the data for the band, including any corridor surface.

Surface 2

Specifies an additional surface sampled by the sample line that supplies the data for the band, including any corridor surface. Not used for Section Segment type data bands.

## Section View Tables Page (Create Section View Wizard)

Use this page to set volume table properties for the section view.

---

**NOTE** This page is not available if there is no material list for the drawing. For information about how to create a material list, see Generating Material Lists (page 1163).

---

Use the following controls to specify the volume table types to draw:

Type

Specifies the type of the volume table(s).

Select Table Style

Specifies the style of the volume table. Standard buttons are also provided to create or edit a label style.

Add >>

Adds a volume table to the list.

### List Of Volume Tables

Table Type

Displays the table type.

Style

Specifies the name of the table style that was added using the Select Table Style list. To change the style, click in this column to open the Select Style dialog box (page 1805). Select a band style in the list or use the standard controls to either create a new style, copy or edit the style selection, or pick a style from the drawing.

Material List

Specifies the material list for the volume table.

Materials

Click ⋯ to specify the materials for the volume table.

Layer

Specifies the drawing layer that contains the sampled source.

Split

Specifies whether the layer is split.

Gap

Specifies the distance in plotted units between the data band and the previous data band (or the nearest section view axis). Enter a positive gap value in plotted units.

Reactivity Mode

Specifies the type of update mode for the section. Select Dynamic to specify that the section data updates dynamically when either the position of the sample line associated with the section changes or the data source (surface, corridor, or pipe) geometry changes.

**Position of Table(s) Relative to Section View**

Section View Anchor

Specifies the section view anchor (Top/Middle/Bottom, Left/Center/Right).

Table Anchor

Specifies the location of the table anchor (Top/Middle/Bottom, Left/Center/Right).

Table Layout

Specifies whether the layout of the tables will be horizontal or vertical, in relation to the section view.

X Offset

Specifies the distance in plotted units to move the title away from the position set by the table anchor. Enter a positive number to move the title right, or a negative number to move it left.

Y Offset

Specifies the distance in plotted units to move the title away from the position set by the table anchor. Enter a positive number to move the title up, or a negative number to move it down.

# Edit Feature Settings - Sample Line Dialog Box

Use this dialog box to view and change sample line-related settings.

This topic documents settings in all sample line-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

- Drawing-level ambient settings are identified by the drawing icon.

- Sample line feature settings are listed near the top of this dialog box, after the General property group, and are identified by the sample line icon.

- Sample line command settings are identified by the command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

## Default Styles

Use these settings to establish the default styles assigned to sample line components:

Sample Line Style

Specifies the default sample line style. Click in the Value column, and click ⊡ to select a style in the Sample Line Style dialog box.

Sample Line Label Style

Specifies the default sample line label style. Click in the Value column, and click ⊡ to select a style in the Sample Line Label Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

### Default Name Format

Use these settings to specify the default name formats for new sample lines and sample line groups. Click in the Value column, and click ⊡ to make changes in the Name Template dialog box (page 1806).

### Default Swath Widths

**NOTE** This property group is displayed when you access the settings from the CreateSampleLine command.

Use these settings to specify the default behavior for sample line swath width.

Left Swath Width

Specifies the swath width to the left of the alignment, using the actual ground units. Enter a width in the Value column or click 🔲 and select a distance in the drawing area.

Right Swath Width

Specifies the swath width to the right of the alignment, using the actual ground units. Enter a width in the Value column or click 🔲 and select a distance in the drawing area.

### Sampling Increments

**NOTE** This property group is displayed when you access the settings from the CreateSampleLine command.

Use these settings to specify the default behavior for sampling increments.

**NOTE** Changing sampling increments can affect performance on rebuild. A shorter increment means more sampling stations, and thus a larger drawing.

Use Sampling Increments

Specifies whether sample lines are created at incremental stations along the alignment.

Increment Along Tangents

Specifies the sample increment distance along tangents, using the actual ground units. Enter a distance in the Value column or click 🔲 and select a distance in the drawing area.

Increment Along Curves

Specifies the sample increment distance along curves, using the actual ground units. Enter a distance in the Value column or click 🔲 and select a distance in the drawing area.

Increment Along Spirals

Specifies the sample increment distance along spirals, using the actual ground units. Enter a distance in the Value column or click 🔲 and select a distance in the drawing area.

### Additional Sample Controls

**NOTE** This property group is displayed when you access the settings from the CreateSampleLine command.

Use these settings to specify the default behavior for additional sample controls.

At Range Start

Specifies whether a sample line is created at the beginning of the specified range.

At Range End

Specifies whether a sample line is created at the end of the specified range.

At Horizontal Geometry Points

Specifies whether additional sample lines are created at horizontal geometry points, such as, at the start of a spiral, or at a spiral-curve point within the current range.

At Superelevation Critical Stations

Specifies whether additional sample lines are created at superelevation critical stations within the current range.

Start Range At Alignment Start

Specifies whether the sampling range starts at the beginning of the alignment.

End Range At Alignment End

Specifies whether the sampling range ends at the end of the alignment.

### Miscellaneous

**NOTE** This property group is displayed when you access the settings from the CreateSampleLine command.

Use this setting to specify miscellaneous default behavior for sample lines.

Lock To Station

Specifies whether the sample lines update when the alignment geometry and properties change.

**Related procedures:**

■  Sample Line Settings (page 1128)

# Edit Feature Settings - Section Dialog Box

Use this dialog box to view and change section-related settings.

This topic documents settings in all section-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

■  Drawing-level ambient settings are identified by the ⬜ drawing icon.

■  Section feature settings are listed near the top of this dialog box, after the General property group, and are identified by the ⬜ section icon.

■  Section command settings are identified by the ⬜ command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

## Default Styles

Section Style

Specifies the default section object style. Click in the Value column, and click  to select a style in the Section Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

## Default Name Format

Use these settings to specify the default name formats for new section object. Click in the Value column, and click  to make changes in the Name Template dialog box (page 1806).

**Related procedures:**

■  Section Settings (page 1129)

# Edit Feature Settings - Section View Dialog Box

Use this dialog box to view and change section view-related settings.

This topic documents settings in all section view-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

■  Drawing-level ambient settings are identified by the  drawing icon.

■  Section view feature settings are listed near the top of this dialog box, after the General property group, and are identified by the  section view icon.

■  Section view command settings are identified by the  command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

## Default Styles

Use these settings to specify the default styles assigned to section view components:

Marker Style

Specifies the default marker style for section view points for offset elevation and depth grade labels. Click in the Value column, and click  to select a style in the Marker Style dialog box.

Section View Offset Elevation Label Style

Specifies the default section view offset elevation label style. Click in the Value column, and click  to select a style in the Section View Offset Elevation Label Style dialog box.

Section View Depth Grade Label Style

Specifies the default section view grade label style. Click in the Value column, and click  to select a style in the Section View Depth Grade Label Style dialog box.

Section View Style

Specifies the default section view style. Click in the Value column, and click [...] to select a style in the Section View Style dialog box.

Section View Band Set

Specifies the default section view band set style. Click in the Value column, and click [...] to select a band set in the Section View Band Set dialog box.

Section Label Set

Specifies the default section label set style. Click in the Value column, and click [...] to select a label set in the Section Label Set dialog box.

Group Plot Style

Specifies the default group plot style for the multiple section view objects. Click in the Value column, and click [...] to select a style in the Group Plot Style dialog box.

Section Projection Label Style

Specifies the default style for labels on projected objects. Click in the Value column, and click [...] to select a style in the Section Projection Label Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

## Default Name Format

Use these settings to specify the template for naming the section view.

Section View Name Template

Specifies the default section view name template.
The default format is <[Section View Station (Uft|FS|P2|RN|Sn|OF|AP|B2|TP|EN|W0|DZY)]> (<[Next Counter(CP)]>).
The Section View Station name is followed by a number of parameters that define how the text is displayed:

- **U—Units**: Select one of ft (foot), m (meter), mile (mile), km (kilometer), in (inch), or yd (yard). The default is Uft.

- **F—Format**: Select either S (station format) or D (DD.DDDDDD decimal). The default is FS.

- **P—Precision**: Select one of 0 (1), 1 (0.1), 2 (0.01), ... , or 8 (0.00000001). The default is P2.

- **R—Rounding**: Select one of N (round normal), U (round up), or T (truncate). The default is RN.

- **S—Sign**: Select one of n (sign negative '-'), Bn ((Bracket negative)), a (sign always ( )), D (drop sign), BL ('(' left prentice), or BR (right prentice '('). The default is Sn.

- **O—Output**: Select one of F (full), LD (left of decimal), RD (right of decimal), DS (decimal character), LB (left of station character), RB (right of station character), BBD (between station character and decimal), or BC (station character). The default is OF.

- **A—Decimal character**: Select either P ('.' period) or C (',' comma). The default is AP.

- **B—Station character position**: Select one of 1 (1+0), 2 (1+00), 3 (1+000), 4 (1+0000), or 5 (1+00000). The default is B2.

- **T—Station character**: Select one of P (plus sign '+'), M (minus sign '-'), A (automatic ( )), U (underscore '_'), or N (none). The default is TP.

- **E—Drop decimal for whole number**: Select either N (No) or Y (Yes). The default is EN.

- **W—Minimum display width**: Select one of 0 (none), 1, 2, ..., 32. The default is W0.

- **DZ—Drop leading zeros**: Select one of Y (yes) or N (no). The default is DZN.

For example, a section view name, using the above defaults and following the "rules" of the parameters, could look like this:
2+50.00 (2)

Click in the Value column, and click ⬚ to make changes in the Name Template dialog box (page 1806).

## Section View Creation

Use these settings to establish the defaults assigned for section view creation:

Specify Section View Offset Range

Specifies whether an offset range is set for the creation of a section view.

Specify Section View Height

Specifies whether the default section view height is set for the creation of a section view.

Section Group Elevation Range

Specifies how the elevation range of the section group is set:

- Lowest Elevation

- Mean Elevation

- Follow a Section

## Default Projection Label Placement

Use these settings to specify the default placement of labels for objects projected to section views:

Dimension Anchor Option

Specifies whether the default anchor option will be Fixed, Above, Below, Graph View Top, or Graph View Bottom.

Dimension Anchor Elevation Value For Projections

Specifies the default value for anchor elevation. Enter a value or click 🔲 and select an elevation in the drawing area.

Dimension Anchor Plot Height Value For Projections

Specifies the default value for anchor plot height. Enter a value or retain the existing default value.

## Table Creation

**NOTE** This property group is displayed when you access the settings from the CreateMultipleSectionView or CreateSectionView commands.

Use these settings to specify defaults for creating tables with section views.

Split Table

Specifies whether a table is split into two or more sections after a specified maximum number of rows has been met.

Maximum Rows Per Table

Specifies the maximum number of rows to include per section. If the number of data rows exceeds the specified maximum, the table is split into sections, and they are displayed either side by side (left to right), or stacked vertically.

Maximum Tables Per Stack

Specifies the maximum number of sections to include in each stack.

Table Spacing
   Specifies the spacing between tables.

Total Volume Table Style

   Specifies the style for a total volume table. Click in the Value column, and click ⊡ to select a style in the
   Total Volume Table Style dialog box.

Material Table Style

   Specifies the styles for a material table. Click in the Value column, and click ⊡ to select a style in the
   Material Table Style dialog box.

X Offset
   Specifies the horizontal offset of the table.

Y Offset
   Specifies the vertical offset of the table.

Tile Direction
   Specifies the direction in which the table tiles (across or down).

Section View Anchor
   Specifies the section view anchor (Top/Middle/Bottom, Left/Center/Right).

Table Anchor
   Specifies the location of the table anchor (Top/Middle/Bottom, Left/Center/Right).

Table Layout
   Specifies whether the layout of the tables will be horizontal or vertical, in relation to the section view.

## Multiple Section View Creation

**NOTE** This property group is displayed when you access the settings from the CreateMultipleSectionView command.

Use these settings to specify defaults for creating multiple section views.

Specify Multiple Section View Station Range
   Specifies whether a station range is set for the creation of multiple section views.

Default Section VIew Height

   Specifies the default height for section views. Enter a height in the Value column or click ⬛ and select
   a height in the drawing area.

**Related procedures:**

- Section View Settings (page 1130)

# Edit Offset and Elevation Ranges Dialog Box

Use this dialog box to specify the offset and elevation range properties for selected section view groups.

**Related procedures:**

- Editing Section View Properties (page 1156)

# Offset Range Tab (Edit Offset and Elevation Ranges Dialog Box)

Use this tab to specify the offset range to which the section views are drawn.

Automatic

Specifies that the offset range is set automatically. The lengths of the left and right swath widths are displayed in the fields next to the selection.

User Specified

Specifies that the offset range is set by the user. Specify the length of the left and right swath widths in the fields next to the selection.

Left

Specifies the offset length of the left swath width.

Right

Specifies the offset length of the right swath width.

# Elevation Range Tab (Edit Offset and Elevation Ranges Dialog Box)

Use this tab to specify the elevation properties of the selected section view.

## Elevation Range

Automatic

Specifies that the elevation range is set automatically. The minimum and maximum heights are displayed in the fields next to the selection.

User Specified

Specifies that the elevation range is set by the user. Specify how the elevation is applied by selecting a Section Views Height Option.

Height

Specifies the height of the elevation.

## Section Views Height Option

From Lowest Elevations Of All Sections

Specifies that the elevation is set from the lowest elevation of each section.

From Mean Elevations Of All Sections

Specifies that the elevation is set from the mean elevation of each section.

Follow A Section

Specifies that the elevation is set from a particular section. Select the section from the Select Section list.

# Edit Sample Line Dialog Box

Use this dialog box to edit some of the values for the parameters of each of the vertices on an existing sample line.

**NOTE** This dialog box is populated with parameters and values only when a valid sample line is selected.

## Information

Name

Specifies the name of the selected sample line.

**General**

Sample Line Vertex Name

Displays the sample line vertex name.
For example, in a straight orthogonal sample line with positive left and right swath width values across an alignment, the vertex names would be Left 1, Center, and Right 1.

Sample Line Vertex Northing

Displays the sample line vertex northing value.

Sample Line Vertex Easting

Displays the sample line vertex easting value.

**Default Swath Widths**

Left Swath Width

Specifies the width of the left swath

Right Swath Width

Specifies the width of the right swath

**Station**

Sample Line Station Value

Specifies the station value of the selected sample line.

**Navigation**

Previous Vertex

Click to display the previous vertex. The previous vertex parameters and values for the selected sample line are displayed.

Next Vertex

Click to display the next vertex. The next vertex parameters and values for the selected sample line are displayed.

**Related procedures:**

■ Editing Sample Lines (page 1145)

# Group Plot Style Dialog Box

Use this dialog box to edit settings that control the layout of multiple section views.

**See also:**

■ Creating and Editing Section View Styles (page 1133)

# Information Tab (Group Plot Style Dialog Box)

Use this tab to display administrative data and edit primary information about the group plot style, such as its name and description.

This tab also contains information about who created or modified the group plot style and the date of these events. The following fields can be modified:

Name

Specifies the name of the selected sheet style.

Description
   Specifies the optional description of the selected sheet style.

# Array Tab (Group Plot Style Dialog Box)

Use this tab to edit settings for the plot rules and page layout features for the section views.

## Plot Rules

Specifies whether to plot the section views by rows or columns.

By Rows
   Plots section views in rows as specified.

By Columns
   Plots section views in columns as specified.

Start Corner
   Specifies the starting corner for plotting the section views.

Align Section Views About
   Specifies how the section views are aligned. Select one:

   ■ Left

   ■ Centerline

   ■ Right

Cell Sizes
   Specifies how the size of each cell in the array will be determined. For this item, the term "cell" refers to the rectangular area in an array of section views in which a single section view is displayed. Select one:

   ■ Uniform For All: When this option is selected, each section view in the array will be displayed in an area (cell) that is the same size for all section views in the array. The size of each cell will be the size of the tallest and the widest section view in the array. Therefore, when this option is selected, all cells in the array will be the same size.

   ■ Uniform Per Row Or Column: When By Rows is selected at the top of this dialog box, and you also select this option, each row in the array will be fit to the height of the tallest section view in the row. Therefore, when this option is selected, each row in an array may have a different height. However, within each row, all section views will display in an area with the same cell height (row height). When By Column is selected at the top of this dialog box, and you also select this option, each column in the array will be fit to the width of the widest section view in the column. Therefore, when this option is selected, each column in an array may have a different width. However, within each column, all section views will display in an area with the same cell width (column width).

## Space Between Adjacent Section Views

Column
   Specifies the spacing between columns.

Row
   Specifies the spacing between rows.

# Plot Area Tab (Group Plot Style Dialog Box)

Use the settings on this tab to specify the method of plotting section views (either all or by page), the sheet style to use, and the gap between successive pages.

Plot All
>Plots all of the section views on a single page.

Plot By Page
>Plots the section views using the specified sheet style and gap values.

Sheet Style
>Specifies the sheet style. Select a sheet style in the list.

Gap Between Successive Pages
>Specifies the plotted distance between each successive page in a multiple section view plot. Enter a positive value in plotted units.

## Summary Tab (Group Plot Style Dialog Box)

Use this tab to edit settings for the group plot style.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Pipe Network Section Properties Dialog Box

Use this dialog box to edit properties of the selected pipe network section, such as its name, section data, and labels.

**See also:**

- Editing Pipe Network Section Properties (page 1152)
- Displaying Pipe Networks in Section Views (page 1221)

## Information Tab (Pipe Network Section Properties Dialog Box)

Use this tab to edit primary information about the selected pipe network section.

Name
>Specifies the name of the section. The default format is <SLG>-n - <SL>-n - <data source>(n).
><SLG> is the parent sample line group name, <SL> is the sample line name, and <data source> is the name of the data source (for example, pipe network) on which the section is drawn.
>n is an integer greater than or equal to one, which increments as each feature is created in the drawing.

Description
>Specifies the optional description of the section.

Show Tooltips
>Controls whether tooltips are displayed for the object in the drawing (not over toolbar icons).

## Section Data Tab (Pipe Network Section Properties Dialog Box)

Use this tab to edit properties of the selected section object.

Description
>Specifies the optional description of the current section.

Type
>Displays a , which indicates that the section was extracted from a pipe network.

Data Source

Displays the name of the data source from which the current section was sampled.

Update Mode

Specifies the type of update mode for the section. Select Dynamic to specify that the section data updates dynamically if the position of the sample line associated with the section changes or the data source (surface or corridor) geometry changes.

Layer

Specifies the drawing layer that contains the current section associated with the selected sample line group. Click in this column to open the Layer Selection dialog box (page 1986). Select a layer in the Layers table.

Style

Specifies the name of the style of the section. Click in this column to open the Select Style dialog box (page 1805). Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Station

Displays the station value of the sample line along which the section is sampled.

Left Offset

Displays the left offset value of the current section.

Right Offset

Displays the right offset value of the current section.

Minimum Elevation

Displays the minimum elevation of the section associated with the selected sample line group.

Maximum Elevation

Displays the maximum elevation of the section associated with the selected sample line group.

# Profile Grade Points Dialog Box

Use this dialog box to select a profile and display its elevation by marking it at the appropriate offset and elevation in the section view.

Alignment

Specifies the parent alignment whose profile grade point is to be displayed in this section view. Select an alignment from the drop-down list or click  to pick an alignment from the drawing.

Add >>

Adds the profile grade point for the currently selected alignment to the list.

Deletes the highlighted profile grade point from the list. The profile grade point will no longer be displayed in the section view.

**List of profile grade points**

Alignment

Displays the name of the parent alignment whose profile grade point is marked in this section view.

Show

Specifies whether the marker is visible in the section view (that is, without having to edit the marker style or layer).

Profile

Displays the name of the profile whose location, with respect to the current section view, is marked.

Marker Style

Displays the marker style used for the profile grade point.

**Related procedures:**

■ Creating/Editing Section Views (page 1153)

## Project Objects to Section View Dialog Box

Use this dialog box to specify objects in the current drawing to be projected into a section view.

To highlight an object in the drawing, select its row in this table.

Name

Displays the objects that can be projected, divided into categories. Select the ones you want to project.

Style

Specifies the current style for each object. You can change the style used to project an object. Select <set all> at the category level to change all objects in that category in one operation.

Elevation Options

Specifies how the elevation of each object is determined.

■ Use Object: Elevation is read from the object properties.

■ Surface: The object is set to the elevation of a selected surface.

■ Manual: You can specify the elevation. This option cannot be used with longitudinal objects.

■ Section: The object is set to the elevation of a selected section.

■ <set all>: Used at the category level to specify the elevation option for all projected objects in the category.

Elevation Value

Specifies the elevation of each projected object. You can change the value here for point objects if the elevation option is manual.

Label Style

Specifies the style of label applied to the projected object. Select <none> to display no label. Select <set all> at the category level to set a label style for all projected objects in the category.

 Pick Objects

Click to select objects in the drawing and add them to the section view.

**Related procedures:**

■ Working with Projected Objects (page 1118)

## Resolve Duplicate Sample Lines Dialog Box

Use this dialog box to resolve duplicate sample lines that have already been defined at some stations.

The properties in this dialog box specify whether duplicate sample lines are deleted from an existing list or appended to a new list. If you select Delete Existing List, you need not do anything further. If you select Append New List, you can specify how the new list is appended.

## Delete Existing List

Removes the existing sample lines in the drawing. Adds only new sample lines.

## Append New List

Station

Displays the station where the duplicate sample line is located. This is the default.

Overwrite

Specifies whether the sample line to be created overwrites the existing sample line in the drawing:

- Selected: The sample line to be created overwrites the existing sample line in the drawing, thus removing the existing sample line at that station.

- Cleared: The sample line to be created does not overwrite the existing sample line, thus preserving the existing sample line.

Add New

Specifies whether the sample line is added as a new sample line in the drawing:

- Selected: The sample line to be created is added as a new sample line in the drawing, thus keeping the existing sample line.

- Cleared: The sample line to be created is not added as a new sample line, thus keeping the existing sample line.

Ignore New

Specifies whether the sample line to be created is ignored and not added in the drawing:

- Selected: The sample line to be created is ignored and not added, thus preserving only the existing sample line in the drawing.

- Cleared: The sample line to be created is not ignored and is added, thus preserving the existing sample line in the drawing.

Name

Specifies the name of the sample line.

Description

Specifies the description of the sample line.

Overwrite All

Specifies that all duplicate sample lines in the list are overwritten in the drawing. Optionally select the Overwrite check box for all duplicate sample lines. This is the default.

Add All

Specifies that all duplicate sample lines in the list are added in the drawing. Optionally select Add New check box for all duplicate sample lines.

Ignore All

Specifies that all duplicate sample lines in the list are ignored, and not added in the drawing. Optionally select the Ignore All check box for all duplicate sample lines.

# Sample Line Group Properties Dialog Box

Use this dialog box to edit properties of the selected sample line group, such as its name, and properties of the displayed sections and section views.

**See also:**

- Editing Sample Line Group Properties (page 1149)

## Information Tab (Sample Line Group Properties Dialog Box)

Use this tab to edit primary information about the selected sample line group.

Name

Specifies the name of the selected sample line group. The default format is <SLG>-n.
<SLG> is the parent sample line group name.
n is an integer greater than or equal to one, which increments as each feature is created in the drawing.

Description

Specifies an optional description.

Show Tooltips

Controls whether tooltips are displayed for the object in the drawing (not over toolbar icons).

## Sample Lines Tab (Sample Line Group Properties Dialog Box)

Use this tab to edit properties of the sample lines that are included in the selected sample line group.

Edit Group Labels

Click to open the Sample Line Labels dialog box (page 2261).

**Sample Lines**

No.

Displays the sequential number of the sample line.

Name

Displays the name of the sample line.

Station

Displays the station that is associated with the sample.

Layer

Specifies the layer on which the sample line is drawn. The default is 0 (base), which is the default layer defined in the drawing layer settings. Click in the Layer column to open the Layer Selection dialog box (page 1986). Select a layer in the Layers table.

Style

Specifies the sample line style. Click in the Style column to open the Pick Sample Line Style dialog box (page 1805). Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Left Offset

Displays the left offset value of the current selection.

Right Offset

Displays the right offset value of the current selection.

Description

Displays the description of the sample line.

## Sections Tab (Sample Line Group Properties Dialog Box)

Use this tab to edit properties of sections that are included in the selected sample line group.

Sample More Sources

Click the Sample More Sources button to open the Section Sources dialog box (page 2273).

### Sections List

Name

Specifies the name of the section associated with the selected sample line group.

Style

Specifies the name of the style of the section. Click in the column to open the Select Style dialog box (page 1805). Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Update Mode

Specifies the type of update mode for the section. Select Dynamic to specify that the section data updates dynamically if the position of the sample line associated with the section changes or the data source (surface, corridor, or pipe) geometry changes.

Layer

Specifies the drawing layer that contains the section associated with the selected sample line group. The default is 0 (base), which is the default layer defined in the drawing layer settings. Click in the Layer column to open the Layer Selection dialog box (page 1986). Select a layer in the Layers table.

Station

Displays the station value of the sample line along which the current section is sampled.

Show Sections For All Sources

Select the Show Sections for all Sources check box to view all stations of each section, arranged in an expandable tree or hierarchy.

### Related procedures:

■ Setting Up Sections

## Section Views Tab (Sample Line Group Properties Dialog Box)

Use this tab to edit properties of the section views in the selected sample line group.

Section View

Displays the names of section views arranged in an expandable tree or hierarchy.

Group Plot Style

Specifies the name of the plot style of the section view associated with the selected sample line group. Click in this column to open the Select Style dialog box (page 1805). Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Style

Specifies the name of the style of the section view associated with the selected sample line group. Click in this column to open the Select Style dialog box. Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Change Band Set

Specifies the optional set of bands to use with the current section view. Click in this column to open the Select Style dialog box. Select a band style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Change Volume Tables

Specifies the volume table(s) to be drawn. Click in this column to open the Change Volume Table dialog box (page 2299). A material list must be exist for the drawing before any volume table can be created.

Section Display

Specifies the section display options for the current section view. Click in this column to open the Section Display Controls dialog box (page 2269). Select section display options in the list.

Profile Grade

Specifies the grid lines displayed at offset alignments and other profiles within the range of section view extents. Click in this column to open the Profile Grade Points dialog box (page 2254).

Station

Displays the station value of the sample line along which this section view is created.

Start Station

Displays the beginning station in the range.

End Station

Displays the end station in the range.

# Material List Tab (Sample Line Group Properties Dialog Box)

Use this tab to view and edit the material lists for a sample line group and add and delete materials from a list.

Add New Material

Adds a new empty criteria to a material list. After you add the criteria, you can edit its quantity type and settings and use the Define Material fields to populate it with data.

Opens the Name Template dialog box (page 1806), where you can modify the material naming template.

Deletes the material or data component that is currently selected in the Material Name column.

**Define Material**

Data Type

Specifies the type of data that is compared and processed when defining the material. Either Surface or Corridor Shape.

Select Surface/Shape

Lists sampled surfaces and corridor shapes for this sample line group. Select a surface or corridor shape.

**NOTE** Corridor shapes can be added only to a material with a Structure quantity type.

Adds the data specified in the Define Material fields to the selected material type.

**NOTE** If a material is not selected, the data is not added.

The properties table contains the following columns:

Material Name

Names of material lists, material names, surfaces, and corridor shapes arranged in a tree or hierarchy. Each instance of applying criteria to materials in a sample line group is added as a numbered list. List names can be edited.

Click ⊞ next to a list name to display its components (materials). Click ⊞ next to a material name to display its components (surfaces or structures).

Condition

Specifies the condition on which to base the calculation:

■ **Above**. Specifies that an area above this surface is included in the material definition. Used with Below to define two or more surfaces for cut, fill, and structures material types.

■ **Below**. Specifies that an area below this surface is included in the material definition. Used with Above to define two or more surfaces for cut, fill, and structures material types.

■ **Base**. Specifies that this surface is the surface to compare against the compare surface. Used with Compare to define two or more surfaces for earthworks and cut and fill material types.

■ **Compare**. Specifies that this surface is the surface to compare against the base surface. Used with Base to define two or more surfaces for earthworks and cut and fill material types.

■ **Include**. Specifies a corridor shape that is included in the structure type definition.

Quantity Type

Specifies the quantity type:

■ **Cut**. Calculates the material to remove.

■ **Fill**. Calculates the material to add.

■ **Cut and Refill**. Defines an area in the section where a material is removed and refilled with fill material.

■ **Earthworks**. Compares two surfaces to calculate both cut and fill areas and displays them separately.

■ **Structures**. Calculates the volume of one or more corridor shapes (as defined by the shape codes that are used to define the corridor). For information about shape codes, see Understanding Point, Link, and Shape Codes (page 1406).

Cut Factor

Specifies the expansion or swell of the cut material.

Fill Factor

Specifies the contraction or shrinkage of the fill material.

Refill Factor

Specifies usability factor used to calculate how much cut material can be reused as fill.

Shape Style

Specifies the default style used to display the material in a section view.

Curve Tolerance

Specifies the curve correction tolerance, if any, that was specified when the criteria was applied. To edit the value, select the check box, and then edit the value. Used only for List entries.

Import Another Criteria

Prompts you to add a new materials list to the sample line group. Prompts you to select a criteria and opens the Compute Materials dialog box.

# Sample Line Labels Dialog Box

Use this dialog box to manage labels for a particular sample line group.

Sample Line Label Style

Specifies the style for the labels. Standard buttons are also provided to create or edit a label style.

Add>>

Adds the specified label type to the set in the label table. These labels appear along the section line in the section view.

✖

Deletes the selected label type from the table. Also removes it from the section.

**Label table**

Type

Specifies the type of section label.

Style

Specifies the label style.

Start Station

Specifies the start station of the sample line group to be labeled.
The check box in front of the column specifies whether the start station can be edited:

■ **Selected**: The start station entry is frozen.

■ **Cleared**: The start station entry can be edited.

End Station

Specifies the end station of the sample line group to be labeled.
The check box in front of the column specifies whether the end station can be edited:

■ **Selected**: The end station entry is frozen.

■ **Cleared**: The end station entry can be edited.

**Related procedures:**

■ Using Sample Line Labels (page 1136)

# Sample Line Properties Dialog Box

Use this dialog box to edit properties of the selected sample line, such as its name, sample line data, and properties of the displayed sections and section views.

**See also:**

■ Editing Sample Line Properties (page 1149)

# Information Tab (Sample Line Properties Dialog Box)

Use this tab to edit primary information about the selected sample line.

Name

Specifies the name of the sample line. The default format is <SL>-n.
<SL> is the name of the sample line.
n is an integer greater than or equal to one, which increments as sample lines are created in the drawing.

Description

Specifies the optional description of the sample line.

Object Style

Specifies the name of the style used by the sample line.

Creates, copies, or edits a style using the Sample Line Style dialog box (page 2264). Click the Down arrow to display the style selection menu:

■ **Create New**: Creates a new style.

■ **Copy Current Selection**: Copies the current style.

■ **Edit Current Selection**: Edits the current style.

■ **Pick From Drawing**: Prompts you to select a style directly from the drawing. The selected style becomes the current style.

Displays details about an existing style. Select the style name in the list. Click to open the Style Detail dialog box (page 1804). Preview the style and creation information.

Show Tooltips

Controls whether tooltips are displayed for the object in the drawing (not over toolbar icons).

# Sample Line Data Tab (Sample Line Properties Dialog Box)

Use this tab to display properties for the sample line and to edit properties about the lock method and label style.

Group Name

Displays the name of the parent sample line group for the current sample line.

Alignment

Displays the name of the parent horizontal alignment for the current sample line.

Sample Line Number

Displays the assigned sample line number of the currently selected sample line.

**NOTE** This is a sequential number of the sample line among all sample lines sorted by station value.

Station

Displays the station at which the sample line intersects with the parent alignment.

Lock To The Station

Locks the sample line to the station:

- **Selected**: If the parent alignment geometry is updated so that the current station value is at a different XY, then the sample line moves to that location. The sample line maintains its relative position to the alignment (that is, it "slides" to the new location.

- **Cleared**: If the parent alignment is modified, the sample line remains in its location. The sample line maintains its geometry and recomputes the updated station where it intersects the alignment. Subsequently, if the check box is (re-)selected, the sample line is locked to the current station.

## Sections Tab (Sample Line Properties Dialog Box)

Use this tab to edit properties that draw and manage the section associated with the current sample line.

Name

Displays the name of the section associated with the current sample line.

Description

Specifies the optional description of the section.

Type

Displays the type of data source from which the section data was extracted. Either , which indicates from an existing TIN surface; , which indicates from a corridor; , which indicates from a corridor surface; or , which indicates a pipe network.

Data Source

Displays the name of the data source used by the section associated with the selected sample line. Can be a surface, corridor, corridor surface, or pipe network.

Update Mode

Specifies the type of update mode for the section. Select Dynamic to specify that the section data updates dynamically if the position of the sample line associated with the section changes or the data source (surface, corridor, or pipe) geometry changes.

Layer

Specifies the drawing layer that contains the section object associated with the selected sample line. Click in this column to open the Layer Selection dialog box (page 1986). Select a layer in the Layers table.

Style

Specifies the name of the style of the section. Click in this column to open the Select Style dialog box (page 1805). Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Left Offset

Displays the left offset value of the current section.

Right Offset

Displays the right offset value of the current section.

Minimum Elevation

Displays the minimum elevation of the section associated with the selected sample line group.

Maximum Elevation

Displays the maximum elevation of the section associated with the selected sample line group.

Station

> Displays the station value at which the sample line is created.

## Section Views Tab (Sample Line Properties Dialog Box)

Use this tab to edit properties of the section views that are associated with the sample line.

Name

> Displays the name of the section view that is created along this sample line.

Description

> Displays the optional description of the section view.

Layer

> Specifies the drawing layer that contains the section view object. Click in this column to open the Layer Selection dialog box (page 1986). Select a layer in the Layers table.

Style

> Specifies the name of the style used by the section view. Click in this column to open the Select Style dialog box (page 1805). Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Change Band Set

> Specifies the optional set of bands to use with the current section view. Click in this column to open the Select Style dialog box. Select a band style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Sample Line Number

> Displays the current sample line number.

Sample Line Name

> Displays the current sample line name.

Station

> Displays the current sample line station value.

# Sample Line Style Dialog Box

Use this dialog box to define a sample line style, which controls the way a sample line is displayed in a drawing.

**See also:**

■ Creating and Editing Sample Line Styles (page 1131)

## Information Tab (Sample Line Style Dialog Box)

Use this tab to display administrative data and edit primary information about the sample line style, such as its name and description.

This tab also contains information about who created or modified the sample line style and the date of these events. The following fields can be modified:

Name

> Specifies the name of the selected sample line style.

Description

Specifies the optional description of the selected sample line style.

## Display Tab (Sample Line Style Dialog Box)

Use this tab to edit settings for the visibility and format styles of sample line components, such as lines and vertices.

On the Display tab, you can use the ByLayer or ByBlock reference settings to set Color, Linetype, Lineweight, and Plot Style values. Reference settings are indirect and require some planning.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Sample Line Style Dialog Box)

Use this tab to edit settings for the sample line style.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

## Sample Line Tools Toolbar

Use this toolbar to create and edit sample lines along a horizontal alignment.

The current sample line creation method, the alignment name associated with the sample line, and the layer on which the sample line is contained are displayed at the bottom of the tool.

Name

Specifies the format of the name of the next sample line to be created. The default format is <SL> - <[Next Counter]>.
<SL> is the name of the sample line.
<[Next Counter]> is an integer greater than or equal to one, which increments as sample lines are created in the drawing. This naming convention is based on the name template.
Enter a name or edit a default naming convention in the Name Template dialog box. For more information, see Name Template dialog box (page 1806).

Opens the Name Template dialog box. Edit the default sample line naming convention.

Prompts you to pick the horizontal alignment in the drawing to associate with the sample line. After you click the alignment in the drawing, the Sample Line Tools toolbar is reopened.

Current Sample Line Group

Displays the current sample line group with which the sample line is associated. If no sample line groups have been defined, you are prompted to enter a new sample line group name. For more information, see the Create/Edit Sample Line Group dialog box (page 2231).

**TIP** To edit a specific sample line group, select the sample line group name in the list.

Sample Line Group Actions

Specifies the sample line group action used to create or modify the sample line group. The default is the last used method. Click the down arrow to display other actions.

- ■ Opens the Create Sample Line Group dialog box. Create a new sample line group.

- ■ Opens the Edit Sample Line Group dialog box. Edit the currently selected sample line group.

- ■ Deletes the currently selected sample line group.

- ■ Prompts you to pick a sample line group from the drawing, which becomes the current sample line group.

- ■ Opens the Edit Sample Line Widths dialog box. Edit the left and right swath widths of the currently selected sample line group. The swath widths of individual sample lines are extended or trimmed to match the group's widths.

- ■ Opens the Section Sources dialog box. Add more source sections to the currently selected sample line group.

Sample Line Creation Methods

Displays the various sample line creation methods used to create the sample line(s). Click the down arrow to display other actions.

- ■ Creates sample lines by specifying individual stations along the alignment.

- ■ Creates sample lines by picking points in the drawing.

- ■ Creates sample lines by picking existing polylines in the drawing.

- ■ Opens the Create Sample Lines - By Station Range dialog box (page 2236). Creates sample lines by specifying a range of stations.

- ■ Opens the Create Sample Lines - From Corridor Stations dialog box (page 2238). Creates sample lines from corridor stations.

Click to select a sample line and view and edit its information in the Edit Sample Line dialog box (page 2250).

Toggles the display of the Edit Sample Line dialog box. To populate the columns of the Edit Sample Line dialog box, select a sample line from the drawing using .

Undoes the last action.

⇨

Redoes the last action. Limited to one operation.

**Related procedures:**

■ Creating Sample Lines (page 1142)

■ Editing Sample Lines (page 1145)

# Section Data Band Style Dialog Box

Use this dialog box to edit settings for section view band styles.

**See also:**

■ Section View Bands (page 1140)

■ Creating and Editing Section View Styles (page 1133)

## Information Tab (Section Data Band Style Dialog Box)

Use this tab to display administrative data and edit primary information about the section view band style, such as its name and description.

This tab also contains information about who created or modified the section view band style and the date of these events. The following fields can be modified:

Name

Specifies the name of the section data band.

Description

Specifies the optional description of the section view band style.

## Band Details Tab (Section Data Band Style Dialog Box)

Use this tab to specify the details of the section view band, including title text, layout, and labels and ticks values.

**NOTE** Both Section Data and Section Segment band styles are explained in this topic.

### Title Text

Compose Label

Click to create a title label in the Label Style Composer dialog box (page 1942).

### Layout

Band Height

Specifies the height of the band in plotted units. Enter a positive value in plotted units.

Text Box Width

Specifies the width of the band text box in plotted units. Enter a positive value in plotted units.

Offset From Band

Specifies the distance from the band to the text box in plotted units. Enter a positive value in plotted units.

Text Box Position
Specifies the location of the title text box with respect to the band.

## Labels And Ticks

Type
Specifies the type of labels and ticks.

---

**NOTE** To compose labels, select the type from the list. Adjust parameters as required. Click Compose Label.

---

The following types are available for section data bands:

- **At Major Increment**: Composes labels at major increments along the band and displays selected tick mark(s) at each major increment. The default is Small Ticks At, with Top and Bottom selected, each with a Tick Size of 0.1000".

- **At Minor Increment**: Composes labels at minor increments along the band and displays selected tick mark(s) at each minor increment. The default is Small Ticks At, with Top and Bottom selected, each with a Tick Size of 0.1000".

- **At Centerline**: Composes labels at centerline and displays selected tick mark(s) at centerline. The default is Full Band Height Ticks.

- **At Sample Line Vertices**: Composes labels at each sample line vertex along the band and displays selected tick mark(s) at each sample line vertex. The default is Small Ticks At, with Top and Bottom selected, each with a Tick Size of 0.1000".

- **At Grade Breaks**: Composes labels at each grade break along the band and displays selected tick mark(s) at each grade break. The default is Small Ticks At, with Top and Bottom selected, each with a Tick Size of 0.1000".

- **At Incremental DIstance**: Composes labels at incremental distances along the band. Click Compose Label to set label styles in the Label Style Composer dialog box (page 1942).

The following type is available for section segment bands:

- **Segment Label**: Composes labels at each segment along the band and displays selected tick mark(s) at each major increment. The default is Full Band Height Ticks.

When you select a Label and Tick type, the appropriate default values for Full Band Height Ticks and Small Ticks At are displayed.

Full Band Height Ticks
Specifies whether the tick is drawn at the full band height. This is the default value for the Centerline type.

Small Ticks At
Specifies whether ticks that are smaller than the size defined in Tick Size are drawn. The default for all types (except Centerline) is selected for both Top and Bottom and cleared for Middle. Select or clear one or more check boxes as required.

- **Top**: Draws the small tick(s) at the top of the selected type.

- **Middle**: Draws the small tick(s) in the middle of the selected type.

- **Bottom**: Draws the small tick(s) at the bottom of the selected type.

**Tick Size**: Specifies the height in plotted units of the Small Ticks. The default is 0.1000" for Top and Bottom ticks and 0.2500" for Middle ticks. Enter a positive value in plotted units.

Compose Label

Composes labels at major/minor increments, centerline, sample line vertices, and grade breaks for the section data band or section segment label. For more information, see Label Style Composer dialog box (page 1942).

## Display Tab (Section Data Band Style Dialog Box)

Use this tab to edit settings for the visibility and format styles of section view components, such as borders, titles, ticks, and labels.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Section Data Band Style Dialog Box)

Use this tab to edit settings for the section view band style.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Section Display Controls Dialog Box

Use this dialog box to edit section display options.

### Edit Section Options Table

Name

Displays the name of the section.

Draw

Specifies whether the section is drawn in the current section view. Select the check box to draw the section in the current section view.

Clip Grid

Specifies whether the grid lines in the current section view are clipped to the section (horizontal and/or vertical depending on the section view style definition). Select the radio button to clip the grid lines in the section view to the section.

Change Labels

Specifies the style set from which the section labels will be drawn. Click in this column to open the Select Style dialog box (page 1805).

Style

Specifies the section style. Click in this column to open the Select Section Style dialog box.

Override Style

Specifies the style for a section. Select the check box to open the Select Section Style dialog box.

# Section Editor Dialog Box

Use this dialog box to edit static sections in a section view and to display information about dynamic sections and corridor sections.

Static sections are those which do not maintain a link with their elevation data source.

This dialog box has a customizable display for the columns. For more information, see Customize Columns Dialog Box (page 1806).

Alignment
   Displays the alignment name associated with the current section.

Station
   Displays the station name associated with the current section.

**Columns**

No.
   Sequential number of the vertex.

Distance from CL
   Distance in ground units from the vertex to the centerline.

Vertex Elevation
   Elevation at the vertex.

Section Grade In
   Angle of the section grade in.

Section Grade Out
   Angle of the section grade out.

---

**NOTE** If you want to edit a dynamic section or a corridor section, you can make a copy of the section and change the type to static.

---

# Section Labels Dialog Box

Use this dialog box to manage labels for a particular section in a section view.

A set of labels created here can be saved and used for other section.

Type
   Specifies the type of label to be added to the section in the section view. One of:

   ■ **Major Offset**. Offsets, elevations, and instantaneous grades at major increments.

   ■ **Minor Offset**. Offsets, elevations, and instantaneous grades at minor increments.

   ■ **Segments**. Section segment labels for each (line) segment of a section object.

   ■ **Grade Breaks**. Grade break labels applied at every grade break point for a section.

Section <Label Type> Label Style
   Specifies the style for the labels. Standard buttons are also provided to create or edit a label style.

Add>>
   Adds the specified label type to the set in the label table. These labels appear along the section line in the section view.

✖
   Deletes the selected label type from the table. Also removes it from the section.

**Label table**

Type
   Specifies the type of section label.

Style
   Specifies the label style.

**Increment**

Specifies the distance between labels of this type. This is used only for station labels.

**Check box**

Indicates whether the labels are applied from the beginning of the section or start at a specified station:

- Selected: The label type is applied from the beginning of the section offset.

- Cleared: The label type is applied to the part of the section that begins at the offset recorded in the Start Offset column.

**Start Offset**

Specifies the offset where the label type is applied.

**Check box**

Indicates whether the labels are applied to the end of the section offset or finish at a specified offset.

- **Selected**: The label type is applied as far as the end of the section offset.

- **Cleared**: The label type is applied to a part of the section that ends at the offset recorded in the End Offset column.

**End Offset**

Specifies the offset where the label type is applied.

**Dim Anchor Opt**

Specifies the location of the anchor used to position dimension lines for the section label.

- **Distance Above**: Moves the dimension line anchor up the distance specified in the Dim Anchor Val field.

- **Fixed Elevation**: Places the dimension line anchor at a fixed elevation on a section view. Specify the elevation in the Dim Anchor Val field.

- **Distance Below**: Moves the dimension line anchor down the distance specified in the Dim Anchor Val field.

- **Graph View Top**: Places the line anchor at the top of the section view grid. This creates a vertical graph line above the label. To ensure the full line extent is displayed, set Dim Anchor Val to 0.

- **Graph View Bottom**: Anchors the line to the bottom of the section view grid. This creates a vertical graph line below the label. To ensure the full line extent is displayed, set Dim Anchor Val to 0.

**Dim Anchor Val**

Specifies the dimension line anchor value to be applied using the Dim Anchor Opt.

**Weeding**

Specifies a label exclusion distance for grade break labels only. Use this setting to remove overlapping labels, making it easier to read the remaining labels. If another grade break occurs within the specified distance, it is not labeled.

**NOTE** This setting is available for Grade Break labels only.

**Import Label Set**

Opens the Select Style dialog box (page 1805). Select an existing label set to use or to use as a basis for modification. This imported set overwrites the existing contents of the label table.

**Save Label Set**

Opens the Label Set dialog box (page 1771). Configure and save the current label set for use with other sections.

■  Using Section Labels (page 1137)

# Section Properties Dialog Box

Use this dialog box to edit properties of the selected section, such as its name, section data, and labels.

**See also:**

■  Editing Sections (page 1148)

■  Editing Section Properties (page 1150)

## Information Tab (Section Properties Dialog Box)

Use this tab to edit primary information about the selected section.

Name

Specifies the name of the section. The default format is <SLG>-n - <SL>-n - <data source>(n).
<SLG> is the parent sample line group name, <SL> is the sample line name, and <data source> is the name of the data source (for example, surface or corridor surface) on which the section is drawn.
n is an integer greater than or equal to one, which increments as each feature is created in the drawing.

Description

Specifies the optional description of the section.

Object Style

Specifies the name of the style used by the section.

Creates, copies, or edits a style using the Section Style dialog box (page 2274). Click the down arrow to display the style selection menu:

■  **Create New**: Creates a new style.

■  **Copy Current Selection**: Copies the current style.

■  **Edit Current Selection**: Edits the current style.

■  **Pick From Drawing**: Prompts you to select a style directly from the drawing. The selected style becomes the current style.

Displays details about an existing style. Select the style by name in the list. Click to open the Style Detail dialog box (page 1804). Preview the style and creation information.

Show Tooltips

Controls whether tooltips are displayed for the object in the drawing (not over toolbar icons).

## Section Data Tab (Section Properties Dialog Box)

Use this tab to edit properties of the selected section object.

Description

Specifies the optional description of the current section.

Type

Displays the type of data source from which the section data was extracted. Either ⌂ , which indicates from an existing TIN surface; ⌂ , which indicates from a corridor; ⌂ , which indicates from a corridor surface; or ⌂ , which indicates from an existing pipe network.

Data Source

Displays the name of the data source from which the current section was sampled.

Update Mode

Specifies the type of update mode for the section. Select Dynamic to specify that the section data updates dynamically if the position of the sample line associated with the section changes or the data source geometry changes.

Layer

Specifies the drawing layer that contains the current section associated with the selected sample line group. Click in the Layer column to open the Layer Selection dialog box (page 1986). Select a layer in the Layers table.

Style

Specifies the name of the style of the section. Click in this column to open the Select Style dialog box (page 1805). Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Left Offset

Displays the left offset value of the current section.

Right Offset

Displays the right offset value of the current section.

Minimum Elevation

Displays the minimum elevation of the section associated with the selected sample line group.

Maximum Elevation

Displays the maximum elevation of the section associated with the selected sample line group.

Station

Displays the station value of the sample line along which the section is sampled.

# Section Sources Dialog Box

Use this dialog box to resample sections of a sample line group.

Sample Line Group Name

Displays the name of the sample line group being resampled.

Alignment Name

Displays the name of the parent alignment of the sample line group.

Add >>

Adds the specified sample line group to the Sampled Sources table.

Remove <<

Removes the specified sample line group from the Sampled Sources table.

**Sampled Sources Table**

Name
  Specifies the name of the sampled source.

Style
  Specifies the style of the sampled source.

Layer
  Specifies the drawing layer that contains the sampled source.

Update Mode
  Specifies the type of update mode for the sampled source. Select Dynamic if the position of the sample line changes.

**Related procedures:**

■ Editing Sample Lines (page 1145)

# Section Style Dialog Box

Use this dialog box to define a section style, which controls the way a section is displayed in a drawing.

**See also:**

■ Creating and Editing Section Styles (page 1132)

# Information Tab (Section Style Dialog Box)

Use this tab to display administrative data and edit primary information about the section style, such as its name and description.

This tab also contains information about who created or modified the section style and the date of these events. The following fields can be modified:

Name
  Specifies the name of the selected section style.

Description
  Specifies the optional description of the selected section style.

# Display Tab (Section Style Dialog Box)

Use this tab to edit settings for the visibility and format styles of section components, such as segments and points.

On the Display tab, you can use the ByLayer or ByBlock reference settings to set Color, Linetype, Lineweight, and Plot Style values. Reference settings are indirect and require some planning.

For more information, see Display Tab (Style Dialog Box) (page 1801).

# Summary Tab (Section Style Dialog Box)

Use this tab to edit the settings for the section style.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Section View Bands Dialog Box

Use this dialog box to specify the source surfaces for data band annotation.

**List Of Bands**

Location

    Specifies the location in the section view of data band annotation.

Band Type

    Displays the type of data band specified in the Band Set properties.

Style

    Specifies the style for the band in the Band Set properties. Click  to open the Select Style dialog box (page 1805).

Surface 1

    Specifies a surface sampled by the sample line that supplies the data for the band, including any corridor surface.

Surface 2

    Specifies an additional surface sampled by the sample line that supplies the data for the band, including any corridor surface. Not used for Section Segment type data bands.

**Related procedures:**

- Creating/Editing Section Views (page 1153)
- Section View Bands (page 1140)

# Section View Band Set Dialog Box

Use this dialog box to create a set of data band styles for section views.

A band style set is useful when you want to apply the same set of data bands to a number of section views. After naming your band set on the Information tab, use the Bands tab to specify the bands included in the set and their location above or below the section view grid.

**See also:**

- Section View Bands (page 1140)

# Information Tab (Section View Band Set Dialog Box)

Use this tab to record basic information about the band set, such as its name and description.

This tab also contains information about who created or modified the section view style and the date of these events. The following fields can be modified:

Name

    Specifies the name of the band style set.

Description

    Specifies the optional description of the selected band style set.

# Bands Tab (Section View Band Set Dialog Box)

Use this tab to specify which data bands are included in the set, along with their styles and positions relative to the section view grid.

Band Type

Specifies the type of data band to add to the set.

Select Band Style

Specifies the style for the band.

To edit a style or create a new one, click ![icon] and select from the list of operations. For more information, see Select Style dialog box (page 1805) and Section Data Band Style dialog box (page 2267). To examine the details of an existing style, select the style name in the list. Click ![icon] . For more information, see the Style Detail dialog box (page 1804).

Add>>

Adds the specified data band type to the style set. Before clicking, ensure that the settings are correct for data band type, style, and location.

## List Of Bands

Location

Specifies either the top or bottom of the section view. For the current location, the table below this field shows the bands in the current band style set.

Band Type

Displays the data band type.

Style

Specifies the style for the band type.

Description

Specifies the optional description of the band style.

Gap

Specifies the distance in plotted units between the current data band and the previous data band (or the nearest section view axis).
For bands below the section view grid, the specified gap is measured from the top of the current band to the bottom of the previous band (or the section view bottom axis, if the current band is the first one). Similarly, for bands above the section view grid, the specified gap is measured from the bottom of the current band to the top of the previous band (or the section view top axis, if the current band is the first one).

Major Interval

Specifies the section view data band major interval distance.

Minor Interval

Specifies the section view data band minor interval distance.

Label End Offset

Specifies whether or not the end of the band is labeled.

Weeding

Used only for labels at vertical geometry points on Section Data bands. Vertical geometry points or grade breaks that are closer than the weeding factor are removed, making it easier to read the remaining labels. Enter a positive number to specify a label exclusion distance.

Stagger Labels

Specifies the location of the label staggering line: No staggering, Stagger both sides, Stagger to right, or Stagger to left.

Stagger Line Height

Specifies the height of the label stagger line.

⇧

Moves the selected data band up in the list.

**NOTE** The order in this list is the order in which the bands appear below/above the section view.

⇩

Moves the selected data band down in the list.

✖

Deletes the selected data band from the list and removes it from the section view.

Match Major/Minor Increments to Vertical Grid Intervals

Specifies if the section data band major/minor intervals for section views matches the section view style's major/minor grid spacing interval distances. Select the checkbox to match major/minor increments to vertical grid intervals. If this checkbox is selected, the major/minor interval fields in the List of Bands table are unavailable.

# Section View Group Bands Dialog Box

Use this dialog box to edit properties that manage the last applied data bands for the section view group.

This dialog box is accessed from the Section View Group Properties dialog box and displays the last applied set of bands.

Band Type

Specifies which type of data band to add to the section view. Select a band type in the list: either Section Data or Section Segment.

Select Band Style

Specifies the style for the band. Select a band style in the list.

Creates, copies, or edits a style using the Section Data Band Style dialog box (page 2267). Click the down arrow to display the style selection menu:

■ **Create New**: Creates a new style.

■ **Copy Current Selection**: Copies the current style.

■ **Edit Current Selection**: Edits the current style.

Displays details about an existing style. Select the style by name in the list. Click to open the Style Detail dialog box (page 1804). Preview the style and creation information.

Add>>

Adds the specified data band type to the set for this section view. Before clicking, ensure that the settings are correct for data band type, style, and location.

### List Of Bands

Location

Specifies the location where you want to draw the data band relative to the current section view.

- **Bottom Of Section View**: Draws the data band at the bottom (below) the current section view.

- **Top Of Section View**: Draws the data band at the top (above) the current section view.

Band Type

Displays the current data band type that was added using the Band Type list.

Style

Specifies the name of the band style that was added using the Select Band Style list. To change the style, click in this column to open the Select Style dialog box (page 1805). Select a band style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Description

Specifies the optional description of the band style.

Gap

Specifies the distance in plotted units between the current data band and the previous data band (or the nearest section view axis). Enter a positive gap value in plotted units.

- For bands below the section view grid, the specified gap is measured from the top of the current band to the bottom of the previous band (or the section view bottom axis, if the current band is the first one).

- For bands above the section view grid, the specified gap is measured from the bottom of the current band to the top of the previous band (or the section view top axis, if the current band is the first one).

Label Start Offset

Specifies whether or not the start end of the band is labeled.

Label End Offset

Specifies whether or not the end of the band is labeled.

Surface1/Surface2

Specifies two surfaces that are used by the band styles to annotate either elevations or the elevation differences between the two sections. Select the surface(s) by name in the list.

Weeding

Used only for labels at vertical geometry points on Section Data bands. Vertical geometry points or grade breaks that are closer than the weeding factor are removed, making it easier to read the remaining labels. Enter a positive number to specify a label exclusion distance.

Stagger Labels

Specifies the location of the data band label staggering line: No staggering, Stagger both sides, Stagger to right, or Stagger to left.

Stagger Line Height

Specifies the height of the data band label stagger line.

⬆

Moves the selected data band up in the list.

**NOTE** The order in this list is the order in which the bands appear below/above the section view.

Moves the selected data band down in the list.

Deletes the selected data band from the list and removes it from the section view.

Match Major/Minor Increments to Vertical Grid Intervals

Specifies if the section data band major/minor intervals for section views matches the section view style's major/minor grid spacing intervals. Select the checkbox to match major/minor increments to vertical grid intervals.

Import Band Set

Imports a band set. In the Band Set dialog box (page 1805), select an existing band set to be added to the current section view in the list.

Save As Band Set

Saves a new band set. Click to open the Section View Band Set dialog box (page 2275). Save the current list of bands as a band set for use with other section views.

**Related procedures:**

■ Adding Section View Bands (page 1141)

# Section View Group Properties Dialog Box

Use this dialog box to edit properties of the selected section view group, such as its name, the name of its parent alignment, properties of its constituent section views, and properties of the displayed sections.

In the Sections tab, you edit all options for the entire group.

In the Section Views tab, you can only edit section view names individually. You can edit section view styles individually or for the entire section view group. You can only set band set, volume tables and profile grade settings for the group.

You cannot edit station location, or the locations of Start and End stations.

**See also:**

■ Editing Section View Properties (page 1156)

# Section Views Tab (Section View Group Properties Dialog Box)

Use this tab to edit properties of the section views in the selected sample line group.

Sample Line Group Name

Specifies the name of the sample line group being resampled.

Alignment Name

Specifies the name of the parent alignment of the sample line group.

**Section View List**

Section View

Displays the names of section views arranged in an expandable tree or hierarchy.

**Group Plot Style**

Specifies the name of the plot style of the section view associated with the selected sample line group. Click in this column to open the Select Style dialog box (page 1805). Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

**Style**

Specifies the name of the style of the section view associated with the selected sample line group. Click in this column to open the Select Style dialog box. Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

**Change Band Set**

Displays the last applied set of bands for the current section view group. Click in this column to open the Section View Group Bands dialog box. Use this dialog box to edit properties that manage the data bands for the section view group.

**Section Display**

Specifies the section display options for the current section view. Click in this column to open the Section Display Controls dialog box (page 2269). Select section display options in the list.

**Profile Grade**

Specifies the grid lines displayed at offset alignments and other profiles within the range of section view extents. Click in this column to open the Profile Grade Points dialog box (page 2254).

**Station**

Displays the station value of the sample line along which this section view is created.

**Start Station**

Displays the beginning station in the range.

**End Station**

Displays the end station in the range.

## Sections Tab (Section View Group Properties Dialog Box)

Use this tab to edit section view display options.

### Edit Section Options Table

**Draw**

Specifies whether the section is drawn in the current section view. Select the check box to draw the section in the current section view.

**Clip Grid**

Specifies whether the grid lines in the current section view are clipped to the section (horizontal and/or vertical depending on the section view style definition). Select the radio button to clip the grid lines in the section view to the section.

**Change Labels**

Specifies the style set from which the section labels will be drawn. Click in this column to open the Select Style dialog box (page 1805).

**Style**

Specifies the section style. Click in this column to open the Select Section Style dialog box.

**Override Style**

Specifies the style for a section. Select the check box to open the Select Section Style dialog box.

# Section View Properties Dialog Box

Use this dialog box to edit properties of the selected section view, such as its name, grid dimensions, and properties of the displayed sections and data bands.

**See also:**

■ Editing Section View Properties (page 1156)

■ Creating and Editing Section Views (page 1152)

## Information Tab (Section View Properties Dialog Box)

Use this tab to edit primary information about the selected section view.

Name

Specifies the name of the section view. The default format is <start-station > (n).
<start-station> is the name of the beginning station in the section view.
n is an integer greater than or equal to one, which increments as section views are created in the drawing.

Description

Specifies the optional description of the section view.

Object Style

Specifies the name of the style used by the section view.

Creates, copies, or edits a style using the Section View Style dialog box (page 2288). Click the down arrow to display the style selection menu:

■ **Create New**: Creates a new style.

■ **Copy Current Selection**: Copies the current style.

■ **Edit Current Selection**: Edits the current style.

■ **Pick From Drawing**: Prompts you to select a style directly from the drawing. The selected style becomes the current style.

Displays details about an existing style. Select the style by name in the list. Click to open the Style Detail dialog box (page 1804). Preview the style and creation information.

Show Tooltips

Controls whether tooltips are displayed for the object in the drawing (not over toolbar icons).

## Offsets Tab (Section View Properties Dialog Box)

Use this tab to display the properties of the selected section view and the section view grid on which sections are displayed.

Sample Line

Displays the name of the parent sample line for the current section view.

Sample Line Group

Displays the name of the parent sample line group for the current section view.

Alignment

Displays the name of the parent horizontal alignment for the current section view.

**Offset Range**

Automatic

Specifies that the offset range is set automatically. The lengths of the left and right swath widths are displayed in the fields next to the selection.

User Specified

Specifies that the offset range is set by the user. Specify the lengths of the left and right swath widths in the fields next to the selection.

Left

Specifies the offset length of the left swath width.

Right

Specifies the offset length of the right swath width.

# Elevations Tab (Section View Properties Dialog Box)

Use this tab to view or specify the elevation properties of the selected section view and the section view grid on which sections are displayed.

**Elevation Range**

Automatic

Specifies that the elevation range is set automatically. The minimum and maximum heights are displayed in the fields next to the selection.

User Specified

Specifies that the elevation range is set by the user. Specify minimum and maximum heights in the fields next to the selection.

Minimum

Specifies the minimum height of the elevation.

Maximum

Specifies the maximum height of the elevation.

# Sections Tab (Section View Properties Dialog Box)

Use this tab to edit properties that determine which sampled sections are drawn in the section view.

Name

Displays the name of the current section.

Draw

Specifies whether the section is drawn in the current section view. Select the check box to draw the section in the current section view.

Clip Grid

Specifies whether the grid lines in the current section view are clipped to the section (horizontal and/or vertical depending on the section view style definition). Select the check box to clip the grid lines in the section view to the section.

Description

Specifies the optional description of the current section.

Type

Displays the type of data source from which the section data was extracted. Either ![icon], which indicates from an existing TIN surface; ![icon], which indicates from a corridor; ![icon], which indicates from a corridor surface; or ![icon], which indicates from an existing pipe network.

Data Source

Displays the name of the data source from which the current section is sampled.

Update Mode

Specifies the type of update mode for the section. Select Dynamic to specify that the section data updates dynamically if the position of the sample line associated with the section changes or the data source (surface or corridor) geometry changes.

Layer

Specifies the drawing layer that contains the current section view associated with the selected sample line group. Click in this column to open the Layer Selection dialog box (page 1986). Select a layer in the Layers table.

Style

Specifies the name of the style of the section. Click in the Style column to open the Select Style dialog box (page 1805). Select a style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Override Style

Specifies whether the current style is overridden in the current section view. If the style is overridden, the cell is selected. The name of the override style is displayed.

Labels

Specifies the section label style. In the Labels column, click <Edit...> to open the Section Labels dialog box (page 2270). Select the label style.

Left Offset

Displays the left offset value of the current section.

Right Offset

Displays the right offset value of the current section.

Minimum Elevation

Displays the minimum elevation of the section associated with the selected sample line group.

Maximum Elevation

Displays the maximum elevation of the section associated with the selected sample line group.

Station

Displays the station value of the sample line along which the section is sampled.

## Bands Tab (Section View Properties Dialog Box)

Use this tab to edit properties that manage the data bands for the section view.

Band Type

Specifies which type of data band to add to the section view. Select a band type in the list: either Section Data or Section Segment.

Select Band Style

Specifies the style for the band. Select a band style in the list.

Creates, copies, or edits a style using the Section Data Band Style dialog box (page 2267). Click the down arrow to display the style selection menu:

■ **Create New**: Creates a new style.

■ **Copy Current Selection**: Copies the current style.

■ **Edit Current Selection**: Edits the current style.

Displays details about an existing style. Select the style by name in the list. Click to open the Style Detail dialog box (page 1804). Preview the style and creation information.

Add>>

Adds the specified data band type to the set for this section view. Before clicking, ensure that the settings are correct for data band type, style, and location.

**List Of Bands**

Location

Specifies the location where you want to draw the data band relative to the current section view.

■ **Bottom Of Section View**: Draws the data band at the bottom (below) the current section view.

■ **Top Of Section View**: Draws the data band at the top (above) the current section view.

Band Type

Displays the current data band type that was added using the Band Type list.

Style

Specifies the name of the band style that was added using the Select Band Style list. To change the style, click in this column to open the Select Style dialog box (page 1805). Select a band style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Description

Specifies the optional description of the band style.

Gap

Specifies the distance in plotted units between the current data band and the previous data band (or the nearest section view axis). Enter a positive gap value in plotted units.

■ For bands below the section view grid, the specified gap is measured from the top of the current band to the bottom of the previous band (or the section view bottom axis, if the current band is the first one).

■ For bands above the section view grid, the specified gap is measured from the bottom of the current band to the top of the previous band (or the section view top axis, if the current band is the first one).

Label Start Offset

Specifies whether or not the start end of the band is labeled.

Label End Offset

Specifies whether or not the end of the band is labeled.

Section1/Section2

Specifies two sections that are used by the band styles to annotate either elevations or the elevation differences between the two sections. Select the section(s) by name in the list.

Weeding

Used only for labels at vertical geometry points on Section Data bands. Vertical geometry points or grade breaks that are closer than the weeding factor are removed, making it easier to read the remaining labels. Enter a positive number to specify a label exclusion distance.

Stagger Labels

Specifies the location of the label staggering line: No staggering, Stagger both sides, Stagger to right, or Stagger to left.

Stagger Line Height

Specifies the height of the label stagger line.

⇧

Moves the selected data band up in the list.

NOTE The order in this list is the order in which the bands appear below/above the section view.

⇩

Moves the selected data band down in the list.

✖

Deletes the selected data band from the list and removes it from the section view.

Match Major/Minor Increments to Vertical Grid Intervals

Specifies if the section data band major/minor interval distances for section views matches the section view style's major/minor grid spacing intervals. Select the checkbox to match major/minor increments to vertical grid intervals. If this checkbox is selected, the major/minor interval fields are unavailable.

Import Band Set

Imports a band set. In the Band Set dialog box (page 1805), select an existing band set to be added to the current section view in the list.

Save As Band Set

Saves a new band set. Click to open the Section View Band Set dialog box (page 2275). Save the current list of bands as a band set for use with other section views.

**Related procedures:**

■ Adding Section View Bands (page 1141)

# Volume Tables Tab (Section View Properties Dialog Box)

Use this tab to set volume table properties for the section view.

Use the following controls to specify the volume table types to draw:

Type

Specifies the type of the volume table(s).

Select Table Style

Specifies the style of the volume table. Standard buttons are also provided to create or edit a label style.

Add >>

Adds a volume table to the list.

**List Of Volume Tables**

Table Type

Displays the current table type.

Style

Specifies the name of the table style that was added using the Select Table Style list. To change the style, click in this column to open the Select Style dialog box (page 1805). Select a band style in the list or use the standard controls to create a new style, copy or edit the current style selection, or pick a style from the drawing.

Material List

Specifies the material list for the volume table.

Materials

Click ⋯ to specify the materials for the volume table.

Layer

Specifies the drawing layer that contains the sampled source.

Split

Specifies whether the layer is split.

Gap

Specifies the distance in plotted units between the current data band and the previous data band (or the nearest section view axis). Enter a positive gap value in plotted units.

Reactivity Mode

Specifies the type of update mode for the section. Select Dynamic to specify that the section data updates dynamically if the position of the sample line associated with the section changes or the data source (surface, corridor, or pipe) geometry changes.

**Position Of Table(s) Relative To Section View**

Section View Anchor

Specifies the section view anchor (Top/Middle/Bottom, Left/Center/Right).

Table Anchor

Specifies the location of the table anchor (Top/Middle/Bottom, Left/Center/Right).

Table Layout

Specifies whether the layout of the tables will be horizontal or vertical, in relation to the section view.

X Offset

Specifies the distance in plotted units to move the title away from the position set by the table anchor. Enter a positive number to move the title right, or a negative number to move it left.

Y Offset

Specifies the distance in plotted units to move the title away from the position set by the table anchor. Enter a positive number to move the title up, or a negative number to move it down.

**Related procedures:**

■ Creating/Editing Section Views (page 1153)

## Profile Grade Lines Tab (Section View Properties Dialog Box)

Use this tab to select a profile and display its elevation by marking it at the appropriate offset and elevation in the section view.

Alignment

Specifies the parent alignment whose profile grade point is to be displayed in this section view. Select an alignment from the drop-down list or click  to pick an alignment from the drawing.

Add>>

Adds the profile grade point for the currently selected alignment to the list.

Deletes the highlighted profile grade point from the list. The profile grade point will no longer be displayed in the section view.

### List Of Profile Grade Points

Alignment

Displays the name of the parent alignment whose profile grade point is marked in this section view.

Show

Specifies whether the marker is visible in the section view (that is, without having to edit the marker style or layer).

Profile

Displays the name of the profile whose location, with respect to the current section view, is marked.

Marker Style

Displays the marker style used for the profile grade point.

## Projections Tab (Section View Properties Dialog Box)

Use this tab to show or hide projected objects in a section view.

Name

Specifies the names and categories of objects that are available for display in the current section view. Click to add or remove objects in the section view.

Style

Specifies the display style of each projected object. Click a single entry to change it, or click <set all> for a category to select a style for all objects of that category.

Elevation Options

Specifies whether the elevation of the projected object is determined by its elevation in plan view or manually controlled in the section view. Click a single entry to change it, or click <set all> for a category to select an option for all objects of that category.

Elevation Value

Specifies the actual elevation of the projected object. Click <set all> for a category to select an elevation for all objects of that category.

Pick Objects

Click to select objects in the drawing and add them to the section view.

# Section View Style Dialog Box

Use this dialog box to define a section view style, which controls the way a section view is displayed in a drawing.

You can change the graph, grid, title, axes ticks, and text. Select which elements to display.

**See also:**

- Creating and Editing Section View Styles (page 1133)
- Creating and Editing Section Views (page 1152)

## Information Tab (Section View Style Dialog Box)

Use this tab to display administrative data and edit primary information about the section view style, such as its name and description.

This tab also contains information about who created or modified the section view style and the date of these events. The following fields can be modified:

Name

Specifies the name of the selected section view style.

Description

Specifies the optional description of the selected section view style.

## Graph Tab (Section View Style Dialog Box)

Use this tab to edit settings for vertical scale.

### Vertical Scale

Use the controls in this area to specify the elevation values, in order to improve visibility in the section view. Specify the section view vertical scale in either of the following ways:

- By Vertical Exaggeration — Enter a value in the Vertical Exaggeration field. The Vertical Scale value is calculated automatically.
  The Current Horizontal Scale (HS) factor of the drawing is divided by the Vertical Scale value (VS) to obtain the profile view Vertical Exaggeration value (VX).

$$\frac{HS}{VS} = VX$$

  For example, if the Current Horizontal Scale is 50, and you want the profile view's Vertical Scale to be 1"=10', then set the Vertical Exaggeration to 5.

$$\frac{50}{10} = 5$$

- By Vertical Scale — Select a scale from the Vertical Scale list. Alternatively, enter a custom value in the Custom field. The Vertical Exaggeration value will be calculated automatically.

Vertical Scale

The section view vertical scale. Select a vertical scale from the list, or enter a custom scale in the Custom Scale field.

Vertical Scale (VS) = Current Horizontal Scale (HS) divided by Vertical Exaggeration (VX)

$$VS = \frac{HS}{VX}$$

Custom Scale

Specifies the current Vertical Scale factor. Enter a value in this field to specify a scale factor that is not provided in the Vertical Scale list.

Current Horizontal Scale

The overall drawing Scale specified in the Drawing Settings dialog box (page 1851). This field is not editable. The horizontal scale must be changed in the Drawing Settings dialog box.

Vertical Exaggeration

Specifies by how much the elevation values increase in the section view for greater visibility. Enter either 1 for no increase in scale or a larger number to increase the scale. The elevation values are multiplied by this value, so a larger number increases the amount of exaggeration in the section view.

# Grid Tab (Section View Style Dialog Box)

Use this tab to specify clipping, padding, and axis offset options on the section view grid.

## Grid Options

 Clip Vertical Grid

Specifies that vertical grid lines are only drawn below the section line. If Clip To Highest Section(s) is not selected, the vertical lines will be drawn only below the section view line that has Clip Grid selected on the Sections tab (page 2282) in the Section View Properties dialog box.

**Clip To Highest Section(s)**: Specifies that vertical section view grid lines will be drawn to the highest of all displayed profiles.

**Omit Grid In Padding Areas**: Specifies that vertical profile view grid lines will not be drawn in the padding areas.

 Clip Horizontal Grid

Specifies that horizontal grid lines are only drawn below the section line. If Clip To Highest Section(s) is not selected, the horizontal lines will be drawn only below the section line that has Clip Grid selected on the Sections tab in the Section View Properties dialog box.

**Clip To Highest Section(s)**: Specifies that vertical section view grid lines will be drawn to the highest of all displayed profiles.

**Omit Grid In Padding Areas**: Specifies that horizontal section view grid lines will not be drawn in the padding areas.

## Grid Padding

 Grid Padding (Major Grids)

Specifies the distance (in major grid blocks) to add to the extents of the section view in relation to the profiles it contains.

## Above Maximum Elevation

Specifies the number of grid blocks that the section view extends above the maximum section elevation. This enables the graph to be taller than the extents of the section drawn in the profile view.

## Below Datum

Specifies the number of grid blocks that the section view extends below the datum or minimum section elevation. This enables the graph to extend below the extents of the section drawn in section view.

## To Left

Specifies the number of major grids to place before the left-most station value of the alignment. This enables the graph to be wider than the extents of the section drawn in the section view.

## To Right

Specifies the number of major grids to place after the right-most station value of the alignment. This enables the graph to be wider than the extents of the section drawn in the section view.

### Axis Offset

**NOTE** The axis offset distance is specified in plotted units, based on the Drawing Units and Scale settings specified on the Units and Zone tab (page 1851) of the Drawing Settings dialog box.

 Axis Offset (Plotted Units)

Specifies the distance (in plotted units) to offset the section view's horizontal and vertical axes from the grid extents (including padding). This creates a blank area between the axis and the grid.

## Above Maximum Elevation

Specifies the distance to offset the horizontal axis above the vertical extent.

## Below Datum

Specifies the distance to offset the horizontal axis below the vertical extent.

## To Left

Specifies the distance to offset the horizontal axis to the left of the horizontal extent.

## To Right

Specifies the distance to offset the horizontal axis to the right of the horizontal extent.

# Title Annotation Tab (Section View Style Dialog Box)

Use this tab to specify settings for the graph view and axis titles.

### Graph View Title

Text Style

Specifies the text style for the section view title.

Text Height

Specifies the current text height in drawing units.

Title Content

Specifies the text elements used to compose the title, such as horizontal alignment (HA) name and station

range. To change title format or content, click  to open the Text Component Editor dialog box (page 1961).

## Title Position

These controls specify the position of the profile view title. Use Location and Justification settings for basic positioning, then X and Y offsets for more precise placement, if necessary.

Location

Specifies the location of the title in relation to the section view grid: either top, bottom, left, or right.

Justification

Specifies the justification (alignment) of the title. If Location is top or bottom, justification values are left, right, or center. If Location is right or left, justification values are top, middle, or bottom.

X Offset

Specifies a horizontal offset from the position set by the Location and Justification values. Enter a positive number to move the title right or a negative number to move it left.

Y Offset

Specifies a vertical offset from the position set by Location and Justification values. Enter a positive number to move the title up or a negative number to move it down.

Border Around The Title

Specifies whether a border line is drawn around the title block.

Gap

Specifies the distance between the title and its border.

## Axis Title Text

Separate titles may be displayed at each of the axes. Use the radio buttons around the graphic to select the axis title to edit. Configure title settings and click Apply. Repeat that process with each axis title.

NOTE The Axis Title selections do not control axis title visibility. Visibility controls for all section components are located on the Display tab (page 2295).

 Axis Title Text

Specifies which axis title is being controlled by the text editing tools.

Title Text

Specifies the title text for the horizontal axis. To change the title content, click  to open the Text Component Editor dialog box (page 1961).

Location

Specifies the location of the title on the axis: either Left, Center, or Right. For more precise control, use the X and Y Offsets.

Rotation

Specifies the angle for the title. Enter a positive or negative value. The angle direction is always counterclockwise. If the value is zero (0), the title is not rotated.

Text Style

Specifies a text style for use in the horizontal axis title.

Text Height

Specifies the title text height (in plotted units).

X Offset

Specifies a horizontal offset from the Location setting. Enter a positive number to move the title right or a negative number to move it left.

Y Offset

Specifies a vertical offset from the Location setting. Enter a positive number to move the title up or a negative number to move it down.

## Horizontal Axes Tab (Section View Style Dialog Box)

Use this tab to edit settings for the section view style, such as the title format, use of tick marks, and annotations on the horizontal axes of the section view.

After you configure horizontal axis title and tick details, click Apply. Later, you can change the Select Axis setting and configure another axis on the opposite side of the grid.

Select Axis To Control

Click either the Top or Bottom radio button to select that axis.

### Major Tick Details

Interval

Specifies the spacing of major ticks on the horizontal axis, using the actual ground units. Enter a positive value in ground units.

Tick Size

Specifies the height of the actual tick on the horizontal axis, using plotted units. Enter a positive value in plotted units.

Tick Justification

Specifies whether the tick is justified Top, Bottom or Center.

Text Height

Specifies the height of text used to label major ticks on the horizontal axis, using in plotted units. Enter a positive value in plotted units.

Tick Label Text

Specifies a property with which the tick is labeled. To change the text format or content, click ![icon] to display the Text Component Editor dialog box (page 1961).

Text Style

Specifies the style of the tick label text.

Rotation

Specifies the angle for the tick label. Enter a positive or negative value.The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

Specifies a horizontal offset for the tick label from the bottom of the tick.

Y Offset

Specifies a vertical offset for the tick label from the bottom of the tick.

### Minor Tick Details

Interval

Specifies the spacing of minor ticks on the horizontal axis, using the actual ground units. Enter a positive value in ground units.

Tick Size

Specifies the height of the actual tick on the horizontal axis, using plotted units. Enter a positive value in plotted units.

Tick Justification

Specifies whether the tick is justified Top, Bottom or Center.

Text Height

Specifies the height of text used to label minor ticks on the horizontal axis, using plotted units. Enter a positive value in plotted units.

Tick Label Text

Specifies a property with which the tick is labeled. To change the text format or content, click ![icon] to display the Text Component Editor dialog box.

Text Style

Specifies the style of the tick label text.

Rotation

Specifies the angle for the tick label. Enter a positive or negative value.The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

Specifies a horizontal offset for the tick label from the bottom of the tick.

Y Offset

Specifies a vertical offset for the tick label from the bottom of the tick.

## Horizontal Geometry Tick Details

Tick Size

Specifies the height of the actual tick on the horizontal axis, using plotted units. Enter a positive value in plotted units.

Tick Justification

Specifies whether the tick is justified Top, Bottom or Center.

Text Height

Specifies the height of text used to label minor ticks on the horizontal axis, using plotted units. Enter a positive value in plotted units.

Tick Label Text

Specifies a property with which the tick is labeled. To change the text format or content, click ![icon] to display the Text Component Editor dialog box.

Text Style

Specifies the style of the tick label text.

Rotation

Specifies the angle for the tick label. Enter a positive or negative value.The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

Specifies a horizontal offset for the tick label from the bottom of the tick.

Y Offset

Specifies a vertical offset for the tick label from the bottom of the tick.

# Vertical Axes Tab (Section View Style Dialog Box)

Use this tab to edit settings for the section view style, such as the title location and format, use of tick marks, and annotations, on the vertical axis of the section view.

After you configure vertical axis title and tick details, click Apply. Later, you can change the Select Axis setting and configure another axis on the opposite side of the grid.

Select Axis To Control

Click either the Left, Center or Right radio button to select that axis.

## Major Tick Details

Interval

Specifies the spacing of major ticks on the vertical axis. Enter a positive value in ground units.

Tick Size

Specifies the length of the actual tick on the vertical axis, using plotted units. Enter a positive value in plotted units.

Tick Justification

Specifies whether the tick is justified Left, Right or Center.

Text Height

Specifies the height of text used to label major ticks on the vertical axis in plotted units. Enter a positive value in plotted units.

Tick Label Text

Specifies a property with which the tick is labeled. To change the text format or content, click ![icon] to display the Text Component Editor dialog box (page 1961).

Text Style

Specifies the style of the tick label text.

Rotation

Specifies the angle for the tick label. Enter a positive or negative value.The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

Specifies a horizontal offset for the tick label from the end of the tick.

Y Offset

Specifies a vertical offset for the tick label from the end of the tick.

## Minor Tick Details

Interval

Specifies the spacing of minor ticks on the vertical axis, using the actual ground units. Enter a positive value in ground units.

Tick Size

Specifies the length of the actual tick on the vertical axis, using plotted units. Enter a positive value in plotted units.

Tick Justification

Specifies whether the tick is justified Left, Right or Center.

Text Height

Specifies the height of text used to label minor ticks on the vertical axis, using plotted units. Enter a positive value in plotted units.

Tick Label Text

Specifies a property with which the tick is labeled. To change the text format or content, click ![icon] to display the Text Component Editor dialog box.

Text Style

Specifies the style of the tick label text.

Rotation

Specifies the angle for the tick label. Enter a positive or negative value. The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

Specifies a horizontal offset for the tick label from the end of the tick.

Y Offset

Specifies a vertical offset for the tick label from the end of the tick.

# Display Tab (Section View Style Dialog Box)

Use this tab to edit settings for the visibility and format styles of section view components, such as titles, axes annotations, tick marks, and grid options.

For more information, see Display Tab (Style Dialog Box) (page 1801).

# Summary Tab (Section View Style Dialog Box)

Use the Summary tab to edit settings for the section style.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Select Page Layout Dialog Box

Use this dialog box to select a page layout for the sheet style.

Specifies the default page layout format. Select a page layout format from the list. Click OK.

## Page Setups

Default (Layout)

Plots section views on a sheet using the Default (Layout) format.

Default (Model)

Plot section views on a sheet using the Default (Model) format.

For more information about the sheet style, see Sheet Style Dialog Box (page 2296).

# Sheet Properties Dialog Box

Use this dialog box to edit properties of a sheet used for multiple section views.

Select an object style; and create, copy, edit or pick a sheet style for your section view sheets.

Name

Specifies the name of the sheet.

Description

Specifies the optional description of the sample line.

Object Style

Specifies the name of the style used by the sheet. Select an object style in the list.

Creates, copies, or edits a style using the Sheet Style dialog box (page 2296). Click the down arrow to display the style selection menu:

- **Create New**: Creates a new style.

- **Copy Current Selection**: Copies the current style.

- **Edit Current Selection**: Edits the current style.

- **Pick From Drawing**: Prompts you to select a style directly from the drawing. The selected style becomes the current style.

Displays details about an existing style. Select the style by name in the list. Click to open the Style Detail dialog box (page 1804). Preview the style and creation information.

**Related procedures:**

- Creating and Editing Section Views (page 1152)

# Sheet Style Dialog Box

Use this dialog box to edit settings that define a sheet style, which controls the way a section sheet is displayed in a drawing.

**See also:**

- Creating and Editing Section View Styles (page 1133)

## Information Tab (Sheet Style Dialog Box)

Use this tab to display administrative data and edit primary information about the sheet style, such as its name and description.

Name

Specifies the name of the selected sheet style.

Description

Specifies the optional description of the selected sheet style.

## Sheet Tab (Sheet Style Dialog Box)

Use this tab to edit settings for the visibility and format styles of sheet components, such as page layout, margins, and plot area grid details.

Page Layout

Specifies the default page layout format. Select a page layout format from the list.

**Page Margins**

Top

Specifies the top page margin in plotted units. Enter a positive value in plotted units.

Bottom

Specifies the bottom page margin in plotted units. Enter a positive value in plotted units.

Left

Specifies the left page margin in plotted units. Enter a positive value in plotted units.

Right

Specifies the right page margin in plotted units. Enter a positive value in plotted units.

**Plot Area Grid Details**

Horizontal Major

Specifies the horizontal major grid line interval in plotted units. Enter a positive value in plotted units.

Horizontal Minor

Specifies the horizontal minor grid line interval in plotted units. Enter a positive value in plotted units.

Vertical Major

Specifies the vertical major grid line interval in plotted units. Enter a positive value in plotted units.

Vertical Minor

Specifies the vertical minor grid line interval in plotted units. Enter a positive value in plotted units.

## Display Tab (Sheet Style Dialog Box)

Use this tab to edit settings for the visibility and format styles of sheet components, such as grids, print area, and sheet border.

For more information, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Sheet Style Dialog Box)

Use this tab to edit settings for the sheet style.

To edit settings, click the Page Layout cell. Click  to open the Select Page Layout dialog box (page 2295).

For more information, see Summary Tab (Style Dialog Box) (page 1803).

# Material Analysis Dialog Boxes

# 68

The following topics provide information about the Quantity Takeoff and Mass Haul dialog boxes.

## Change Volume Table Dialog Box

Use this dialog box to change volume table(s) in the drawing.

Use the following controls to specify the volume table types to draw:

Type
  Specifies the type of the volume table(s).

Select Table Style
  Specifies the style of the volume table. Standard buttons are also provided to create or edit a label style.

Add >>
  Adds a volume table to the list.

### List Of Volume Tables

Table Type
  Displays the current table type.

Style
  Specifies the name of the table style that was added using the Select Table Style list. To change the style, click in this column to open the Select Style dialog box (page 1805). Select a band style in the list or use the standard controls to either create a new style, copy or edit the current style selection, or pick a style from the drawing.

Material List
  Specifies the material list for the volume table.

Materials
  Click  to specify the materials for the volume table.

Layer
  Specifies the drawing layer that contains the sampled source.

Split

Specifies whether the layer is split.

Gap

Specifies the distance in plotted units between the current data band and the previous data band (or the nearest section view axis). Enter a positive gap value in plotted units.

Reactivity Mode

Specifies the type of update mode for the section. Select Dynamic to specify that the section data updates dynamically when either the position of the sample line associated with the section changes or the data source (surface, corridor, or pipe) geometry changes.

**Position Of Table(s) Relative To Section View**

Section View Anchor

Specifies the section view anchor (Top/Middle/Bottom, Left/Center/Right).

Table Anchor

Specifies the location of the table anchor (Top/Middle/Bottom, Left/Center/Right).

Table Layout

Specifies whether the layout of the tables is horizontal or vertical, in relation to the section view.

X Offset

Specifies the distance, in plotted units, to move the title away from the position set by the table anchor. Enter a positive number to move the title right, or a negative number to move it left.

Y Offset

Specifies the distance, in plotted units, to move the title away from the position set by the table anchor. Enter a positive number to move the title up, or a negative number to move it down.

**Related procedures:**

■  Creating/Editing Section Views (page 1153)

# Compute Materials Dialog Box

Use this dialog box to create material lists for a sample line group.

Quantity Takeoff Criteria

Specifies the criteria to use. Select from the list or click  to edit or create a criteria.

Curve Correction Tolerance

Specifies whether curve tolerance is used. If selected, enter a value for the curve tolerance in the adjacent field.

Map Objects With Same Name

Maps criteria surface or corridor shape names with surface or corridor shape names in the drawing that are the same.

The Properties table contains the following columns:

Name In Criteria

Displays the surface and corridor shape names that are used in the criteria.

Object Name

Specifies the actual object name to map to the surface or corridor shape name in the criteria.

Material Name

Displays the material name that is referenced by the corresponding surface or corridor shape in the list.

**Related procedures:**

■ Analyzing Sectional Volumes (page 1168)

# Create Mass Haul Diagram Wizard

Use this wizard to create mass haul diagrams.

---

**NOTE** A material list must be created for the drawing before a mass haul diagram can be created. For information about how to create a material list, see Generating Material Lists (page 1163).

---

## General Page (Create Mass Haul Diagram Wizard)

Use this page to specify basic information about the mass haul diagram, including the parent alignment and sample line group, mass haul view name, description, style, and layer.

Select Alignment

Specifies the name of the parent horizontal alignment. Select a name from the list or click ![icon] to pick an alignment from the drawing.

Sample Line Group

Specifies the parent sample line group. Select a name from the list or click ![icon] to pick an alignment from the drawing.

Mass Haul View Name

Specifies a system-generated name that you can edit. The name must remain unique within the drawing.

Click ![icon] to open the Name Template dialog box (page 1806), where you can modify the material naming template.

Description

Specifies an optional description of the mass haul diagram.

Mass Haul View Style

Specifies the style for the mass haul view. Use the standard controls to review or change the style.

Mass Haul View Layer

Specifies the drawing layer for the mass haul view. To review or change layer data, click ![icon] .

**Related procedures:**

■ Creating Mass Haul Diagrams (page 1174)

## Mass Haul Display Options Page (Create Mass Haul Diagram Wizard)

Use this page to specify mass haul diagram display options.

### Material

Material List

Specifies the material list for the mass haul diagram.

Choose A Material To Display As Mass Haul Line

Specifies the material to display as the mass haul line. Select from Total Volume, Total Cut Volume, Total Fill Volume, Total Unusable Volume, and materials specific to the material list you have selected.

**Mass Haul Line**

Mass Haul Line Name

Specifies a system-generated name that you can edit. The name must remain unique within the drawing.

Description

Specifies an optional description of the mass haul diagram.

Mass Haul Line Style

Specifies the style for the mass haul line. Use the standard controls to review or change the style.

Mass Haul Line Layer

Specifies the drawing layer for the mass haul line. To review or change layer data, click  .

**Related procedures:**

■ Creating Mass Haul Diagrams (page 1174)

# Balancing Options Page (Create Mass Haul Diagram Wizard)

Use this page to set free haul distance, and borrow pit/dump site properties for the mass haul diagram.

Use the following controls to specify the free haul distance and type, location and capacity of borrow pits/dump sites:

**Free Haul Options**

Free Haul Distance

Select this option to set a free haul distance value. If the option is cleared, no free haul distance is assigned to the mass haul diagram. If you select the option, you can either accept the default or set your own free haul distance in the field below.

**Add/Remove Borrow Pits And Dump Sites**

Add Borrow Pit

Click to add a borrow pit to the list.

Add Dump Site

Click to add a dump site to the list.

Deletes any selected borrow pit or dump site from the list.

**List**

Type

Specifies whether the balancing feature is a borrow pit or a dump site. Click in this field to change the type of balancing feature.

Station

Specifies the station at which the borrow pit or dump site will be located. The station can be specified either by entering a station value or selecting the station in the viewport. When you select the station in the viewport, you must select it from a point along the alignment in the plan view, and not along the X axis of the mass haul view.

Capacity
>Specifies the volume to be borrowed or dumped at the borrow pit or dump site.

**Related procedures:**

■ Creating Mass Haul Diagrams (page 1174)

# Create Material Volume Table Dialog Box

Use this dialog box to create a table in the drawing that contains volume data for a specific material in a material list.

Most of the controls in this dialog box are generic table creation controls. For more information, see Table Creation Dialog Box (page 2441).

Use the following controls to specify the materials information to be included in the material volume table:

Select Alignment

>Specifies the alignment. Select an alignment from the list or click  to select an alignment in the drawing. The alignments in the list are associated with at least one sample line group.

Select Sample Line Group
>Specifies the sample line group to use. Select a group from the list.

Select Material List
>Specifies which material list defined in the sample line group properties is used.

Select A Material
>Specifies which material from the material list is used to generate the table.

**Related procedures:**

■ Analyzing Sectional Volumes (page 1168)

# Create Total Volume Table Dialog Box

Use this dialog box to create a table in the drawing using volume data from material list for a sample line group.

Most of the controls in this dialog box are generic table creation controls. For a description of these controls, see Table Creation Dialog Box (page 2441).

Use the following controls to specify the materials information to be included in the total volume table:

Select Alignment

>Specifies the alignment. Select an alignment from the list or click  to select an alignment in the drawing. The alignments in the list are associated with at least one sample line group.

Select Sample Line Group
>Specifies the sample line group to use. Select a group from the list.

Select Material List
>Specifies which material list defined in the sample line group properties is used.

**Related procedures:**

■ Analyzing Sectional Volumes (page 1168)

# Define Material Criteria Dialog Box

Use this dialog box to define quantity takeoff criteria from a sample line group.

Select Alignment

Specifies the alignment. Click  to select an alignment in the drawing.

Select Sample Line Group

Specifies the sample line group to use. Select a group from the list.

Select Surfaces

Displays the available surfaces from which sections are to be cut. Select the check box next to surface to use it to define a criteria material.

**NOTE** At least two surfaces must be selected. Surfaces selected are compared at each station and the enclosed areas at each cross section are added as a material type to the criteria.

**Related procedures:**

■ Creating Quantity Takeoff Criteria (page 1165)

# Edit Feature Settings - Mass Haul Line Dialog Box

Use this dialog box to view and change standard drawing ambient settings for mass haul line.

The standard ambient settings are preceded with  . For feature-specific Mass Haul Line Style and Mass Haul Line Name Template information, see Edit Feature Settings - Mass Haul View Dialog Box (page 2304).

For more information about this dialog box, see Working with the Standard Settings Dialog Box Controls (page 62).

**Related procedures:**

■ Editing Mass Haul Line Settings (page 1178)

# Edit Feature Settings - Mass Haul View Dialog Box

Use this dialog box to view and change mass haul view settings.

This topic documents settings in all mass haul-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

■ Drawing-level ambient settings are identified by the  drawing icon.

■ Mass haul feature settings are listed near the top of this dialog box, after the General property group, and are identified by the  mass haul view icon.

■ Mass haul command settings are identified by the  command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

### ⌁ Default Styles

Use these settings to specify the default styles for mass haul components.

Mass Haul Line Style

Specifies the default style used for mass haul lines. Click in the Value column, and click ⊡ to select a style in the Mass Haul Line Style dialog box.

Mass Haul View Style

Specifies the default style used for mass haul views. Click in the Value column, and click ⊡ to select a style in the Mass Haul View Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

### ⌁ Default Name Format

Use these settings to specify the default name format for new mass haul lines and new mass haul views.

Click in the Value column, and click ⊡ to make changes in the Name Template dialog box (page 1806).

### ⌁ Mass Haul Creation

Use these standard table settings, which are available when accessing the settings from the CreateMassHaul command, to establish the default settings when you create a mass haul diagram.

Analyze Free Haul
Specifies whether the free haul distance is analyzed.

Free Haul Distance
Specifies the free haul distance.

Borrow Pit Capacity
Specifies the capacity of a borrow pit.

Dump Site Capacity
Specifies the capacity of a dump site.

**Related procedures:**

■ Editing Mass Haul View Settings (page 1179)

## Edit Feature Settings - Quantity Takeoff Dialog Box

Use this dialog box to view and change quantity takeoff-related settings.

This topic documents settings in all quantity takeoff-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

■ Drawing-level ambient settings are identified by the ⬚ drawing icon.

■ Quantity takeoff feature settings are listed near the top of this dialog box, after the General property group, and are identified by the ⊞ quantity takeoff icon.

■ Quantity takeoff command settings are identified by the ⊞ command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

## Default Styles

Use this setting to establish the default quantity takeoff criteria and styles assigned to quantity takeoff components.

Quantity Takeoff Criteria
Specifies the default quantity takeoff criteria when creating a quantity takeoff report. Click in the Value column, and click ⋯ to select criteria in the Quantity Takeoff Criteria dialog box.

Material Shape Style
Specifies the default style used for a material section when it is displayed in a section view. Click in the Value column, and click ⋯ to select a style in the Material Shape Style dialog box.

For information about style selection, see Select Style Dialog Box (page 1805).

## Default Name Format

Use these settings to specify the default name format for new quantity takeoff material lists and materials. Click in the Value column, and click ⋯ to make changes in the Name Template dialog box (page 1806).

## Table Creation

**NOTE** This property group is displayed when you access the settings from the AddMaterialVolumeTable and AddTotalVolumeTable commands.

Use these settings to establish the defaults when you add a volume table.

Table Style

Specifies the style for a table. Click in the Value column, and click ⋯ to select a style in the Table Style dialog box.

Split Table
Specifies whether a table is split into two or more sections after a specified maximum number of rows has been met.

Maximum Number of Rows
Specifies the maximum number of rows to include per section. If the number of data rows exceeds the specified maximum, the table is split into sections, and they are displayed either side by side (left to right), or stacked vertically.

Maximum Tables Per Stack
Specifies the maximum number of sections to include in each stack.

Table Spacing
Specifies the spacing between tables.

Tile Direction
Specifies the direction in which the table tiles (across or down).

## Define Materials Options

**NOTE** This property group is displayed when you access the settings from the ComputeMaterials and GenerateQuantitesReport commands.

Use these settings to establish the default settings when you create a new quantity takeoff report.

Apply Curve Correction

Specifies whether curve correction is used when the Curve Correction Tolerance value is exceeded. Curve correction may be required to correct volume calculations within a curvilinear section of an alignment (or on two sides of a horizontal intersection point).

Curve Correction Tolerance

Specifies the curve tolerance value. If the sample lines are within the tolerance or if the angle of deflection between the successive stations is small, then curve correction is not used. Enter an angle in degrees in the Value column or click  and select an angle in the drawing area.

 **Quantity Report Options**

**NOTE** This property group is displayed when you access the settings from the GenerateQuantitesReport command.

Use these settings to establish the default settings when you create a new quantity takeoff report.

Display XML Report

Specifies whether XML reports are displayed by default when you generate a quantity takeoff report.

# Edit Material List Dialog Box

Use this dialog box to review the material lists for a sample line group and add or delete materials from a list.

Add New Material

Adds a new empty material to a list. After you add the material, you can edit its type and settings and use the Define Material fields to populate it with data.

Opens the Name Template dialog box (page 1806), where you can modify the material naming template.

**Define Material**

Data Type

Specifies the type of data that is compared and processed when defining the material. Either Surface or Corridor Shape.

Select Surface/Corridor Shape

Lists the available surfaces or corridor shapes in the drawing. Select a surface or corridor shape or enter a surface or corridor shape name.

**NOTE** Corridor shapes can be added only to a material with a Structure quantity type.

Adds the data specified in the Define Material fields to the selected material name.

**NOTE** If a material is not selected, the data is not added.

Deletes the material or data component that is currently selected in the Material Name column.

**Material List**

The properties table contains the following columns:

**Material Name**

Specifies the material lists and names. Each instance of applying criteria to materials in a sample line group is added as a numbered list. List names can be edited.

Click ⊞ next to a list name to display its components (materials).Click ⊞ next to a material name to display its components (surfaces or structures).

**Condition**

Specifies the condition on which to base the calculation:

- **Above**. Specifies that an area above this surface is included in the material definition. Used with Below to define two or more surfaces for cut, fill, and structures material types.

- **Below**. Specifies that an area below this surface is included in the material definition. Used with Above to define two or more surfaces for cut, fill, and structures material types.

- **Base**. Specifies that this surface is the surface to compare against the compare surface. Used with Compare to define two or more surfaces for earthworks or cut and fill material types.

- **Compare**. Specifies that this surface is the surface to compare against the base surface. Used with Base to define two or more surfaces for earthworks or cut and fill material types.

- **Include**. Specifies a corridor shape that is included in the structure type definition.

**Quantity Type**

Specifies the quantity type:

- **Cut**. Calculates the material to remove.

- **Fill**. Calculates the material to add.

- **Cut And Refill**. Defines an area in the section where a material is removed and refilled with fill material.

- **Earthworks**. Compares two surfaces to calculate both cut and fill areas and displays them separately.

- **Structures**. Calculates the volume of one or more corridor shapes (as defined by the shape codes that are used to define the corridor). For information about shape codes, see Understanding Point, Link, and Shape Codes (page 1406).

**Cut Factor**

Specifies the expansion or swell of the cut material.

**Fill Factor**

Specifies the contraction or shrinkage of the fill material.

**Refill Factor**

Specifies usability factor used to calculate how much cut material can be reused as fill.

**Shape Style**

Specifies the default style used to display the material in a section view.

**Curve Tolerance**

Specifies the curve correction tolerance, if any, that was specified when the criteria was applied. To edit the value, select the check box, and then edit the value. Used only for List entries.

**Import Another Criteria**

Prompts you to define a new materials list for the sample line group. Opens the Compute Materials dialog box after you select a criteria.

**Related procedures:**

- Generating Material Lists (page 1163)

# Mass Haul Line Properties Dialog Box

Use this dialog box to edit mass haul line properties.

Mass haul line information can be viewed, but not edited, from the Mass Haul Line Data Tab (Mass Haul Line Properties Dialog Box).

## Information Tab (Mass Haul Line Properties Dialog Box)

Use this tab to edit the name, description, or object style of a mass haul diagram.

Name
  Specifies the name of the mass haul line.

Description
  Specifies the optional description of the mass haul line.

Object Style
  Specifies the name of the style used by the mass haul line.

  Creates, copies, or edits a style using the Mass Haul Line Style dialog box. Click the Down arrow to display the style selection menu:

  ■ **Create New**: Creates a new style.

  ■ **Copy Current Selection**: Copies the current style.

  ■ **Edit Current Selection**: Edits the current style.

  ■ **Pick From Drawing**: Prompts you to select a style directly from the drawing. The selected style becomes the current style.

  Displays details about an existing style. Select the style name in the list. Click to open the Style Detail dialog box (page 1804). Preview the style and creation information.

**Related procedures:**

■ Editing Mass Haul Line Properties (page 1175)

## Mass Haul Line Data Tab (Mass Haul Line Properties Dialog Box)

Use this tab to specify mass haul line data.

Material List Name
  Displays the name of the material list for the mass haul line.

Material Name
  Displays the material name that is referenced by the mass haul line.

Alignment Name
  Displays the name of the parent alignment of the mass haul line.

Sample Line Group

Displays the name of the parent sample line group.

**Related procedures:**

■ Editing Mass Haul Line Properties (page 1175)

## Balancing Options Tab (Mass Haul Line Properties Dialog Box)

Use this page to set free haul distance, and borrow pit/dump site properties for the mass haul diagram.

Use the following controls to specify the free haul distance and type, location, and capacity of borrow pits/dump sites:

### Free Haul Options

Free Haul Distance

Select this option to enter a free haul distance value in the field below. If the option is cleared, the free haul distance is set to its default.

### Add/Remove Borrow Pits and Dump Sites

Add Borrow Pit

Click to add a borrow pit to the list.

Add Dump Site

Click to add a dump site to the list.

✖

Deletes any selected borrow pit or dump site from the list.

### List

Type

Specifies whether the balancing feature is a borrow pit or a dump site. Click in this field to change the type of balancing feature.

Station

Specifies the station at which the borrow pit or dump site will be located.

Capacity

Specifies the volume either to be borrowed or dumped at the borrow pit or dump site.

**Related procedures:**

■ Editing Mass Haul Line Properties (page 1175)

## Mass Haul Line Style Dialog Box

Use this dialog box to define a mass haul line style, which controls the way a mass haul line is displayed in a drawing.

On the Display tab, you can use the ByLayer or ByBlock reference settings to set Color, Linetype, Lineweight, and Plot Style values. Reference settings are indirect and require some planning.

# Information Tab (Mass Haul Line Style Dialog Box)

Use this tab to display administrative data and edit primary information about the mass haul line style, such as its name and description.

This tab also contains information about who created or modified the mass haul line style and the date the style was created or modified. The following fields can be modified:

Name

Specifies the name of the selected mass haul line style.

Description

Specifies an optional description of the selected mass haul line style.

**Related procedures:**

■ Editing Mass Haul Line Styles (page 1177)

# Free Haul Tab (Mass Haul Line Style Dialog Box)

Use this tab to specify how you want to show free haul in graph.

Use the following controls to specify how free haul is graphed:

**Free Haul Options**

Measure From Grade Point

Select this option to show the free haul distance as measured from grade point in the mass haul diagram.

Measure From Balance Point

Select this option to show the free haul distance as measured from balance point in the mass haul diagram.

**Related procedures:**

■ Editing Mass Haul Line Styles (page 1177)

# Display Tab (Mass Haul Line Style Dialog Box)

Use this tab to edit settings for the visibility and format styles of mass haul line components, such as mass haul and free haul lines, and mass haul and free haul area hatch.

For more information, see Display Tab (Style Dialog Box) (page 1801).

**Related procedures:**

■ Editing Mass Haul Line Styles (page 1177)

## Summary Tab (Mass Haul Line Style Dialog Box)

Use this tab to edit settings for the mass haul line style.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

**Related procedures:**

■ Editing Mass Haul Line Styles (page 1177)

# Mass Haul View Properties Dialog Box

Use this dialog box to edit mass haul view properties.

Mass haul line information can be viewed, but not edited, from the Mass Haul Line Data Tab (Mass Haul View Properties Dialog Box).

# Information Tab (Mass Haul View Properties Dialog Box)

Use this tab to edit the name, description, or object style of a mass haul view.

Name
   Specifies the name of the mass haul view.

Description
   Specifies the optional description of the mass haul view.

Object Style
   Specifies the name of the style used by the mass haul view.

   Creates, copies, or edits a style using the Mass Haul View Style dialog box. Click the Down arrow to display the style selection menu:

   ■ **Create New**: Creates a new style.

   ■ **Copy Current Selection**: Copies the current style.

   ■ **Edit Current Selection**: Edits the current style.

   ■ **Pick From Drawing**: Prompts you to select a style directly from the drawing. The selected style becomes the current style.

   Displays details about an existing style. Select the style name from the list. Click to open the Style Detail dialog box (page 1804). Preview the style and creation information.

**Related procedures:**

■ Editing Mass Haul View Properties (page 1176)

# Mass Haul Line Tab (Mass Haul View Properties Dialog Box)

Use this tab to specify mass haul line data.

Mass Haul Line Name
   Displays the name of the mass haul line.

Alignment Name

Displays the name of the parent horizontal alignment.

Sample Line Group

Displays the name of the parent sample line group.

Material List Name

Displays the name of the material list for the mass haul line.

Material Name

Displays the material name that is referenced by the mass haul line.

**Mass Haul Line Display Options**

Mass Haul Line Display Style In This View

Specifies the name of the style used by the mass haul line in this view.

Creates, copies, or edits a style using the Mass Haul Line Style dialog box. Click the Down arrow to display the style selection menu:

■ **Create New**: Creates a new style.

■ **Copy Current Selection**: Copies the current style.

■ **Edit Current Selection**: Edits the current style.

■ **Pick From Drawing**: Prompts you to select a style directly from the drawing. The selected style becomes the current style.

Displays details about an existing style. Select the style name from the list. Click to open the Style Detail dialog box (page 1804). Preview the style and creation information.

**Related procedures:**

■ Editing Mass Haul View Properties (page 1176)

# Mass Haul View Style Dialog Box

Use this dialog box to define a mass haul view style, which controls the way a mass haul view is displayed in a drawing.

You can change the mass haul view graph, grid, title, axes ticks, and text. Select which elements to display.

# Information Tab (Mass Haul View Style Dialog Box)

Use this tab to display administrative data and edit primary information about the mass haul view style, such as its name and description.

This tab also contains information about who created or modified the mass haul view style and the date of these events. The following fields can be modified:

Name

Specifies the name of the selected mass haul view style.

Description

Specifies the optional description of the selected mass haul view style.

**Related procedures:**

- Editing Mass Haul View Styles (page 1178)

# Graph Tab (Mass Haul View Style Dialog Box)

Use this tab to edit settings for vertical scale.

### Vertical Scale

Vertical Scale

Specifies the vertical scale ratio. Standard ratios run from 1″ = 1′ to 1″ = 100′. Specifying a number in the Custom Scale field sets the scale to Custom.

Custom Scale

Specifies a custom vertical scale ratio.

Current Horizontal Scale

Displays the current horizontal scale from drawing settings.

Vertical Exaggeration

Displays a value specifying the increase in the elevation values in the mass haul view. The vertical exaggeration is equal to the current horizontal scale divided by the vertical scale.

### Mass Haul View Direction

Specifies the direction of the mass haul line for the mass haul view grid:

**Left To Right**

The mass haul view is drawn with either 0 or the lowest station number on the left the highest station number on the right.

**Right To Left**

The mass haul view is drawn with the highest station number on the left and either 0 or the lowest station number on the right.

**Related procedures:**

- Editing Mass Haul View Styles (page 1178)

# Grid Tab (Mass Haul View Style Dialog Box)

Use this tab to specify clipping, padding, and axis offset options on the mass haul view grid.

## Grid Options

Clip Vertical Grid

Specifies that vertical grid lines are drawn only between the mass haul line and the balancing line. Select **Omit Grid In Padding Areas** to specify that vertical grid lines are not drawn in the padding areas.

Clip Horizontal Grid

Specifies that horizontal grid lines are drawn only between the mass haul line and the balancing line. Select **Omit Grid In Padding Areas** to specify that horizontal grid lines are not drawn in the padding areas.

## Grid Padding

Grid Padding (Major Grids)

Specifies a value (in major grid blocks) that adds to the extents of the mass haul view in relation to the mass haul line it contains. This creates a graph that is taller than the extents of the mass haul line drawn in the mass haul view.

Above Maximum Point On Graph

Specifies the number of grid blocks that extend the mass haul view above the maximum point on the graph. This creates a graph that is taller than the extents of the mass haul line.

Below Minimum Point On Graph

Specifies the number of grid blocks that extend the mass haul view below the minimum point on the graph. This creates a graph that extends lower than the extents of the mass haul line.

To Left

Specifies the number of major grids to place before the left-most station value of the alignment. This creates a graph that is wider than the extents of the mass haul line.

To Right

Specifies the number of major grids to place after the right-most station value of the alignment. This creates a graph that is wider than the extents of the mass haul line.

## Axis Offset

NOTE  The axis offset distance is specified in plotted units, based on the Drawing Units and Scale settings specified on the Units and Zone tab (page 1851) of the Drawing Settings dialog box.

Axis Offset (Plotted Units)

Specifies the distance (in plotted units) to offset the mass haul view's horizontal and vertical axes from the grid extents (including padding). This creates a blank area between the axis and the grid.

Above Maximum Point On Graph

Specifies the distance to offset the horizontal axis above the vertical extent.

**Below Minimum Point On Graph**

Specifies the distance to offset the horizontal axis below the vertical extent.

**To Left**

Specifies the distance to offset the horizontal axis to the left of the horizontal extent.

**To Right**

Specifies the distance to offset the horizontal axis to the right of the horizontal extent.

**Related procedures:**

■ Editing Mass Haul View Styles (page 1178)

# Title Annotation Tab (Mass Haul View Style Dialog Box)

Use this tab to specify settings for the graph view and axis titles.

## Graph View Title

**Text Style**

Specifies the text style for the section view title.

**Text Height**

Specifies the current text height in drawing units.

**Title Content**

Specifies the text elements used to compose the title. Click ![icon] to open the Text Component Editor dialog box (page 1961), where you can change title format or content.

## Title Position

These controls specify the position of the mass haul view title. Use Location and Justification settings for basic positioning, then X and Y offsets for more precise placement, if necessary.

**Location**

Specifies the location of the title in relation to the mass haul view grid, either: Top, Bottom, Right, or Left.

**Justification**

Specifies the justification (alignment) of the title. If Location is Top or Bottom, justification values are Left, Center, or Right. If Location is Right or Left, justification values are Bottom, Middle, or Top.

**X Offset**

Specifies a horizontal offset from the position set by the Location and Justification values. Enter a positive number to move the title right or a negative number to move it left.

**Y Offset**

Specifies a vertical offset from the position set by Location and Justification values. Enter a positive number to move the title up or a negative number to move it down.

**Border Around The Title**

Specifies whether a border line is drawn around the title block.

**Gap**

Specifies the distance between the title and its border.

## Axis Title Text

Separate titles may be displayed at each of the axes. Use the radio buttons to select the axis title to edit. Configure title settings and click Apply. Repeat that process with each axis title.

**NOTE** The Axis Title selections do not control axis title visibility. Visibility controls for all section components are located on the Display tab.

Axis Title Text

Specifies which axis title is being controlled by the text editing tools.

Title Text

Specifies the title text for the horizontal axis. Click  to open the Text Component Editor dialog box (page 1961), where you can change title format or content.

Location

Specifies the location of the title on the axis, either: Left, Center, or Right. For more precise control, use the X and Y offsets.

Rotation

Specifies the angle for the title. Enter a positive or negative value. The angle direction is always counterclockwise. If the value is zero (0), the title is not rotated.

Text Style

Specifies a text style for use in the horizontal axis title.

Text Height

Specifies the title text height (in plotted units).

X Offset

Specifies a horizontal offset from the Location setting. Enter a positive number to move the title right or a negative number to move it left.

Y Offset

Specifies a vertical offset from the Location setting. Enter a positive number to move the title up or a negative number to move it down.

**Related procedures:**

■ Editing Mass Haul View Styles (page 1178)

## Horizontal Axes Tab (Mass Haul View Style Dialog Box)

Use this tab to edit settings for the mass haul view style, such as the title format, use of tick marks, and annotations on the horizontal axes of the section view.

After you configure horizontal axis title and tick details, click Apply. Later, you can change the Select Axis setting and configure another axis on the opposite side of the grid.

Select Axis To Control

Click either Top, Middle, or Bottom to select that axis.

**Major Tick Details**

Interval

Specifies the spacing of major ticks on the horizontal axis, using the actual ground units. Enter a positive value in ground units.

Tick Size

Specifies the height of the actual tick on the horizontal axis, using plotted units. Enter a positive value in plotted units.

Tick Justification

Specifies whether the tick is justified, either: Top, Bottom, or Center.

Text Height

Specifies the height of text used to label major ticks on the horizontal axis, using in plotted units. Enter a positive value in plotted units.

Tick Label Text

Specifies a property with which the tick is labeled. Click ![icon] to open the Text Component Editor dialog box (page 1961), where you can change text format or content.

Text Style

Specifies the style of the tick label text.

Rotation

Specifies the angle for the tick label. Enter a positive or negative value.The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

Specifies a horizontal offset for the tick label from the bottom of the tick.

Y Offset

Specifies a vertical offset for the tick label from the bottom of the tick.

## Minor Tick Details

Interval

Specifies the spacing of minor ticks on the horizontal axis, using the actual ground units. Enter a positive value in ground units.

Tick Size

Specifies the height of the actual tick on the horizontal axis, using plotted units. Enter a positive value in plotted units.

Tick Justification

Specifies whether the tick is justified, either: Top, Bottom or Center.

Text Height

Specifies the height of text used to label minor ticks on the horizontal axis, using plotted units. Enter a positive value in plotted units.

Tick Label Text

Specifies a property with which the tick is labeled. Click ![icon] to open the Text Component Editor dialog box, to change the text format or content.

Text Style

Specifies the style of the tick label text.

Rotation

Specifies the angle for the tick label. Enter a positive or negative value.The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

Specifies a horizontal offset for the tick label from the bottom of the tick.

Y Offset

Specifies a vertical offset for the tick label from the bottom of the tick.

**Horizontal Geometry Tick Details**

Tick Size

Specifies the height of the actual tick on the horizontal axis, using plotted units. Enter a positive value in plotted units.

Tick Justification

Specifies whether the tick is justified, either: Top, Bottom or Center.

Text Height

Specifies the height of text used to label minor ticks on the horizontal axis, using plotted units. Enter a positive value in plotted units.

Tick Label Text

Specifies a property with which the tick is labeled. Click ![icon] to open the Text Component Editor dialog box, to change the text format or content.

Text Style

Specifies the style of the tick label text.

Rotation

Specifies the angle for the tick label. Enter a positive or negative value. The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

Specifies a horizontal offset for the tick label from the bottom of the tick.

Y Offset

Specifies a vertical offset for the tick label from the bottom of the tick.

**Related procedures:**

■  Editing Mass Haul View Styles (page 1178)

# Vertical Axes Tab (Mass Haul View Style Dialog Box)

Use this tab to edit settings for the mass haul view style, such as the title location and format, use of tick marks, and annotations, on the vertical axis of the mass haul view.

After you configure vertical axis title and tick details, click Apply. Later, you can change the Select Axis setting and configure another axis on the opposite side of the grid.

Select Axis To Control

Click either Left or Right to select that axis.

**Major Tick Details**

Interval

Specifies the spacing of major ticks on the vertical axis. Enter a positive value in ground units.

Tick Size

Specifies the length of the actual tick on the vertical axis, using plotted units. Enter a positive value in plotted units.

Tick Justification

Specifies whether the tick is justified, either: Left, Right or Center.

Text Height

Specifies the height of text used to label major ticks on the vertical axis in plotted units. Enter a positive value in plotted units.

Tick Label Text

Specifies a property with which the tick is labeled. Click  to open the Text Component Editor dialog box (page 1961), where you can change text format or content.

Text Style

Specifies the style of the tick label text.

Rotation

Specifies the angle for the tick label. Enter a positive or negative value.The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

Specifies a horizontal offset for the tick label from the end of the tick.

Y Offset

Specifies a vertical offset for the tick label from the end of the tick.

## Minor Tick Details

Interval

Specifies the spacing of minor ticks on the vertical axis, using the actual ground units. Enter a positive value in ground units.

Tick Size

Specifies the length of the actual tick on the vertical axis, using plotted units. Enter a positive value in plotted units.

Tick Justification

Specifies whether the tick is justified, either: Left, Right or Center.

Text Height

Specifies the height of text used to label minor ticks on the vertical axis, using plotted units. Enter a positive value in plotted units.

Tick Label Text

Specifies a property with which the tick is labeled. Click  to open the Text Component Editor dialog box, to change the text format or content.

Text Style

Specifies the style of the tick label text.

Rotation

Specifies the angle for the tick label. Enter a positive or negative value.The angle direction is always counterclockwise. If the value is zero (0), the label is not rotated.

X Offset

Specifies a horizontal offset for the tick label from the end of the tick.

Y Offset

Specifies a vertical offset for the tick label from the end of the tick.

**Related procedures:**

■ Editing Mass Haul View Styles (page 1178)

## Display Tab (Mass Haul View Style Dialog Box)

Use this tab to edit settings for mass haul view components and format their styles, such as visibility and color.

For more information, see Display Tab (Style Dialog Box) (page 1801).

**Related procedures:**

■ Editing Mass Haul View Styles (page 1178)

## Summary Tab (Mass Haul View Style Dialog Box)

Use this tab to edit settings for the mass haul view style.

For more information, see Summary Tab (Style Dialog Box) (page 1803).

**Related procedures:**

■ Editing Mass Haul View Styles (page 1178)

# Quantity Takeoff Criteria Dialog Box

Use this dialog box to create and edit quantity takeoff criteria.

**See also:**

■ Creating Quantity Takeoff Criteria (page 1165)

## Information Tab (Quantity Takeoff Criteria Dialog Box)

Use this tab to view or change general information for the quantity takeoff criteria.

Name

Specifies the name of the quantity takeoff criteria.

Description

Specifies the description for the quantity takeoff criteria.

**Related procedures:**

■ Creating Quantity Takeoff Criteria (page 1165)

## Material List Tab (Quantity Takeoff Criteria Dialog Box)

Use this tab to define the quantity takeoff criteria.

Add New Material

Adds a new empty material to the list. After you add the material, you can edit its type and settings and use the Define Material fields to populate it with components that define the criteria for calculating volumes.

Opens the Name Template dialog box (page 1806), where you can modify the material naming template.

Deletes the material or data component that is currently selected in the Material Name column.

**Define Material**

Data Type

Specifies the type of data that is compared and processed when defining the material. Either Surface or Corridor Shape.

Select Surface/Shape

Lists sampled surfaces and corridor shapes for this sample line group. Select a surface or corridor shape. Surface and corridor shape names in the material criteria are mapped to actual surfaces and shapes when you generate the quantity takeoff report.

**NOTE** Corridor shapes can be added only to a material with a Structure quantity type.

Adds the data specified in the Define Material fields to the selected material name.

**NOTE** If a material is not selected, the data is not added.

The properties table contains the following columns:

Material Name

Specifies the material name. Click ⊞ next to the material name to display its components (surfaces).

Condition

Specifies the condition on which to base the calculation:

- **Above**. Specifies that an area above this surface is included in the material definition. Used with Below to define two or more surfaces for cut, fill, and structures material types.

- **Below**. Specifies that an area below this surface is included in the material definition. Used with Above to define two or more surfaces for cut, fill, and structures material types.

- **Base**. Specifies that this surface is the surface to compare against the compare surface. Used with Compare to define two or more surfaces for earthworks or cut and fill material types.

- **Compare**. Specifies that this surface is the surface to compare against the base surface. Used with Base to define two or more surfaces for earthworks or cut and fill material types.

- **Include**. Specifies a corridor shape that is included in the structure type definition.

Quantity Type

Specifies the quantity type:

- **Cut**. Calculates the material to remove.

- **Fill**. Calculates the material to add.

- **Cut and Refill**. Defines an area in the section where a material is removed and refilled with fill material.

- **Earthworks**. Compares two surfaces to calculate both cut and fill areas and displays them separately.

- **Structures**. Calculates the volume of one or more corridor shapes (as defined by the shape codes that are used to define the corridor). For information about shape codes, see Understanding Point, Link, and Shape Codes (page 1406).

Shape Style

Specifies the default style used to display the material in a section view.

Cut Factor

Specifies the expansion or swell of the cut material.

Fill Factor

Specifies the contraction or shrinkage of the fill material.

Refill Factor

Specifies usability factor used to calculate how much cut material can be reused as fill.

Define From A Sample Line Group

Specifies that criteria is defined from sections in a sample line group. Opens the Define Material Criteria dialog box (page 2304).

**Related procedures:**

■ Creating Quantity Takeoff Criteria (page 1165)

# Report Quantities Dialog Box

Use this dialog box to create external reports in XML using a material list for a sample line group.

Select Alignment

Specifies the alignment. Select an alignment from the list or click  to select an alignment in the drawing. The alignments in the list are associated with at least one sample line group.

Select Sample Line Group

Specifies the sample line group to use. Select a group from the list.

Select Material List

Specifies which material list defined in the sample line group properties is used to create the report.

Select A Style Sheet

Specifies the style sheet to use for the report. Enter the path and name or click  to open the Select Style Sheet dialog box where you can browse for the style sheet.

Display XML Report

Specifies whether to display an XML report for the quantity takeoff.

**Related procedures:**

■ Analyzing Sectional Volumes (page 1168)

# Select a Sample Line Group Dialog Box

Use this dialog box to select a sample line group from which to generate quantity takeoff information.

Select Alignment

Specifies the alignment. Click  to select an alignment in the drawing. The alignments in the list are associated with at least one sample line group.

Select Sample Line Group

Specifies the sample line group to use. Select a group from the list.

■ Generating Material Lists (page 1163)

# Select Materials Dialog Box

Use this dialog box to specify the materials for the volume table.

Materials

Select or clear the check boxes to specify the addition or removal of materials from the volume table.

# Sites Dialog Boxes

# 69

Use the following links to access information about the Sites dialog boxes.

## Site Properties Dialog Box

Use this dialog box to view or edit the general properties for a site.

**NOTE** You can set and view site parcel properties in the Site Parcel Properties (page 2015) dialog box.

**Related procedures:**

- Editing Site Properties (page 724)
- Creating a Site (page 723)

## Information Tab (Site Properties Dialog Box)

Use this tab to specify and edit the name and description for a site.

Name
Specifies the name of the site, which is used to identify the site topology collection under the Sites node in the Prospector tree.

Description
Specifies the description of the site topology collection.

**Related procedures:**

- Editing Site Properties (page 724)
- Creating a Site (page 723)

## 3D Geometry Tab (Site Properties Dialog Box)

Use this tab to define how alignments and parcel geometry should be displayed when viewed in 3D.

NOTE These settings apply only to geometry. The display properties are defined by the style that the objects reference.

**3D Geometry**

Site Display Mode

Specifies how a site's elevation is displayed in 3D:

- **Use Elevation**: Displays the site geometry at the actual elevation to which it was drawn.

- **Flatten To Elevation**: Displays the geometry flattened or projected to the elevation value specified by the Site Elevation property.

Site Elevation

Specifies the elevation used to flatten the geometry; enabled when the Site Display Mode property is set to Flatten To Elevation. All site geometry will be displayed at the specified elevation, regardless of the existing physical elevation of the geometry. The object elevations are not physically changed; they are only displayed at a single elevation.

Curve Tesselation: Mid-ordinate Distance

Specifies the mid-ordinate distance for the 3D polylines, which is used to tessellate the feature line and lot line arcs from which the polyline is being created.

**Construction Geometry**

Specifies the layers that construction geometry uses for 3D display.

When you create parcels or alignments, there may be solved and unsolved portions of the feature. The unsolved portion includes any unconnected elements of a feature.

For example, if you use the tan-tan method and create a number of lines, the whole feature is solved and the display characteristics are controlled by the parcel style. If you create some connected lines and then add a line that is not connected, the result is a piece of 'construction' geometry.

Construction Line Layer

Specifies the layer for line construction geometry. Click ⌶ to open the Layer Selection dialog box where you can select a layer.

Construction Arc Layer

Specifies the layer for arc construction geometry. Click ⌶ to open the Layer Selection dialog box where you can select a layer.

Construction Spiral Layer

Specifies the layer for spiral construction geometry. Not used.

**Related procedures:**

- Creating a Site (page 723)

- Editing Site Properties (page 724)

# Numbering Tab (Site Properties Dialog Box)

Use this tab to define how parcel and alignments components are numbered.

There are two numbering counters:

- **Automatic**. Used for numbering at creation time.

- **Manual**. Used when renumbering.

If you create a number of parcels at the same time, the Next Automatic Counter property is used to generate the starting number and the numbering automatically increments by one. For example, if the Next Automatic Counter is set to 100, the parcels would be numbered starting at 100. If you renumber the parcels, the renumbering is generated from the Next Manual Counter property. You can set the automatic and manual numbers to avoid collisions when renumbering.

### Parcels

Parcel: Next Automatic Area Counter

Specifies the starting number for new parcels to be created in the site. The numbering is incremented with creation of new parcels.

**TIP** Set this range sufficiently above the manual range to avoid collisions while renumbering manually.

Parcel: Next Manual Area Counter

Specifies the default starting number for renumbering parcels in the site. This value can also be edited in the parcel Renumbering dialog box.

**Related procedures:**

- Creating a Site (page 723)

- Editing Site Properties (page 724)

# Move To Site Dialog Box

Use this dialog box to move objects from one site to another. The contents of an entire site, including alignments, grading groups, or parcels, can be moved together.

**NOTE** If there is a naming conflict, duplicate objects must be deleted from the destination site prior to moving or copying sites or objects within a site. If duplicates objects occur, the names are automatically resolved. For example, if the destination site contains an Alignment - (1), it is renamed to Alignment - (1) (1).

Destination Site

Specifies the destination site. Select an existing site from the list, or click  to either pick a site in the drawing or create a new site, which is then returned and displayed in the list.

**NOTE** If only alignments are selected, accepting the default <None> selection places the alignments in the top-level Alignments collection in the Prospector. See Alignment and Site Interaction (page 721) for more information.

Selected Objects

Navigate in the data tree to view its subcomponents and expand the collections. The contents of the data tree are dependent on the commands entry point (that is, the location in the Prospector, or drawing, from which the command was invoked). Select or clear the check boxes to filter the objects that you want to move.

**NOTE** The check boxes have a tri-state display. If only some objects are selected under a collection, the check box is dimmed and not available.

**Related procedures:**

- Move Objects to a Site (page 726)

# Copy To Site Dialog Box

Use this dialog box to copy objects from one site to another. The contents of an entire site, including alignments, grading groups, or parcels, can be copied together.

**NOTE** If there is a naming conflict, duplicate objects must be deleted from the destination site prior to moving or copying sites or objects within a site. If duplicates objects occur, the names are automatically resolved. For example, if the destination site contains an Alignment - (1), it is renamed to Alignment - (1) (1).

Destination Site

Specifies the destination site. Select an existing site from the list, or click  to either pick a site in the drawing or create a new site, which is then returned and displayed in the list.

**NOTE** If only alignments are selected, accepting the default <None> selection places the alignments in the top-level Alignments collection in the Prospector. See Alignment and Site Interaction (page 721) for more information.

Selected Objects

Navigate in the data tree to view its subcomponents and expand the collections. The contents of the data tree are dependent on the commands entry point (that is, the location in the Prospector, or drawing, from which the command was invoked). Select or clear the check boxes to filter the objects that you want to copy.

**NOTE** The check boxes have a tri-state display. If only some objects are selected under a collection, the check box is dimmed and not available.

**Related procedures:**

■ Copy Objects to a Site (page 727)

# Surfaces Dialog Boxes

# 70

The following topics provide information about surfaces dialog boxes.

## Edit Feature Settings - Surface Dialog Box

Use this dialog box to view and change surface-related settings.

This topic documents settings in all surface-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

- Drawing-level ambient settings are identified by the drawing icon.

- Surface feature settings are listed near the top of this dialog box, after the General property group, and are identified by the surface icon.

- Surface command settings are identified by the command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

### Default Styles

Use these settings to specify the default styles assigned to surfaces and surface-related labels.

Surface Default Style

Specifies the default surface style (page 692). Click in the Value column, and click ⋯ to select a style in the Surface Default Style dialog box.

Marker Style

Specifies the default marker style. Click in the Value column, and click ⋯ to select a style in the Marker Style dialog box.

Surface Spot Elevation Label Style

Specifies the default spot elevation label style. Click in the Value column, and click ⋯ to select a style in the Surface Spot Elevation Label Style dialog box.

Surface Slope Label Style

Specifies the default slope label style. Click in the Value column, and click ⋯ to select a style in the Surface Slope Label Style dialog box.

Render Material

Specifies the default render material. Click in the Value column, and click ⋯ to select a render material in the Render Material dialog box (page 1810).

For information about style selection, see Select Style Dialog Box (page 1805).

## Default Name Format

Use this setting to specify the default name format for new surfaces. Click in the Value column, and click ⋯ to make changes in the Name Template dialog box (page 1806).

## Contour Labeling Defaults

Use these settings to specify the defaults assigned to surface labels.

Display Contour Label Line

Specifies whether or not the contour label lines are displayed.

Surface Contour Label Style Major

Specifies the default major contour label style. Click in the Value column, and click ⋯ to select a style in the Surface Contour Label Style Major dialog box.

Surface Contour Label Style Minor

Specifies the default minor contour label style. Click in the Value column, and click ⋯ to select a style in the Surface Contour Label Style Minor dialog box.

Surface Contour Label Style User-defined

Specifies the default user-defined contour label style. Click in the Value column, and click ⋯ to select a style in the Surface Contour Label Style User-defined dialog box.

## Surface Defaults

Default Rebuild -Automatic

Specifies Automatic as the default setting for the Rebuild Surface command.

## Add Contour Labeling

**NOTE** This property group is displayed when accessing the settings from the AddContourLabelingGroup command.

Use this setting to specify the defaults assigned to surface labels.

Interval Along Contour

Specifies the default distance between labels along the contour. Enter a value or click 🔲 to graphically select a distance in the drawing area.

## Import Options

**NOTE** This property group is displayed when accessing the settings from the AddSurfaceFromDemFile and CreateSurfaceGridFromDemFile commands.

Use these settings to specify the defaults assigned when creating surfaces.

Use Custom Null Elevation

Specifies whether a custom null elevation is used when importing a surface from a DEM file.

Null Elevation

Specifies the default custom null elevation used when importing a surface from a DEM file.

## Surface Creation

**NOTE** This property group is displayed when accessing the settings from the CreateSurface command.

Use these settings to specify the defaults assigned when creating surfaces.

Surface Default Type

Specifies the default surface type that is used when creating a surface. For more information, see Understanding Surfaces (page 599).

Grid Surface X-Spacing

Specifies the default value for a grid surfaces X spacing.

Grid Surface Y-Spacing

Specifies the default value for a grid surfaces Y spacing.

Grid Surface Orientation

Specifies the default orientation for a grid. Enter a value or click ![icon] to graphically select an orientation in the drawing area.

## Build Options

**NOTE** This property group is displayed (in different forms) when accessing the settings from the CreateSurface and CreateSurfaceGridFromDemFile commands.

Use these settings to specify the build options assigned when creating surfaces.

**NOTE** Use these settings when creating a surface, but not when importing a surface from LandXML, DEM, or TIN.

Copy Deleted Dependent Objects

Specifies whether a drawing object is copied to the surface definition item if the object is deleted.

Exclude Elevations Less Than

Specifies whether an elevation less than a certain value should be excluded when the surface is built.

Elevation <

Specifies the elevations to exclude when the Exclude Elevations Less Than property is set to Yes. Enter a value or click ![icon] to select an elevation in the drawing area.

Exclude Elevations Greater Than

Specifies whether an elevation greater than a certain value should be excluded when the surface is built.

Elevation >

Specifies the elevations to exclude when the Exclude Elevations Greater Than property is set to Yes. Enter a value or click ![icon] to select an elevation in the drawing area.

Use Maximum Triangle Length

Specifies whether the surface triangles that exceed the length specified by the Maximum Triangle Length property are removed from the boundary of the surface (CreateSurface command only).

Maximum Triangle Length

Specifies the triangle length to use when the Use Maximum Triangle Length property is set to Yes. Enter a value or click ![icon] to select a length in the drawing area (CreateSurface command only).

Convert Proximity Breaklines to Standard

Specifies whether proximity breaklines are converted to standard breaklines when the surface is built (CreateSurface command only).

Allow Crossing Breaklines

Specifies whether breaklines can cross each other (CreateSurface command only).

Elevation To Use

Specifies the elevation to use for the crossing breaklines (CreateSurface command only):

- **Use First Breakline Elevation At Intersection**: Uses the first breakline elevation to determine the elevation at the intersection.

- **Use Last Breakline Elevation At Intersection**: Uses the last breakline elevation to determine the elevation at the intersection.

- **Use Average Elevation At Intersection**: Uses the average of the first and last breakline to determine the elevation at the intersection.

For more information on these settings, see the Build properties in Definition Tab (Surface Properties Dialog Box) (page 2346).

## Water Drop Path

**NOTE** This property group is displayed when accessing the settings from the CreateSurfaceWaterdrop command.

Use these settings to specify default water drop path options for surfaces.

Path Layer

Specifies the default layer on which to draw the water drop path. Click in the Value column, and click ![icon] to select a type of path in the Path Layer dialog box.

Path Object Type

Specifies the default type of AutoCAD object to use for the water drop path. Either 2D Polyline or 3D Polyline.

## Water Drop Marker

**NOTE** This property group is displayed when accessing the settings from the CreateSurfaceWaterdrop command.

Use these settings to specify default water drop marker options for surfaces.

Place Marker At Start Point

Specifies whether to draw a marker at the start point of the water drop path.

Start Point Marker Style

Specifies the default start point marker style. Click in the Value column, and click ![icon] to select a style in the Start Point Marker Style dialog box.

## Google Earth Options

**NOTE** This property group is displayed when accessing the settings from the ImportGEData and ImportGESurface commands.

Use these settings to specify the default number of rows and columns collected when importing Google Earth information.

Google Earth Rows

Specifies the number of rows of data that are collected when importing terrain information from Google Earth.

Google Earth Columns

Specifies the number of columns of data that are collected when importing terrain information from Google Earth.

## ⊞ SimplifySurface

**NOTE** This property group is displayed when accessing the settings from the SimplifySurface command.

Use these settings to specify default options for simplifying surfaces.

Simplify Method

Specifies the default method by which surfaces will be simplified:

- Edge Contraction: Contracts triangle edges to single points.

- Point Removal: Selects and removes surface points.

Region Options

Specifies the default method by which surfaces will be simplified:

- Use Existing Surface Border: You specify the existing surface border as the boundary of the surface simplification region.

- Specify Window/Polygon: You specify the surface simplification region within a drawn rectangle.

- Select Objects: You specify one of either 2D or 3D polylines, parcels, circles, feature lines, or survey figures.

Use Percentage Of Points To Remove

Specifies whether simplify the image by removing a percent of surface points.

Percentage Of Points To Remove

Specifies the percent of surface points to remove.

Use Maximum Change In Elevation

Specifies whether you will set a default maximum change in elevation.

Maximum Change In Elevation

Specifies the maximum allowed difference between the elevation of the original surface and the elevation of the simplified surface.

For more information about simplifying surfaces, see Simplify Surface Wizard (page 2370).

## ⊞ Export Options

**NOTE** This property group is displayed when accessing the settings from the SurfaceExportToDem command.

Use these settings to specify the defaults assigned when exporting surfaces to a DEM file.

Use Custom Null Elevation

Specifies whether a custom null elevation is used when exporting to a DEM file.

Null Elevation

Specifies the default custom null elevation used when exporting to a DEM file.

Grid Spacing

Specifies the spacing between grids when exporting to a DEM file.

### 🖳 Add Data Options

---

**NOTE** This property group is displayed when accessing the settings from the AddSurfaceContours, AddSurfaceBoundaries, and AddSurfaceBreaklines commands.

---

Use these settings to specify the defaults assigned when adding contours, boundaries, and breaklines to a surface.

Default Weeding Distance

Specifies the default weeding distance.

Default Weeding Angle

Specifies the default weeding angle.

Default Supplementing Distance

Specifies the default supplementing distance.

Default Mid-ordinate Distance

Specifies the default mid-ordinate distance.

Default Boundary Type

Specifies the default boundary type.

Default Non-destructive Setting

Specifies the default selection of a type of breakline (destructive of non-destructive).

**Related procedures:**

- Editing Surface Settings (page 687)
- Adding and Editing Surface Data (page 611)
- Analyzing Surfaces (page 708)

# Surface Style Dialog Box

Use this dialog box to define a surface style, which controls the way a surface and its components, such as watersheds and contours, are displayed.

**See also:**

- Surface Styles and Visualization (page 692)
- Analyzing Surfaces (page 708)

## Information Tab (Surface Style Dialog Box)

Use this tab to change the surface style name and description information, and to review details, such as when you recently modified the style.

Name

Specifies a name for the current style. The style name identifies the style on the Settings tab in Toolspace and is listed in the Styles dialog box. Changes to a style name are reflected in the title bar of the Surface Style dialog box.

Description

Specifies a description for the current style.

Created By

Displays the AutoCAD login name of the person who created the style.

Date Created

Displays the style creation date and time.

Last Modified By

Displays the AutoCAD login name of the person who last modified the style.

Date Modified

Displays the last date and time of the style modifications.

**Related procedures:**

- Surface Styles and Visualization (page 692)

- Analyzing Surfaces (page 708)

# Borders Tab (Surface Style Dialog Box)

Use this tab to specify settings for the border component of a surface object.

Borders display the actual extents of the surface, which can be different from boundaries (page 612), which are used to define the surface extents.

## 3D Geometry

Border Display Mode

Specifies how to display the border:

- **Use Surface Elevation**: Displays the border at its actual elevation values.

- **Flatten Elevations**: Flattens or projects the border to the elevation value specified by the Flatten Borders To Elevation property.

- **Exaggerate Elevation**: Scales the border by the factor specified in the Exaggerate Borders By Scale Factor property.

Flatten Borders To Elevation

Specifies the elevation used to flatten the borders; available only when Border Display Mode is set to Flatten Elevations.

Exaggerate Borders By Scale Factor

Specifies the scale factor used to exaggerate the borders; available when Border Display Mode is set to Exaggerate Elevation.

## Border Types

Display Exterior Borders

Specifies whether to display outer borders. The outer border is the outer extents of the surface.

Display Interior Borders

Specifies whether to display all interior borders. This option is useful when you want to build footprints or "holes" in your surface where survey data is not present or applicable, and you do not want to represent elevations for that area.

**Datum**

Use Datum

Specifies whether or not the outer boundary can display a datum. The datum is displayed at the elevation specified in the Datum Elevation property.

Project Grid To Datum

Specifies whether the outer boundary segments are projected to the datum. The projection of outer boundary segments to the datum is only visible when viewing the surface object in 3D.

Datum Elevation

Specifies the datum elevation. The datum is only visible when the border is displayed in 3D.

**Related procedures:**

■ Surface Styles and Visualization (page 692)

# Contours Tab (Surface Style Dialog Box)

Use this tab to specify settings for the contour components of the surface object.

## 3D Geometry

Contour Display Mode

Specifies the display properties of the contours:

■ **Use Surface Elevation**: Displays the contours at their actual elevation values.

■ **Flatten Elevations**: Flattens or projects the contours to the elevation value specified by the Flatten Contours To Elevation property.

■ **Exaggerate Elevation**: Scales the contours by the factor specified in the Exaggerate Contours By Scale Factor property.

Flatten Contours To Elevation

Specifies the elevation used to flatten the contours; available only when the Contour Display Mode is set to Flatten Elevations.

Exaggerate Contours By Scale Factor

Specifies the scale factor used to exaggerate the contours; available only when the Contour Display Mode is set to Exaggerate Elevation.

## Legend

Contour Legend Style

Specifies the default contour table (legend) style. Click  to open the Contour Legend Style dialog box where you can select a style.

## Contour Intervals

Base Elevation

Specifies the relative base elevation for the contour intervals. The contour at the base elevation is a major contour.

Minor Interval

Specifies the distance between minor contours. This value is displayed in the drawings linear units. The interval is relative to the Base Elevation value.

Major Interval

Specifies the distance between major contours. This value is displayed in the drawings linear units. The value entered here is divisible by the minor interval. The interval is relative to the base elevation value.

## Contour Ranges

Specifies the default values for the contour analysis type. The contour analysis is created using the Surface Properties - Analysis tab (page 2349).

Group Values By

Specifies the creation options for the contour ranges:

- **Equal Interval**: Divides the data into the specified number of ranges from the minimum value to the maximum. Also known as equal step, this method often over-generalizes the data, with large sets of values in one group while others have a sparse set of values.

- **Quantile**: Divides the data so that the specified number of ranges contains an equal number of values. Also known as equal count, this method is most appropriate where the data values are linear (equally distributed).

- **Standard Deviation**: Calculates and divides the data based on how far data values differ from the arithmetic mean. This method is most effective when the data approximates a normal distribution (bell-shaped curve), and because of this curve preference, it is best used with an even number of ranges. Standard deviations are often used to highlight how far above or below a specific value is in relation to the mean value.

Number Of Ranges

Specifies the number of ranges to be used. For information about setting the display properties for contours within each range, see the Major Display and Minor Display columns in the display table on this tab.

Range Precision

Specifies the formatting and rounding of range values. The rounding only affects the range value calculations and resulting range intervals. It does not affect the actual data values.

Use Color Scheme

Specifies whether or not major and minor color schemes are active.

Major Color Scheme

Specifies the major color scheme for the contour range. Available only if you set Use Color Scheme to True.

Minor Color Scheme

Specifies the minor color scheme for the contour range. Available only if you set Use Color Scheme to True.

## Contour Depressions

Display Depression Contours

Specifies whether or not depression contours are displayed.

Tick Mark Interval

Specifies the spacing of the tick marks along the depression contour.

Tick Mark Length

Specifies the length of the tick mark along the depression contour. The tick mark is drawn on the downhill side of the depression contour.

## Contour Smoothing

**NOTE** Do not enable contour smoothing if you plan to use surface smoothing. For more information, see Smoothing Surfaces (page 662).

Smooth Contours

Specifies whether or not to use contour smoothing. Click True to smooth contours in accordance with the Smoothing Type parameter and the value set in the Contour Smoothing slider.

**NOTE** Use the Contour Smoothing slider (at the bottom of the dialog box) to increase or decrease the smoothing.

Smoothing Type

Specifies the type of smoothing used to display contour curves:

- **Add Vertices**: Adds vertices along the contours. This option supplements points on the contours when smoothing them, giving them a more noticeably curved appearance, while maintaining the highest level of integrity relative to the surface.

- **Spline Curve**: Passes a spline curve through the contour points. This option creates the smoothest contour representation.

### Display table

Use the following settings for each contour range specified using the Contour Ranges property group in the Properties list:

Number

Displays the number for the contour range. The numbers match the value set in the Number of Ranges property.

Major Display

Specifies a display properties for major contours. Click ▦ to select a linetype. Click ▤ to select a lineweight. Click ▥ to select a color.

Minor Display

Specifies a display properties for minor contours. Click ▦ to select a linetype. Click ▤ to select a lineweight. Click ▥ to select a color.

**NOTE** After you specify the Contour Ranges properties and set the display properties, run the contour analysis to see the changes in the surface. For information, see Creating Surface Analysis (page 708).

### Contour Smoothing slidebar

Use the Contour Smoothing slidebar to give the contours a smoother appearance. The slidebar is enabled if the Smooth Contours property (under the Contour Smoothing property group) is set to True.

**Related procedures:**

- Surface Styles and Visualization (page 692)

- Contours (page 629)

# Grid Tab (Surface Style Dialog Box)

Use this tab to specify the settings for the grid line components of the surface object.

### 3D Geometry

Grid Display Mode

Specifies how the grid is displayed:

- **Use Surface Elevation**: Displays the grid at its actual elevation values.

- **Flatten Elevations**: Flattens or projects the grid to the elevation value specified by the Flatten Grid To Elevation property.

- **Exaggerate Elevation**: Scales the grid by the factor specified in the Exaggerate Grid By Scale Factor property.

Flatten Grid To Elevation

Specifies the elevation used to flatten the grid; available only when you set the Grid Display Mode to Flatten Elevations.

Exaggerate Grid By Scale Factor

Specifies the scale factor used to exaggerate the grid; available only when you set the Grid Display Mode to Exaggerate Elevation.

### Primary Grid

Specifies whether the primary grid lines are used in the grid display as well as the primary grid interval value and orientation.

Use Primary Grid

Specifies whether or not the primary grid lines are used in the grid display. Click True to use the primary grid lines in the grid display.

Interval

Specifies the primary grid interval value in drawing linear units. The primary grid lines are the north-south, or longitudinal grid lines.

Orientation

Specifies the angle of orientation for the primary grid lines. The angle is clockwise (+), or counterclockwise (-) from the North-South meridian.

### Secondary Grid

Specifies whether the secondary grid lines are used in the grid display as well as the secondary grid interval value and orientation.

Use Secondary Grid

Specifies whether or not the secondary grid lines are used in the grid display. Click True to use the secondary grid lines in the grid display.

Interval

Specifies the secondary grid interval value in drawing linear units. The secondary grid lines are the east-west, or latitudinal, grid lines.

Orientation

Specifies the angle of orientation for the secondary grid lines. The angle is clockwise (+), or counterclockwise (-) from the East-West meridian.

**Related procedures:**

- Surface Styles and Visualization (page 692)

# Points Tab (Surface Style Dialog Box)

Use this tab to specify the settings for point components of the surface objects.

**3D Geometry**

Point Display Mode

Specifies the points display properties:

- **Use Surface Elevation**: Displays the points at their actual elevation values.

- **Flatten Elevations**: Flattens or projects the points to the elevation value specified by the Flatten Points To Elevation property.

- **Exaggerate Elevation**: Scales the points by the factor specified in the Exaggerate Points By Scale Factor property.

Flatten Points To Elevation

Specifies the elevation used to flatten the points; available only when you set the Point Display Mode to Flatten Elevations.

Exaggerate Points By Scale Factor

Specifies the scale factor used to exaggerate the points; available only when you set the Point Display Mode to Exaggerate Elevation.

## Point Size

Point Scaling Method

Specifies the scaling method, which, in combination with the Point Units value, determines the point symbol size:

- **Use Drawing Scale**: Specifies that the point size is a product of the value specified in the Point Units property and the drawing scale. For example, with a 1"=40' drawing scale, using a Point Units value of 0.1 is the equivalent of using Size In Absolute Units with a value of 4'.

- **Size Relative To Screen**: Specifies that the point symbol size is a percentage of the screen size. The percentage value is specified by the Point Units property.

- **Size In Absolute Units**: The value specified in the Point Units property is the absolute point symbol size.

Point Units

Specifies the value used for the point size.

## Point Display

Data Point Symbol

Specifies the symbology of the data point display. Click  to select a data point symbol.

Data Point Color

Specifies the color of the data point. Click  to select a data point color.

Derived Point Symbol

Specifies the symbology of the derived point display. A derived point is not a data point, but a calculated one (for example, from a surface smoothing operation). Click  to select a derived point symbol.

Derived Point Color

Specifies the color of the derived point. Click  to select a derived point color.

Non-Destructive Point Symbol

Specifies the symbology of the non-destructive point display. Non-destructive points are creating when adding non-destructive breaklines. Click  to select a non-destructive point symbol.

Non-Destructive Point Color

Specifies the color of the non-destructive point. Click ▣ to select a non-destructive point color.

---

**NOTE** If you specify a color for the points using the Point Display properties, it overrides the color specified on the Display tab. The default color value is set to ByBlock when a new style is initialized. When set to ByBlock, the color specified on the Display tab is used.

---

**Related procedures:**

■ Surface Styles and Visualization (page 692)

# Triangles Tab (Surface Style Dialog Box)

Use this tab to specify the properties of the triangle components of the surface object.

### 3D Geometry

Triangle Display Mode

Specifies the triangles display properties:

■ **Use Surface Elevation**: Displays the triangles at their actual elevation values.

■ **Flatten Elevations**: Flattens or projects the triangles to the elevation value specified by the Flatten Triangles To Elevation property.

■ **Exaggerate Elevation**: Scales the triangles by the factor specified in the Exaggerate Triangles By Scale Factor property.

Flatten Triangles To Elevation

Specifies the elevation used to flatten the triangles; available only when you set the Triangle Display Mode to Flatten Elevations.

Exaggerate Triangles By Scale Factor

Specifies the scale factor used to exaggerate the triangles; available only when you set the Triangle Display Mode to Exaggerate Elevation.

**Related procedures:**

■ Surface Styles and Visualization (page 692)

# Watersheds Tab (Surface Style Dialog Box)

Use this tab to control the display of watersheds.

### 3D Geometry

Watershed Display Mode

Specifies the watersheds display properties:

■ **Use Surface Elevation**: Displays the watersheds at their actual elevation values.

■ **Flatten Elevations**: Flattens or projects the watersheds to the elevation value specified by the Flatten Watersheds To Elevation property.

■ **Exaggerate Elevation**: Scales the watersheds by the factor specified in the Exaggerate Watersheds By Scale Factor property.

**Flatten Watersheds To Elevation**

Specifies the elevation used to flatten the watersheds; available only when you set the Watershed Display Mode to Flatten Elevations.

**Exaggerate Watersheds By Scale Factor**

Specifies the scale factor used to exaggerate the watersheds; available only when you set the Watershed Display Mode to Exaggerate Elevation.

## Point Size

Specifies the size and scaling method of the drain target points.

**Watershed Scaling Method**

Specifies the scaling method, which, in combination with the Watershed Units value, determines the point symbol size:

- **Use Drawing Scale**: Specifies that the point size is a product of the value specified in the Watershed Units property and the drawing scale. For example, with a 1"=40' drawing scale, using a Watershed Units value of 0.1 is the equivalent of using Size In Absolute Units with a value of 4'.

- **Size Relative To Screen**: Specifies that the point symbol size is a percentage of the screen size. The percentage value is specified by the Watershed Units property.

- **Size In Absolute Units**: The value specified in the Watershed Units property is the absolute point symbol size.

**Watershed Units**

Specifies the value for the point size.

## Surface

**Surface Watershed Label Style**

Specifies the default watershed label style. Click ⬚ to select a style.

## Legend

**Watershed Legend Style**

Specifies the default watershed table (legend) style. Click ⬚ to select a style.

## Boundary Point, Boundary Segment, Depression, Flat Area, Multi-drain, Multi-drain Notch

The above watershed categories have the following common properties.

**Color**

Specifies the color of the watershed. Click ⬚ to select the color.

**Linetype**

Specifies a linetype for the watershed. Click ⬚ to select a linetype.

**Use Hatching**

Specifies whether or not to use a hatch pattern for the watershed.

**Hatch Pattern**

Specifies the hatch pattern to use for the watershed; available only when you set the Use Hatching parameter mode to True. Click ⬚ to open the Hatch Properties Dialog Box (page 2365) where you can select a hatch pattern.

**Draw Drain Target Point**

Specifies whether or not to display drain target points for the watershed.

Drain Target Point Display

Specifies the symbology of the drain target point display. Click ⬚ to select a drain target point symbol.

Drain Target Point Color

Specifies the color of the drain target point. Click ⬚ to select a drain target point color.

Draw Drain Target Segment

Specifies whether or not to display drain target segments for the watershed.

Drain Target Segment Color

Specifies the color of the drain target segment. Click ⬚ to select a drain target segment color.

Drain Target Segment Linetype

Specifies a linetype for the drain target segment. Click ⬚ to select a linetype.

**Related procedures:**

■  Watersheds (page 675)

■  Surface Styles and Visualization (page 692)

# Analysis Tab (Surface Style Dialog Box)

Use this tab to specify the display parameters for the surface analysis displays that have common view properties.

## Directions

Specifies the display properties for directional (aspect) analysis. Renders surface triangles according to the direction that they face.

Group By

Specifies the direction ranges creation properties:

■  **Equal Interval**: Divides the data into the specified number of ranges from the minimum value to the maximum. Also known as equal step, this method often over-generalizes the data, with large sets of values in one group while others have a sparse set of values.

■  **Quantile**: Divides the data such that the specified number of ranges contains an equal number of values. Also known as equal count, this method is most appropriate where the data values are linear (equally distributed).

■  **Standard Deviation**: Calculates and divides the data based on how far data values differ from the arithmetic mean. This method is most effective when the data approximates a normal distribution (bell-shaped curve), and because of this curve preference, it is best used with an even number of ranges. Standard deviations are often used to highlight how far above or below a specific value is in relation to the mean value.

Number of Ranges

Specifies the number of ranges to be used.

Range Precision

Specifies the range precision value.

Display Type

Specifies the entity type to be drawn within the analysis view:

- **3D Faces**: Generates a surface analysis display containing 3D Faces. Useful when viewing the object in 3D. If you use the AutoCAD Explode command, the analysis view explodes to 3D Face entities.

- **2D Solid**: Generates a surface analysis display containing 2D Solid hatching. Useful when viewing the object in 2D. If you use the AutoCAD Explode command, the analysis view explodes to Solid entities.

- **Hatch Solid**: Generates hatching within polygons containing triangle faces that match the criteria for a specific range. Useful when viewing the object in 2D. If you use the AutoCAD Explode command, the analysis view explodes to Hatch entities.

- **Mesh**: Generates a surface analysis display containing a mesh. Useful when viewing the object in 3D.

Scheme

Specifies the color scheme for the range.

Legend Style

Specifies the default analysis table (legend) style. Click ... to select a style.

Directions Display Mode

Specifies watersheds display properties:

- **Use Surface Elevation**: Displays the directions at their actual elevation values.

- **Flatten Elevations**: Flattens or projects the directions to the elevation value specified by the Flatten Directions To Elevation property.

- **Exaggerate Elevation**: Scales the directions by the factor specified in the Exaggerate Directions By Scale Factor property.

Flatten Directions To Elevation

Specifies the elevation used to flatten the directions display. Available only when you set the Directions Display Mode to Flatten Elevations.

Exaggerate Directions By Scale Factor

Specifies the scale factor used to exaggerate the directions display. Available only when you set the Directions Display Mode to Exaggerate Elevation.

## Elevations

Specifies the display properties for elevation banding analysis. Renders surface triangles within an elevation range.

**NOTE** Elevations analysis display properties are the same as the Directions properties.

## Slopes

Specifies the display properties for slope analysis. Renders surface triangles within a slope range.

**NOTE** Slopes analysis display properties are the same as the Directions properties.

## Slope Arrows

Used for slope direction analysis. Places a slope directional arrow at each triangle centroid. Arrow color is based on the color assigned to a slope range (similar to slope analysis).

Uses the same display properties as the Directions properties, with the following additional properties:

Arrow Type

Specifies the type of arrow to use:

- **Filled:** 

- **Closed:** 

- **Open:** 

- **Double:** 

Arrow Length

Specifies the length of the slope arrow that is displayed in a Slope Arrows surface analysis view.

**Related procedures:**

- Analyzing Surfaces (page 708)

## Display Tab (Surface Style Dialog Box)

Use this tab to control the visibility and display of the components that make up a surface. You can change the visibility, color, or layer for the surface components at various phases in a project.

Surface components include:

- **Points:** All surface points for the TIN or grid surfaces.

- **Triangles**: TIN face lines.

- **Border**: Interior and exterior border lines.

- **Major Contour**: Contour lines defined as major interval.

- **Minor Contour**: Contour lines defined as minor interval.

- **User Contours**: User-defined contour lines.

- **Gridded**: Primary and secondary grid lines.

- **Directions**: Direction or aspect analysis display.

- **Elevations**: Elevation banding analysis display.

- **Slopes**: Slope analysis display.

- **Slope Arrows**: Slope arrow analysis display.

- **Watersheds**: Watershed analysis display.

**NOTE** Surface styles have unique display values and varying numbers of displayed components, depending on whether you select 2D or 3D view.

For more information about the properties in this tab, see Display Tab (Style Dialog Box) (page 1801).

## Summary Tab (Surface Style Dialog Box)

Use this tab to view all the surface style properties. For more information about the properties in this tab, see Summary Tab (Style Dialog Box) (page 1803).

# Surface Properties Dialog Box

Use this dialog box to change the properties of a surface.

Surface properties control which data is included in the surface. You also use the Surface Properties dialog box to perform analysis calculations on the surface.

**See also:**

■ Understanding the Surface Definition (page 611)

■ Excluding Data from the Surface Build (page 667)

■ Analyzing Surfaces (page 708)

## Information Tab (Surface Properties Dialog Box)

Use this tab to view or change general information for the surface.

Name

Specifies the name of the current surface.

Description

Specifies the description of the current surface.

Object Style

Specifies the default surface style used to display a surface. Select a style in the list or use the standard selection tools. For more information about the standard selection tools, see Select Style Dialog Box (page 1805).

Render Material

Specifies the default render material used to display a surface. Select a render material in the list or use the standard selection tools. For more information, see Applying Render Materials to Objects (page 1578), Select Render Material Dialog Box (page 2366).

Object Locked

Specifies whether the surface is locked and cannot be edited.

Show Tooltips

Controls whether tooltips are displayed for the object in the drawing (does not affect tooltips over toolbar icons).

**Related procedures:**

■ Creating Surfaces (page 601)

■ Project Management (page 125)

## Definition Tab (Surface Properties Dialog Box)

Use this tab to switch various data and edit items on or off, or remove surface definition items.

The bottom part of the tab lists the surface definition (operation types) in the order that the operations were performed. You can reorder the surface operations in the list.

**NOTE** Properties that are not applicable for the current surface type are unavailable.

## Build

NOTE You can set the default settings for the Build properties in the Edit Command Settings - CreateSurface dialog box, which is accessed from the Settings tab on the Toolspace (under <drawing-name> ➤ Surface ➤ Commands, right-click ▣ CreateSurface and click Edit Commands Settings).

Copy Deleted Dependent Objects

Specifies whether a drawing object is copied to the surface definition item if the object is deleted:

- **Yes**: Copies the drawing object data to the surface definition if you delete the drawing object data. When you add a surface boundary, breakline, or point group to a surface, the surface definition stores the Object ID. If the drawing object, such as the original polyline used to define the surface boundary, is deleted from the drawing, the coordinates of the polyline vertices are copied into the surface definition and saved. Thus, the surface boundary definition remains in the surface definition.

- **No**: Deletes the surface boundary, breakline, or point group definition if the drawing object is deleted. The definition item is removed from the surface definition when the surface is rebuilt.

Exclude Elevations Less Than

Specifies whether an elevation less than a certain value should be excluded when the surface is built. Click Yes to exclude elevations less than the value specified in the Elevation < when the surface is built.

Elevation <

Specifies the elevations to exclude when the Exclude Elevations Less Than property is set to Yes.

Exclude Elevations Greater Than

Specifies whether an elevation greater than a certain value should be excluded when the surface is built. Click Yes to exclude elevations greater than the value specified in the Elevation > when the surface is built.

Elevation >

Specifies the elevations to exclude when the Exclude Elevations Greater Than property is set to Yes.

Use Maximum Triangle Length

Specifies whether the surface triangles that exceed the length specified by the Maximum Triangle Length property are removed from the boundary of the surface. Click Yes to remove triangles with a length greater than the value specified in the Maximum Triangle Length when the surface is built.

Maximum Triangle Length

Specifies the triangle length to use when the Use Maximum Triangle Length property is set to Yes.

Convert Proximity Breaklines to Standard

Specifies whether proximity breaklines are converted to standard breaklines when the surface is built. For more information, see Types of Breaklines (page 619). Click Yes to convert proximity breaklines to standard breaklines.

Allow Crossing Breaklines

Specifies whether breaklines can cross each other. Click Yes to enable the correction of crossing breaklines when they occur. If a new breakline touches an existing breakline, you can specify what elevation to use at the calculated point of intersection. The XY coordinate location is calculated and the elevation is set by the Elevation To Use property.
This setting does not apply to breakline intersections that occur at the endpoints of breaklines. You can change the elevation of such points using the surface Modify Point operation. For more information, see Modifying Surface Points (page 654).

Elevation To Use

Specifies the elevation to use for the crossing breaklines:

- **Use First Breakline Elevation At Intersection**: Uses the first breakline elevation to determine the elevation at the intersection.

- **Use Last Breakline Elevation At Intersection**: Uses the last breakline elevation to determine the elevation at the intersection.

- **Use Average Elevation At Intersection**: Uses the average of the first and last breakline to determine the elevation at the intersection.

## Data Operations

All Data Operations properties specify whether a data definition of a certain type is included in the surface build.

- **Yes**: All data operations of the specified type are selected in the Operation Type list and included in the surface build.

- **No**: All data operations of the specified type are cleared in the Operation Type list and not included in the surface build.

If the Operation Type list contains mixed selected and cleared items of a specific data type, the specific data operation is displayed as **Varies**.

For information about data operations supported by each surface type, see Understanding the Surface Definition (page 611).

## Edit Operations

All Edit Operations specify whether surface operations of a specific type are included in the surface build.

- **Yes**: All edit operations of specified type are selected in the Operation Type list and included in the surface build.

- **No**: All edit operations of the specified type are cleared in the Operation Type list and not included in the surface build.

If the Operation Type list contains mixed selected and cleared items of a specific edit type, the specific edit is displayed as **Varies**.

For information on edit operations supported by each surface type, see Surface Editing Operations (page 650).

## Operation Type

The Operation Type list displays the surface operations and their applicable parameters in the order in which they were performed. Clear an operation to remove it from the surface definition.

Edit the definition list by selecting or clearing a definition item, or deleting the item from the list. When definition items are cleared, the surface is updated, but the surface still has a reference to the definition item. If the definition item is deleted from the list, the definition item data is permanently removed from the surface.

Reorder surface operations in the surface definition using the following controls:

⇧

Moves a selected operation to the top of the list.

⇧

Moves a selected operation one position up.

Moves a selected operation one position down.

Moves a selected operation to the bottom of the list.

For information about errors that can occur in the Operation Type list, see Surface Errors and Issues (page 647).

**Related procedures:**

- Understanding the Surface Definition (page 611)

- Excluding Data from the Surface Build (page 667)

- Editing and Viewing the Surface Definition (page 681)

# Analysis Tab (Surface Properties Dialog Box)

Use this tab to modify the properties of a selected surface analysis type.

**NOTE** The Analysis tab displays varying fields and options depending on the type of analysis that you select.

Analysis Type

Specifies the current analysis type properties that you can modify.

**NOTE** You set the default values for the analysis in the Analysis tab of the Surface Style dialog box.

- **Contours**: Specifies the contours analysis properties.

- **Directions**: Specifies the directions analysis properties.

- **Elevations**: Specifies the elevations analysis properties.

- **Slopes**: Specifies the slopes analysis properties.

- **Slope Arrows**: Specifies the slope arrows analysis properties.

- **User-Defined Contours**: Specifies the user-defined contours analysis properties.

- **Watersheds**: Specifies the watersheds analysis properties.

Preview

Displays a preview of the legend table for the current analysis type. Clear the check box to disable the preview option.

Legend

Specifies the legend style for the current analysis type.

**NOTE** You set the default style on the Analysis tab of the Surface Styles dialog box.

## Ranges

Specifies the number of ranges to use for contours, directions, elevations, slopes, slope arrows, and user-defined contour analysis.

Number

Specifies the numbers of ranges in the analysis. Enter a number or click the up/down arrows to increment the value.

Generates the analysis and updates the Range Details group box with the analysis information.

## Watershed Parameters

Displayed if Analysis Type is set to Watersheds. Specifies the minimum depression depth and area for watershed analysis.

Minimum Average Depth Threshold

Specifies the minimum average depth at which a depression in the surface may be considered a watershed. This prevents minor depression depths from being defined as watersheds.

Merge Adjacent Boundary Watersheds

Specifies that adjacent boundary segment and or boundary point watersheds (along the edges of the outer surface border) should be merged.

Generates the analysis and updates the Details group box with the analysis information.

## Range Details

**NOTE** The Range Details area of the Analysis tab displays varying fields and columns depending on the type of analysis that you have selected.

Scale Scheme To Fit

Specifies whether the number of entries is scaled or read sequentially:

■ Selected: The number of entries in the scheme is scaled to uniformly cover the number of ranges, that is, an even sampling is taken from the scheme between the first and last entries.

■ Cleared: The scheme is read sequentially starting at the first entry.

**NOTE** If there are fewer entries in the scheme than the number of values in the list of ranges, AutoCAD Civil functions as if the check box is cleared. This means that the scheme is read sequentially until all the entries in the scheme have been used. In all cases, the last entry in the scheme is used when there are more ranges than scheme entries.

## Range Details

Specifies various details in table form depending on the type of analysis that is performed. Details are displayed in the following columns:

ID

Displays an index number for each range.

Description

Specifies a description for user-defined contours and watersheds.

Elevation

Displays the elevation value of the user-defined contour.

Minimum Elevation/Direction/Slope

Displays the minimum range value for the analysis view.

Maximum Elevation/Direction/Slope

Displays the maximum range value for the analysis view.

Scheme

Specifies a color preview assigned by the Scheme property in the surface styles Analysis tab (page 2343). Double-click the column to select a different color.

Major Contour

Specifies how the ranges major contours are displayed:

- Click ⬛ to select a display color for the major contour display.

- Click ▤ to select a display lineweight for the major contour display.

- Click ▦ to select a display linetype for the major contours.

**NOTE** You set the default display for the surface style on the Analysis tab (page 2343).

Minor Contour

Specifies how the ranges minor contours are displayed:

- Click ⬛ to select a display color for the minor contour display.

- Click ▤ to select a display lineweight for the minor contour display.

- Click ▦ to select a display linetype for the minor contours.

**NOTE** You set the default display for the surface style on the Analysis tab (page 2343).

Type

Displays the watershed type and specifies if the individual watershed is displayed or hidden in the drawing. Click the light bulb icon to display 💡 or hide 💡 .

**NOTE** To change the display for the watersheds by type rather than individually, click 💡 above the Details table.

Drains Into

Displays a comma-delimited string containing the subarea watershed IDs that the subarea watershed drains into. For example, the string "4,5,6" indicates that the subarea drains into subareas 4, 5, and 6.

Segment Display

Specifies how the segments of the watershed subarea are displayed:

- Click ⬛ to select a display color for the segment.

- Click ▤ to select a display lineweight for the segment.

- Click ▦ to select a display linetype for the segment.

**NOTE** You set the default display for the surface style on the Analysis tab (page 2343).

Area Display

Specifies and previews the hatch pattern for the watershed subarea.

- Click the hatch pattern preview to change the pattern using the Hatch Properties (page 2365) dialog box.

- Click ⬛ to select a display color for the hatching.

**NOTE** You set the default display for the surface style on the Analysis tab (page 2343).

💡

Click to open the Watershed Display (page 2359) dialog box where you can hide or display watersheds by type.

**Related procedures:**

■ Analyzing Surfaces (page 708)

■ Watersheds (page 675)

# Statistics Tab (Surface Properties Dialog Box)

Use this tab to display surface statistics that are based on the current state of the surface.

## General

Displays the general statistics for a surface:

Revision Number

Displays the revision number of the surface.

Number of Points

Displays the number of vertex points in the surface.

Minimum X Coordinate

Displays the minimum X coordinate for the surface area.

Minimum Y Coordinate

Displays the minimum Y coordinate for the surface area.

Maximum X Coordinate

Displays the maximum X coordinate for the surface area.

Maximum Y Coordinate

Displays the maximum Y coordinate for the surface area.

Minimum Elevation

Displays the minimum elevation value found in the surface.

Maximum Elevation

Displays the maximum elevation value found in the surface.

Mean Elevation

Displays the mean or average elevation of all the points on the surface.

## Extended

2D Surface Area

Displays the two-dimensional area of the surface.

3D Surface Area

Displays the three-dimensional area of the surface.

Minimum Grade/Slope

Displays the minimum grade or slope found on the surface. Expressed in the units specified in the Edit Feature Settings - Surface Dialog Box (page 2329).

Maximum Grade/Slope

Displays the maximum grade or slope found on the surface. Expressed in the units specified in the Edit Feature Settings - Surface Dialog Box (page 2329).

Mean Grade/Slope

The mean or average grade or slope for the surface. Expressed in the units specified in the Edit Feature Settings - Surface Dialog Box (page 2329).

## TIN

**NOTE** The following properties are displayed for TIN surfaces.

Number Of Triangles

Displays the number of triangles found in the surface.

Maximum Triangle Area

Displays the area of the largest triangle contained in the surface.

Minimum Triangle Area

Displays the area of the smallest triangle contained in the surface.

## Grid

**NOTE** The following properties are displayed for grid surfaces.

X Spacing

Displays the distance between the grid lines in the X direction.

Y Spacing

Displays the distance between the grid lines in the Y direction.

Orientation

Displays the orientation of the grid (in degrees). The angle is clockwise (+), or counterclockwise (-) from the North-South meridian.

## Volume

**NOTE** The following properties are displayed for volume surfaces.

Base Surface

Displays the name of the base surface from which the volume surface is generated.

Comparison Surface

Displays the name of the comparison surface from which the volume surface is generated.

Cut volume (unadjusted)

Displays the total cut volume for the surface, without a cut factor applied.

Fill volume (unadjusted)

The total fill volume for the surface, without a fill factor applied.

Net volume (unadjusted)

The difference between the cut and fill volumes.

**Related procedures:**

■ Viewing Surface Statistics (page 689)

# Create Surface Dialog Box

Use this dialog box to specify the initial surface creation parameters, including surface type and layer.

Type

Specifies the type of surface to create.

Surface Layer

Displays the layer on which the surface is created.

Click to open the Object Layer dialog box where you can select a different layer for the surface.

The properties table section of the dialog box displays varying properties depending on the type of surface selected in the Type field.

## Information

Name

Specifies the name of the surface.

> **NOTE** To name the surface, click its default name and enter a new name, or click the Name Template button and use the name template. For more information, see Name Template Dialog Box (page 1806).

Description

Specifies a description of the surface.

Style

Specifies the style for the surface. Click ⋯ to open the Select Surface Style (page 1801) dialog box where you can select a different style.

Render Material

Specifies the render material (page 1577). Click ⋯ to select a render material.

## Grid Parameters

This property group is displayed when Grid Surface is selected in the Type list.

Grid-X Spacing

Specifies the X distance between the grid lines. When selected, you can click ⬚ to digitize the spacing in the drawing area.

Grid-Y Spacing

Specifies the Y distance between the grid lines. When selected, you can click ⬚ to digitize the spacing in the drawing area.

Orientation

Specifies the direction for the grid in the X and Y directions. When selected, you can click ⬚ to pick two points in the drawing to define the orientation direction.

## Volume Surfaces

Base Surface

Specifies the base surface from which the volume surface is generated. Enter the surface name or click ⋯ to open the Select Base Surface (page 1810) dialog box where you can select the surface from the list.

Comparison Surface

Specifies the comparison surface from which the volume surface is generated. Enter the surface name or click ⬚ o open the Select Comparison Surface (page 1810) dialog box where you can select the surface from the list.

Cut Factor

Specifies the expansion value of the material (page 1166).

Fill Factor

Specifies the compaction value of the material (page 1166).

**Related procedures:**

■  Creating Surfaces (page 601)

# Add Contour Data Dialog Box

Use this dialog box to add contour data to the surface definition of the selected surface. Weeding and supplementing factors are used to add or remove vertices along a contour.

Description

Specifies the description of the contour data operation. If no description is specified, a default naming convention is used: "Contour Data<#>". For example, if you do not enter a description, the first contour data operation is named "Contour Data1," the second contour is named "Contour Data2," and so on.

## Weeding Factors

Distance

Specifies the contour weeding distance. Enter the distance value or click ⬛ to select it in the drawing.

Angle

Specifies the contour weeding angle. Enter the angle value or click ⬛ to select it in the drawing.

## Supplementing Factors

Distance

Specifies the contour supplementing distance. Enter the distance value or click ⬛ to select it in the drawing.

Mid-Ordinate Distance

Specifies the contour mid-ordinate distance. Enter the distance value or click ⬛ to select it in the drawing.

## Minimize Flat Areas By

Filling Gaps In Contour Data

Specifies that small gaps in contours should be filled in.

Swapping Edges

Specifies that a non-contour common edge shared between a flat triangle and a non-flat triangle should be swapped.

Adding Points To Flat Triangle Edges

Specifies that a new point should be added at the midpoint of an edge shared between a flat triangle and a non-flat triangle.

Adding Points To Flat Edges

Specifies that a new point should be added to edges that bridge two same-elevation data contours and are not in flat triangles.

OK

Click to accept the contour values. You are then prompted at the command line to select objects (Polylines) from the drawing to define as contour data. When the objects are selected, the contour data is added to the surface definition.

**Related procedures:**

■ Weeding and Supplementing Factors for Contours (page 630)

■ Adding Contour Data to a Surface (page 632)

■ Minimizing Flat Areas in a Surface (page 656)

# DEM File (Add/Properties) Dialog Box

Use this dialog box to specify or view the DEM (*.dem*) file and DEM file information.

DEM File Name

Specifies the file name and path for an existing DEM file. Enter the name and path or click 🖳 to open the Import Surface dialog box and browse to the location of the DEM file.

**NOTE** If you are viewing the properties of a DEM file, this field is read only.

DEM File Information

Displays the header information for the selected DEM file. For more information, see About DEM File Data (page 635).

**DEM File**

CS Code

Specifies the coordinate system code for the DEM file. Click ⊡ to select a code in the list of coordinate systems.

Description

Displays the coordinate system description associated with CS Code.

Projection

Displays the coordinate system projection name.

Datum

Displays the coordinate system datum name.

**Current Drawing**

Displays the drawing coordinate system zone information. The drawing coordinate system is specified in the Drawing Settings Dialog Box (page 1851).

CS Code

Displays the current drawings coordinate system code.

Description

Displays the current drawings coordinate system description.

Projection

Displays the current drawing coordinate system projection name.

Datum

   Displays the current drawing coordinate system datum name.

---

**NOTE** The points of the DEM file are transformed from the specified coordinate system of the DEM file to the coordinate system of the current drawing plus any Transformation settings specified in the Drawing Settings dialog box. DEM files cannot be transformed for grid surfaces. If you include a DEM file as part of a grid surface definition, its coordinate system must match that of the drawing, or it cannot be added.

---

**Related procedures:**

■ Adding DEM Files to a Surface (page 637)

■ Creating a Grid Surface from a DEM (page 608)

# Smooth Surface Dialog Box

Use this dialog box to set up the parameters for surface smoothing.

### Smoothing Methods

Select Method

   Specifies the type of surface smoothing to perform:

   ■ **Natural Neighbor Interpolation**: Specifies NNI and disables the Kriging Method property group.

   ■ **Kriging**: Specifies the Kriging method.

### Kriging Method

Specifies the parameters for the Kriging surface smoothing method. Available when the Smoothing Methods property is set to Kriging.

Semivariogram Model

   Specifies the semivariogram to use. For more information, see Smoothing a Surface Using Kriging Method (page 665).

Point Selection Method

   Specifies the points to use for the surface smoothing extrapolation:

   ■ **Select Points**: Selects all points inside a rectangle, polygon, or surface, or parcel.

   ■ **Random Points**: Selects random points inside a rectangle, polygon, or surface, or parcel.

   ■ **Select All Points**: Selects all points on a surface.

Select Points

   Specifies the points that are selected. Available only when either the Select Points or Random Points parameters are selected. Click ⊡ and follow the command line prompts to select the points.

### Point Interpolation/Extrapolation Output

Output Locations

   Specifies the output location for the points:

   ■ **Grid Based**: Outputs points on a grid defined within specified polygon areas selected in the drawing.

   ■ **Centroids**: Outputs points at the existing surface triangle centroids within specified polygon areas selected in the drawing.

   ■ **Random Points**: Outputs a specified number of random points within polygon areas selected in the drawing.

For more information, see Understanding Point Interpolation/Extrapolation Output (page 663).

Select Output Region

Specifies the area which to output the points. Click ⊡ and follow the command line prompts to select the area.

Grid X - Spacing

Specifies the X distance between the grid lines. Available only when the Grid Based option for point output is selected. Click ⊡ to digitize the spacing in the drawing area.

Grid Y - Spacing

Specifies the Y distance between the grid lines. Available only when the Grid Based option for point output is selected. Click ⊡ to digitize the spacing in the drawing area.

Grid Orientation

The orientation direction for the grid in the Y and X directions. Available only when the Grid Based option for point output is selected. Click ⊡ to pick two points in the drawing to define the orientation direction.

Number Of Output Points

Displays the number of points that are output.

**Kriging Semivariogram Model**

This area of the dialog box is displayed if the Kriging surface smoothing method is selected.

Parameter A

Specifies the semivariogram scale factor.

Parameter C

Specifies the semivariogram range factor.

Nugget Effect

Specifies the discontinuity at the origin of the semivariogram model. The magnitude of the discontinuity is called the nugget and must be greater than 0.

Graph display area

Displays the semivariogram model (in red) against the actual surface points (in white). You can visually verify both the model and the surface points at the same time.

**Related procedures:**

■ Smoothing Surfaces (page 662)

# Breakline Properties Vista

Use this panorama vista to view the properties of the breaklines in a surface.

For general information about using panorama vistas, see The Panorama Window (page 102).

The properties grid displays the following columns:

Description

Displays a tree-view of breakline descriptions. Click a breakline to expand it and display its vertices.

Easting (X)

Displays the X coordinate value of a breakline vertex.

Northing (Y)
Displays the Y coordinate value of a breakline vertex.

Elevation (Z)
Displays the Z coordinate value of a breakline vertex.

**Related procedures:**

■ Viewing Breakline Information (page 627)

■ Breaklines (page 618)

# Watershed Display Dialog Box

Use this dialog box to display or hide watersheds by type.

Watershed Type
Specifies whether the watershed type is displayed or hidden. Click the light bulb icon to hide or display the watershed type:

■ 💡 : Specifies that the watershed type is displayed in the analysis and the drawing.

■ 💡 : Specifies that the watershed type is hidden in the analysis and the drawing.

**Related procedures:**

■ Watersheds (page 675)

■ Surface Styles and Visualization (page 692)

# Add Boundaries Dialog Box

Use this dialog box to add boundaries to the surface definition of the selected surface.

Name
Specifies the name of the boundary to be created. If you do not specify a name, the following default naming convention is used: "Boundary<#>." For example, if you do not enter a name, the first boundary is named "Boundary1," the second boundary is named "Boundary2," and so on.

Type
Specifies the type of boundary to add. See Boundaries (page 612):

■ **Outer**: Creates an outer boundary for the surface.

---

**NOTE** Although you can define more than one outer boundary for a surface, only the last one created is used by the surface.

---

■ **Show**: Creates a show boundary. Show boundaries are used to display an area inside a hide boundary.

■ **Hide**: Creates a hide boundary.

■ **Data Clip**: Creates a surface boundary limited by a polygon object from the drawing, such as 2D and 3D polylines, feature lines, survey figures, parcels, and circles. Any data added to a surface following a data clip boundary is clipped to that boundary.

Non-Destructive Breakline

Specifies whether or not to create boundaries with non-destructive breaklines. This clips the triangle edges exactly where they cross the boundary. This option is unavailable when Data Clip is selected as a boundary type.

Mid-Ordinate Distance

Specifies the mid-ordinate distance for the boundaries breaklines, which is used to tessellate the polyline arcs from which the boundary is being created. Click  to digitize the mid-ordinate distance in the drawing area.

**Related procedures:**

■ Boundaries (page 612)

# Boundary Properties Dialog Box

Use this dialog box to view the properties of the boundary in a surface.

Name

Specifies the boundary name.

Type

Displays the boundary type.

**Properties Table**

Displays the following properties:

Vertex

The vertex number of the boundary.

Easting (X)

The X-coordinate value of a boundary vertex.

Northing (Y)

The Y-coordinate value of a boundary vertex.

Elevation (Z)

The Z-coordinate value of a boundary vertex.

**Related procedures:**

■ Editing Boundary Properties (page 617)

■ Adding Boundaries to a Surface (page 615)

# Add Breaklines Dialog Box

Use this dialog box to add breaklines to a surface.

Description

Specifies the description of the breaklines to be created.

Type

Specifies the type of breakline to add:

■ **Standard**: Creates standard breaklines.

- **Proximity**: Creates proximity breaklines.

- **Wall**: Creates wall breaklines.

- **From File**: Imports breaklines from an FLT(.flt) format file.

- **Non-Destructive**: Creates non-destructive breaklines.

For more information, see Types of Breaklines (page 619).

File Link Options

Specifies the file link option to use when importing breaklines from a file:

- **Break Link To File**: Copies breaklines to the surface definition. The file is no longer referenced.

- **Maintain Link To File**: Maintains a reference to the breakline file. The file is used when the surface is rebuilt.

For more information, see Importing Breaklines from a File (page 625).

### Weeding Factors

Available if you select Standard or Wall as the breakline type.

Distance

Specifies the weeding distance (page 630). Enter a value or click  to digitize the mid-ordinate distance in the drawing area.

Angle

Specifies the weeding angle (page 630). Enter a value or click  to digitize the mid-ordinate angle in the drawing area.

### Supplementing Factors

Distance

Specifies the weeding distance. Enter a value or click  to specify the distance in the drawing.

Mid-Ordinate Distance

Specifies the mid-ordinate distance (page 619) for the breaklines. Enter a value or click  to digitize the mid-ordinate distance in the drawing.

**Related procedures:**

- Breaklines (page 618)

# Add Point File Dialog Box

Use this dialog box to specify options before you add a point file to a surface.

Format

Specifies the format of the point data in the file.

Opens the Point File Format (page 2120) dialog box. Select a point file format, edit a point file format, or create a point file format to use when importing the point data.

Source File

Specifies the name of the point data file. Enter a file name, including the full path name.

Opens the Select Source File dialog box. Browse to the location of the point data file. Select the file name, and click Open.

**Advanced Options**

Do Elevation Adjustment If Possible

Specifies that elevation adjustments are performed. The point file format must contain Z+, Z-, or Thickness columns. For more information, see Adjusting Elevation During Import and Transfer (page 499).

Do Coordinate Transformation If Possible

Specifies that coordinate transformations should occur. The point file format must have a coordinate zone assigned to it, and the current drawing must have coordinate zone and transformation information defined. The points are transformed to match the zone of the current drawing.

Do Coordinate Data Expansion If Possible

Specifies that coordinate data properties of the points, such as degrees, minutes, seconds, and hemisphere for latitude and longitude, should be calculated if possible. These values are calculated from known coordinate data information contained in the point data file, such as grid northing and grid easting.

**Related procedures:**

■ Adding Surface Data from a Point File (page 643)

# Add Points from Drawing Objects Dialog Box

Use this dialog box to add point data from AutoCAD objects to the surface definition.

Object Type

Specifies the type of AutoCAD object to add:

■ **Points**: Creates surface point data from AutoCAD Point objects. The points XYZ coordinates are used to define the surface point.

■ **Lines**: Creates point data from AutoCAD Line objects. The XYZ coordinates of the objects endpoints are used to define surface points.

■ **Blocks**: Creates point data from AutoCAD Block Reference objects. The block insertion point XYZ coordinates are used to define the surface point.

■ **Text**: Creates point data from AutoCAD Text objects. The text insertion point XYZ coordinates are used to define the surface point.

■ **3D Faces**: Creates point data from AutoCAD 3DFace objects. The XYZ coordinates of the objects endpoints are used to define surface points.

■ **Polyface**: Creates point data from AutoCAD PolyFaceMesh objects. The XYZ coordinates of the objects endpoints are used to define surface point.

Maintain Edges From Objects

Specifies whether to define the AutoCAD Civil triangle edges based on the edges defined in the original AutoCAD object. If selected, AutoCAD Civil maintains the edges and does not attempt to optimize the edges. Available when importing points from lines, 3D faces, and polyfaces.

Description

Specifies the description for the point data to be created.

■ [Adding Surface Point Data from AutoCAD Drawing Objects](#) (page 640)

# Create Mask/Mask Properties Dialog Box

Use this dialog box to create a mask or to modify the properties of an existing mask.

### Information

Name
Specifies the name of the mask.

Description
Specifies the description of the mask.

### Masking

Mask Type
Specifies the mask type:

■ **Inside**: Creates an inside mask, which clips and hides the area inside the parcel or polygon area.

■ **Outside**: Creates an outside mask, which clips and hides the area outside the parcel or polygon area.

Render Only
Specifies whether you want to create a render-only mask with the specified render material applied to the inside of the parcel or polygon.

Mid-Ordinate Distance
Specifies the mid-ordinate distance for the region segments, which is used to tessellate the polyline arcs from which the region is being created. Click  to digitize the mid-ordinate distance in the drawing area.

Render Material
Specifies the render material (page 1577). Click  to select a render material.

### Related procedures:

■ [Masks](#) (page 669)

# Mask Display Order Dialog Box

Use this dialog box to control the display order for render-only masks.

Masks listed higher are displayed on top of masks that are listed lower.

### Mask List

This area lists the existing masks. Click a mask to select it.

Name
Displays the name of the mask.

Description
Displays the description for the mask.

⇧

Click to move the selected mask up in the display order list.

Click to move the selected mask down in the display order list.

**Related procedures:**

■ Changing the Display Order of Render Only Masks (page 673)

# Composite Volume Vista (Panorama)

Use this panorama vista to create composite volume calculations.

 Create New Volume Entry

Creates a new composite volume entry.

 Delete Volume Entry

Deletes the highlighted composite volume entry from the list.

 Import Volume Entries

Imports a volume entry that has been saved in XML format. Click to open the Import Volume Entries dialog box, where you can browse for the XML file. After you select the file, a new volume entry is created in the list.

 Export Volume Entries

Exports the selected volume entry to an XML file. Click to display the Export Volume Entries dialog box, from which you enter the file name and can browse to a location to save the XML file.

 Recompute Volumes

Recalculates the composite volume. For example, if you have created a composite volume on a surface that has been updated, you can click this button to recalculate the volume.

 Create New Volume Entry from Surfaces

Creates a new composite volume entry. You are prompted to select the base surface (Surface 1) and comparison surface (Surface 2). The cut, fill, net, and net graph are calculated and displayed in the table.

Index

Displays a list of numerical identifier assigned to each composite volume calculation.

**Surface Pair**

Base Surface

Specifies the base surface from which to create the composite volume. Click on the field and select the surface from the list.

Comparison Surface

Specifies the comparison surface from which to create the composite volume. Click on the field and select the surface from the list.

**Volume**

Cut

Displays the amount of material that has to be removed for the base surface to equal the comparison surface.

Fill

Displays the amount of material that has to be added for the base surface to equal the comparison surface.

Net

Displays the cut minus the fill. For example, if a volume is 200 m3 of cut, and 100 m3 of fill, the net is 100 m3<cut>.

Net Graph

Displays a graphical percentage representation of the whole volume. A fill net is displayed as a green bar indicating that material needs to be added to the project site. A cut net is displayed as a red bar, indicating that material must be removed.

**Related procedures:**

■ [Calculating Composite Volumes](#) (page 690)

# Hatch Properties Dialog Box

Use this dialog box to select the display of the watershed hatching pattern.

Type

Sets the pattern type. Click the ![button] button to select the hatching type from the drawing area:

■ **Predefined**: Specifies a predefined AutoCAD pattern. These patterns are stored in the *acad.pat* and *acadiso.pat* files. You can control the angle and scale of any predefined pattern. For predefined ISO patterns, you can also control the ISO pen width.

---

**NOTE** When you use the Solid predefined pattern, ensure that the boundary is closed and does not intersect itself. In addition, if the hatch area contains more than one loop, the loops must not intersect. These limitations do not apply to standard hatch patterns.

---

■ **User-Defined**: Creates a pattern of lines based on the current linetype in your drawing. You can control the angle and spacing of the lines in your user-defined pattern.

■ **Custom**: Specifies a pattern that is defined in any custom PAT file that you have added to the AutoCAD search path. (To use the patterns in the supplied *acad.pat* and *acadiso.pat* files, choose Predefined.) You can control the angle and scale of any custom pattern.

Pattern

Lists the available predefined patterns. The six most recently used predefined patterns appear at the top of the list. The selected patterns are stored in the HPNAME system variable. Available only if Type is set to Predefined.

Click ![button] to open the Hatch Pattern Palette dialog box, where you can view preview images for all predefined patterns.

Custom Pattern

Lists the available custom patterns. The six most recently used custom patterns appear at the top of the list. AutoCAD stores the selected pattern in the HPNAME system variable. Available only if Type is set to Custom.

Click ![button] to open the Hatch Pattern Palette dialog box, where you can view preview images for all custom patterns.

Angle

Specifies an angle for the hatch pattern relative to the X axis of the current UCS. AutoCAD stores the angle in the HPANG system variable.

ISO Pen Width

Specifies that an ISO predefined pattern is scaled based on the selected pen width. Available only if you set Type to Predefined and set Pattern to one of the available ISO patterns.

Scale

Expands or contracts a predefined or custom pattern. AutoCAD stores the scale in the HPSCALE system variable. This option is available only if you set Type to Predefined or Custom.

Relative to Paper Space

Specifies that the hatch pattern is scaled relative to paper space units. Using this option, you can easily display hatch patterns at a scale that is appropriate for your layout. Available only from a layout.

Spacing

Specifies the spacing of lines in a user-defined pattern. AutoCAD stores the spacing in the HPSPACE system variable. Available only if you set Type to User-Defined.

**Related procedures:**

■ Watersheds (page 675)

# Select Coordinate Zone Dialog Box

Use this dialog box to select the coordinate system.

**Zone**

Categories

Specifies the category of the coordinate system. This constrains the available coordinate systems.

Available Coordinate Systems

Specifies the available coordinate systems. Select from the list or enter a known coordinate system.

Selected Coordinate System Code

Specifies the code for the coordinate system. Populated when you specify a coordinate system or you can enter a coordinate system code.

Description

Displays a description for the selected coordinate system.

Projection

Displays the projection for the selected coordinate system. For example, LL for Latitude/Longitude or TM for Transverse Mercator.

Datum

Displays the datum for the selected coordinate system.

**Related procedures:**

■ Creating a Grid Surface from a DEM (page 608)

# Select Render Material Dialog Box

Use this dialog box to specify a render material for an object.

Render materials list

Select a render material from the list.

Click to select a render material from the drawing.

**Related procedures:**

■ [Applying Render Materials to Objects](page 1578)

# Water Drop Dialog Box

Use this dialog box to specify the parameters for drawing water drop paths on a surface.

---

**NOTE** The default values for these parameters can be set in the Edit Command Settings - CreateSurfaceWaterdrop dialog box. For information about setting command parameters, see [Specifying Command-Level Settings](page 69).

---

## Water Drop Path

Path Layer

Specifies the layer on which to draw the water drop path. Click  to open the [Object Layer](page 1985)dialog box where you can select a layer.

Path Object Type

Specifies the type of AutoCAD object to use for the water drop path. Either 2D Polyline or 3D Polyline.

## Water Drop Marker

Place Marker At Start Point

Specifies whether to draw a marker at the start point of the water drop path.

Start Point Marker Style

Specifies the style for the start point marker. Click  to open the [Select Point Style](page 1801) dialog box where you can select a style.

**Related procedures:**

■ [Drawing Water Drop Paths](page 711)

# Minimize Flat Areas Dialog Box

Use this dialog box to specify the parameters for minimizing flat areas on a surface.

## Minimize Flat Areas By

Filling Gaps In Contour Data

Specifies that small gaps in contours should be filled in.

Swapping Edges

Specifies that a non-contour common edge shared between a flat triangle and a non-flat triangle should be swapped.

Adding Points To Flat Triangle Edges

Specifies that a new point should be added at the midpoint of an edge shared between a flat triangle and a non-flat triangle.

Adding Points To Flat Edges

Specifies that a new point should be added to edges that bridge two same-elevation data contours and are not in flat triangles.

**Related procedures:**

■ [Minimizing Flat Areas in a Surface](#) (page 656)

# Export Surface to DEM Dialog Box

Use this dialog box to specify the parameters for exporting a surface to a DEM file.

## Selected Surface

Name

Displays the name of the selected surface.

Description

Displays the description for the selected surface.

Drawing Coordinate Zone

Displays the drawing coordinate zone, if specified.

## Export

DEM File Name

Specifies the file name, location, and file type of your new DEM file. The file can be of type USGS (*.dem*) or GEOTIFF (*.tiff*). Click  to open the Export Surface to DEM dialog box, then browse to the location, enter the file name and select file type.

Export Coordinate Zone

Specifies the coordinate zone of the exported surface. If the drawing has a coordinate zone assigned, this coordinate zone is displayed. Click  to open the Select Coordinate System dialog box to select the required coordinate system from the list.

Grid Spacing

Specifies the horizontal spacing for the DEM profile points. Enter an integer value that is greater than or equal to 1. This value is specified in units used in the export coordinate zone.

Determine Elevations By

Specifies how the elevations of the DEM file are determined from the exported surface. Select one of the following values:

■ Sample surface at grid point: Ensures that for each point along a DEM profile, the elevation is sampled from the selected surface.

■ Average: Ensures that for each point along a DEM profile, the elevation value corresponds to the mean elevation in a grid cell-sized region centered at this point.

Use Custom Null Elevation

Specifies whether to use a custom value for null elevation.

Null Elevation

Specifies the default value for null elevation.

**Related procedures:**

■ [Exporting to DEM](#) (page 714)

# Select Coordinate System Dialog Box

Use this dialog box to specify a coordinate system for an exported DEM file.

Drawing Coordinate System

Displays the coordinate system used in the drawing that references the surface.

Select DEM System

Specifies the available coordinate systems in the Projected category. Click to see the complete list of Projected coordinate systems.

Code

Displays the code for the selected coordinate system.

Area Of Use

Displays the region of the world where the selected coordinate system is used.

Properties

Click to see the detailed properties of the selected coordinate system and its projection.

**Related procedures:**

■ Exporting to DEM (page 714)

# DEM Coordinate System Properties Dialog Box

Use this dialog box to view the detailed properties of the coordinate system specified in the Select Coordinate System dialog box.

# Extract Objects from Surface Dialog Box

Use this dialog box to extract AutoCAD objects from a surface.

Property

Displays the currently visible surface components based on the surface style settings (see Display Tab (Surface Style Dialog Box) (page 2345). By default, all the displayed surface components are selected when the dialog box is opened.

Value

Specifies one of the following options:

■ Select All Extracts all the surface objects of the selected type.

■ Select from Drawing  Extracts an individual surface element. Click  to select the object you want to extract from the drawing.

**Related procedures:**

■ Extracting Surface Data (page 646)

# Move Blocks to Surface Dialog Box

Use this dialog box to move selected Block Reference objects to the elevation on the selected surface.

**Select block reference names**

Displays the names of each block definition that is referenced in the drawing. Select a block definition name from the list to select all Block Reference objects in the drawing or click  to select individual Block Reference objects and then press Enter.

**Total block reference objects selected**

Displays the number of Block Reference objects selected.

**Related procedures:**

■ Moving Blocks to a Surface Elevation (page 645)

# Move Blocks to Attribute Elevation Dialog Box

Use this dialog box to move selected Block Reference objects to a selected attribute elevation.

**Select block reference name**

Use to select a block definition name from the list. Click  to select individual Block Reference objects from the drawing and then press Enter.

**Select elevation attribute tag**

Specifies attribute tags for the selected Block Reference objects. If the Block Reference object does not have associated attribute tags, this option is unavailable.

**Total block reference objects selected**

Specifies the number of Block Reference objects selected.

**Related procedures:**

■ Moving Blocks to Attribute Elevation (page 641)

# Drape Image Dialog Box

Use this dialog box to select an image from the drawing and overlay it over a surface.

**Image**

Specifies the image from the drawing to be overlaid on the surface. Click  to select the image.

**Surface**

Specifies the surface on which the image is draped.

**Render Material Name**

Specifies the name of the render material associated with the current image. Once created, this render material can be applied to a different suitable surface.

**Related procedures:**

■ Draping Images On Surfaces (page 695)

# Simplify Surface Wizard

Use this wizard to reduce the number of points in a TIN surface.

# Simplify Methods Page (Simplify Surface Wizard)

Specify the surface simplification methods.

Edge Contraction

Contracts triangle edges to single points. The location of the point to which an edge is contracted is chosen so that the change to the surface is minimal. Each edge contraction results in the removal of one point.

Point Removal

Selects and removes surface points. More points are removed from the denser areas of the surface.

**Related procedures:**

■ Simplifying Surfaces (page 666)

# Region Options Page (Simplify Surface Wizard)

Specify surface regions for simplification.

**Region Options**

Use Existing Surface Border

Specifies the existing surface border as the boundary of the surface simplification region.

Specify Window/Polygon

Specifies the surface simplification region within a drawn rectangle.

Pick In Drawing

Click to specify the first and second points of the rectangle that delimits the surface simplification region. The button is unavailable, if Use Existing Surface Border is selected as a simplification option.

Select Objects

Specifies one of the following surface objects: 2D or 3D polyline, parcel, circle, feature line, or survey figure.

Mid-Ordinate Distance

Specifies the default mid-ordinate length used for the Select Objects option. If the selected object contains arc segments, each segment is tessellated into chord segments. The length of each chord segment is derived from the specified mid-ordinate distance. See also Mid-ordinate distance (page 615). Enter the distance value or click  to select the distance in the drawing.

Pick In Drawing

Click to select an object for simplification. The button is unavailable if Use Existing Surface Border is selected as a simplification option.

Total Points Selected In Region

Specifies the total number of points in the selected surface simplification region.

**Related procedures:**

■ Simplifying Surfaces (page 666)

# Reduction Options Page (Simplify Surface Wizard)

Fine-tune surface point reduction options.

### Reduction Options

Total Points Selected In Region

Specifies the total number of points in the selected surface simplification region.

Percentage Of Points To Remove

Specifies the percent of surface points to remove.

Maximum Change In Elevation

Specifies the maximum allowed difference between the elevation of the original surface and the elevation of the simplified surface.

Maximum Edge Contraction Error

Appears if you select Edge Contraction as a surface simplification method. It specifies a degree of the surface change if the edge were contracted to a point. 100 represents the maximum error over all surface edges and 0 represents the minimum.

Total Points Removed

Specifies the number of points removed after surface simplification. Press Apply to display the number.

**Related procedures:**

■ Simplifying Surfaces (page 666)

# Catchment Area Dialog Box

Specify the properties of a catchment boundary and catchment point marker.

### Catchment Area

Catchment Layer

Specifies the layer for the catchment region. The default value is zero. Click  in the Value column to select a different layer.

Catchment Object Type

Specifies the object type for the catchment boundary.

■ Select 2D Polyline if you simply want to delineate a catchment region.

■ Select 3D Polyline if you want to perform visualization and drape the catchment boundary line over the surface.

Catchment Marker

Specifies whether or not to add a catchment point marker to a catchment region.

Catchment Marker Style

Specifies the style of the catchment point marker. The default style is Standard. Click  to specify a different style.

**Related procedures:**

■ Displaying and Calculating Catchment Areas (page 712)

# Survey Dialog Boxes

# 71

## Edit Feature Settings - Survey Dialog Box

Use this dialog box to view and change survey-specific settings.

This topic documents settings in all survey-related Edit Settings dialog boxes (drawing-level, feature-level, and command-level).

- Drawing-level ambient settings are identified by the ⬚ drawing icon.

- Survey feature settings are listed near the top of this dialog box, after the General property group, and are identified by the 📷 survey icon.

- Survey command settings are identified by the 🗹 command icon.

For general information about drawing, feature, and command settings and their interaction, see Working with the Standard Settings Dialog Box Controls (page 62).

For information about drawing-level ambient settings, see Ambient Settings Tab (Drawing Settings Dialog Box) (page 1856)

### 📷 Default Styles

Specify the default styles for the survey features.

Default Figure Style

   Specifies the default style for a survey figure. Click in the Value column, and click ⬚ to select a style in the Survey Default Figure Style dialog box

Default Network Style

   Specifies the default style for a survey network. Click in the Value column, and click ⬚ to select a style in the Survey Default Network Style dialog box

For information about style selection, see Select Style Dialog Box (page 1805).

# Survey User Settings Dialog Box

Use this dialog box to change and view survey user settings.

Survey user settings are specific to a Windows user login account and affect the survey features, not database, or drawing data.

**Miscellaneous**

Establish default external editor settings.

Use External Editor

Specifies whether to use an external editor for displaying analysis input and output and editing field book and batch file. Click the check box to use an external editor.

> **NOTE** If you do not specify to use an external editor, the default editor, specified in the AutoCAD Options dialog box, is used.

External Editor

Specifies the path and name of the external editor. Enter a name and path or click ⌕ to browse to a location.

Preview Vertical Exaggeration

Specifies if the network, setup, and figures previews are exaggerated vertically. Enter a value, which is the factor applied to the elevations of the objects displayed in the previews.

**Survey Database Defaults**

Establish default locations for the survey database settings.

Survey Database Settings Path

Specifies the path for the location of the survey database settings files. The .*sdb_set* files located in this path can be selected in the Survey Database Settings.

Survey Database Settings

Specifies the survey .*sdb_set* file. This file contains the default database settings that are used when you create a new survey database.

Extended Properties Definition Path

Specifies the path for the location of the survey extended properties definition files. The .*sdx_set* files located in this path can be selected in the Extended Properties Definition.

Extended Properties Definition

Specifies the .*sdx_set* file. This pre-defined schema contains both LandXML and user defined properties that can be specified as the default when you create a new survey database.

**Equipment Defaults**

Establish default equipment database settings.

Equipment Database Path

Specifies the path for the equipment databases. This is the path where all new equipment databases are stored. Enter a path or click ⌕ to browse to a location.

Current Equipment Database

Specifies the current equipment database. Click the equipment database from the drop-down list.

> **NOTE** The list of available databases is determined by the databases listed in the Equipment Databases collection in the Toolspace Survey tab.

Current Equipment

Specifies the current equipment to use. Click the equipment name from the drop-down list.
The current equipment sets the values associated with a specific surveying instrument, such as the standard
deviations associated with the measuring capabilities for the equipment. This information is used in
various calculations including least squares.

## Linework Processing Defaults

Establish the default location for the linework code set and specify the linework code set to be used to do
linework processing during the import.

Linework Code Sets Path

Specifies the path for the Linework Code Sets. This is the path where all linework code sets are stored.

Enter a path, or click ⬛ to browse to a location.

Process Linework During Import

Specify Yes to process linework during an import command.

Current Linework Code

Specifies the default linework code set to use when linework processing occurs.

Process Linework Sequence

Specifies the order in which survey point descriptions are processed to determine linework connectivity.
Select one of the following:

■ By Import Order - processes points in the order in which they are imported. Point names are always
processed by import order.

■ By Point Number - processes points sequentially by point number (ascending order only).

## Figure Defaults

Establish equipment and figure prefix database information as well as the default external editor.

Figure Prefix Database Path

Specifies the path for the figure prefix database. This is the path where all new equipment databases are

stored. Enter a path or click ⬛ to browse to a location.

Current Figure Prefix Database

Specifies the current figure prefix database. Click the figure prefix database from the drop-down list.
Figure prefixes enable you to determine the layer that a figure is drawn on by creating a prefix for a group
of figure names. All figures with a specific prefix are placed on a specific layer.

NOTE The list of available databases is determined from the databases listed in the Figure Prefix Databases
collection on the Toolspace Survey tab.

Figure Style

Specifies the default style for figures inserted into the drawing.

Figure Layer

Specifies the default layer for figures inserted into the drawing.

## Interactive Graphics

Control the display of survey components during import and entry of survey data.

NOTE To change the colors for the components, click the color swatch to open the Select Color dialog box, from
which you can select a color.

Automatic Pan and Zoom

Specifies if the drawing automatically pans and zooms to the survey observations when they are imported or entered.

Show Backsight Line

Specifies whether a line, which represents the line backsighted by the survey instrument setup, is displayed.

Show Backsight Prism

Specifies whether a symbol, which represents the prism at the backsight point, is displayed.

Show Station Instrument

Specifies whether a symbol, which represents the instrument (transit) at the station (or occupied) point, is displayed.

Show Foresight Line

Specifies whether a line, which represents the line foresighted by the survey instrument setup, is displayed.

Show Foresight Prism

Specifies whether a symbol, which represents the prism at the foresight point, is displayed.

Show Baseline

Specifies whether a line, which represents the line established as a baseline, is displayed.

Show Baseline Prism

Specifies whether a symbol, which represents the prism at any new point created from a baseline, is displayed.

Show Baseline Offset Line

Specifies whether a line, which represents the baseline offset to any new point created, is displayed.

Show Current Figure

Specifies whether a line, which represents the current figure, is displayed.

## Import Defaults

Specify the properties for importing a batch file into the selected survey network.

Show Interactive Graphics

Specifies whether to display interactive graphics during the import of survey data. Use Interactive Graphics settings to control the display of individual graphics components.

Erase Survey Points From Drawing

Specifies whether to erase all the points referenced by the selected network from the drawing.

**NOTE** Points referenced by other networks are not erased from the drawing and database.

Reset Network

Specifies whether to remove all the observations in the survey database for the selected network. When this property is unchecked, incoming observations are appended to the observation database for the selected network.

Delete Network Figures

Specifies whether to erase figures, which have a reference to the selected network, from the drawing and database.

Insert Network Object

Specifies whether to create a network object in the drawing.

Insert Figure Objects

Specifies whether to create figure objects in the drawing.

Insert Survey Points

Specifies that Survey points are inserted into the drawing.

Default Figure Site

Specifies the default site for figures that are set to create Lot Lines. When inserting a figure into the current drawing:

■ If this site does not exist in the current drawing, it is created.

■ This site is used if the Lot Line property for the figure is set to True, and the Site property for the figure is blank.

Display Tolerance Errors In Event Viewer

Select Yes to display tolerance errors in the Event Viewer when you import data using the Import Field Book, Import LandXML, or Import Batch File commands. For more information, see Reporting Tolerance Errors (page 211).

## Export Defaults

Specify the properties for exporting survey data to a field book file.

Export Figures With Network

Select Yes to export the figures in the database when you use the Export Field Book command.
The figure type determines what is added to the field book. For information on the conditions and syntax that is added to the field book, see Setting Export Defaults (page 213).

Export Point Identifiers

Specifies if point IDs are used to define figures when figures are exported to a field book.
For information on the conditions and syntax that is added to the field book, see Setting Export Defaults (page 213).

Export Point Data

This check box is active when the Export Point Identifiers property is not set to None. Select Yes if you want each figure vertex that references a point identifier to output the following to the field book file prior to the section defining the figures: NE SS <point ID> <north> <east> <elevation> <description>

## Network Preview

Specify the network preview properties when selecting a Network item in the Survey Toolspace tab.

Show Network

Specifies whether to preview the network lines for the selected network item.

Show Sideshots

Specifies whether to preview the sideshot lines for the selected network item.

Show Points

Specifies whether to preview the points for the selected network item.

Show Figures

Specifies whether to preview the figures that reference the selected network item.

## Setup Preview

Specify the setup preview properties when selecting a Setup item in the Survey Toolspace tab.

Show Sideshots

Specifies whether to preview the sideshot lines for the selected setup item.

Show Points

Specifies whether to preview the points for the selected setup item.

Show Figures

Specifies whether to preview the figures affected by the selected setup item.

**Figure Preview**

Specify the setup preview properties when selecting a Figure item in the Survey Toolspace tab.

Show Figure

Specifies whether to preview the line segments for the selected figure item.

Show Points

Specifies whether to preview the display of the points referenced by the selected figure item.

**Related procedures:**

■ User Settings (page 205)

# Survey Database Settings Dialog Box

Use this dialog box to modify the survey database settings. These settings are specifically for the survey database features. By default, the survey database settings are stored in C:\Civil Projects\<database name>\Survey.sdb file.

**Units**

Establish specify the database units.

Coordinate Zone

Click ⬚ to display the Select Coordinate Zone dialog box where you can specify the coordinate zone for the survey database data. The default zone is set to None.

Distance

Specifies the distance unit. Click the cell in Value column and select a distance unit from the list.

**NOTE** If you specify a Coordinate Zone, the distance unit is obtained from the zone and the Distance property field is not active.

Angle

Specifies the angle unit for the survey database data. Click the cell in the Value column and select an angle type from the list.

Direction

Specifies the direction type for the Survey database data. Click the cell in the Value column and select a direction type from the list.

Temperature

Specifies the temperature unit for the survey database data when temperature corrections are applied to observations. Click the cell in the Value column and select a temperature type from the list.

Pressure

Specifies the atmospheric pressure unit for the survey database when pressure corrections are applied to observations. Click the cell in the Value column and select a pressure type from the list.

**Precision**

Establish the display precision of the survey data.

**NOTE** These precision settings are independent of the Drawing Settings precision settings. These settings affect all aspects of the user interface that displays survey data.

Angle

Specifies the precision value for all angle (including direction) values. The default precision is 4.

Distance

Specifies the precision value for all distance values. The default precision for Meters is 3, the default precision for Feet is 2.

Elevation

Specifies the precision value for all elevation values. The default precision for Meters is 3 and Feet is 2.

Coordinate

Specifies the precision value for all coordinate values. The default precision is 4.

Latitude and Longitude

Specifies the precision value for all latitude and longitude values. The default precision is 8.

## Measurement Type Defaults

Establish the default types assigned to the measurements.

**NOTE** For more information about the measurement types, see the Setting Measurement Type Defaults (page 217).

Angle Type

Specifies the default angle type. Click the cell in the Value column and select a distance type from the list.

Distance Type

Specifies the default distance type. Click the cell in the Value column and select a distance type from the list.

Vertical Type

Specifies the default vertical type. Click the cell in the Value column and select a vertical type from the list.

Target Type

Specifies the default target type. Click the cell in the Value column and select a target type from the list.

## Measurement Corrections

Specify the default measurement corrections to apply to the survey observations.

**NOTE** For information on formulas used to calculate corrections, see Setting Measurement Corrections (page 218).

Curvature and Refraction

Select Yes to correct measurement calculations for curvature of the earth and refraction of the sun light.

Sea Level

Select Yes to correct measurement calculations to sea level.

Atmospheric Conditions

Select Yes to correct measurement calculations for temperature and pressure.

Horizontal Collimation

Select Yes to correct Face 1 Angle and Face 2 Angle types for horizontal collimation (page 2470).

Vertical Collimation

Select Yes to correct Face 1 Angle and Face 2 Angle types for vertical collimation.

Scale Factor

Select Yes to correct calculated horizontal distances for scale factor.

EDM-Prism Eccentricity

Select Yes to correct distance measurements for EDM (page 2473) and prism (page 2480) offsets.

## Traverse Analysis Defaults

Do Traverse Analysis

Select Yes to perform a mathematical analysis based on the method you specify as the Horizontal Adjustment Method.

Do Angle Balance

Select Yes to have the angular error evenly distributed throughout the traverse.

Horizontal Adjustment Method

Specify one of the following traverse analysis methods:

- Compass Rule: A method of corrections where the closing errors are assumed to be as much due to errors in observed angles as by the errors in measured distances. The closing errors in latitude and departure are distributed according to the ratio of the length of the line to the total length of the traverse.

- Transit Rule: A method of balancing a traverse where the closing errors are assumed to be caused less by the errors in the observed angles than by the errors in measured distance. Corrections are distributed according to the ratio of the latitude and departure of each leg of the traverse to the sums of the latitude and departures of the entire traverse.

- Crandall Rule: A method of balancing a traverse where all the angular error is distributed throughout the traverse and all adjustments to the traverse are due to modifying the traverse distances. The modification distance made to each leg is such that the sum of the squares is a minimum. Corrections corresponding to the closing errors assume that the closing errors are random and normally distributed, and that all the angular error has been adjusted prior to the adjustment routine.

- Least Squares: A method of balancing a traverse. The squares of the differences between the unadjusted and adjusted measurements (angles and distances) are summed and reduced to a minimum. This method weights the individual measurements according to the specifications set in the Equipment correction settings to determine the source of error. You can adjust the data for an individual traverse loop, or a traverse network, if located from multiple observations.

Vertical Adjustment Method

Specify one of the following vertical adjustment methods:

- None: No vertical adjustment performed.

- Length Weighted Distribution: Vertical adjustment distributes the vertical closing error to each line at the same ratio as the length of the line to the total length of the traverse (similar to the Compass rule).

- Equal Distribution: Vertical adjustment distributes the vertical closing error equally to each of the traverse stations.

- Least Squares: A method of distributing the vertical error throughout a traverse. The squares of the differences between the unadjusted and adjusted measurements (angles and distances) are summed and reduced to a minimum. This method weights the individual measurements according to the specifications set in the Equipment correction settings to determine the source of error. You can adjust the data for an individual traverse loop, or a traverse network, if located from multiple observations.

**NOTE** The Least squares vertical adjustment method is only available if Least squares has been selected as the horizontal adjustment method. When this method is selected, a 3D least squares adjustment is performed. If this method is not selected a 2D least squares adjustment is performed.

Horizontal Closure Limit 1:X

Specifies the minimum allowable error of closure in the horizontal direction, for example a value of 15000.00 is 1 part in 15000.

Vertical Closure Limit 1:X

Specifies the minimum allowable error of closure in the vertical direction, for example a value of 15000.00 is 1 part in 15000.

Angle Error Per Set

Specifics the maximum angular error per traverse observation set.

## Least Squares Analysis Defaults

Specify the survey database setting defaults for performing a least square analysis on a network or a traverse.

Network Adjustment Type

Specifies the adjustment type for network least squares analysis only. The Traverse Analysis Defaults settings determine either a 2D or 3D analysis. Click the cell in the Value column and select one of the following from the list:

■ 2-Dimensional: Sets the adjustment type to 2D. No adjustments are made to elevations. Adjustments are only made to horizontal positions.

■ 3-Dimensional: Sets the adjustment type to 3D. Adjustments are made to both horizontal and vertical positions.

Maximum Number of Iterations

Specifies the maximum number of times the least squares routine adjusts the observations before a solution is reached. This default setting is 8. The maximum number of iterations that you can enter is 10. Generally, the solution is reached within two or three iterations.

Coordinate Convergence

Specifies the maximum difference that is allowed between the coordinates before the solution is accepted.

Confidence Level

Specifies either 95% or 99% as the percentages calculated in conjunction with the F distribution. F is the ratio of two independent chi square variables, which are divided by the respective degrees of freedom. For example, if the confidence level is set to 99%, then you can be 99% sure that the calculated ellipse contains the true location for the point.

Perform Blunder Detection

Select Yes to include blunder detection in the least squares output (*.lso) file.

## Survey Command Window

Specify the survey database settings for interacting with the Survey Command Window.

Ditto Feature

Select Yes to automatically repeat the last command in the Survey Command Window. This setting is on by default. When this setting is on, you can enter the command name once, and then continue to use the command by entering numeric data. To end the command, enter another command name.

Auto Point Numbering

Select Yes to enable automatic point numbering. When automatic point numbering is on, new points are automatically assigned the next available point number. When automatic point numbering is off, you must specify new point numbers as they are needed.

Start Point Numbering From

Specifies the number at which to start Auto Point Numbering.

Point Course Echo

Select Yes to have the Survey Command Window report the course taken to reach a point, including the direction and the distance.

Affects output in both the output file and the output view of the Survey Command Window.

Figure Course Echo

Select Yes to have the Survey Command Window report the course taken to create a figure, including direction and distance.

Affects output in both the output file and the output view of the Survey Command Window.

Point Coordinate Echo

Select Yes to have the Survey Command Window display the point coordinates, including northing, easting, and elevation information.

Affects output in both the output file and the output view of the Survey Command Window.

Figure Coordinate Echo

Select Yes to have the Survey Command Window display figure point coordinates, including northing, easting, and elevation information.

Affects output in both the output file and the output view of the Survey Command Window.

Command Echo

Select Yes to have the Survey Command Window display the commands that are entered.

Affects output in both the output file and the output view of the Survey Command Window.

Use Batch File

Select Yes and specify a batch file to record Survey Command Window input per network. The batch file for each network in a survey database is saved to *Civil Projects\<named> Survey Database\<named> Network\Batch.txt*.

If set to No, no commands are displayed in the Batch view of the Survey Command Window.

Use Output File

Select Yes and specify an output file name to record Survey Command Window output. The output file for each network in a survey database is saved to *Civil Projects\<named> Survey Database\<named> Network\Output.txt*.

## Error Tolerance

**NOTE** Redundant observations that exceed the error tolerance values create an event in the Event Viewer. For more information, see Reporting Tolerance Errors (page 211).

Distance Difference

Specifies a maximum difference in distance. If you observe a distance to a point more than once and the difference is greater than the acceptable value then an event is listed in the Event Viewer and a warning icon is displayed on the observation in Toolspace. If the difference in distance is less than the acceptable value, then the distance difference is averaged to establish the point coordinates.

Angular Difference

Specifies the maximum angular difference. If you observed an angle to a point more than once and the difference is greater than the acceptable value then an event is listed in the Event Viewer and a warning icon is displayed on the observation in Toolspace. If the angular difference is less than the acceptable value, then the angular difference is averaged to establish the point coordinates.

Elevation Difference

Specifies the maximum elevation difference. If you observed an elevation to a point more than once and the difference is greater than the acceptable value then an event is listed in the Event Viewer and a warning icon is displayed on the observation in Toolspace. If the elevation difference is less than the acceptable value, then the elevation difference is averaged to establish the point elevation.

Coordinate Difference

Specifies the maximum coordinate difference. If you located a point from more than one setup, and the difference is greater than the acceptable value then an event is listed in the Event Viewer and a warning icon is displayed on the observation in Toolspace. If the coordinate difference is less than the acceptable value, then it is averaged to establish the point coordinates.

## Extended Properties

Specify the survey database extended property settings.

Create New Definitions Automatically

Specify Yes to automatically create Survey LandXML properties in the LandXML file that do not exist in the Survey database.

Display Warnings For Missing Required Properties

Specify Yes to display a warning in the Event Viewer for any instance of a <SurveyFeatureClass> that is missing a required property. The Event Viewer tree displays the survey database name and the command name. The Event Viewer description column displays the <SurveyFeatureClass><ObjectID>:Missing required <property name> value.

**Related procedures:**

■ Survey Database (page 196)

# Survey Tab Item View

Use the Survey tab item view to display information about the contents of an individual item or a collection and to access related commands.

For some collections and some individual items, you can display additional information in an item view, which is displayed in a pane next to the tree when the Toolspace window is floating and beneath the tree when the Toolspace window is docked. To display the item view for a collection or an individual item in the tree, click the item name.

---

**NOTE** To see the item view, you may need to increase the size of the Toolspace window or move the bar that separates the item view from the tree. To move the bar that separates the item view from the tree, you must first select a collection that displays an item view.

---

An item view can be a collection list view, properties list view, or graphical view, depending on the selected item.

If there are editable fields in the list view, the following icons are displayed:

Discards any edits made to the properties and reloads the properties from the relevant database.

Saves any edits made to the properties back to the relevant database.

Bold text in the survey item view indicates that there are unsaved changes made to data. Click to save the changes or to discard the changes and revert the data.

## LandXML

If you are using the extended properties feature, the LandXML elements as defined in the *.sdx_def* file that are relevant to networks are displayed. Click the cell in the Value column to assign an attribute.

### User-defined

If you are using the extended properties feature, and have created User-defined properties they are displayed. Click the cell in the Value column to assign an attribute.

### Collection List View

A collection list view is a grid of rows and labeled columns displayed by the Toolspace trees for collection items. The list view can be displayed beneath or next to the Toolspace tree, depending on the state of the Toolspace window. The data displayed in the list view depends on the item selected in the tree.

### Properties List View

A properties list view displays an editable view of the properties of the item selected, for example, and individual figure, control point, or setup.

### Graphical View

A graphical view displays information about the selected item in a graphical (picture) form.

You can right-click in the graphical preview to display a shortcut menu that allows you to manipulate the image using commands such as Pan and Zoom.

### Related procedures:

- The Toolspace Item View (page 82)
- The Toolspace Survey Tab (page 97)

# New Equipment/Equipment Properties Dialog Box

Use this dialog box to change and view survey equipment properties.

### Miscellaneous

Name

Specifies the name of the equipment that displays in the selected equipment database.

> **NOTE** A best practice is to use the model number or the name of the equipment manufacturer.

Description

Specifies a description of the surveying equipment.

### Units

Distance

Specifies the type of distance units to be used for the equipment distance property values. Changing this value affects other settings that use angles, for example Standard Deviations.

Angle

Specifies the type of angle units to be used for the equipment angle property values.
When you change this value, other settings (for example Standard Deviations) that use angles are changed accordingly.

### Angle

Horizontal Collimation

Specifies the horizontal collimation correction applied to the FACE 1 and FACE 2 horizontal angles. The default value is 0.0 angle units.

Angle Type

Specifies the horizontal angle type. Select one of the following:

■ Right: measures the angle clockwise. (default)

■ Left: measures the angle counter-clockwise.

Vertical Collimation

Specifies the vertical collimation correction applied to the FACE 1 and FACE 2 vertical angles. Default value is 0.0 angle units.

Vertical Angle Type

Specifies the vertical angle type. Select one of the following:

**NOTE** A 90° Zenith angle equals a 0° Horizontal angle or a 270° Nadir angle. Also, an 89° Zenith angle equals a 1° Horizontal angle and a 269° Nadir angle.

■ Zenith: Select this value to measure the vertical angle between zenith and the object that is observed. (default)

■ Horizontal: Select this value to measure the vertical angle with respect to the horizon.

■ Nadir: Select this value to measure the vertical angle directly beneath the observer and directly opposite the zenith.

## Electronic Distance Meter (EDM)

Refractive Index

Specifies the refractive index for the carrier wavelength for the EDM, provided by the EDM manufacturer. Default value is 287.9600.

Wave Constant

Specifies the constant for the carrier wavelength for the EDM. Default value is 105.45.

Offset

Specifies the vertical distance between the scope center and the EDM center. Default value is 0.0000 mm.

Measuring Device

Specifies the type of device used for measuring distances. Select one of the following:

■ Scope: Select this value if the EDM is mounted above the scope; this type of EDM rotates radially about the horizontal axis as the scope is rotated.(default)

■ Non-scope: Select this value if the EDM is mounted on the scope; it is usually mounted on the standards and it does not rotate with the scope.

■ Other: Select this value if a device other than an EDM, such as steel tape or stadia rod, is used to measure distances.

## Prism

Tilting

Specifies the correction for EDM offset and prism offset. If this property is set to No, the following formulas are used to calculate the slope distance:
For a non-scope mounted EDM with non-tilting reflector:

$$SD = [(EO - PO) \times \cos VA] + \sqrt{OSD^2 - (PO - EO)^2 \times (\sin VA)^2}$$

For a scope mounted EDM with non-tilting reflector:

$$SD = \sqrt{OSD^2 - [EO - PO \times \sin VA]^2} - (PO \times \cos VA)$$

- EO: EDM offset

- PO: Prism offset

- OSD: Old slope distance

- SD: Slope distance

- VA: Vertical angle

**NOTE** Prism and EDM offset are not applied in tilting prism systems.

Prism Offset

Specifies a value for the prism offset (mm) to establish the vertical distance between the reflector (prism) and the target. Default value is 0.0000 distance units.

Prism Constant

Specifies the value for the prism constant (mm) to establish the horizontal distance between the effective prism and the actual prism placement. The value is added to all measured distances. Default value is 0.0000 distance units.

## Standard Deviations

Use these settings to specify the accuracy of the surveying equipment. These values are used to calculate the standard errors that appear in the least squares input file.

EDM Proportional Error (ppm)

Specifies the proportional error, in parts per-million, associated with the EDM. This value can also be determined from the manufacturers documentation for the EDM. Default value is 5.0000 ppm.

EDM Constant Error

Specifies the constant error, in millimeters, associated with the EDM. This value can also be determined from the manufacturers documentation for the EDM. Default value is 0.005 meters (5mm).

Centering Error

Specifies the centering error, in millimeters, involved with centering the instrument over a point. Default value is 0.0015 Meters (1.5 mm).

Target Alignment Error

Specifies the target alignment error, in millimeters, involved with aligning the instrument with the target. Default value is 0.0025 Meters (2.5 mm).

Pointing Error

Specifies the pointing error, in seconds of a degree, involved with pointing the instrument at the target. Default value is 0.0001 Degrees DMS (1.0 seconds).

Horizontal Circle

Specifies the horizontal circle error, in seconds of a degree, associated with reading a horizontal circle. Default value is 0.0015 Degrees DMS (1.5 seconds).

Direction Error

Specifies the direction error, in seconds of a degree, associated with the measurement of an azimuth or bearing. Default value is 0.0010 Degrees DMS (10 seconds).

Vertical Circle

Specifies the vertical circle error, in seconds of a degree, associated with reading a vertical circle. Default value is 0.00015 Degrees DMS (1.5 seconds).

Prism Height Error

Specifies the error, in millimeters, associated with measuring the prism height. Default value is 0.001 Meters (1.0 mm).

Theodolite Height Error

Specifies the error, in millimeters, associated with measuring the theodolite height. Default value is 0.001 Meters (1.0 mm).

# Translate Survey Database Dialog Box

Use this dialog box to specify the values needed to perform a simple translation on an open survey database.

This command is useful when you need to move the data in a survey database from an assumed location to a known location, subsequent to importing the survey data into AutoCAD Civil.

## Base Point Page (Translate Survey Database Dialog Box)

Specify the base point from which the survey network will be moved.

Number

Enter an existing survey point number in the survey database. The Name, Easting, Northing, Elevation, Description, Latitude, and Longitude property values are displayed.

**NOTE** The values for the Base Point properties are displayed in the current Survey database units.

Name

Displays the name of the base point.

Easting

Displays the Easting value for the base point.

Northing

Displays the Northing value for the base point.

Elevation

Displays the elevation value for the base point.

Description

Displays an optional description for the base point.

Longitude

Displays the Longitude for the base point. If the Survey database has been assigned a coordinate zone, the Longitude property displays the longitude of the easting value.

Latitude

Displays the Latitude value for the base point. If the Survey database has been assigned a coordinate zone, the Latitude property displays the latitude of the Northing value.

Pick In Drawing

In the drawing, select the northing and easting for the base point. If the drawing has been assigned a coordinate zone that is different from the assigned zone of the Survey Database, the coordinates of the point that you pick in the drawing are transformed to the Survey Database coordinates.

## Rotation Angle Page (Translate Survey Database Dialog Box)

Specify the rotation angle for the survey database.

Rotation Angle

Specify a positive or negative rotation angle.

---

**NOTE** The values for the Rotation Angle are displayed in the current Survey database units.

---

Pick In Drawing

Specify the start point of the existing direction, the second point, the start point of new direction, and a second point.

# Destination Point Page (Translate Survey Database Dialog Box)

Specify the destination point to which the survey database will be moved.

Easting

Specifies the easting value.

Northing

Specifies the northing value.

Longitude

Displays the Longitude for the base point. If the Survey database has been assigned a coordinate zone, the Longitude property displays the longitude of the easting value.

Latitude

Displays the Latitude value for the base point. If the Survey database has been assigned a coordinate zone, the Latitude property displays the latitude of the Northing value.

Elevation Change

Specifies the change in elevation. (optional)

Pick In Drawing

Specify the start point of the existing direction, the second point, the start point of new direction, and a second point.

# Summary Page (Translate Survey Database Dialog Box)

Displays a summary of the Base Point, Destination Point, and the Translation values

# Survey Network Style Dialog Box

Define survey network styles to control the appearance of network components such as markers and lines, and the display of components in the drawing.

# Information Tab (Survey Network Style Dialog Box)

Use this tab to change the survey network style name and description information, and to review details, such as when the style was most recently modified.

Name

Specifies a name for the current style. The style name identifies the style on the Settings tab in Toolspace and is listed in the Style Selection dialog box. Changes to a style name are reflected in the title bar of the Style dialog box.

Description

Specifies the description for the current style.

# Components Tab (Survey Network Style Dialog Box)

Use this tab to specify how survey network style components are displayed, such as component scaling, and symbols.

### Marker Styles

Use these settings to specify how markers are displayed. Markers are used to control the display of network points.

Marker Style For Known Control Points

   Specifies a marker style for known (fixed) control points in the survey network.

Marker Style For Unknown Control Points

   Specifies a marker style for the unknown control points in the survey network.
   Unknown points are the vertices of the network lines whose locations are determined from observations relative to the known Control Point locations. Typically, an unknown control point is an instrument setup. However, Sideshot observations made from unknown control points are recalculated when a network is updated from a network adjustment, such as a Traverse or Least Squares adjustment.

Marker Style For Non-Control Points

   Specifies a marker style for non control points in the survey network.

Marker Style For Sideshot Points

   Specifies a marker style for the sideshot points in the survey network.

Marker Style For Tolerance Error Points

   Specifies a marker style for the tolerance error points in the survey network.

### Error Ellipses

Error Ellipses Scale Factor

   Specifies a scale factor for displaying an error ellipse (page 2473) of a survey network.

# 3D Geometry Tab (Survey Network Style Dialog Box)

Use this tab to specify how the survey network style components display in 3D views.

### 3D Geometry

Network Display Mode

   Specifies the mode in which the network elevations are displayed in the drawing. Click the cell in the Value column and select one of the following from the list:

   ■ Use Network Elevations: Displays network components at the actual elevations.

   ■ Flatten Network To Elevation: Flattens the network component elevations to a specified value.

   ■ Exaggerate Network Elevations By Scale Factor: Scales network component elevations by a specified scale factor.

Flatten Network To Elevation

   Flattens the network component elevations to a specified value. This option is only active when you specify the value Flatten Network To Elevation as the Network Display Mode.

Exaggerate Network Elevations By Scale Factor

   Scales network component elevations by a specified scale factor. This option is only active when you specify the value Exaggerate Network Elevations By Scale Factor: as the Network Display Mode.

## Display Tab (Survey Network Style Dialog Box)

Use this tab to specify the survey network style component display in Plan (2D) and Model (3D) views. This is the standard AutoCAD Civil Display tab. For more information, see Display Tab (Style Dialog Box) (page 1801)

Survey Network Display components include:

- Known Control Points: a point symbol representing a known point in a survey network. All other unknown points are dependent on the location of a known point.

- Unknown Control Points: a point symbol representing a point in the survey network where the point location is calculated relative to an observation made to a known control point. An unknown control point may represent an instrument setup or an adjusted control point.

- Non-Control Points: a point symbol representing a point with its location determined from a reduced observation, for example a point created by the NE SS survey command. A non-control point is not connected to other survey observations and remains unaffected by network analysis, but it still a component of the survey network. A non-control point may be promoted to a control point if it is referenced by observations.

- Sideshot Points: a point symbol representing a sideshot point in the survey network with its location determined from an observation made from either a known or unknown point. In most cases a sideshot point is not connected to any other point in the network.

- Network Lines: a line representing observations that connect two control points.

- Direction Lines: a line representing observed direction data from either a known or unknown point in the survey network.

- Sideshot Lines: a line representing observations between a control point and a sideshot.

- Error Ellipses: this component represents the positional error of an unknown control point as a result of least squares analysis.

- Tolerance Error Points: this component represents an observed point where the observation(s) exceeds the tolerance error values specified in the Survey Database Settings.

- Tolerance Error Lines: this component represents the line of sight between the setup and the observed point that exceeds the tolerance error values that were specified in the Survey Database Settings.

## Summary Tab (Survey Network Style Dialog Box)

Use this tab to view all the survey network style properties. For more information about the properties in this tab, see Summary Tab (Style Dialog Box) (page 1803).

# Survey Figure Style Dialog Box

Use survey figure styles to control the way a figure and its components, such as points and lines, are displayed in the drawing.

# Information Tab (Survey Figure Style Dialog Box)

Use this tab to view or change general information for the survey figure style.

Name

Specifies the name of the current figure style.

Description
    Specifies an optional description for the current style.

Created By
    Displays the AutoCAD login name of the person who created the style.

Date Created
    Displays the date and time the style was created.

Last Modified By
    Displays the AutoCAD login name of the person who last modified the style.

Date Modified
    Displays the date and time the style was last modified.

# Plan and Model Tab (Survey Figure Style Dialog Box)

Use this tab to specify marker styles and marker placement options for each figure marker component. These figure marker components display on the Display tab of the figure style.

### Vertex Markers

Use these settings to specify the marker properties for figure Vertex Markers component. You can use the vertex markers component to create a marker style for the original data points from which the figure was created, for example the point located in field that defined the figure.

Marker Style

Specifies the marker style for the marker component. Click ⋯ to display the Figure Vertex Marker Style dialog to specify the marker style.

Align Markers With Figure
    Specifies if the markers are aligned normal to the figure segments. Click the cell in the Value Column and select to Yes, to override the specified marker style orientation properties.

### Midpoint Markers

Use these settings to specify the marker properties for the figure Midpoint Markers component. The midpoint markers component can be used to display a marker style for the midpoint of each figure segment.

Marker Style

Specifies the marker style for the marker component. Click ⋯ to display the Marker Style dialog to specify the marker style.

Align Markers With Figure
    Specifies if the markers are aligned normal to the figure segments. Click the cell in the Value column and select to Yes to override the specified marker style orientation properties.

### Endpoint Markers

Use these settings to specify the marker properties for the starting point and the ending point of the figure.

Start Point Marker Style
    Specifies the marker style for the start point of the figure.

End Point Marker Style
    Specifies the marker style for the end point of the figure.

Align Markers With Figure
    Specifies if the markers are aligned normal to the figure segments. Click the cell in the Value column and select to Yes, to override the specified marker style orientation properties.

**Additional Markers**

Use these settings to specify if additional markers and marker styles to use on figures. Markers are considered additional when they are not placed at a vertex, start, mid, or endpoint on the figure.

Marker Style

Specifies the marker style for the marker component. Click ![button] to display the Marker Style dialog to specify the marker style.

Additional Marker Placement Method

Specifies the placement of additional markers. Click the cell in the Value column and select one of the following from the list:

■ None: disables the placement of intermediate additional markers on the figure.

> **NOTE** if you specify this option, At Interval and Divide Figure By properties in the Additional Markers category are disabled.

■ At Interval: places additional markers at the specified interval.

■ Divide Figure: places markers on the figure segments determined by the Divide By property.

■ Continuous: specifies that additional markers are placed continuously along the figure. Each marker is placed outside the extents of the previous marker.

Interval

Specifies the interval if you set the Marker Placement Method to At Interval. Click the cell in the Value column and enter a number that is greater than zero.

Divide Figure By

Specifies the value to divide the figure by if you set the Marker Placement Method to Divide By. Click the cell in the Value column and enter a number that is greater than zero.

Place Marker At Figure Start Point

Specify Yes to have the Marker Placement Method always places an additional marker at the start point of the figure.

> **NOTE** This setting overrides the setting of None in the Marker Placement Method.

Place Marker At Figure End Point

Specify Yes to have the Marker Placement Method always places an additional marker at the end point of the figure.

> **NOTE** This setting overrides the setting of None in the Marker Placement Method.

Align Markers With Figure

Specifies if the markers are aligned normal to the figure segments. Click the cell in the Value column and select to Yes, to override the specified marker style orientation properties.

# 3D Geometry Tab (Survey Figure Style Dialog Box)

Use this tab to specify the 3D display of the survey figure style components.

Figure Display Mode

Specifies the display mode for figure elevations in the drawing. Click the cell in the Value column and select one of the following:

■ Use Figure Elevations: displays figure components at the actual elevations.

- Flatten Figure To Elevation: flattens figure component elevations to a specified value:

- Exaggerate Figure Elevations By Scale Factor: scales figure component elevations by a specified scale factor.

Flatten Figure To Elevation

This field is enabled if you specify Flatten Figure To Elevation as the Figure Display Mode. All figure component elevations are displayed at the specified elevation.

Exaggerate Figure Elevations By Scale Factor

This field is enabled if you specify Exaggerate Figure Elevations By Scale Factor as the Figure Display Mode. Click the cell in the Value column and enter a value. All figure component elevations are multiplied by the value you enter.

# Profile Tab (Survey Figure Style Dialog Box)

Use this tab to specify the marker styles for survey figures projected into profile views.

You can select different markers for the beginning, internal, and end vertices of a survey figure.

# Section Tab (Survey Figure Style Dialog Box)

Use this tab to specify the marker style for survey figures projected into section views.

This marker is used to indicate where a survey figure crosses the sample line displayed in the section view.

# Display Tab (Survey Figure Style Dialog Box)

Use this tab to specify the display styles for survey lines and markers in different contexts.

This is the standard AutoCAD Civil Display tab. For more information, see Display Tab (Style Dialog Box) (page 1801).

View Direction

Specifies the context for which you are setting the display:

- **Plan** – the printed drawing

- **Model** – the on-screen design window

- **Profile** – projection into a profile view

- **Section** – projection into a section view

Survey figure display components include:

- Figure Line

- Vertex Markers

- Midpoint Markers

- Endpoint Markers

- Additional Markers

## Summary Tab (Survey Figure Style Dialog Box)

Use this tab to view all the survey network style properties. For more information about the properties in this tab, see Summary Tab (Style Dialog Box) (page 1803).

# New Equipment Database Dialog Box

Use this dialog box to specify the name for a new equipment database.

Enter a unique name for the new equipment database.

---

**NOTE** A best practice is to create an equipment database per equipment manufacturer. For example, create one equipment database for Leica surveying instruments, and another for Trimble surveying instruments.

---

**Related procedures:**

■ Survey Equipment Database (page 199)

# New Figure Prefix Database Dialog Box

Use this dialog box to specify the name for a new figure prefix database.

Enter a unique name for the new figure prefix database.

**Related procedures:**

■ Survey Figure Prefix Database (page 200)

# New Figure Prefix/Figure Prefix Properties Dialog Box

Use this dialog box to specify the properties for a new figure prefix.

Name

Specifies the name for the figure prefix. The prefix name is used to match on a figure name at figure creation time, for example, when importing a field book file.

Breakline

Specifies that the matched figures can be used as breaklines (when creating surface breaklines from figures).

Lot Line

Specifies that the figure behaves as a parcel segment. When this property is selected and the figure is inserted into drawing, the figure behaves as a parcel segment in the site that it is placed on. Figures with this property may create parcels and can be labeled as parcel segments.

Layer

Specifies the layer that the figure object is placed on when inserting figures into a drawing. When there is a prefix match, the following occurs:

■ If the specified layer exists in the drawing, the figure is placed on that layer.

■ If the specified layer does not exist in the drawing, the layer is created and the figure is placed on the specified layer.

Style

Specifies the figure style that is assigned to the figure when the figure is inserted into a drawing. When there is a prefix match, the following occurs:

■ If the specified style name exists in the drawing, the style is used.

■ If the specified style does not exist in the drawing, a new style with the specified name is created.

Site

Specifies the site name that is assigned to the figure if a figure prefix match occurs. The figure is placed in this site when it is inserted into a drawing. If the site name does not exist in the current drawing it is created.

**Related procedures:**

■ Survey Figure Prefix Database (page 200)

# Survey Panorama Vistas

Use the Survey Panorama vistas to display and edit collections of survey data, in a grid.

The Panorama displays many types of data. Each different type of data is displayed using a vista that is specific to that data type. To conserve screen space if more than one vista is active, the Panorama displays a tab for each one.

Click a tab to bring a vista to the front.

You can dock and move the Panorama, and you can use Auto-hide to reduce the amount of screen space it requires when you are not using it. For more information, see The Panorama Window (page 102).

## Control Points Editor

Use this dialog box to edit existing control points or create new ones.

Point Number

Specifies the point number.

Name

Specifies the point name. Optional.

Northing

Specifies the point northing.

**NOTE** If the survey database has been assigned a coordinate system zone, the Latitude property value is calculated from the value entered in this field.

Easting

Specifies the point easting.

**NOTE** If the survey database has been assigned a coordinate system zone, the Longitude property value is calculated from the value entered in this field.

Elevation

Specifies the point elevation.

Description

Specifies the point description.

**NOTE** Latitude and Longitude values are only displayed when the survey database has an assigned coordinate system zone.

Latitude
   Specifies the point latitude. The Northing property value is calculated from the value entered in this field.

Longitude
   Specifies the point longitude. The Easting property value is calculated from the value entered in this field.

**Related procedures:**

■ The Panorama Window (page 102)

■ Control Points (page 253)

## Non-Control Points Editor

Use this dialog box to edit existing non-control points or create new ones.

Point Number
   Specifies the point number.

Name
   Specifies the point name.

Northing
   Specifies the point northing.

   **NOTE** If the survey database has been assigned a coordinate system zone, the Latitude property value is calculated from the value entered in this field.

Easting
   Specifies the point easting.

   **NOTE** If the survey database has been assigned a coordinate system zone, the Longitude property value is calculated from the value entered in this field.

Elevation
   Specifies the point elevation.

Description
   Specifies the point description.

**NOTE** Latitude and Longitude values are only displayed when the survey database has an assigned coordinate system zone.

Latitude
   Specifies the point latitude. The Northing property value is calculated from the value entered in this field.

Longitude
   Specifies the point longitude. The Easting property value is calculated from the value entered in this field.

**Related procedures:**

■ The Panorama Window (page 102)

■ Non-Control Points (page 256)

# Setups Editor

Use this dialog box to view and edit survey setups.

**Station Point**

Displays the station point number.

**Backsight Point**

Displays the backsight point number.

**Backsight Direction**

Displays the direction of the backsight in the specified units.

**Backsight Orientation**

Specifies the orientation of the horizontal circle when backsighting the point. This is an optional value, and is assumed to be 0.00 unless you specify otherwise.

**Backsight Face1**

Specifies the direct angle reference on the backsight for face 1 (page 2473) angles.

**Backsight Face2**

Specifies the direct angle reference on the backsight for face 2 (page 2473) angles.

**Instrument Height**

Specifies the measured instrument (theodolite) height. This is typically measured from the center of the theodolite optics to the setup point on the ground.

**Instrument Elevation**

Specifies or displays the instrument elevation. If the setup point has an elevation, this field is read-only and displays the calculated instrument elevation (setup point elevation plus the instrument height). If the setup point has no elevation, then this column can be used to specify the instrument elevation.

**Northing**

Displays the northing value for the setup.

**Easting**

Displays the easting value for the setup.

**Elevation**

Specifies the elevation of the setup.

**Related procedures:**

- The Panorama Window (page 102)
- Setups (page 259)

# Directions Editor

Use this dialog box to view and edit survey directions.

**From Point**

Displays the originating control point.

**To Point**

Displays the destination reference point for the direction.

Direction

Specifies the direction value. The unit type is determined by the direction type setting. For more information, see Database Settings (page 216)

Direction Type

Specifies the direction type. Either an azimuth (page 2467) or a bearing (page 2468).

**Related procedures:**

■ The Panorama Window (page 102)

■ Directions (page 283)

## Observations Editor

Use this dialog box to view and edit survey observations.

Point Number

Specifies the point number.
When creating a new point and automatic point numbering is off, you must specify the point number. If automatic point numbering is on, then the points are automatically numbered.

Name

Specifies an optional name for the point.

Angle

Specifies the measured horizontal angle. It is assumed to be clockwise (right). Use a negative number (-) to turn counter-clockwise (left). Expressed in the current units.

Angle Type

Specifies the angle type to locate the point. Either angle (page 2467), deflection angle (page 2472), face 1 (page 2473), face 2 (page 2473), or bearing (page 2468).

Distance

Specifies the distance from the instrument point to the point being located. It is measured in the current units.

Distance Type

Specifies the distance type to locate the point. Specify slope (page 2482), horizontal, or None.

Vertical

Specifies the vertical angle or distance depending on the Vertical Type.

Vertical Type

Specifies the method of measuring the vertical. Either Vertical Angle or Vertical Distance.

Target Height

Specifies the vertical distance between the ground elevation and the focal point of the prism or stadia.

Target Type

Specifies the target type. Either prism (page 2480), stadia (page 2483), or None.

Scale Factor

Specifies the scale factor that affects how ground measurements are translated into grid measurements.The horizontal distances are then multiplied by this factor when the Scale Factor correction is checked in the Measurement Corrections property in the Survey Database Settings dialog.

Northing

    Displays the calculated northing for the point.

Easting

    Displays the calculated easting for the point.

Elevation

    Displays the calculated elevation for the point.

**Related procedures:**

- The Panorama Window (page 102)
- Observations (page 263)

## Survey Points Editor

Use this dialog box to view and edit all survey points.

The point icon in the first column indicates the point type:

- ⬖ Control point.
- ⬖ A control point derived from an adjustment, such Traverse or Least Squares analysis.
- ⬖ Non-control point.
- ⬖ Setup.
- ⬖ Observation.

Number

    Displays the point number.

Name

    Specifies the point name.

Easting

    Displays the point easting.

> **NOTE** If the survey database has been assigned a coordinate system zone, the Longitude property value is calculated from the value in this field.

Northing

    Displays the point northing.

> **NOTE** If the survey database has been assigned a coordinate system zone, the Latitude property value is calculated from the value in this field.

Elevation

    Displays the point elevation.

Description

    Specifies the point description.

> **NOTE** Latitude and Longitude values are only displayed when the survey database has an assigned coordinate system zone.

Longitude

Displays the point longitude, if applicable.

Latitude

Displays the point latitude, if applicable.

**Related procedures:**

■ The Panorama Window (page 102)

# Figure Prefixes Editor

Use this dialog box to view and edit the properties of a figure prefix.

Name

Specifies the name for the figure prefix. The prefix name is used to match on a figure name at figure creation-time, for example when importing a field book file.

Breakline

Specifies that the matched figures can be used as breaklines (when creating surface breaklines from figures).

Lot Line

Specifies that the figure behaves as a parcel segment. When this property is selected and the figure is inserted into drawing, the figure behaves as a parcel segment in the site that it is placed on. Figures with this property may create parcels and can be labeled as parcel segments.

Layer

Specifies the layer that the figure object is placed on when inserting figures into a drawing. When there is a prefix match, the following occurs:

■ If the specified layer exists in the drawing, the figure is placed on that layer.

■ If the specified layer does not exist in the drawing, the layer is created and the figure is placed on the specified layer.

Style

Specifies the figure style that is assigned to the figure when the figure is inserted into a drawing. When there is a prefix match, the following occurs:

■ If the specified style name exists in the drawing, the style is used.

■ If the specified style does not exist in the drawing, it is created with the specified name.

Site

Specifies the site name that is assigned to the figure if a figure prefix match occurs. The figure is placed in this site when it is inserted into a drawing. If the site name does not exist in the current drawing it is created.

**Related procedures:**

■ Survey Figure Prefix Database (page 200)

■ The Panorama Window (page 102)

# Figures Editor

Use this dialog box to view and edit survey figures.

Name

Specifies the name of the figure. The figure name can be composed of characters that are number, alpha, or alpha-numeric.

Breakline

Specifies that the figure is used as a breakline (when creating surface breaklines from figures).

Lot Line

Specifies that the figure behaves as a parcel segment. When this property is selected and the figure is inserted into drawing, the figure behaves as a parcel segment in the site that it is placed on. Figures with this property may create parcels and can be labeled as parcel segments.

Layer

Specifies the layer that the figure object is placed on when inserting figures into a drawing.

Style

Specifies the style that the figure object uses when inserting figures into a drawing.

Site

Specifies the site for the figure. When inserting a figure into the current drawing:

■ If this site does not exist in the current drawing, it is created.

■ The figure is placed on this site. If the Lot Line property is checked for the figure, a parcel segment is created.

Vertices

Displays the number of vertices in the figure.

Length

Displays the length of the figure.

Area

Displays the area of the figure.

**Related procedures:**

■ The Panorama Window (page 102)

■ Survey Figures (page 321)

## Figure Groups Editor

Use this dialog box to select and edit a survey figures within a figure group.

Name

Specifies the name of the Figure Group.

**Related procedures:**

■ The Panorama Window (page 102)

■ Using Groups to Manage Survey Data (page 248)

## Network Groups Editor

Use this dialog box to select and edit a survey network from within a survey network group.

**LandXML and User-Defined**

> **NOTE** If you are using the Extended Properties feature, relevant LandXML and User-defined properties for each group are displayed in the panorama. To edit a group, select the group in the panorama and make edits in the Extended Data panel (left pane). Click  to open or close the extended data panel.

Name
   Specifies the name of the Network Group.

Description
   Specifies an optional description.

**Related procedures:**

■ The Panorama Window (page 102)

■ Using Groups to Manage Survey Data (page 248)

## Networks Editor

Use this dialog box to edit a survey network.

### LandXML and User-Defined

> **NOTE** If you are using the Extended Properties feature, relevant LandXML and User-defined properties for each Network are displayed in the panorama. To edit a network, select the network in the panorama and make edits in the Extended Data panel (left pane). Click  to open or close the extended data panel.

Name
   Specifies the Network name.

Description
   Specifies an optional description.

**Related procedures:**

■ The Panorama Window (page 102)

■ Survey Networks (page 201)

## Survey Point Groups Editor

Use this dialog box to select and edit a survey point within a survey point group.

### LandXML and User-Defined

> **NOTE** If you are using the Extended Properties feature, relevant LandXML and User-defined properties for each group are displayed in the panorama. To edit a group, select the group in the panorama and make edits in the Extended Data panel (left pane). Click  to open or close the extended data panel.

Name
   Specifies the name of the Survey Point Group.

Description
   Specifies an optional description.

# Figure Display

Use this dialog box to display Inverse or Mapcheck information for a figure.

# Traverse Editor

Use this dialog box to edit the observations of an existing named traverse or to enter traverse observations for a new empty traverse.

The left pane of the Traverse Editor displays the following properties for the selected setup within the current station point:

Station Point
   Displays the station point number.

Backsight Point
   Displays the backsight number.

Backsight Direction
   Specifies the backsight direction.

Backsight Orientation
   Specifies the orientation of the horizontal circle when backsighting the point.

Backsight Face1
   Specifies the direct angle reference on the backsight for face1 angles.

Backsight Face2
   Specifies the direct angle reference on the backsight for face2 angles.

Instrument Height
   Specifies the measured instrument height.

Instrument Elevation
   Displays the instrument elevation.

Northing
   Displays the northing value.

Easting
   Displays the easting value.

Elevation
   Displays the elevation.

**Latitude**

Displays the latitude.

**Longitude**

Displays the longitude.

In the right pane of the Traverse Editor you can enter observations for each Setup and specify the following;

**Name**

Specifies a traverse station point name.

**Angle**

Specifies the angle using the current Survey database units.

**Angle Type**

Specify one of the following:

- Angle

- Deflection

- Face1 Angle

- Face2 Angle

- Azimuth

- Bearing-NE

- Bearing-SE

- Bearing-SW

- Bearing-NW

- None

**Distance**

Specify the distance in the current Survey database units.

**Distance Type**

Specify one of the following:

- Slope

- Horizontal

- None

**Vertical**

Specifies the vertical type.

**Vertical Type**

Specify one of the following:

- Vertical Angle

- Vertical Distance

- None

**Target Height**

Specifies the target height.

Target Type

Specify one of the following:

■ Stadia

■ Prism

■ None

Scale Factor

Specifies the scale factor.

Description

Specifies a description.

Easting

Displays the easting.

Northing

Displays the northing.

Elevation

Displays the elevation.

Longitude

Displays the latitude.

Latitude

Displays the longitude.

**Related procedures:**

■ The Panorama Window (page 102)

## Traverses Editor

Use this vista to edit and view information for multiple traverses.

Name

Specifies the name for the traverse.

Description

Specifies a description for the traverse.

Initial Station

Specifies the starting setup point ID in the traverse.

Initial Backsight

Specifies the initial backsight. The initial backsight point number must not be 0. The initial backsight must be to either an existing survey point, or there must be a direction observation from the initial station point to the initial backsight point. In cases where there is a direction observation, the backsight point does not have to exist as a survey point.

Stations

Specifies the points that are included in the traverse. Separate a range of points with a hyphen (-), and separate individual points with a comma (,). For example: 1-5,8,10,12-15.

Final Foresight

Specifies the final foresight point ID. This establishes the final foresight station point in the traverse definition, onto which the closing angle was turned.

**Related procedures:**

■ Traverses (page 373)

■ The Panorama Window (page 102)

# Import / Re-import Field Book Dialog Box

Use this dialog box to edit user and survey database settings associated with a field book import operation.

The current user and survey database setting defaults are displayed when the dialog is initialized. The settings here are not saved back to the user and survey database settings and are only applicable for the field book import operation.

Field Book Filename (.FBK)

Specifies the field book (*.fbk*) to import. Click ![browse icon] to browse to a location.

Current Equipment Database

Specifies the equipment database to use. Select the equipment database from the drop-down list.

**NOTE** The list of available databases is determined by the databases listed in the Equipment Databases collection in the Toolspace Survey tab.

Current Equipment

Specifies the current equipment to use. Click the equipment name from the drop-down list.
The current equipment sets the values associated with a specific surveying instrument, such as the standard deviations associated with the measuring capabilities of the equipment. This information is used in various calculations including least squares.

Current Figure Prefix Database

Specifies the current figure prefix database. Click the figure prefix database from the drop-down list. Figure prefixes enable you to determine the layer that a figure is drawn on by creating a prefix for a group of figure names. All figures with a specific prefix are placed on a specific layer

**NOTE** The list of available databases is determined from the databases listed in the Figure Prefix Databases collection on the Toolspace Survey tab.

Show Interactive Graphics

Specifies whether to display interactive graphics during the import of survey data. Use Interactive Graphics settings to control the display of individual graphics components.

Process Linework During Import

Specify Yes to process linework during the import.

Current Linework Code Set

Specifies the default linework code set to use when linework processing occurs.

Process Linework Sequence

Specifies the order in which survey point descriptions are processed to determine linework connectivity. Select one of the following:

■ By Import Order - processes points in the order which they are imported. Point names are always processed by import order.

- By Point Number - processes points sequentially by point number (ascending order only).

Import Event Name

Specifies a file name for the import event. The name of the file you are importing is displayed as the default name.

Import Event Description

Optionally, enter a description of the import event.

Assign Offset To Point Identifiers

Specifies that an offset is applied to the point identifier before the points are imported into the survey database.

Point Identifier Offset

Specifies the offset value that is applied to the point identifier. For example, if the offset value is 1000, the point number 101 is renumbered to 1101, or point name KC101 is renamed as KC101.1000.

Insert Network Object

Specifies whether a network object is created in the drawing upon completion of the import command.

Insert Figure Objects

Specifies whether figure objects are created in the drawing upon completion of the import command.

Insert Survey Points

Specifies whether AutoCAD Civil points are created in the drawing upon completion of the import command.

Display Tolerance Errors In Event Viewer

Select Yes to display tolerance errors in the Event Viewer when you import field book files. For more information, see Reporting Tolerance Errors (page 211).

**Related procedures:**

- Survey Database Settings Dialog Box (page 2378)
- Survey User Settings Dialog Box (page 2374)
- Field Book Files (page 240)

# Least Squares Analysis Dialog Box

Use this dialog box specify Least Squares settings. The settings default to the setting in the Survey Database Settings for Least Squares.

**Input**

Create Input File

Specifies that the Input file name is created, or overwritten if it already exists, in the *<Working folder>\<Project>\Survey\<Network>* folder.

Input File Name

Specifies name of the least squares input file. If the Create Input File property is checked, the input file name (without the **\***.*lsi* extension) can be entered in the combo box, or an existing input file can be selected from the list. If an existing input file is selected it is overwritten with new content.

Network Adjustment Type

Changes the default network adjustment type of the least analysis performed on the survey network. Specify one of the following:

■ 2-Dimensional: The input file contains content to perform a 2-dimensional least squares analysis.

■ 3-Dimensional: The input file contains content to perform a 3-dimensional least squares analysis.

**NOTE** This property is enabled if the Create Input File property is checked.

### Procedure

Maximum Number of Iterations

Specifies the number of iterations of least squares analysis that is performed on the network.

Coordinate Convergence

Specifies the default coordinate convergence of the least squares analysis performed on the survey network.

Confidence Level

Specifies the confidence level of the least squares analysis performed on the survey network.

Perform Blunder Detection

Specify Yes to perform Blunder Detection on the least squares analysis performed on the survey network.

Update Survey Database

Specify Yes to update the Survey Database with the adjusted coordinates from the analysis.

# Traverse Analysis Dialog Box

Use this dialog box to enter settings for traverse analysis. Initially, the Traverse Analysis settings you enter in the Survey Database settings are displayed as the default settings.

### Traverse Analysis Property

Do Traverse Analysis

Select Yes to perform a mathematical analysis based on the method you specify as the Horizontal Adjustment Method.

Do Angle Balance

Select Yes to have the angular error evenly distributed throughout the traverse.

Horizontal Adjustment Method

Specify one of the following traverse analysis methods:

■ Compass Rule: A method of corrections where the closing errors are assumed to be as much due to errors in observed angles as by the errors in measured distances. The closing errors in latitude and departure are distributed according to the ratio of the length of the line to the total length of the traverse

■ Transit Rule: A method of balancing a traverse where the closing errors are assumed to be caused less by the errors in the observed angles than by the errors in measured distance. Corrections are distributed according to the ratio of the latitude and departure of each leg of the traverse to the sums of the latitude and departures of the entire traverse.

■ Crandall Rule: A method of balancing a traverse where all the angular error is distributed throughout the traverse and all adjustments to the traverse are due to modifying the traverse distances. The modification distance made to each leg is such that the sum of the squares is a minimum. Corrections corresponding to the closing errors assume that the closing errors are random and normally distributed, and that all the angular error has been adjusted prior to the adjustment routine.

- Least Squares: A method of balancing a traverse. The squares of the differences between the unadjusted and adjusted measurements (angles and distances) are summed and reduced to a minimum. This method weights the individual measurements according to the specifications set in the Equipment correction settings to determine the source of error. You can adjust the data for an individual traverse loop, or a traverse network, if located from multiple observations.

Vertical Adjustment Method

Specify one of the following vertical adjustment methods:

- None: No vertical adjustment performed

- Length Weighted Distribution: Vertical adjustment distributes the vertical closing error to each line at the same ratio as the length of the line to the total length of the traverse (similar to the Compass rule).

- Equal Distribution: Vertical adjustment distributes the vertical closing error equally to each of the traverse stations.

- Least Squares: A method of distributing the vertical error throughout a traverse. The squares of the differences between the unadjusted and adjusted measurements (angles and distances) are summed and reduced to a minimum. This method weights the individual measurements according to the specifications set in the Equipment correction settings to determine the source of error. You can adjust the data for an individual traverse loop, or a traverse network, if located from multiple observations.

**NOTE** The Least squares vertical adjustment method is only available if Least squares has been selected as the horizontal adjustment method. When this method is selected, a 3D least squares adjustment is performed. If this method is not selected a 2D least squares adjustment is performed.

Horizontal Closure Limit 1:X

Specifies the minimum allowable error of closure in the horizontal direction, for example a value of 15000.00 is 1 part in 15000.

Vertical Closure Limit 1:X

Specifies the minimum allowable error of closure in the vertical direction, for example a value of 15000.00 is 1 part in 15000.

Angle Error Per Set

Specifics the maximum angular error per traverse setup.

Update Survey Database

Specify Yes to update the Survey database with the adjusted coordinates.

**NOTE** During the analysis, if the specified limits for the horizontal, vertical, or angle limits are exceeded, a warning message box is displayed. Select Yes to update the database or No if you do not want the database updated.

# Preview Settings Dialog Box

Use this dialog box to specify the preview settings for networks, figures, and setups.

Previews are displayed in the Toolspace item graphical view. For more information, see The Toolspace Item View (page 82).

Select the check box for the components that you want to display in the preview.

# Survey Network Properties Dialog Box

Specify a name and styles for the network components, 3D Geometry, and Display options.

Name

Displays the name of the current network.

Description

Displays the description of the current network.

Object Style

Specifies the style used to display the network. Select a style from the list or use the standard selection tools. For more information about the standard selection tools, see Select Style Dialog Box (page 1805).

Show Tooltips

Controls whether tooltips are displayed for the object in the drawing (does not affect tooltips over toolbar icons).

## LandXML

If you are using the extended properties feature, the LandXML elements as defined in the *.sdx_def* file are displayed. Click the cell in the Value column to assign an attribute.

## User-defined

If you are using the extended properties feature, and have created user-defined properties they are displayed. Click the cell in the Value column to assign an attribute.

# Create Figure From Object Dialog Box

Use this dialog box to create a figure from an AutoCAD Civil or AutoCAD object.

The following object types can be selected in the drawing to define a survey figure:

- 2D Line

- 3D Line

- 2D Polyline

- 3D Polyline

- Feature Line

- Lot Line

- Parcel (select the parcel area label)

Name

Displays the name of the current figure. The name entered here is checked for a match in the current figure prefix database. If the name matches to a figure prefix the properties in the figure prefix is assigned to the new figure. If the name does not match a figure prefix, then the figure is assigned the default figure style from the User Settings.

Current Figure Prefix Database

Displays the default figure prefix database that is assigned in the User Settings. This is the figure prefix database that is used to match against the Name property value.

Associate Survey Points To Vertices

Specifies to associate survey points to vertices. When this property is checked, for each figure vertex:

- The X-Y coordinates are checked for a match with an X-Y location of an existing survey point in the survey database.

- If the vertex X-Y coordinates match a survey point, then figure vertex references that survey point.

**Related procedures:**

- Creating Figures (page 321)

# Create Breaklines Dialog Box

Use this dialog box to add breaklines to a surface from existing figures.

Select Surface

Specifies the surface for which you want to add the breakline data. Click the surface in the drop-down list or click ⬦ to select a surface in the drawing.

Name

Displays the name of the figure.

Breakline

Specifies if the figure is to be used as breakline data in the surface. Only figures that have their Breakline property checked are displayed in this list. Select the check box to create breaklines from the figure.

**Related procedures:**

- Creating Breaklines from Figures (page 324)

# Survey Figure Properties Dialog Box

Specify or change the figure properties such as name, layer, style, and the site the figure is associated with.

Name

Specifies the name of the figure. The figure name can be composed of characters that are number, alpha, or alpha-numeric.

Breakline

Specifies that the figure is used as a breakline (when creating surface breaklines from figures).

Lot Line

Specifies that the figure behaves as a parcel segment. When this property is selected and the figure is inserted into drawing, the figure behaves as a parcel segment in the site that it is placed on. Figures with this property may create parcels and can be labeled as parcel segments.

Layer

Specifies the layer that the figure object is placed on when inserting figures into a drawing.

Style

Specifies the style that the figure object uses when inserting figures into a drawing.

Site

Specifies the site for the figure if Lot Lines property is enabled. When inserting a figure into the current drawing, if the site does not exist in the current drawing, it is created. The figure is placed on the specified site

Vertices
  Displays the number of vertices in the figure.

Length
  Displays the length of the figure.

Area
  Displays the area of the figure.

Network
  Displays the name of the network that the figure is associated with.

Import Event
  Displays the name of the import event that the figure is associated with.

Auto-generated
  Displays Yes or No to indicate whether the figure was automatically generated.

**LandXML**

If you are using the extended properties feature, the LandXML elements as defined in the *.sdx_def* file are displayed. Click the cell in the Value column to assign an attribute.

**User-defined**

If you are using the extended properties feature, and have created user-defined properties they are displayed. Click the cell in the Value column to assign an attribute.

**Related procedures:**

■ Survey Objects (page 194)

# New Local Survey Database Dialog Box

Use this dialog box to specify the name for a new survey database.

Local survey databases are not stored in Vault. You can subsequently convert the database to a Vault project.

Name
  Specify the name for the new survey database.

**Related procedures:**

■ Survey Database (page 196)

# New Survey Network Dialog Box/Survey Network Properties Dialog

Use this dialog box to specify the name for a new survey network.

New Survey Network
  Specify the name for the new survey network.

**LandXML**

If you are using the extended properties feature, the LandXML elements as defined in the .sdx_def file are displayed. Click the cell in the Value column to assign an attribute.

**User-defined**

If you are using the extended properties feature, and have created user-defined properties they are displayed. Click the cell in the Value column to assign an attribute.

**Related procedures:**

■ Survey Networks (page 201)

## Batch File Dialog Box

Use this dialog box to specify the name for a new batch file.

Enter Name For Batch File
Specify the name for the new batch file.

**Related procedures:**

■ Batch Files (page 318)

## Output File Dialog Box

Use this dialog box to specify the name for a new output file.

Enter Name For Output File
Specify the name for the new output file.

**Related procedures:**

■ Outputting Survey Files (page 388)

## Export Field Book Dialog Box

Use this dialog box to edit settings associated with exporting AutoCAD Civil survey data to a field book.

The settings here are not saved back to the user settings and are only applicable for the field book export operation.

Field Book Filename (.FBK)

Specifies the name and location of the field book. Click  to specify a different name and location.
For information on the conditions and syntax that is added to the field book, see Setting Export Defaults (page 213).

Export Figures With Network
Select Yes to export the figures in the database when you use the Export Field Book command.
The figure type determines what is added to the field book. For information on the conditions and syntax that is added to the field book, see Setting Export Defaults (page 213).

Export Point Identifiers
Specifies if point IDs are used to define figures when figures are exported to a field book.
For information on the conditions and syntax that is added to the field book, see Setting Export Defaults (page 213).

Export Point Data
This check box is active when the Export Point Identifiers property is not set to None. Select Yes if you want each figure vertex that references a point identifier to output the following to the field book file prior to the section defining the figures: NE SS <point ID> <north> <east> <elevation> <description>

# New Control Point/Control Point Properties Dialog Box

Use this dialog box to specify or edit the properties of a control point.

If you are editing the properties of a control point using the Survey tab item view, for more information on the functions available, see Survey Tab Item View (page 2383).

Point Number

Specifies the point number.

Name

Specifies the point name. Optional.

Easting

Specifies the point easting. Required.

**NOTE** If the survey database has been assigned a coordinate system zone, the Longitude property value is calculated from the value entered in this field.

Northing

Specifies the point northing. Required.

**NOTE** If the survey database has been assigned a coordinate system zone, the Latitude property value is calculated from the value entered in this field.

Elevation

Specifies the point elevation. Optional.

Description

Specifies the point description. Optional.

**NOTE** Latitude and Longitude values are only displayed when the survey database has an assigned coordinate system zone.

Longitude

Specifies the point longitude. The Easting property value is calculated from the value entered in this field.

Latitude

Specifies the point latitude. The Northing property value is calculated from the value entered in this field.

Network

Displays the name of the network that first observed the point.

Import Event

Displays the name of the import event if the survey point was created by an import command.

Original Number

Displays the original survey point number if a point identifier offset was applied during the import command.

Original Name

Displays the original survey point name if the survey point was renamed during the import command.

**LandXML**

If you are using the extended properties feature, the LandXML elements as defined in the *.sdx_def* file are displayed. Click the cell in the Value column to assign an attribute.

**User-defined**

If you are using the extended properties feature, and have created user-defined properties they are displayed. Click the cell in the Value column to assign an attribute.

**Related procedures:**

■ Control Points (page 253)

# New Non-Control Point/Non-Control Point Properties Dialog Box

Use this dialog box to specify or edit the properties of a non-control point.

If you are editing the properties of a non-control point using the Survey tab item view, for more information on the functions available, see Survey Tab Item View (page 2383).

Point Number
  Specifies the point number.

Name
  Specifies the point name. Optional.

Northing
  Specifies the point northing. Required.

  **NOTE** If the survey database has been assigned a coordinate system zone, the Latitude property value is calculated from the value entered in this field.

Easting
  Specifies the point easting. Required.

  **NOTE** If the survey database has been assigned a coordinate system zone, the Longitude property value is calculated from the value entered in this field.

Elevation
  Specifies the point elevation. Optional.

Description
  Specifies the point description. Optional.

**NOTE** Latitude and Longitude values are only displayed when the survey database has an assigned coordinate system zone.

Latitude
  Specifies the point latitude. The Northing property value is calculated from the value entered in this field.

Longitude
  Specifies the point longitude. The Easting property value is calculated from the value entered in this field.

Network
  Displays the name of the network that first observed the point.

Import Event
  Displays the name of the import event if the survey point was created by an import command.

Original Number
  Displays the original survey point number if a point identifier offset was applied during the import command.

Original Name

Displays the original survey point name if the survey point was renamed during the import command.

**LandXML**

If you are using the extended properties feature, the LandXML elements as defined in the *.sdx_def* file are displayed. Click the cell in the Value column to assign an attribute.

**User-defined**

If you are using the extended properties feature, and have created user-defined properties they are displayed. Click the cell in the Value column to assign an attribute.

**Related procedures:**

■ Non-Control Points (page 256)

# Survey Point Properties Dialog Box

Use this dialog box to view or edit the properties of a survey point.

Survey points can be control points, non-control points, setups, or observations.

If you are editing the properties of a point using the Survey tab item view, for more information on the functions available, see Survey Tab Item View (page 2383).

Number

Displays the point number.

Name

Specifies the point name.

Easting

Displays the point easting.

**NOTE** If the survey database has been assigned a coordinate system zone, the Longitude property value is calculated from the value in this field.

Northing

Displays the point northing.

**NOTE** If the survey database has been assigned a coordinate system zone, the Latitude property value is calculated from the value in this field.

Elevation

Displays the point elevation.

Description

Specifies the point description.

**NOTE** Latitude and Longitude values are only displayed when the survey database has an assigned coordinate system zone.

Longitude

Displays the point longitude. The Easting property value is calculated from the value entered in this field.

Latitude

Displays the point latitude. The Northing property value is calculated from the value in this field.

Network

Displays the name of the network that first observed the point.

Import Event

Displays the name of the import event if the survey point was created by an import command.

Original Number

Displays the original survey point number if a point identifier offset was applied during the import command.

Original Name

Displays the original survey point name if the survey point was renamed during the import command.

**LandXML**

If you are using the extended properties feature, the LandXML elements as defined in the *.sdx_def* file are displayed. Click the cell in the Value column to assign an attribute.

**User-defined**

If you are using the extended properties feature, and have created user-defined properties they are displayed. Click the cell in the Value column to assign an attribute.

# New Direction/Direction Properties Dialog Box

Use this dialog box to specify or edit the properties of a direction.

For more information on the functions available if you are editing the properties of a direction using the Survey tab item view, see Survey Tab Item View (page 2383).

From Point

Specifies the originating control point.

To Point

Specifies the destination point reference for the direction.

Direction

Specifies the direction value. The unit type is determined by the direction type setting. For more information, see Database Settings (page 216).

Direction Type

Specifies the direction type. Either an azimuth (page 2467) or a bearing (page 2468).

**Related procedures:**

■ Directions (page 283)

# New Setup/Setup Properties Dialog Box

Use this dialog box to specify or edit the properties of a setup.

If you are editing the properties of a setup using the Survey tab item view, for more information on the functions available, see Survey Tab Item View (page 2383).

Station Point

Specifies the station point number for the setup.

NOTE If you enter a non-existent station point, you are prompted to create a point and the New Control Point dialog box is displayed from which you can create a new station point.

Backsight Point

Specifies the backsight point for the setup. When this column contains a valid entry, the Backsight Direction column displays the calculated backsight direction value and is read-only.

Backsight Direction

Specifies the backsight direction. This field is read-only if the Backsight Point column contains a valid point number.

Backsight Orientation

Specifies the backsight orientation angle for the setup. This is the reference angle for the all angle observations except Face 1 and Face 2 angles.

Backsight Face 1

Specifies the direct angle reference on the backsight for Face 1 angles.

Backsight Face 2

Specifies the direct angle reference on the backsight for Face 2 angles.

Instrument Height

Specifies the measured instrument (theodolite) height. This is typically measured from the center of the theodolite optics to the setup point on the ground.

Instrument Elevation

Specifies the instrument elevation.

NOTE If the setup point has an elevation, this field is read-only and displays the calculated instrument elevation (setup point elevation plus the instrument height). If the setup point has no elevation, then this column can be used to specify the instrument elevation

Easting

Displays the point easting.

Northing

Displays the point northing.

Longitude

Displays the point longitude.

Latitude

Displays the point latitude.

Setup Equipment Properties

Displays the name of the equipment properties for the selected setup. To edit the Setup Equipment Properties, click ⌹ to display the Setup Equipment Properties dialog box.

**Related procedures:**

■  Setups (page 259)

# Edit Setups That Observe Dialog Box

Use this dialog box to specify the point identifier for the observation that you want to find.

All setups that observe the point are displayed in the Setups Editor vista.

**Related procedures:**

■  Setups (page 259)

# New Traverse/Traverse Properties

Use this dialog box to specify or edit the properties of a traverse.

If you are editing the properties of a traverse using the Survey tab item view, for more information on the functions available, see Survey Tab Item View (page 2383).

Name
Specifies the name of the traverse. The traverse name can be composed of characters that are number, alpha, or alpha-numeric.

Description
Specifies a description for the traverse.

Initial Station
Specifies the starting station point.

Initial Backsight
Specifies the initial backsight point.

Stations
Specifies the setups as a comma delimited list.

Final Foresight
Specifies the final foresight point.

**Related procedures:**

■ Traverses (page 373)

# Figure Properties (Drawing Object)

Use this dialog box to specify a style for the figure drawing object.

Name
Specifies the name of the figure. The figure name can be composed of characters that are number, alpha, or alpha-numeric.

Style
Specifies the figure style.

**Related procedures:**

■ Survey Figures (page 321)

# Survey Command Window

Use this dialog box to enter survey commands directly using command line input or interactively using the menus.

The menus on this dialog box provide quick access to extended survey functionality including batch and output file usage, baseline, centerline, and intersection input, and to obtain point information.

Use the command input field to enter survey command language commands directly. For more information, see Survey Command Reference (page 391).

Main menu

Provides access to:

- [User settings](page 205)
- [Database settings](page 216)
- [Batch file functionality](page 318)
- [Output file functionality](page 388)
- [Baseline functions](page 285)
- [Centerline functions](page 289)
- [Intersection functions](page 304)
- [Point Information](page 376)
- Drawing zoom and pan functions

Output view

Displays all survey command output. All output is prefixed with the "!" character. Erroneous commands are recorded as comments. For example: !Duplicate point. (Point number ' 1 ' already exists).

Batch view

Displays the input history for the current Survey Command Window session. All commands echoed here are also written to the batch file (if turned on). Input errors are trapped and not recorded to the batch file.

Command line

Enter survey command language commands directly. The survey command language is the basic format for all survey data entry. After you become familiar with the survey command Language, you may find that it is an efficient way to access and query data. Commands entered at the survey command line use a specific syntax.

**Related procedures:**

- [Survey Command Language Commands](page 393)
- [Survey User Interface](page 193)

# Import / Re-import Survey LandXML Data Dialog Box

Use this dialog box to specify the import settings and the survey data to import from a LandXML file.

## Import Settings

Current Equipment Database

Specifies the current equipment database. Click the equipment database from the drop-down list. For more information, see [Survey Equipment Database](page 199).

NOTE  The list of available databases is determined by the databases listed in the Equipment Databases collection in the Toolspace Survey tab.

Current Equipment

Specifies the current equipment to use. Click the equipment name from the drop-down list.
The current equipment sets the values associated with a specific surveying instrument, such as the units used to measure angles and distances, and/or the standard deviations associated with the equipment's measuring capabilities. This information is used in various calculations including least squares.

Current Figure Prefix Database

Specifies the current figure prefix database. Click the figure prefix database from the drop-down list. Figure prefixes enable you to determine the layer that a figure is drawn on by creating a prefix for a group of figure names. All figures with a specific prefix are placed on a specific layer.

The list of available databases is determined from the databases listed in the Figure Prefix Databases collection on the Toolspace Survey tab.

Process Linework During Import

Click Yes to process line work during the import.

Current Linework Code Set

Specifies the linework code file to use when linework processing occurs.

Process Linework Sequence

Specifies the order in which survey point descriptions are processed to determine linework connectivity. Select one of the following:

■ By Import Order - processes points in the order which they are imported. Point names are always processed by import order.

■ By Point Number - processes points sequentially by point number (ascending order only).

Import Event Name

Specify a name for the import event. The name of the file you are importing is displayed by default.

Import Event Description

Optionally, enter a description of the import event.

Assign Offset To Point Identifiers

Specifies that an offset is applied to the point identifier before the points are imported into the survey database.

Point Identifier Offset

Specifies the offset value that is applied to the point identifier. For example, if the offset value is 1000, point number 101 is renumbered to 1101, or point name KC101 is renamed as KC101.1000.

Insert Network Object

Specifies whether to create a network object in the drawing.

Insert Figure Objects

Specifies whether to create figure objects in the drawing.

Insert Survey Points

Specifies that survey points are inserted into the drawing.

Display Tolerance Errors In Event Viewer

Select Yes to display tolerance errors in the Event Viewer when you import Survey LandXML files. For more information, see Reporting Tolerance Errors (page 211).

**LandXML Data tree**

Lists the LandXML header information for each data component that can be imported. Only the following LandXML components are displayed in the LandXML Data tree (if they exist in the selected LandXML file). Non-survey LandXML elements are not displayed.

Expand each of the collections to display all of the sub-components.

Select or clear the check boxes to the left of each data component name to filter the data that is imported into AutoCAD Civil. By default, all data components are selected for import.

File Name

Displays the path and file name of the selected LandXML file.

CoordinateSystem

If current Coordinate Zone property in the Survey Database Settings is set and this value is different, a coordinate transformation is attempted (the Survey Database Settings Distance property is also used to scale the coordinate values during the transformation).

Units

If the Units ➤ linearUnit setting is different from the Survey Database Settings ➤ Units Distance property, observation distance and target heights values are converted.
If the Units ➤ angularUnit settings is different from the Survey Database Settings ➤ Units Angle property, observation angle (horizontal, vertical, and direction) values are converted.

**NOTE** The internal units of the survey database are angle values in Radians and distance and coordinate values in Meters.

SurveyHeader

This element maps to a survey network in AutoCAD Civil. The Name attribute sets the name of new network in the survey database, or if a network of the same name exists in the survey database, it may be overwritten or appended to, depending on the LandXML Import Settings.

PlanFeatures

Maps to a survey figure. For each PlanFeature:

■ The PlanFeature Name attribute is the name assigned to the new figure.

■ If the PlanFeature name matches a figure prefix in the current figure prefix database, the figure prefix properties are assigned to the new or existing figure.

Parcels

A Parcel maps to a survey figure. For each Parcel:

■ The Parcel Name attribute is the name assigned to the new figure.

■ If the Parcel name matches a figure prefix in the current figure prefix database, the figure prefix properties are assigned to the figure, except for the Lot Line property.

■ The Lot Line property is always set to True for each Parcel imported into a figure. This overrides a figure prefix property if a figure prefix match occurs.

**NOTE** If the figure prefix does not have a Site name, the default Site name is used when the figure is inserted into a drawing.

CgPoints

A CgPoint point maps to a survey point. Each CgPoint is added to the Non-Control Points collection in the survey database.

**Related procedures:**

■ Importing Survey LandXML Data (page 244)

■ Importing Survey XML Data

# Export Survey LandXML Data Dialog Box

Use this dialog box to select the data in the export settings and survey data to export in LandXML format.

**Export Settings**

File Name

Specifies the file name to contain the exported LandXML survey data. Enter a path or click  to browse to a location.

Coordinate Zone

Click  to display the Select Coordinate Zone dialog box where you can specify the coordinate zone for the survey database data. The default zone is set to None.

Distance

Specifies the distance unit. Click the cell in Value column and select a distance unit from the list.

**NOTE** If you specify a Coordinate Zone, the distance unit is obtained from the zone and the Distance property field is not active.

Angle

Specifies the angle unit for the survey data. Click the cell in the Value column and select an angle type from the list.

Direction

Specifies the direction unit for the survey data. Click the cell in the Value column and select a direction type from the list.

Temperature

Specifies the temperature unit for the survey data when temperature corrections are applied to observations. Click the cell in the Value column and select a temperature type from the list.

Pressure

Specifies the atmospheric pressure unit for the survey data when pressure corrections are applied to observations. Click the cell in the Value column and select a pressure type from the list.

**Export Data**

Data tree

Lists the AutoCAD Civil survey data that you can export in LandXML format. Expand each of the collections to display all of the sub-components.
Select or clear the check box to the left of each feature name to filter the data that you want to export in LandXML format.

**NOTE** The check boxes have a tri-state display. If only some items are selected under a collection, the check box is dimmed  ; if all the items are selected, the check box is selected  ; if all the items below the collection are cleared, the check box for the collection is cleared  .

OK

Converts AutoCAD Civil objects to LandXML format and exports the LandXML data.

**Related procedures:**

■ Exporting Survey Data to LandXML (page 244)

# Astronomic Direction Calculator Dialog Box

Use this calculator to calculate astronomic directions from Sunshots and Starshots.

Calculation Type

Specifies the calculation types. Select one of the following from the type list:

- Sun shot calculation: Calculates the astronomic direction from solar observations by the hour angle method and uses a multiple foresight field method.

- Star shot calculation: Calculates the astronomic direction from Polaris or star observations by the hour angle method and uses a single foresight method.

## Observation Station Data

Station Point

Specifies the point ID for the station for which you want to calculate the direction.

Backsight Point

Specifies the backsight point ID for the station for which you want to calculate the direction.

Station Latitude

Specifies the Latitude of the station in the drawing's ambient settings format. Specify - for south.

Station Longitude

Specifies the Longitude of the station in the drawing's ambient settings format. Specify - for west.

UT1 Time

Specifies the UT1 time, which is determined by adding the correction (DUT) to the Coordinated Universal Time (UTC). UTC time is broadcast over WWV and other radio stations. You can also get DUT corrections via WWV; they are broadcast after the start of each minute.

## Ephemeris Data

GHA 00 Hours

Specifies the Greenwich Hour Angle (GHA) at zero (0) hours for the day on which the observations were made.

GHA 24 Hours

Specifies the GHA at 24 hours for the day the observations were made.

Declination 00 Hours

Specifies the declination at zero (0) hours on the day the observations were made.

Declination 24 Hours

Specifies the declination at 24 hours on the day the observations were made.

Sun Semi-diameter

Specifies the semi-diameter of the sun.
Enter zero (0) if you are sighting either the center or both the trailing and leading edges of the sun. The left edge is always the leading edge at latitudes greater than 23.5 degrees north and greater than 23.5 degrees south. If only the left edge is being sighted (left when facing the sun), then the semi- diameter is positive; likewise, the semi-diameter is negative when only the right edge is sighted.

## Observations

Creates a new observation set.

Deletes the selected observation set.

**Observation Sets**

Displays each observation set.

**Backsight Observation**

Specifies the backsight orientation.

**Sun Observation or Star Observation**

Specifies the sun or star observation.

**Stop Time**

Specifies the stop time for the observation.

**Observed Direction**

Calculated observed direction.

**Average Direction**

Calculated average direction.

**Mean Direction (Station To Backsight)**

Value calculated by the editor.

**Related procedures:**

■  Astronomic Direction Calculations (page 389)

# Manage Extended Properties Dialog Box

Use this dialog box to manage the extended property definitions in the Survey *.sdx* file.

 Expands All

Expands all items in the tree.

 Collapses All

Collapses all items in the tree.

 Export Settings

Exports the extended properties schema to a specified *.sdx* file. You specify the location of this *.sdx* file in the Database Defaults of Survey User Settings.

 Import Settings

Imports an extended properties definition schema into the existing *.sdx* file.

**NOTE** Existing extended property definitions that are referenced by an instance of a SurveyFeatureClass are not redefined during the import process. Existing extended property definitions that are not referenced are redefined by the definition in the selected *.sdx_def* file.

 Select All

Selects all category and property check boxes.

 Clear All

Clears all category and property check boxes.

 Create New

Displays the New Extended Property dialog box. This button is only enabled when a user-defined category is selected.

 Edit Selected Item

Displays the Edit Extended Property dialog box. This button is only enabled when a user-defined property is selected.

 Delete Selected Item

Displays the Delete Extended Property warning message box. This button is only enabled when a user-defined property is selected and that property is not referenced by another instance of the <SurveyFeatureClass>.

Property column

Lists the extended properties categories.

Description column

Displays the description of the extended property. This description can be assigned from the New/Edit Extended Property dialog box.

Depending on your *.sdx_def* file, each SurveyFeatureClass has relevant LandXML and User-defined collections. If you expand these collections, and select an attribute you can use the right-click short cut menu to edit or copy the property.

Survey Database

SurveyFeatureClass used to manage the extended properties of survey databases and projects.

Network

SurveyFeatureClass used to manage the extended properties of survey networks.

Network Group

SurveyFeatureClass used to manage the extended properties of Network Groups.

Figure

SurveyFeatureClass used to manage the extended properties of survey figures.

Figure Group

SurveyFeatureClass used to manage the extended properties of figure groups.

Survey Point

SurveyFeatureClass used to manage the extended properties of survey points.

Survey Point Group

SurveyFeatureClass used to manage the extended properties of survey point groups.

# New/Edit Extended Property Dialog Box

Use this dialog box to create a new property or edit an existing property in the Survey *.sdx* file.

XML Name

Specifies the XML name of the extended property.

Display Name

Specifies the display name of the property.

Description

Specifies a description of the property. This description is displayed in the Manage Extended Properties dialog box.

Property Field Type

Specifies the data type for the property. For more information on property field types, see Property Field Types Table (page 246).

Required Value

Select this check box to display a warning icon indicating that a required property has not been assigned to an instance of a <SurveyFeatureClass>.

Display In Survey User Interface

Select this check box to display the extended property in the Survey user interface. This check box is selected by default when you create a new user-defined property.

String Values

Specifies a list of string values if the Property Field type is set to String. You can enumerate the list of string values when you assign a value to a <SurveyFeatureClass>. Use the arrows to change the display order of the strings in this dialog box and in the Survey user-interface.

# New Network Group/Network Group Properties Dialog Box

Use this dialog box to create a new network group. To support LandXML, named collections of elements such as CgPoints or PlanFeature collections, Network Groups are added as a root collection within a Survey database item on the Survey tab in Toolspace.

## Network Group

Name

Specifies the name for the Network Group.

Description

Specifies a description for the Network Group.

## LandXML

If you are using the extended properties feature, the LandXML elements as defined in the *.sdx_def* file that are relevant to networks are displayed. Click the cell in the Value column to assign an attribute.

## User-defined

If you are using the extended properties feature, and have created User-defined properties they are displayed. Click the cell in the Value column to assign an attribute.

Add To Group

Select the check box to add the named network to the group

Name

Displays the name of the networks that can be added to the Network Group.

Description

Displays the description of the networks that can be added to the Network Group.

# New Figure Group/Figure Group Properties Dialog Box

Use this dialog box to create a new figure group. To support LandXML, named collections of elements such as CgPoints or PlanFeature collections, Figure Groups are added as a root collection within a Survey database item on the Survey tab in Toolspace.

### Figure Group

Name
    Specifies the name of the Figure Group.

Description
    Specifies the description of the Figure Group.

### LandXML

If you are using the extended properties feature, the LandXML elements as defined in the *.sdx_def* file are displayed. Click the cell in the Value column to assign an attribute.

### User-defined

If you are using the extended properties feature, and have created user-defined properties they are displayed. Click the cell in the Value column to assign an attribute.

Add To Group
    Select the check box to add the figure to the new Figure Group.

Name
    Displays the name of the figure to add to the Figure Group.

Breakline
    Displays the status of the figure as a breakline.

Lot Line
    Displays the status of the figure as a lot line.

Layer
    Displays the layer the figure is drawn on.

Style
    Displays the figure style.

Site
    Displays the site to which the figure belongs.

Vertices
    Displays the number of vertices in the figure.

Length
    Displays the length of the figure.

Area
    Displays the area of the figure.

# New Survey Point Group/Survey Point Group Properties Dialog Box

Use this dialog box to create a new survey point group. To support LandXML, named collections of elements such as CgPoints or PlanFeature collections, Survey Point Groups are added as a root collection within a Survey database item on the Survey tab in Toolspace.

### Survey Point Group

Name
  Specifies the name of the Survey Point Group.

Description
  Specifies the description of the Survey Point Group.

### LandXML

If you are using the extended properties feature, the LandXML elements as defined in the *.sdx_def* file are displayed. Click the cell in the Value column to assign an attribute.

### User-defined

If you are using the extended properties feature, and have created user-defined properties they are displayed. Click the cell in the Value column to assign an attribute.

Add To Group
  Select the check box to add the survey point to the new Survey Point Group.

Number
  Displays the survey point number.

Name
  Displays the survey point name.

Easting
  Displays the easting of the survey point.

Northing
  Displays the northing of the survey point.

Elevation
  Displays the elevation of the survey point.

Description
  Displays a description of the survey point.

Longitude
  Displays the longitude of the survey point.

Latitude
  Displays the latitude of the survey point.

## Import / Re-import Point File Dialog Box

Import points into the survey database and survey network, as control points or non-control points, and specify options for linework processing.

Point File Format
  Displays the point file formats contained in the current drawing. The point file format determines the column order, delimiter, and coordinate zone for the file you are importing.

  > **NOTE** In linework processing, the point file format must have a Raw Description column.

Point File Name
  Displays the file path of the point file you want to import.

Point Type
  Specifies the imported points as either control points or non-control points in the network.

Current Figure Prefix Database
  Specifies the name of the prefix database. Select a database from the list.

Process Linework During Import
  Specify Yes to process linework during the file import.

Current Linework Code Set
  Specifies the linework code set that is used in the linework processing.

Process Linework Sequence
  Specifies the order in which survey point descriptions are processed to determine linework connectivity. Select one of the following:

  ■ By Import Order - processes points in the order in which they are imported. Point names are always processed by import order.

  ■ By Point Number - processes points sequentially, by point number (ascending order only).

Import Event Name
  Specifies the name of the import event that is created by the import command.

Import Event Description
  Optionally, specify a description for the import event.

Assign Offset To Point Identifiers
  Specifies that an offset is applied to point identifiers before the points are imported into the survey database.

Point Identifier Offset
  Specifies the offset value that is applied to the point identifier. For example, if the offset value is 1000, point number 101 is renumbered to 1101, or point name KC101 is renamed as KC101.1000.

Insert Network Object
  Specifies that the network object is inserted into the drawing when the import process is complete.

Insert Figure Objects
  Specifies that the figure object is inserted into the drawing when the import process is complete.

Insert Survey Points
  Specifies that the survey points are inserted into the drawing when the import process is complete.

# Import / Re-import Points From Drawing Dialog Box

Import points from the current drawing into the survey database and survey network, as control points or non-control points, and specify options for linework processing.

Point Type
  Specifies the imported points as either control points or non-control points in the network.

Current Figure Prefix Database
  Specifies the name of the figure prefix database. Select the database from the list.

Process Linework During Import
  Specify Yes to process linework during the file import.

Current Linework Code Set
  Specifies the linework code set that is used in the linework processing.

Process Linework Sequence

Specifies the order in which survey point descriptions are processed to determine linework connectivity. Select one of the following:

■ By Import Order - processes points in the order in which they are imported. Point names are always processed by import order.

■ By Point Number - processes points sequentially by point number (ascending order only).

Import Event Name

Specifies the name of the import event that is created by the import command. By default the import event name is the name of the imported file.

Import Event Description

Optionally, specify a description for the import event.

Assign Offset To Point Identifiers

Specifies that an offset is applied to point identifiers before the points are imported into the survey database.

Point Identifier Offset

Specifies the offset value that is applied to the point identifier. For example, if the offset value is 1000, point number 101 is renumbered to 1101, or point name KC101 is renamed as KC101.1000.

# Import Event Properties

Displays the properties of the selected event in the Import Events collection in the list view or the Import Events Panorama vista.

Name

By default, displays the name of the file that was imported.

Description

Displays an optional description.

Date/Time

Read-only property that is assigned at the time of the import and updated when there is a re-import.

User Name

DIsplays the read-only property of the user's Windows login name that is used at the time of the import and updated when there is a re-import.

File

Displays the assigned name of the imported file. (Read-only).

Import Type

Displays one of the read-only following import types:

■ Field Book File

■ Survey LandXML

■ Point File

■ Points From Drawing

Point Identifier Offset

Displays the offset value that was specified in the import command.

Point File Format

Displays the type of point file format used during the Import Point File command, or specified during the import survey data command.

Linework Code Set

Displays the name of the linework code set.

Process Linework Sequence

Displays the order in which survey point descriptions are processed to determine linework connectivity.

- By Import Order - processes points in the order in which they are imported. Point names are always processed by import order.

- By Point Number - processes points sequentially by point number (ascending order only).

Equipment Database

Displays the name of the equipment database associated with the import event.

Equipment

Displays the name of the equipment associated with the import event.

Figure Prefix Database

Displays the name of the figure prefix database associated with the import event.

# Import Events Editor

Use the Import Events Editor vista to access all events associated with a survey network.

The Import Events Editor displays the properties for each event. Right-click an individual event to access the shortcut menu commands.

# Process Linework Dialog Box

The Process Linework command processes linework connectivity between points, using a specified linework code set in situations where a linework code set was not previously specified.

You can also reprocesses linework connectivity after you make corrections to the survey point descriptions in the Survey Point Properties dialog box (page 2416).

Current Figure Prefix Database

Specify the figure prefix database.

Current Linework Code Set

Specify the linework code set.

Process Linework Sequence

Specifies the order in which survey point descriptions are processed to determine linework connectivity. Select one of the following:

- By Import Order - processes points in the order in which they are imported. Point names are always processed by import order.

- By Point Number - processes points sequentially by point number (ascending order only).

Insert Figure Objects

Inserts figures in the current drawing.

Insert Survey Points

Inserts survey points in the current drawing.

**Related procedures:**

■ Processing Survey Linework (page 251)

# New Linework Code Set Dialog Box

Specify the name for the linework code set.

Enter a unique name for the linework code set.

# Edit Linework Code Set Dialog Box

Specify the syntax of the field code for a survey point description.

This syntax is interpreted when you process linework by importing or re-importing survey data, or use the Process Linework command.

For more information, see Examples - Linework Codes (page 231).

### Information

Name

Specifies the name of the linework code. To re-name the linework code, enter a new name and click OK or Apply.

Description

Specifies a description for the linework code.

### Coding Methods

**Codes**: All codes in the linework code must be unique. If you create a duplicate code, a warning icon is displayed on both the category and the property. Before you can close the Edit Linework Code Set dialog box, you must resolve all duplicate codes.

**Undefined codes**: If a code has no assigned value (empty string/blank value) it is considered unused and not defined. Undefined codes may be necessary in situations where you are using an older model data collector that may not have enough physical keys to support the codes.

---

**WARNING** It is recommended that you use a <space> as the Feature /Code Delimiter Property Value. Using decimal characters in the Feature/Code Delimiter Property Value may cause certain codes to fail. For example the . (decimal) character is valid for a right-turn value and the - (minus sign) character is valid for a negative right-turn value.

---

For more details on linework code properties, see Examples - Linework Codes (page 231).

Feature/Code Delimiter

Specifies the code that separates the feature name from the code. It is recommended that you use a space (" ") character.

Field Code Escape

Specifies the code that stops the evaluation of the field code. Characters displayed after the escape character are considered comments. It is recommended that you use a / (slash) character.

### Special Codes

Begin

Specifies the code that indicates a new figure starts at the specified point.

Continue

Specifies the code that indicates a figure continues from its last vertex.

End

Specifies the code that terminates the specified figure.

Close

Specifies the code that continues an active figure from its last vertex to the current point and closes the figure with a line segment back to the starting vertex for the figure.

Horizontal Offset

Specifies the code that indicates a relative horizontal offset for creating a parallel figure starting at the current point, or transitioning to another offset if the active figure has a previous horizontal offset. A value must follow the Horizontal offset code. A negative value offsets the active figure to the left and a positive value offsets the active figure to the right.

Vertical Offset

Specifies the code that indicates a relative vertical offset starting at the current point. A value must follow the Vertical offset code. A positive value is added to the elevation of the current vertex for the active figure and a negative value is subtracted from the current vertex for the active figure.

Stop Offset

Specifies the code that terminates all offsets on the active figure, and allows only the active figure to be continued.

## Line Segment Codes

Recall Point

Specifies the code that connects the active figure with a segment from the last point, or a specified pointID.

Connect Point

Specifies the code that creates a new figure (of the same feature) with a single line segment from the current point to the specified point ID. The specified point ID follows the Connect point code.

Rectangle

Specifies the code to offset the segment coming into the current point by the specified number.

Right Turn

Specifies the code for a <Right turn> line segment that allows for additional vertices to be inserted into the figure, perpendicular or extensions (straight offsets). Offset values, <Extend>, or <Rectangle> codes follow the <Right turn> code. Positive numbers indicate a turn to the right and negative numbers indicate a turn to the left.

Extend

Specifies the code that with a number is used to make an extension of a line segment ahead through the current point by using a positive value or short of the current point by using a negative value, for example <Figure Name><Delimiter><Extend><Value>.

**NOTE** The Extend code can be used within the Right turn code.

## Curve Segment Codes

Begin Curve

Specifies the code that indicates the current point is the beginning of a curve (arc) segment. The current point with this code is the first point on the curve. The next point with the same figure name is considered a point on the curve, and third point with the same figure name is the curve endpoint.

### End Curve

Specifies the code that is used with the <Begin curve> code and is used to define curved segments with more than three points. Starting at the point with the <Begin curve> code, the linework processor will look for a <End curve> code. If the <End curve> code is found, all the points between the <Begin curve> code and <End curve> code are used to fit arc segments of the figure, such that the curves pass through each of the points (similar to the PEDIT/Fit [curve] option).

### Circle

Specifies the code that stops the linework on the previous point (an implied <End> code) and causes the current point to create a circle in one of three methods.

### Point on Curve

Specifies the code to indicate that the current point resides on a curve segment.

# Import Survey Data Wizard

Use this wizard to import field book files, point files, Survey LandXML files, or selected points in a drawing. At the completion of the import an import event is created.

For more information, see Import Events (page 249).

## Import Survey Data Wizard - Specify Database Page

Specify an existing survey database or create a new one.

### Survey Databases

Select an existing survey database.

### Create New Survey Database

Displays the New Local Survey Database dialog box where you can enter the folder name.

### Edit Survey Database Settings

Displays the Survey Database Settings dialog box.

## Import Survey Data Wizard - Specify Data Source Page

Specify the data source type and select the data.

### Data Source Type

- Field Book File

- LandXML file

- Point File

- Points From Drawing

### Source File

Browse to the source file and select the file you want to import.

## Import Survey Data Wizard - Specify Network Page

Select an existing survey network or create a new network.

### Survey Network

Displays the existing networks in the survey database.

Create New Network

Displays the New Network dialog box where you can enter a name and description for the network.

## Import Survey Data Wizard - Import Options Page

Specify the import settings for the selected data source.

■ Field Book File: Import / Re-import Field Book Dialog Box (page 2406)

■ LandXML File: Import / Re-import Survey LandXML Data Dialog Box (page 2420)

■ Point File: Import / Re-import Point File Dialog Box (page 2429)

# Tables Dialog Boxes

# 72

Use the following links to access information about the Table dialog boxes.

## Table Style Dialog Box

Use this dialog box to create or edit table styles.

## Information Tab (Table Style Dialog Box)

Use this tab to change the table style name and description information.

Name
Specifies a name for the style.

Description
Specifies a description for the style.

Created By
Displays the AutoCAD login name of the person who created the style.

Date Created
Displays the date and time the table style was created.

Last Modified By
Displays the AutoCAD login name of the person who last modified the style.

Date Modified
Displays the date and time the table style was last modified.

**Related procedures:**

■ Defining a New Table Style (page 1556)

## Data Properties Tab (Table Style Dialog Box)

Use this tab to format table text style and structure.

## Table Settings

Wrap Text

Forces text to fit within a specified column width by wrapping it in multiple lines.

**NOTE** Wrap text applies to columns that are not set to automatic width.

Maintain View Orientation

Specifies whether the table is realigned if the drawing view is rotated or twisted.

- **Selected**: Realigns the table to the view direction.

- **Cleared**: Does not realign the table.

Repeat Title In Split Tables

Specifies whether titles are duplicated in split tables.

- **Selected**: Duplicates the title in all table sections.

- **Cleared**: Creates split tables without titles on the second and additional sections.

Repeat Column Headers In Split Tables

Specifies whether column headers are duplicated in split tables.

- **Selected**: Duplicates the column headers in all table sections.

- **Cleared**: Creates split tables without headers on the second and additional sections.

Sort Data

Specifies whether table data is sorted based on a selected column.

- **Selected**: Sorts table data based on the specified column.

- **Cleared**: Orders table contents in the order in which the objects are drawn.

Sorting Column

Specifies the column to sort.

Order

Specifies how to sort the column.

- **Ascending**: Sorts from lowest to highest.

- **Descending**: Sorts from highest to lowest.

## Text Settings

Title Style

Specifies a text style for the title.

Header Style

Specifies a text style for the column headings.

Data Style

Specifies a text style for the row data.

Height

Specifies the height values for Title, Header, and Data text.

## Structure

Controls the composition of data. You can do the following:

■ Edit the title or column headings. Double-click the text to display the Text Component Editor (page 1964).

■ Edit the column widths (see Column Width below).

■ Edit the content of the data columns. Double-click a Column Value cell to display the Text Component Editor (page 1962).

■ Rearrange the order of columns. Select the column and drag it. The first column is reserved as the tag column and cannot be moved.

## Table Headers

Table Title (for example, "Line Table")

Specifies the title contents. To edit the title, double-click the text (such as "Line Table") to display the Text Component Editor. For more information, see Text Component Editor (page 1964).

Column Title

Specifies the column heading contents. To edit the headings, double-click the text to display the Text Component Editor.

**NOTE** Except for alignment table styles, the Properties tab in the Text Component Editor is disabled when you edit column heading text.

## Columns

Column Width

Specifies column widths. Click ![icon] and select one of the following options:

■ ![icon] **Automatic**: Sizes the column width according to the longest text string in the table.

■ ![icon] **Manual**: Sets the column width according to a specified character width.

**NOTE** When you specify a fixed width and do not select the Wrap Text option, and the content exceeds the column width, the value in the column is a series of #### characters equal to the width of the column.

Column Value

Specifies the content for each table column. The content can be derived from a combination of static text and property fields associated with a feature.
To edit the column values, double-click a cell in the row. Use the Properties (page 1962) tab in the Text Component Editor to define the column's dynamic content.

![plus icon]

Adds a column at the end of the table. Because the new column is empty, you must define a column heading, width, and value. The column width is set to Automatic width by default.

![delete icon]

Deletes a column. Select the column you want to delete and then click the icon.
The first column cannot be deleted.

-

# Display Tab (Table Style Dialog Box)

Use this tab to determine values for components in a table.

## View Direction

Specifies the view direction for defining display settings.

2D

Selects the 2D set of display properties for viewing and editing.

3D

Selects the 3D set of display properties for viewing and editing.

## Component Display

Component Type

Specifies display settings for each table component.

- **Overall Border**: Graphic line that forms a boundary around the outside of table.

- **Title Separator**: Horizontal graphic line that separates title from column headings.

- **Header Separator**: Horizontal graphic line that separates column headings from data rows.

- **Data Separator**: Horizontal graphic line that separates data rows.

- **Data Divider**: Vertical graphic line that separates columns.

- **Title Area Fill**: Solid hatch pattern that serves as background fill for the table title area.

- **Header Area Fill**: Solid hatch pattern that serves as background fill for the column heading areas.

- **Data Area Fill**: Solid hatch pattern that serves as background fill for all data rows.

- **Title Text**: Table name in first row.

- **Header Text**: Column names in second row.

- **Data Text**: All text in data rows.

Visible

Specifies whether the component is visible. Click 💡 to switch between visible and hidden 💡 .

Layer

Specifies the layer from which the component derives its layer properties. Click the column to display the Layer Selection dialog box.
If you set the layer to zero (0), the components use the layer properties as specified in the Drawing Settings dialog box.

Color

Specifies the color of the component. Click the column to display the Select Color dialog box.

Linetype
   Specifies the linetype of the component. Click the column to display the Select Linetype dialog box.

LT Scale
   Specifies the linetype scale of the component. To change the linetype scale for an object component, highlight the linetype scale and enter a new value in the cell.

Lineweight
   Specifies the lineweight of the component. Click the column to display the Lineweight dialog box.

Plot Style
   Specifies a set of overrides to be used when plotting.

**Related procedures:**

■ Table Display (page 1563)

## Summary Tab (Table Style Dialog Box)

Use this tab to review style settings. The property window contains two columns: Property and Value.

You can make changes to values in the Value column of the Summary tab; however, the display settings are not available on this tab.

**Related procedures:**

■ Viewing a Summary of Table Settings (page 1563)

# Table Creation Dialog Box

Use this dialog box to add tables to a drawing.

Table Style
   Specifies the table style to use.

 Style Selection Menu
   Creates a new table style, edits a table style, or selects a table style from the drawing.

 Style Detail
   Displays the Style Detail dialog box.

Table Layer
   Specifies the layer on which the table is drawn. Click  to select a layer.

**Selection**

Controls what data is inserted into the table.

---

NOTE Because objects must be labeled to create a table that contains their data, most tables require you to specify the table data by selecting a label style or a label in the drawing. Exceptions are point tables and alignment segment tables, which allow you to specify point groups and alignments.

---

Label Style Name
   Adds data to the table from all objects labeled with the selected label style. Select the check box next to the style name to select a label style.

Selection Rule

Controls whether existing or new data is added to the table. After selecting the Apply check box, click the Selection Rule field and select one of the following options.

- **Add Existing**: Creates a table from existing objects labeled with the style. Data from new objects labeled with the style is not added to the table.

- **Add Existing and New**: Creates a table from existing and new objects that are labeled with the style.

By Alignment (alignment segment tables only)

Adds data from the selected alignment to the table.

⌖ Select Point Groups (point tables only)

Adds data from the selected point group to the table.

▣ Pick On-Screen

Adds data to the table from the objects or labels that you select in the drawing.

**NOTE** This area of the Table Creation dialog box is not displayed for the Tangent-Tangent Intersection (PI) table.

## Split Table

Split Table Option

- **Selected**: Divides a table into two or more sections after a specified maximum number of rows has been met.

- **Cleared**: Does not divide the table.

Maximum Rows Per Table

Specifies the maximum number of rows to include per section.
If the number of data rows exceeds the specified maximum, the table is split into sections, and they are displayed either side by side (left to right), or stacked vertically.

Maximum Tables Per Stack

Specifies the maximum number of sections to include in each stack. See also the following Tile Tables option.

Offset

Specifies the gap between split tables.

Tile Tables

Specifies the direction in which tables are stacked.

- **Across**: Places split tables in a row from left to right. When the maximum tables per stack is reached, a new row is started.

- **Down**: Places split tables in a column from top to bottom. When the maximum tables per stack is reached, a new column is started.

## Behavior

Reactivity Mode

Specifies whether tables are updated automatically.

- **Static**: Keeps table data fixed. If you want to see changes, click Update Table from the shortcut menu.

- **Dynamic**: Updates table data dynamically when you make changes.

# Table Properties Dialog Box

Use this dialog box to review table properties and to change styles and appearance.

Table Style

Specifies the table style to use.

 Style Selection Menu

Creates a new table style, edits a table style, or selects a table style from the drawing.

 Style Detail

Displays the Style Detail dialog box.

## Split Table

Split Table Option

■ **Selected**: Divides a table into two or more sections after a specified maximum number of rows has been met.

■ **Cleared**: Does not divide the table.

Maximum Rows Per Table

Specifies the maximum number of rows to include per section.
If the number of data rows exceeds the specified maximum, the table is split into sections, and they are displayed either side by side (left to right), or stacked vertically.

Maximum Tables Per Stack

Specifies the maximum number of sections to include in each stack. See also the following Tile Tables option.

Offset

Specifies the gap between split tables.

Tile Tables

Specifies the direction in which tables are stacked.

■ **Across**: Places split tables in a row from left to right. When the maximum tables per stack is reached, a new row is started.

■ **Down**: Places split tables in a column from top to bottom. When the maximum tables per stack is reached, a new column is started.

 Force Realignment Of Stacks

Realigns the stacks in a split table.

## Behavior

Reactivity Mode

Specifies whether tables are updated automatically.

■ **Static**: Keeps table data fixed. If you want to see changes, click Update Table from the shortcut menu.

■ **Dynamic**: Updates table data dynamically when you make changes.

 **Force Content Update**

Refreshes the table if the Reactivity Mode is set to Static.

**Related procedures:**

■ Changing Table Properties (page 1567)

# Renumbering Dialog Box

Use this dialog box to set the starting number and increment value for renumbering.

This dialog box is used for renumbering parcels and for renumbering alignment tags.

Site Name

Specifies the site in which the parcels, parcel tags, or alignment tags are renumbered. Click  to select a site in the drawing by selecting an object in the site.

## Increment Format

Starting Number

Specifies the next number that is used for renumbering the objects or tags.

Increment Value

Specifies the difference between numbers in the numbering sequence.

**Related procedures:**

■ Renumbering Label Tags (page 1544)

# Add Selection Dialog Box

Adds content to a table.

Use the Add Selection dialog box to add content to a table.

Append to Current Selection Set

Controls what data is added to the table.

---

**NOTE** Because objects must be labeled to create a table that contains their data, most tables require you to specify the table data by selecting a label style or a label in the drawing. Exceptions are point tables and alignment segment tables, which allow you to specify point groups and alignments.

---

Label Style Name

Adds data from all objects labeled with the selected label style to the table. Select the Apply check box to select a label style.

Selection Rule

Controls whether existing or new data is added to the table. After selecting the Apply check box, click the Selection Rule field and select one of the following options.

■ **Add Existing**: Creates a table from existing objects labeled with the selected style. Any new objects labeled with the specified style are not added to the table.

■ **Add Existing and New**: Creates a table from existing and new objects that are labeled with the selected style.

Pick On-Screen

Adds data selected in the drawing to the table.

 Select Point Groups (point tables only)

Adds data from the selected point group to the table.

**Related procedures:**

■  Changing Table Data (page 1568)

# Remove Selection Dialog Box

Deletes rows from a table.

Use the Remove Selection dialog box to remove rows from a table.

Exclude From Current Selection Set

Controls what data is removed from the table.

Label Style Name

Removes data for all objects labeled with the selected label style. Select the Apply check box to select a label style.

Exclusion Rule

**Remove All**: Removes all data currently labeled with the specified label style.

 Pick On-Screen

Removes selected table rows.

 Select Point Groups (point tables only)

Removes data from the selected point group from the table.

**Related procedures:**

■  Changing Table Data (page 1568)

# Replace Selection Dialog Box

Replaces table data.

Use the Replace Selection dialog box to replace table content with other data.

Replace Current Selection Set

Controls what data is added to the table, replacing all the data that is currently in the table.

Label Style Name

Adds data to the table from all objects labeled with the selected label style. Select the Apply check box to select a label style.

Exclusion Rule

Controls whether existing or new data is added to the table. After selecting the Apply check box, click the Selection Rule field and select one of the following options.

- **Add Existing**: Creates a table from existing objects labeled with the selected style. Any new objects labeled with the specified style are not added to the table.

- **Add Existing and New**: Creates a table from existing and new objects that are labeled with the selected style

Pick On-Screen

Adds data selected in the drawing to the table.

Select Point Groups (point tables only)

Adds data from the selected point group to the table.

**Related procedures:**

- Changing Table Data (page 1568)

# Utilities Dialog Boxes

# 73

Use the following links to access information about the Utilities dialog boxes.

## Description Dialog Box

Use this dialog box to change the description of an object.

Description Box
Specifies the description of the object.

## Mapcheck Analysis Window

Use this window to create, edit, and output a Mapcheck Report.

Collapse All
Collapses all items in the tree view.

Expand All
Expands all items in the tree view.

Use Command Line Interface
Toggles on and off the command line input. When this button is toggled on you are prompted to pick labels in the drawing to create the mapcheck. Toggle this button off to create a mapcheck by entering data manually.

New Mapcheck Report
Clears the existing mapcheck report and starts a new report.

New Mapcheck
Creates a new mapcheck and Point of Beginning (POB) in the Mapcheck Report.

New Side
Adds a new side to the end of the current mapcheck.

---

**NOTE** This button is disabled if you have not entered a POB.

---

 Insert Side Before

Inserts a new side before the current side.

 Insert Side After

Inserts a new side after the current side.

---

**NOTE** This button is disabled if a side is not selected, or if you have not entered a POB.

---

 Delete

Deletes the current side or current mapcheck if no side is current.

 Input View

Displays the Mapcheck Analysis window in input mode. You can enter and modify values in the view.

 Output View

Displays the Mapcheck Analysis window in output mode. This view displays the closure summary.

 Copy to Clipboard

Copies the contents of the input view or output view to the Windows Clipboard.
If a mapcheck is current then only that mapcheck is copied to the clipboard. If no mapcheck is current then all mapchecks are copied. Press ESC to clear a selection in tree view.

 Insert MTEXT

Inserts the contents of the input view or output view as an Mtext object in the drawing.
If a mapcheck is current then only that mapcheck is inserted into the drawing. If no mapcheck is current then all mapchecks are inserted into the drawing as separate Mtext objects. Press ESC to clear a selection in tree view.

 Create Polyline

Inserts a polyline into the drawing representing the current mapcheck. If there is no current mapcheck then a polyline for all mapchecks is inserted into the drawing. Press ESC to clear a selection in tree view.

**Mapcheck Tree**

Name

Specifies the optional mapcheck name. If a name is not assigned, the display is Mapcheck <number>.

 Point of Beginning (POB)

Click to specify the Point Of Beginning (POB) in the drawing. All other Side points are calculated from the POB.

Easting

Modify the easting value for the POB.

Northing

Modify the northing value for the POB.

**Side**

A side can be either a line or a curve. The following section describes the values for a line Side type.

Side Type

Specifies the Side as line.

Angle Type

Specifies the angle type to be used. Select Direction, Angle, or Deflection from the drop-down list.

**Angle**

Specifies the angle value for the Side based on the angle type.

**Reverse Direction**

Select the check box to reverse the line direction or the curve chord direction by 180 degrees to calculate the endpoint coordinates for the Side.

**Distance**

Specifies the distance value for the Side.

**Easting**

Displays the calculated easting value for the Side.

**Northing**

Displays the calculated northing value for the Side.

A side can be either a line or a curve. The following section describes the values for a curve Side type.

**Side Type**

Specifies the Side as a curve.

**Curve Direction**

Specifies the curve directions as Clockwise or Counter-clockwise.

**Traverse Method**

Specifies how the error of closure is calculated and displayed in the Output View.
Specify one of the following:

- Across Chord: The endpoint of the curve is calculated from the Chord direction and distance.

- Through Radius: The endpoint of the curve is calculated based on the direction to the radius point, the radius length, the delta angle, and the direction from the radius point to the point of tangency. If this option is selected, additional information is displayed in the Output View.

**Radius**

Specifies the radius value. This value is required.

---

**NOTE** Calculated curve properties do not display in the Input View. Click  Output View to display the output view.

---

**Arc Length**

Specifies the length of the curve.

**Delta Angle**

Specifies the curve delta angle.

**Tangent**

Specifies the curve tangent distance.

**Chord Angle Type**

Specifies the angle type as Direction, Angle, or Deflection. If the angle type is set to Angle or Deflection, the specified angle value is relative from a tangent line at the point of curvature to the point of tangency (long chord).

**Chord Angle**

Specifies the chord angle value.

Reverse Direction

Select the check box to reverse the line direction or the curve chord direction by 180 degrees to calculate the endpoint coordinates for the Side.

Chord Distance

Specifies the chord distance value.

Easting

Displays the calculated easting value of the Side endpoint.

Northing

Displays the calculated northing value of the Side endpoint.

**Related procedures:**

■ Performing a Mapcheck Analysis (page 1608)

# Adjust Mapcheck Analysis Dialog Box

Use this dialog box to adjust a mapcheck report for closure.

Do Angle Balance

Select Yes to perform a mathematical analysis based on the method you specify as the Horizontal Adjustment Method.

Horizontal Adjustment Method

Specify one of the following traverse analysis methods:

■ Compass Rule: A method of corrections where the closing errors are assumed to be as much due to errors in observed angles as by the errors in measured distances. The closing errors in latitude and departure are distributed according to the ratio of the length of the line to the total length of the traverse

■ Transit Rule: A method of balancing a traverse where the closing errors are assumed to be caused less by the errors in the observed angles than by the errors in measured distance. Corrections are distributed according to the ratio of the latitude and departure of each leg of the traverse to the sums of the latitude and departures of the entire traverse.

■ Crandall Rule: A method of balancing a traverse where all the angular error is distributed throughout the traverse and all adjustments to the traverse are due to modifying the traverse distances. The modification distance made to each leg is such that the sum of the squares is a minimum. Corrections corresponding to the closing errors assume that the closing errors are random and normally distributed, and that all the angular error has been adjusted prior to the adjustment routine.

■ Least Squares: A method of balancing a traverse. The squares of the differences between the unadjusted and adjusted measurements (angles and distances) are summed and reduced to a minimum. This method weights the individual measurements according to the specifications set in the Equipment correction settings to determine the source of error. You can adjust the data for an individual traverse loop, or a traverse network, if located from multiple observations.

**NOTE** The Least Squares option uses the specified values for the Standard Deviations in the Equipment Properties for the current Survey Equipment Database. Make sure that values are appropriate for the least squares method of adjustment. For more information, see New Equipment/Equipment Properties Dialog Box (page 2384).

Horizontal Closure Limit

Specifies the minimum allowable error of closure in the horizontal direction, for example a value of 15000.00 is 1 part in 15000.

Angle Error Per Set
    Specifies the maximum angle error.

Update Mapcheck
    Specify Yes to update the mapcheck report with the adjusted coordinates.

---

**NOTE** In the Mapcheck Analysis Input View, the 🔧 icon is displayed next to the Mapcheck name indicating the mapcheck has been adjusted. To clear an adjustment, right-click the Mapcheck ➤ Clear Adjustment.

---

**Related procedures:**

■ Adjusting a Mapcheck Analysis (page 1614)

# Notes Dialog Box

Use this dialog box to attach notes or reference documents to an object.

# Notes Tab (Notes Dialog Box)

Use this tab to attach notes to an object.

Notes Text Box
    Specifies comments to associate with the object.

**Related procedures:**

■ Attaching Text to an Object (page 1616)

# Reference Docs Tab (Notes Dialog Box)

Use this tab to attach reference documents to an object.

Document Column
    Specifies the reference document name.

Type Column
    Displays the file type for the attached reference file.

Description Column
    Displays the file description for the attached reference files.

Add
    Displays the Select Reference Document dialog box. Browse to select the reference file that you want to attach.

Edit
    Displays the Reference Document dialog box. Click File to browse for another document. You can edit the reference document description in the Description box.

Delete
    Deletes the selected reference document.

**Related procedures:**

■ Attaching External Reference Documents to an Object (page 1616)

# Object Viewer Dialog Box

Use this dialog box to control the view of selected objects in your drawing.

The Object Viewer contains the ViewCube and the SteeringWheel. For more information, see Use ViewCubeand Navigation Wheelsin the AutoCAD Help.

### ![icon] Save Image

Saves the current view as a separate file. The supported file formats are PNG, JPG, BMP, TIF.

### Visual Style List

Specifies the object appearance style. Set the style to one of the following:

- 3D Hidden: Displays objects in the current view in a 3D wireframe representation with all visible lines displayed as continuous and all hidden lines displayed as dashed.

- 3D Wireframe: Displays objects in the current view in a 3D wireframe representation with all lines displayed, including those hidden by other objects.

- Conceptual: Displays objects in a transparently shaded 3D view with all lines visible.

- Realistic: Displays objects in a shaded 3D view.

### ![icon] Pan

Moves the current view without changing its size.

### ![icon] Zoom

Increases or decreases the apparent size of objects in the current viewport.

### ![icon] SteeringWheel

Provides a Navigation Wheels menu that is divided into different sections known as wedges. Each wedge on the wheel represents a single navigation tool. You can pan, zoom, or manipulate the current view of a model in different ways.

### ![icon] 3D Orbit

Sets the display window to 3D orbit view.

**NOTE** Hold down Shift and click to pan in the Object Viewer. Hold down Ctrl and click to zoom in the Object Viewer.

### ![icon] Adjust Distance

Displaces objects a specified distance in a specified direction. This control is available only when the Perspective control is selected.

### View Control List

Specifies the current view. Set the view to either Top, Bottom, Left, Right, Front, or Back. Set the isometric view to either SW Isometric, SE Isometric, NE Isometric, or NW Isometric

### ![icon] Parallel

Sets the view to a parallel plane.

### ![icon] Perspective

Sets a perspective view and makes the Adjust Distance and Lens Length controls available.

 Lens Length

Sets the length of the lens used in perspective viewing for the current viewport. This control is available only when the Perspective control is selected.

 Zoom Window

Zooms to display an area specified by a rectangular window.

 Zoom Center

Zooms to display a window defined by a center point.

 Zoom Extents

Zooms to display the drawing extents and results in the largest possible display of all the objects in the window area.

 Zoom In

Zooms in an increment as defined by the Zoom Factor.

 Zoom Out

Zooms out an increment as defined by the Zoom Factor.

 Zoom Factor

Sets the zoom increments used by the Zoom In and Zoom Out commands.

 Set View

Sets the view in the drawing equal to the view in the Object Viewer.

Display Configuration List

Specifies the object viewer display configuration.

NOTE AutoCAD Civil supports only the Standard Display Configuration.

**Related procedures:**

■   Using the Object Viewer (page 1617)

# AEC Editor Tab (Options Dialog Box)

Use the AEC Editor tab in the Options dialog box to control the visibility of the design criteria warning marker, and settings that affect the Export To AutoCAD commands.

**Solution Tip**

Controls the visibility of the design criteria warning marker. This warning marker is displayed in the drawing window when an alignment or profile entity violates the specified design criteria.

NOTE If either of these check boxes are cleared, the warning marker will not be displayed on any alignment or profile objects that violate the specified design criteria. However, the alignments and profiles will still be validated against the specified design criteria, and warning markers will appear the Alignment Entities and Profile Entities vistas and the Alignment Layout Parameters and Profile Layout Parameters dialog boxes.

Drafting

Displays the warning marker in the drawing window.

Plotting/Publishing

Displays the warning marker in plotted or published output.

## Export to AutoCAD

Bind Xrefs

Binds xrefs to the host drawing when using the Export To AutoCAD commands, creating local block definitions. If you select this option, all xrefs and their dependent named objects become a part of the exported drawing.

Use Insert Method When Binding Xrefs

- **Selected**: The drawing names of the xref drawings are discarded when the exported drawing is created. In addition, the xref layers and styles are incorporated into the host drawing, and layers with the same name acquire the properties of the layers of the host drawing.
  This option binds the xref to the current drawing in a way similar to detaching and inserting the reference drawing. Rather than being renamed using *blockname$n$definitionname* syntax, xref-dependent named objects are stripped of the xref name. As with inserting drawings, no name-incrementing occurs if a local named object shares the same name as a bound xref-dependent named object. The bound xref-dependent named object assumes the properties of the locally defined named object. For example, if you have an xref named FLOOR1 containing a layer named WALL, after binding with the Insert option, the xref-dependent layer FLOOR1|WALL becomes the locally defined layer WALL.

- **Cleared**: The xref identities, such as layer names, are retained when you export a file to AutoCAD. By clearing this check box, xref-dependent named objects are changed from *blockname|definitionname* to *blockname$n$definitionname* syntax. In this manner, unique named objects are created for all xref-dependent definition tables bound to the current drawing.

  For example, if you have an xref named FLOOR1 containing a layer named WALL, after binding the xref, the xref-dependent layer FLOOR1|WALL becomes a locally defined layer named FLOOR1$0$WALL. The number $n$ is automatically incremented if a local named object with the same name already exists. In this example, if FLOOR1$0$WALL already existed in the drawing, the xref-dependent layer FLOOR1|WALL would be renamed FLOOR1$1$WALL.

Filename Prefix

Adds the specified prefix to a file created with the Export To AutoCAD commands.

Filename Suffix

Adds the specified suffix to a file created with the Export To AutoCAD commands.

## Block Properties of Exploded Object

Maintain Resolved Layer, Color, Linetype

Maintains the layer, color, and linetype of AutoCAD Civil objects when you explode them.
When you explode an object, you create several primitive objects grouped in a block definition. If this option is selected any objects whose component layer, color, and linetype properties are set to ByBlock take the layer, color, and linetype of the parent object. If this option is cleared, when you explode an object, properties that are ByBlock remain ByBlock. Clear this option if you want to explode the block definition even further.

## Unselected Grip Colors

Controls the colors of several types of unselected grips.

Object

Specifies the color of the AutoCAD Civil unselected object grips. For example, if you click on a profile, the unselected grips use this color.

Secondary Object

Not used by AutoCAD Civil.

Style

Not used by AutoCAD Civil

Auxillary

Not used by AutoCAD Civil

---

**NOTE** The other settings on this tab are not used by AutoCAD Civil.

**Related procedures:**

■ Changing the AEC Editor Settings (page 1658)

■ Viewing and Correcting Alignment Design Criteria Violations (page 1008)

■ Viewing and Correcting Profile Design Criteria Violations (page 1103)

# Event Viewer Vista

Use the Event Viewer to view messages that are logged during an AutoCAD Civil session.

## Menu and Toolbar

Action menu

Contains general Event Viewer commands, including commands for working with log files, exporting an event list, and listing event properties. Click a command on the menu.

View menu

Contains commands that control what events are displayed in the event list and how they are displayed. Click a command on the menu.

⇐

Returns to a previously selected collection in the event tree.

⇒

Moves forward to a previously selected collection in the event tree.

▢

Makes the Event Viewer collection in the event tree active, displaying all events in the event list.

▤

Shows or hides the event tree.

⚠

Displays the Event Properties (page 2456) dialog box for the selected event.

↻

Refreshes the Event Viewer.

▤→

Exports the event list to a file. For more information, see Exporting an Event List to a Text File (page 1630).

**Event Tree**

Tree

Controls the events that are listed in the event list. Expand the tree and select a collection to list the events in the collection. For more information, see The Event Viewer Vista (page 1626).

**Event List**

Type

Specifies the type of event: either Information, Warning, or Error.

Date

Specifies the date the event was logged to the Event Viewer.

Time

Specifies the time the event was logged to the Event Viewer.

Source

Specifies the feature that logged the event to the Event Viewer.

User

Specifies the user who performed the action that caused the event to be logged to the Event Viewer.

Description

Describes the event.

> **NOTE** You can control the columns and the events that are displayed in the event list. For more information, see Controlling the Columns Displayed in the Event Viewer (page 1627) and Controlling the Events Displayed in the Event Viewer (page 1628).

**Related procedures:**

■ The Event Viewer Vista (page 1626)

# Event Properties Dialog Box

Use this dialog box to display detailed information about a specific event in the Event Viewer and to copy the information to the Windows clipboard.

Type

Specifies the type of event: either Information, Warning, or Error.

Date

Specifies the date the event was logged to the Event Viewer.

Time

Specifies the time the event was logged to the Event Viewer.

Source

Specifies the feature that logged the event to the Event Viewer.

User

Specifies the user who performed the action that caused the event to be logged to the Event Viewer.

Description

Describes the event.

⬆ Up Arrow

Changes the event displayed in the dialog box to the previous event in the event list.

⬇ Down Arrow

Changes the event displayed in the dialog box to the next event in the event list.

 Copy to Clipboard

Copies the contents of the Event Properties dialog box so that it can be pasted into another application.

**Related procedures:**

■ The Event Viewer Vista (page 1626)

# Filter Events Dialog Box

Use this dialog box to control the events that are listed in Event Viewer event list.

Event Types

Specifies the types of events to be included in the event list. Select the check box next to any or all of the following event types:

■ Information

■ Warning

■ Error

Event Source

Displays only the events logged by the specified source. Select the name of a source in the list or click All to display all events, regardless of their source.

User

Displays only the events associated with the specified user. Select the name of a user in the list or click All.

**NOTE** You can see more than one user name in the event list if you open a log file that contained events that were created by another user and you then perform actions that cause events to be logged using your login name.

**From Event**

From list

Specifies the date and time of the first event displayed in the event list. In the list, select one of the following:

■ First Event: Begins the display with the first event in the event list.

■ Events On: Begins the display with the first event in the list that falls on or after the specified date and time.

From Date

When Events On is specified, specifies the date for the first event in the event list. Do one of the following:

■ Enter a date.

■ Click the list arrow to display a calendar. Click Today at the bottom of the calendar to set the date to the current date. Click the right and left arrows to specify a month. Click a day on the calendar to specify a day.

From Time
When Events On is specified, specifies the time for the first event in the event list.

**To Event**

To list
Specifies the date and time of the last event displayed in the event list. In the list, select one of the following:

■ Last Event: Ends the display with the last event in the event list.

■ Events On: Ends the display with the last event in the event list that falls on or before the specified date and time.

To Date
When Events On is specified, specifies the date for the last event in the event list. Do one of the following:

■ Enter a date.

■ Click the list arrow to display a calendar. Click Today at the bottom of the calendar to set the date to the current date. Click the right and left arrows to specify a month. Click a day on the calendar to specify a day.

To Time
When Events On is specified, specifies the time for the last event in the event list.

**Related procedures:**

■ Customizing the Event Viewer (page 1627)

# Find Event Dialog Box

Use this dialog box to locate a specific event in the Event Viewer event list.

Event Types
Specifies the types of event to search for. Select the check box next to any or all of the following event types:

■ Information

■ Warning

■ Error

Event Source
Searches for events logged by the specified source. Select the name of a source in the list or click All.

User
Searches for events associated with the specified user. Select the name of a user in the list or click All.

Search Direction
Specifies the direction of the search, beginning with the selected event. Select Up or Down.

Find Next

Selects an event in the event list that matches the specified criteria. Click to search for the next event that matches the specified criteria.

**Related procedures:**

■ Finding a Specific Event in the Event Viewer (page 1630)

# Choose Columns Dialog Box

Use this dialog box to control the columns that are displayed in the event list of the Event Viewer.

Hidden Columns

Displays a list of the columns currently not displayed in the event list.

Add

Adds a column to the event list. Select the column name in the Hidden Columns list and click Add.

Remove

Removes a column from the event list. Select the column name in the Displayed Columns list and click Remove.

**NOTE** The Type column cannot be removed.

Displayed Columns

Displays a list of the columns that are currently displayed in the event list.

**Related procedures:**

■ Controlling the Columns Displayed in the Event Viewer (page 1627)

# Multi-View Block Definition Properties Dialog Box

Use this dialog box to create new multi-view blocks and edit existing multi-view blocks in the current drawing.

Multi-view Block Name

Displays the name of the multi-view block currently being edited or created. The list displays the names of all multi-view blocks defined in the drawing.

Edit

Displays the Edit Multi-View Block Definition dialog box, which allows you to edit the name of a multi-view block definition.

New

Displays the New Multi-View Block Definition dialog box, which allows you to specify a name for a new multi-view block definition.

Multi-view Block Description

Specifies a description for the multi-view block.

**Multi-view block components**

2D View Blocks

When selected, the view blocks list displays the names of the blocks that are shown when the view direction is a plan view.

3D View Blocks

When selected, the view blocks list displays the names of the blocks that are shown when the view direction is a 3D view (any direction other than plan).

Add

Displays the Blocks dialog box, which you can use to select blocks for the current multi-view block definition. The selected blocks are added to the 2D view block list or 3D view block list depending on the state of 2D view blocks and 3D view blocks buttons.

Remove

Removes the blocks selected in the view blocks list from the multi-view block definition. It is valid to remove all blocks from the list box control. No confirmation dialog box is displayed when the remove button is selected.

### Multi-view block preview

2D View

Sets the preview pane to plan view, and performs a zoom to extents to display all of the 2D blocks that define the multi-view block.

3D View

Sets the preview pane to a South-West isometric view, and performs a zoom to extents to display all of the 3D blocks that define the multi-view block.

Preview Pane

Provides a preview of the current multi-view block definition.

**Related procedures:**

■ Understanding Multi-View Blocks (page 1632)

# Multi-View Block Definition Properties Dialog Box

Use this dialog box to edit existing multi-view blocks in the current drawing.

# General Tab (Multi-View Block Definition Properties Dialog Box)

Use this tab to edit the name and description of the multi-view block.

Name

Specifies the name of the block.

Description

Specifies the description of the block.

This Style May Act As a Boundary For Automatic Spaces

This setting is not used by AutoCAD Civil.

Notes

Attaches notes (page 2451) to the block.

Floating Viewer

Displays a viewer dialog box where you can preview the appearance of the block.

# View Blocks Tab (Multi-View Block Definition Properties Dialog Box)

Use this tab to connect multi-view blocks to the view directions of individual display representations. To ensure that the multi-view block is visible in all views, assign a block to every view direction.

Display Representations

Specifies which display representation will use the view block settings that you specify. Select General to make assignments for plan views and Model for other model space views.

View Blocks

Specifies the block to use for each display representation. Click Add, and select a view block for the display representation. With the block selected, specify the View Directions that correspond to the selected block (see below).

View Directions

Specifies the view directions that correspond to the selected block. For example, to connect the view block to the left side of the multi-view block definition, select Left and clear all other directions.

You can connect a view block to multiple view directions. For example, if you have a symmetrical element that looks identical from left and right, you can select Left and Right.

The Other view direction represents a view that displays the block three-dimensionally. It is used for non-orthogonal (isometric or perspective) views of the custom object.

To ensure that the multi-view block is visible in all views, assign a block to every view direction.

Set Interference Block

Specifies a cut body for the multi-view block when the block is used as interference in other objects.

# Classifications Tab (Multi-View Block Definition Properties Dialog Box)

This tab is not used by AutoCAD Civil.

# Edit Multi-View Block Definition Dialog Box

Use this dialog box edit the name for an existing multi-view block definition.

Multi-view Block Name

Rename an existing multi-view block definition.

**Related procedures:**

■ Understanding Multi-View Blocks (page 1632)

# New Multi-View Block Definition Dialog Box

Use this dialog box to enter the name for a new multi-view block definition.

Multi-view Block Name

Provide a name for a new multi-view block definition.

**Related procedures:**

■ Understanding Multi-View Blocks (page 1632)

# Blocks Dialog Box

Use this dialog box to select blocks for the current multi-view block definition properties.

Blocks

Displays the names of all blocks in the current drawing. Select the blocks to add to the multi-view block definition. Multiple selection is supported.

**Related procedures:**

■ Understanding Multi-View Blocks (page 1632)

# Inquiry Tool Dialog Box

Use the Inquiry Tool to run inquiries on AutoCAD Civil objects.

Select An Inquiry Type

Specifies the inquiry to run. After you select an inquiry type, you are prompted to select the objects needed to run the inquiry.
Inquiry results are displayed in the Results area.

After the prompts are complete, you can click ![icon] or ![icon] in the value rows to change any of the selections you made. Some value rows also have lists you can use to change the selection.
For more information about the inquiry types, see Inquiry Types (page 1620).

---

**NOTE** To run Corridor queries, a corridor section view must be active. Click Corridor menu ➤ View/Edit Corridor Section and then select the station. Use the Zoom command as needed to zoom closer to the view.

---

![icon] Copy To Clipboard

Copies the inquiry results to the clipboard so you can paste it into other applications, such as Microsoft© Excel.

![icon] Copy To Text Screen

When selected, continually sends the inquiry data to the AutoCAD text window.

# Coordinate Tracker Dialog Box

Use this dialog box to track and capture X, Y, and Z drawing coordinates. The precision of the displayed value is determined by the coordinate precision drawing setting.

**X, Y, Z**

X:

Displays the X coordinate of the cursor location in the drawing.

Y:

Displays the Y coordinate of the cursor location in the drawing.

Z:

Displays the Z coordinate (elevation) of the cursor location in the drawing on the specified surface.

![icon] Continue Tracking

Resumes coordinate tracking after it has been suspended due to the entry of the coordinate capture keys.

![icon] Send XY

Sends the displayed X and Y values to the command line for use by the active command.

![icon] Send Z

Sends the displayed Z value to the command line for use by the active command.

| Send XYZ

Sends the displayed X, Y, and Z values to the command line for use by the active command.
For more information, see Sending Coordinate Tracker Values to the Current Command (page 1624).

### Surface

Surface

Displays the name of the surface from which the elevation value is read. Select a surface from the list. All surfaces in the active drawing are listed. If the drawing contains only one surface, that surface is automatically used to calculate Z values.

Surface Selector

Selects a surface in the drawing.

### Coordinate Capture Keys

Coordinate Capture Keys

Displays the keys that suspend coordinate tracking and capture the current coordinates. When the keys are pressed and held down, one by one in the specified order until all keys are pressed, cursor tracking is suspended and the X, Y, and Z values are captured at the current location of the cursor. You can then edit the coordinate values.

Coordinate Capture Keys Selector

Changes the coordinate capture keys. Enter the new coordinate capture keys. For more information, see Changing the Coordinate Tracker Coordinate Capture Keys (page 1625).

**Related procedures:**

■ The Coordinate Tracker (page 1623)

# Export To SDF Dialog Box

Use this dialog box to save a AutoCAD Civil drawing in Spatial Data Format (SDF). You can use an SDF file in AutoCAD Map 3D and MapGuide Enterprise.

The AutoCAD Civil alignment, point, parcel, and pipe network data is converted to AutoCAD objects with attributes. For more information, see Exporting Civil Data to SDF Files (page 1660).

SDF File Name

Specifies the file name. Defaults to the last file name used.

### Select Coordinate System

If the drawing already has a coordinate system specified, it is used automatically and these controls are not available.

Categories

Specifies the geographic zone.

Available Coordinate Systems

Specifies the coordinate system within the selected zone category. If you do not select a zone category, then the default (No Datum, No Projection) is enabled. If you select a zone category but do not select a coordinate system, then, by default, the first entry in the list is selected.

Selected Coordinate System Code

Displays the coordinate system code.

Description

Displays a description of the selected zone.

Projection

Displays the projection method for the coordinate system.

Datum

Displays the abbreviation for the datum on which the coordinate system is based.

**Related procedures:**

■ Exporting Civil Data to SDF Files (page 1660)

# DWF Publishing Options Dialog Box

Use this dialog box to access AutoCAD Civil-related settings for publishing 3D DWF data.

You can specify the objects to publish to the DWF file, how they are organized, and if the object properties are included in the DWF file.

## Object To Publish

All Model Space Objects

Specifies that all the objects in the drawing model space are published to the DWF file.

Selected Model Space Objects

Specifies that the selected objects in the drawing model space are published to the DWF file. Use the object picker button to select objects from the drawing.

## 3D DWF Organization

Specifies how to organize the objects in the DWF file.

Group By Xref Hierarchy

Specifies that objects in the DWF are arranged by Xref hierarchy in the viewer. If unchecked, externally referenced files are listed in the viewer like other objects.

Group Individual Objects By

Specifies how to group objects in the Model panel of the DWF Viewer. You can group them either by object type and style, or by the layer that the objects reside on.

## Options

Specifies additional DWF publishing options.

Publish With Materials

Specifies that the model will be exported with associated textures to various objects (for example, surfaces, pipes, or AutoCAD solids).
If you've assigned texture mapped materials to your models, those materials can be published with the 3D DWF file. Texture map orientation and scaling that is set in the drawing editor is retained in the published 3D DWF file.
There are some limitations to materials publishing.

■ The Diffuse Map channel is the only mapping that gets published. If you use Opacity, Reflection, or Bump maps in your material, they do not get published.

■ Procedural materials such as Wood or Marble do not get published.

**NOTE** Because the DWF Viewer and the rendering engine are different, you may encounter some deviation in how the texture maps appear in the DWF Viewer.

Include Properties From Objects

Specifies that the object properties will be available in the DWF file. The properties vary from object to object and include common properties such as Name, Description, Date Created, Created By, Date Modified, Modified By, Object Style, Layer, and Color. Each object has special properties as well. For example, an alignment includes start station, end station, and length.

**Related procedures:**

■ Exporting a Drawing to a 3D DWF File (page 1662)

# Glossary

This glossary contains terms relevant to AutoCAD Civil. Please see the AutoCAD glossary for additional platform terms.

**2D polyline**  A polyline with all vertices at the same elevation.

**3D face** A 3D face is an AutoCAD object that represents the surface of a 3- or 4-sided area, with each vertex potentially at a different elevation. You can view TINs (Triangulated Irregular Networks) as 3D faces. Using the SHADE command, you can shade 3D faces. Using the RENDER command, you can render the 3D faces. *See also* TIN (page 2485).

**3D polyline** A polyline with vertices at varying elevations.

**A** Grade Change.

**A.A.S.H.T.O.** American Association of State, Highway, and Transportation Officials.

**acre** A measure of land: 160 square rods; 4,840 square yards; 43,560 square feet.

**adjustment** A process that removes inconsistencies from the mathematical model of measured observations such as angles and distances.

**alignment** A series of 2D coordinates (northings and eastings), connected by lines, curves, or spirals, used to represent features such as the road centerlines, edges of pavement, sidewalks, or rights-of-way.

**angle** The difference in direction between two convergent lines measured in the units of degrees, radians, or grads.

**area** The quantity of plane space in a horizontal plane enclosed by the boundary of any polygonal figure.

**assembly** An AutoCAD Civil drawing object (AECCAssembly) that manages a collection of subassembly components, such as travel lanes, curbs, shoulders, and ditches, to form the structural elements of a roadway or other corridor-type structure.

**assembly set** The set of assemblies that are specified (referenced) by an assembly set file, used during intersection object creation (intersection design).

**astronomic azimuth** An azimuth derived from sunshots or starshots.

**azimuth** A clockwise angle measured from a reference meridian. Also known as north azimuth. It can range from 0 to 360 degrees. A negative azimuth is converted to a clockwise value.

**backsight** A previously established point used as a direction reference to another point. A survey instrument movements typically are locked to an angle of 0 degrees, and the vertical crosshair is set on the backsight. All subsequent shots are then taken by turning the instrument and the upper movement together, while the lower movement stays set on the backsight. All angles measured are, therefore, relative to the backsight.

**balance line** The line in a mass haul diagram at which cut and fill balance. *See also* mass haul line (page 2478).

**balance point** The point at which the mass haul line crosses the balance line (the station at which the cut volume and fill volume are equal). *See also* balance line (page 2468), mass haul line (page 2478).

**base surface** An existing ground or undeveloped terrain. Specified when creating volume surfaces. *See also* comparison surface (page 2470).

**baseline** *See* footprint (page 2474).

**BC:L** Curve Beginning.

**bearing** An angle measured from North or South, whichever is nearest, with the added designation of East or West. The angle is always less than 90 degrees (PI/2 radians or 100 grads) and is referenced by a quadrant number.

**BFS** Begin Full Super.

**BNC** Begin Normal Crown.

**BNS** Begin Normal Shoulder.

**BOA** Begin of Alignment.

**border** The visible limits of a surface. The border can be defined from a boundary or can be the result of a defined boundary and operations performed on a surface, such as a Delete Line operation (a hole is created in the surface). If a boundary is not defined on a surface, the exterior border is always defined as the extents of the surface triangulation.

**borrow pit** A pit that is created at a station along an alignment, to provide material to be used as fill in a mass haul diagram. *See also* dump site (page 2473).

**boundaries** Three kinds of closed polylines that limit the display area of the digital terrain model. Most common are outer surface boundaries constructed just outside the extremities of the dataset, eliminating unwanted interpolations across empty space where the surface has a concave shape. The following two types of internal surface boundaries are also used: hide boundaries, to punch holes in a surface (for example, a building footprint), or show boundaries, to create smaller surfaces by eliminating areas that fall outside the boundary.

**bounded volume** A method of calculating volumes using an existing AutoCAD object (for example, a polyline or polygon) to calculate the cut, fill, and net volume for the area bounded by the object.

**BP** Alignment Beginning.

**BP:STA** Alignment Beginning Point.

**BREAK** Grade break.

**breakline** A line used to connect the data representing a distinct surface feature, like a ridge line, edge of pavement, toe of a slope, centerline of a road, or flowline of a ditch or stream. When a breakline is defined, the surface triangulation must first follow the breakline, by placing triangle edges coincident with the breakline segments. This ensures the feature in the model is accurately depicted. Then, the rest of the interpolation is performed based on proximity. Breaklines are typically critical to creating an accurate surface model. It is the interpolation of the data, not just the data itself, that determines the shape of the model. *See also* non-destructive breakline (page 2478).

**breakline point** A point that is included in the defined breakline's list of vertices.

**BVC** Vertical Tangent-Curve Intersect.

**BVCE** Vertical Tangent-Curve Intersect Elevation.

**BVCS** Vertical Tangent-Curve Intersect Station.

**BVP** Profile Start.

**ByBlock** A setting specifying that a component of an object inherits the color or linetype associated with the object, or block, that contains it.

**ByLayer** A setting specifying that an object or component of an object inherits the color or linetype associated with the assigned layer.

**bypass target** A part in a pipe network that has been identified by the user to act as the target for any bypass flows to be directed to.

**catchment area** The area tributary to a lake, stream, or drainage system.

**center marker** A diamond-shaped graphic that marks the location of the centroid of a grading object. Right-click the center marker to access the Grading shortcut menu.

**chord** A straight line connecting two points on a curve: the Point of Curvature (PC) and Point of Tangency (PT). The curve joins with a line or another curve at these points.

**closure** The relative position of a traverse station as it compares to the same station position determined by a different set of observations or route of survey.

**clothoid spiral** A spiral in which the curvature is a linear function of the length of the spiral, so that the degree of curvature is zero when it meets the tangent and then increases to match the curvature of the adjacent curve. *See also* compound spiral, simple spiral.

**COGO** Coordinate Geometry.

**COGO points** The point objects that you create using the point-creation or point-import. COGO points are referred to simply as "points" in this documentation. The pieces of data associated with a point, such as point number, northing, and easting, are referred to as properties. *See also* properties (page 2480).

**collimation** The process of adjusting the line of sight or lens of an optical instrument so that it is properly located based on the other parts of the instrument.

**comparison surface** A proposed or existing terrain surface used in the creation of volume surfaces. *See also* base surface (page 2468), volume surface (page 2487).

**Compass rule** Corrections corresponding to the closing errors that assumes the closing errors are as much due to of errors in observed angles as errors in measured distances. Use the compass rule option when this is the case.

**composite volumes** A method of calculating volumes using top and bottom surfaces (a surface pair) to establish cut, fill, and net volume values.

**compound curve** A curve consisting of two or more arcs of different radii curving in the same direction, and having a common tangent or transition curve at their point of junction.

**compound spiral** A spiral that provides a smooth transition between two adjoining curves of different radii but in the same direction. It has a finite radius on either side/end. *See also* clothoid spiral (page 2470).

**confidence interval** In statistics, a region or area that has a known probability of containing a random sample. In surveying, a 95% confidence interval indicates that the surveyor can be 95% sure that a point or observation lies within the region or established parameters.

**construction geometry** Unconnected portions of parcel and alignment geometry. For example, if you use the tan-tan method and create a number of connected lines, the whole feature is solved and the display characteristics are controlled by the object style. If you create some connected lines and then add a line that is not connected, the result is a piece of 'construction' geometry.

**contour** A line that connects points of the same elevation or value relative to a specified reference datum.

**control point** Points with a unique identifier that are created at a known location (northing, easting, or latitude, longitude, with an optional elevation or description) and are not affected by adjustments or corrections. Control points are added to a survey database and are managed within a named survey network.

**control region** A region that is defined by applying grading criteria to a footprint. A footprint can have a single region along its entire length, or it can be subdivided into a number of control, transition, and void regions. *See also* footprint (page 2474).

**coordinates** Values that specify exactly where a point is in space in terms of three planes: X, Y, and Z (easting, northing, and elevation).

**corridor** Any path, the length and location of which are typically governed by one or more horizontal and vertical alignments. Examples are roadways, railways, traveled ways, channels, ditches, utility runs, and airport runways.

**corridor feature line** A component of a corridor object. Created by joining subassembly point codes from one station to another.

**corridor surface** A component of a corridor object. Surface triangulation is created from a corridor subassembly point and link codes.

**Crandall rule** A method of balancing a traverse in which all the angular error is distributed throughout the traverse and all adjustments to the traverse result from modifying the traverse distances. The modification distance made to each leg is such that the sum of the squares is a minimum.

Corrections correspond to the closing errors, which assumes the closing errors are random and normally distributed. It assumes all the angular error has been adjusted before the adjustment routine.

**crest curve** In a profile, a vertical curve on the crest of a hill or similar location where the grade leading into the curve is greater than the grade leading out of the curve. In a crest curve, the point of vertical intersection (PVI) for the tangents is above the curve. *See also* sag curve (page 2482).

**criteria-based design** The process of associating agency-specific standards to an alignment or profile. Agency standards, which are typically based on superelevation and design speed requirements, are contained in a customizable design criteria file.

When an alignment or profile object is created, standards from the design criteria file can be associated with the alignment or profile to ensure that the horizontal and vertical curves comply with the minimum standards. User-defined design checks can be used to identify and report standards violations. *See also* design criteria file (page 2472).

**cross section** *See* section (page 2482).

**CS** Curve-Spiral Intersect. *See* curve to spiral (page 2471).

**CS_LRB:L** Compound Spiral Large Radius at Beginning.

**CS_LRE:STA** Compound Spiral Large Radius at End.

**CS_SRB:L** Compound Spiral Small Radius at Beginning.

**CS_SRE:STA** Compound Spiral Small Radius at End.

**curb return alignment** An alignment that connects the edges of two intersecting roadways. The most common curb return geometry is a simple circular fillet. In a typical intersection, curb return alignments are placed in each of the four quadrants, between edges of pavement.

**curve to spiral** A point on a horizontal alignment where a curve meets a spiral.

**cut slope** The slope created when the footprint falls below the existing ground line. The resulting slope matching up into the existing ground is called a cut slope because the existing ground must be cut (removed) during construction.

**data band** A graphic frame that is associated with a profile view object or section view object. The data band contains annotations for the profile or section view, as well as for the parent horizontal alignment. Some common annotations include elevation data, stations, and cut/fill depths.

**data collector** A device surveyors use to automatically record the observation data they collect in the field. They then download and convert the raw survey data to a field book file, which is written in the Survey Command Language format, or a LandXML file, which uses the LandXML schema to describe the Survey data. Surveyors can then import this file to create points in the database and figures in the drawing.

**data reference** A read-only copy of an object from another drawing. The referenced object can be used in multiple drawings and stylized locally. After the official copy of the object is updated, drawings with references to it are notified of the opportunity to update their local copy. There are two data reference types used in AutoCAD Civil: data shortcuts and Vault references. Both types can reference surfaces, alignments, profiles, pipe networks, and view frame groups.

**data shortcut** An object that can create a data reference between drawings in a project. Data shortcuts are not used with Vault projects.

**datum** A reference value. All elevations or coordinates are set relative to this value. In surveying, you can use two datums (horizontal and vertical).

For global coordinate systems, a datum refers to the ellipsoid information and the techniques used to determine positions on the Earth's surface. An ellipsoid is part of a datum definition.

**daylight line** A line showing the line of zero cut or fill within the job area. For grading objects, it represents the target line produced by grading to a specified surface, distance, or elevation.

**decimal degree** The measure of an angle in decimal units. For example, 3°30'36" equals 3.51 decimal degrees.

**Decreasing** Station Equation Decreasing.

**definition list** A list that contains all the operations performed on a surface. By turning the items in the list on and off, you can modify the surface, return it to a previous state, and so on.

**deflection angle** A horizontal angle measured from an extension of the preceding line, right or left.

**degrees, minutes, seconds** (DMS) A representation of an angle in degrees, minutes, and seconds in which a full circle contains 360 degrees, each degree 60 minutes, and each minute 60 seconds. A typical bearing in DMS measurement looks like: N45°45'58"E. Using this format, 3°30'36" is entered as 3.3036.

**Delaunay triangulation** A calculation method used in the creation of TIN networks. Given a set of data points, Delaunay triangulation produces a set of lines connecting each point to its natural neighbors.

**DEM** (Digital Elevation Model) An array of elevations taken on a regularly spaced horizontal grid.

**description keys** A method of translating descriptions to help standardize point data when a variety of data sources are used. For example, descriptions of EROAD, EPAVE, ERD, and EDGEROAD can all be translated to a description of EOP. The layer, point style, and point label style options can greatly enhance automatic base plan generation and the overall organization of the drawing.

**design check** A user-defined expression used to verify that an entity meets the minimum design standards that were established for the alignment or profile object. Design checks may be defined for different entity types, such as lines, curves, and spirals. A design check must be saved in a design check set to be applied to an alignment or profile. *See also* design check set (page 2472).

**design check set** A user-defined collection of commonly used design checks. You specify a design check set either during alignment or profile creation, or after creation using the object properties dialog box. *See also* design check (page 2472).

**design criteria file** A file that contains minimum design standards for alignment and profile objects. The design criteria file may be customized to support local design standards for design speed, superelevation, and minimum speed, radius, and length of individual entities. *See also* criteria-based design (page 2471).

**design rule**  A set of automatic constraints for some objects in the drawing that are enforced by applying a specific style. For example, if you are laying out alignments, you can specify a rule for a curve radius.

**drawing objects** Objects that exist in a single drawing. *See also* project objects (page 2480).

**dump site** A site that is created at a station along an alignment, at which cut material removed from a mass haul diagram is dumped. *See also* borrow pit (page 2469).

**easting** A linear distance eastwards from the North-South line which passes through the origin of a grid. Equivalent to the X coordinate in an XYZ coordinate system.

**EC:STA** Curve End.

**EDM** Electronic distance measuring devices that measure the round-trip transit time of a pulsed signal from which distance is computed.

**EDM Offset** The vertical distance from the scope center to the EDM center. AutoCAD Civil uses this value to calculate distance.

**EFS** End Full Super.

**EGL** Energy Grade Line.

**elevation** The vertical distance from a datum to a point or object on the Earth's surface. The datum is considered to be at sea level. Equivalent to the Z coordinate in an XYZ coordinate system.

**elevation point** A point that marks an elevation change but does not break the horizontal geometry.

**ENC** End Normal Crown.

**energy grade line** A line in a pipe network or storm sewer drainage system that represents the total available energy in the system (potential energy, or static head, plus kinetic energy, or velocity head).

**ENS** End Normal Shoulder.

**EOA** End of Alignment.

**EP** Alignment End.

**EP:STA** Alignment End Point.

**error ellipse** An elliptical region that shows the confidence interval of an adjusted point. For example, if the confidence is set to 99 %, you can be 99 % sure the calculated ellipse contains the true location of the point.

**EVC** Vertical Curve-Tangent Intersect.

**EVCE** Vertical Curve-Tangent Intersect Elevation.

**EVCS** Vertical Curve-Tangent Intersect Station.

**EVP** Profile End.

**face** A three-dimensional surface triangle. A face is represented by either a 3D face object or 3D line objects.

**face 1** An angle measurement in which the scope is not flopped. Also called direct.

**face 2** An angle measurement in which the scope is flopped. Also called inverse or indirect.

**feature line** An object in that the grading commands can recognize and use as a footprint. Usually, a line that marks some important feature in the drawing, such as a ridge line, or the bottom of a swale. *See also* footprint (page 2474).

**field book** The permanent detailed record a surveyor makes of all observations made in the field. In AutoCAD Civil, a field book file, (*.fbk), it can be used as a source of survey data.

**field code** Syntax that corresponds to a predefined convention in a surveying application. Field codes are assigned to each survey point to automate the assignment of point and line properties and to determine the linework connectivity.

**Field to Finish** A process of determining the line and curve connectivity between points surveyed in the field that have the same feature name within a point code. This process also assigns symbols to point features based on a feature name within a point code.

**figure** Special linework automatically created in a drawing when you import a field book containing figure data. Also created when using AutoCAD Civil survey figure commands. You can control the layers for figures by using figure prefixes.

**figure prefix** Used to automatically place figures on user-defined layers based on the beginning part of the figure name. For example, the figure prefix EP can be used to place the figures EP, EP1, EP2, and EPL all on the same layer. Using figure prefixes in conjunction with description keys can largely automate the process of constructing a well organized base plan.

**fill slope** The slope created when the footprint falls above the existing ground line. The resulting slope matching down into the existing ground is called a fill slope because material must be brought in to fill the area during construction.

**fixed entity** An alignment entity with a fixed position, not necessarily tangent to another entity for the definition of its geometry. *See also* floating entity (page 2474), free entity (page 2474).

**floating entity** An alignment entity that is tangent to one other entity (before or after) for the definition of its geometry. *See also* fixed entity (page 2474), free entity (page 2474).

**flow rate** A hydraulic property, often used in desigining storm sewer and other systems, that represents the volume of fluid over time that flows through a system.

**footprint** The object to which grading criteria are applied. A footprint can be an open or closed 2D or 3D geometric figure that is a feature line, parcel line, or survey figure. *See also* feature line (page 2473).

**footprint vertices** The endpoints that define the segments of a footprint with an XYZ location and stationing starting at the first vertex.

**foresight** A point to which an instrument sighting is made to measure or establish its elevation or horizontal position.

**free entity** An entity that is tangent to two other entities (before and after) for the definition of its geometry. *See also* fixed entity (page 2474), floating entity (page 2474).

**free haul** The material moved within a certain defined distance of its point of excavation (the free haul distance), free of charge by the contractor. *See also* mass haul (page 2477), overhaul (page 2479).

**front yard** The offset distance from the parcel frontage segments to the setback line.

**frontage** The parcel segments that are adjacent to a right-of-way. The frontage is also considered to be the parcel segments located at the front of the parcel.

**frontage offset** A user-defined length used to offset the current frontage definition to the inside of the parcel being subdivided. When the frontage offset is used, the minimum frontage length is applied at and along the frontage offset instead of the frontage.

**full description** The expanded description of a point after description key matching has taken place.

**geodesic** On a surface, the shortest line between two points, either a line or curve from one point along an ellipsoid to another.

**geodetic** A basic relationship to the Earth that takes into account the curvature of the Earth's sea level surface. For example, a geodetic distance is a distance or angle in which the Earth's curvature is taken into account, versus a distance or angle measured on a flat paper map.

**grade** A method of reporting ground inclination in which the change in elevation is expressed as a percentage of the horizontal distance travelled. For example, if the ground rises one linear unit (meter or foot) over a horizontal distance of five units, the grade is 20%. *See also* slope (page 2482).

**grade line** *See* layout profile (page 2476).

**grade point** A point in a mass haul diagram at which mass haul transitions from cut to fill. When free haul is measured from grade points, the highest point (or lowest, if below the balance line) is the grade point. *See also* balance line (page 2468), mass haul line (page 2478).

**grading** The process used to model the finished ground surface.

**grading criteria** Parameters such as target and projection method for the grading.

**grading face** The area bounded by the footprint, the daylight line, and the two projection lines.

**grading group** A collection that ties grading objects together for the purposes of surface creation and volume calculation.

**grading target** The grading target defines what the projection lines from the footprint will intercept. The three choices for targets are: surface, relative or absolute elevation, and distance. *See also* daylight line (page 2472).

**grads** A system of angle measurement in which one grad equals 1/100 of a 90° angle, or 360° = 400 grads.

**grid** A system of lines parallel to a given set of axes at a specific spacing. Grids are used to visualize surfaces and calculate volumes. A grid is also used for geodetic purposes.

**grid distance** The distance between two points based on a coordinate zone, not on local northing and easting coordinates.

**grid easting** The easting coordinate that is based on a selected coordinate zone, as opposed to the local easting, which is based on the surveyor's base point. *See also* local easting (page 2477).

**grid northing** The northing coordinate that is based on a selected coordinate zone, as opposed to the local northing, which is based on the surveyor's base point. *See also* local northing (page 2477).

**grid surface** A type of surface created from a DEM or SDTS file, or imported from a LandXML file. A grid surface consists of a sampled array of elevations for a number of ground positions at regularly spaced intervals.

**grid volume surface** A differential grid surface based on user-specified base and comparison surfaces. The grid method of volume calculation measures the difference in elevation between two surfaces at each intersection in a user-defined grid.

**grip** A moveable point on an object that you can drag to edit the object dynamically.

**handle** The unique identifier of a drawing object, used as a reference within the software. Users normally do not need to know about handles unless they are using the Data Shortcut Editor.

**hectare** A measure of area, generally relating to land, of 10,000 square meters or approximately 2.47 acres.

**HGL** Hydraulic Grade Line.

**High-definition surveying (HDS)** 3D laser scanning typically associated with terrestrial based laser scanners. The terms "High-Definition" and "HDS" are trademarks of Leica Geosystems.

**horizon** An axis that the scope of a theodolite or transit rotates about when moved vertically. The axis of rotation perpendicular to the vertical axis.

**HP** High Point.

**hydraulic grade line** A line in a pipe network or storm sewer drainage system that represents the elevation head and pressure head of fluid at any point along a system.

**import event** A named collection in a survey database that provides a context to the specific data that was imported using any of the Survey Import commands, such as the Import Survey LandXML command, or the Import Survey Data wizard.

**Increasing** Station Equation Increasing.

**incurve** A spiral with a curve radius that decreases along the route of the defined direction.

**interference checking** A AutoCAD Civil feature available with pipe networks that lets you identify pipe network parts (pipes and or structures) that physically overlap each other, or are too close to one another based on predefined proximity criteria.

**intersection** The point where two or more lines, arcs, figures, or objects join or cross in two- or three-dimensional space.

**inverse** An inverse calculation on a closed figure calculates the bearings and distances between coordinates and reports the area. Because you use exact numbers (coordinates) to determine corners, no closure error is reported.

**junction loss** Or junction loss coefficient. A hydraulic property value used in storm sewer drainage systems that can be computed and defined in a pipe network. It is associated with the loss of energy through a junction. This numeric value has no units associated with it, and can be automatically calculated or manually entered using the Hydraflow Storm Sewers extension application. It is used to compute minor loss for hydraulic analysis.

**K** Curve Coefficient.

**known capacity** A numeric value that represents the flow in a pipe network or storm sewer drainage system as designated by the user.

**Kriging** A method of surface smoothing that uses known values and a semivariogram to determine unknown values. Based on the semivariogram used, optimal weights are assigned to known values to calculate unknown ones. Since the variogram changes with distance, the weights depend on the known sample distribution.

**L** Left.

**label component** Text, a block, direction arrow, line, or tick that is used to construct a label style. Label styles can be made up of multiple label components.

**label set** A collection of label definitions for multiple label types, such as station labels and geometry point labels. For example, alignment station labeling can be composed of major station labels, minor station labels, and geometry point labels.

**latitude** The angular distance measured on a meridian north or south from the equator.

**layout profile** A profile object that represents the finished ground elevations along a horizontal alignment or other linear feature that supports profile views. Typically, this data is designed, not derived from a pre-existing source, and consists of a series of vertical tangents connected by vertical curves located at each point of vertical intersection (PVI). This profile is also known as vertical alignment, profile grade line, grade line, and finished grade profile.

**layout toolbar** A floating, dockable toolbar that groups object-specific design and editing tools.

**LB:L** Line Beginning.

**LC** Level Crown.

**LE:STA** Line End.

**least squares** A method of balancing a traverse in which the squares of the differences between the unadjusted and adjusted measurements (angles and distances) are summed and reduced to a minimum. This method uses the error specifications in the current equipment settings to determine the expected source of errors, and weights the individual measurements accordingly.

**length weighted distribution** A vertical adjustment that distributes the vertical closing error to each line, at the same ratio as the length of that line is to the total length of the traverse (similar to the Compass rule).

**LIDAR** Light Detection and Ranging. Typically associated with airborne laser scanning.

**linework code set** A file that dictates the syntax of linework connectivity commands that are specified within a field code. A feature that is an edge of pavement may be abbreviated as EP or EOP in the field code but the set of abbreviations are part of the field coding standard established by a company. The linework code accompanies the feature name within the field code, for example "EP B", where "EP" is the feature name, and "B" is the linework code to begin a survey figure.

**link codes** A set of standard codes that define the display and behavior of links used in subassemblies.

**local copy** A copy of a project drawing that resides in your local folder, as opposed to the master copy of the file in the project Vault database. Also refers to a copy of a project point that exists in a local drawing.

**local easting** The easting coordinate that is based on the surveyor's assumed horizontal base point, as opposed to the grid easting, which is based on the global coordinate zone. *See also* grid easting (page 2475).

**local elevation** The elevation coordinate based on the surveyor's assumed vertical base point, or benchmark, versus a real world elevation value.

**local northing** The northing coordinate that is based on the surveyor's assumed horizontal base point, as opposed to the grid northing, which is based on the global coordinate zone. *See also* grid northing (page 2475).

**locked point** A drawing point whose coordinate data cannot be modified. Point locking applies only to the drawing in which the point resides. *See also* protected point (page 2481).

**logical name mapping** The process of mapping logical names in subassemblies to actual AutoCAD Civil object names.

**longitude** The angle between the plane of a given meridian and the plane of the Greenwich meridian.

**LP** Low Point.

**LSM** Low Shoulder Match.

**MAN** Manual.

**map check** A map check reports how accurate your angle observations are, and the area of closed figures. You can perform a map check on an open or closed figure that was drawn by using angles. Because the accuracy of the figure is based on the precision of your angle measurements, an amount of closure error is associated with such a figure. The greater the precision you use, the less error there will be. In contrast, if you draw a figure between known coordinates, then there is no need to perform a map check, because there will be no error.

A map check reports precision and mathematical closure based either on bearing and distance entries of a closed figure, or for an open figure between two known points. The accuracy of a map check is based on the precision used to calculate it. For example, if you use data that is rounded to the nearest foot, then the results are less accurate than if you use data rounded to the nearest one-hundredth of a foot.

**masking** A process of obscuring objects so that text can be placed over them in a clear area. Masking maintains legible text without destroying the objects underneath.

**masks** Polygons used to mask the visible portions of a surface.

**mass haul** The volume of excavated material times the distance it is required to be moved. A mass haul diagram presents a visual representation of the cumulative cut and fill material volumes on a project. Mass haul diagrams (along with grading summaries) are the contractor's primary tools for bidding earthwork. *See also* free haul (page 2474), overhaul (page 2479).

**mass haul line** A line marking the balance between cut and fill in a mass haul diagram. When the mass haul line is above a balance line, it indicates material to be cut. When the mass haul line is below the balance line, it indicates a volume to be filled. *See also* balance line (page 2468), mass haul (page 2477).

**match line** *See* daylight line (page 2472).

**mid-ordinate** On a circular arc, the distance from the midpoint of a chord to the midpoint of the subtended arc.

**modifier** A formula for formatting property field values, such as decimal precision for an area. You can use predefined modifiers, such as acres, feet, and meters, or you can define a custom modifier. *See also* property fields (page 2481).

**nadir angle** The nadir angle is opposite the zenith.

**Natural Neighbor Interpolation (NNI)** A method of surface smoothing supported on TIN surfaces. NNI uses Delaunay triangulation to determine the elevation of an arbitrary point based on the elevations of known neighbor points.

**network** A series of interconnected lines that represent the observed instrument setups.

**non-control point** Points that are created with a unique identifier, northing, easting (or Latitude, Longitude), and optional elevation and description. A non-control point represents a point whose location is determined from a reduced coordinate (N,E,Z) observation, such as point created by the NE SS survey command. A non-control point is not connected to other survey observations and remains unaffected by a network analysis, but still resides within the context of a survey network. Non-control points are added to the survey database and are managed with a named survey network. Non-control points can be promoted to control points if you reference the point as a control point for creating a traverse, or reference the point as a setup to make observations to other points that can affect locations during an analysis.

**non-destructive breakline** A breakline that is not crossed by triangulation lines in a TIN. Instead, new vertices are added to the breakline at the intersection of each TIN line and the breakline. The new points create additional surface triangles. This is useful when you do not want the elevation of a surface to be interpolated inside an area that you know to be a constant elevation.

**northing** A linear distance northwards from the East-West line which passes through the origin of a grid. Equivalent to the Y coordinate in an XYZ coordinate system.

**note reduction** The process of taking field measurements and converting them from 3-dimensional to 2-dimensional in order to use the measurements in a plan view of the drawing. For example, note reduction includes the process of converting vertical distances to horizontal distances.

**null assembly** A placeholder assembly that is used during intersection object creation, when a referenced assembly cannot be found. A null assembly generally contains no subassemblies other than a marked point. *See also* assembly set.

**object** In AutoCAD Civil, an element in a drawing, for example, a surface, that can maintain a relationship with other objects.

**object model** The underlying system of links and dependencies between objects. In the object model, changes in one object can be passed on automatically to all the objects associated with it.

**occupied point** A point in a traverse loop where the survey instrument is set up and observations are recorded.

**offset alignment** A dynamic alignment created at an offset distance from another alignment, such as a road edge offset from a centerline alignment. The offset alignment geometry cannot be edited directly, but it responds dynamically to edits of the parent alignment.

**outcurve** A spiral with a curve radius that increases along the route of the defined direction.

**overhaul** The excavated material that must be hauled beyond the free haul distance. *See also* free haul (page 2474), mass haul (page 2477).

**override** A value for a setting that replaces the value already set at the next higher level.

**Panorama** A window that displays data in table form for the objects in a collection that is selected in Toolspace. For example, if you select a point group, the Panorama table displays a row for each point.

**parcel** A discrete piece of 2D area. For example, a subdivision is composed of numerous parcels. Synonymous with lot.

**parcel node** A point where two or more parcel segment ends join.

**parcel segment** A parcel boundary element, a line, or a curve.

**Part Builder** A parametric modeling tool used to create and modify the set of pipe network parts (pipe and structure shapes) that are available in pipe network part catalogs.

**part catalog** An xml file that contains definitions for the three-dimensional, parametric shapes of pipe and structure objects used in pipe networks.

**parts list** A set of references to pipe network parts (pipes and structures) whose shapes are defined in a catalog called the part catalog.

**pass-through point** A point on the path of a line or curve, often used to define an alignment. A pass-through point on a curve can be used as a grip to control the position of the curve. However the alignment is edited, its geometry has to go through the pass-through point.

**passing sight distance** The distance measured to a point where an approaching vehicle comes into view ahead of a driver on an undivided road. This is used to calculate vertical crest curves.

**pay item** A specific unit of work for which a price is provided and paid to a contractor while a project is under construction.

**pay item list** A master list provided by the contracting authority, listing pay item numbers, item specifications, and item units of measure.

**PC** Tangent-Curve Intersect. *See* point of curvature (page 2480).

**PCC** Compound Curve-Curve Intersect.

**PI** Tangent-Tangent Intersect. *See* point of intersection (page 2480).

**pipe network** A pipe network object manages a collection of pipe objects and structure objects that are used to represent a pipe network in a drawing.

**pipe object** A type of object used to visually represent a pipe in a pipe network, such as a circular, rectangular, or egg-shaped pipe.

**plan readable** Text that you can read easily in a normal plan view, that is, placed at an angle less than 270 degrees and more than 90 degrees. Also called right-reading.

**plan view** The view of a site if you look straight down from an elevated position.

**point codes** A set of standard codes that define the display and behavior of points used in subassemblies.

**point group** Collection used to group the points in a drawing into smaller, more manageable units. For example, you can create a point group that contains all of the points in a drawing that meet certain elevation criteria.

**point list** The list of the points that belong to a point group.

**point marker** *See* point symbol (page 2480).

**point of curvature** (PC) The point where an arc is drawn from a tangent.

**point of intersection** (PI) The point where two tangents meet on a horizontal alignment. Curves and spirals also have points of intersection, which indicate where the tangents would meet if they were extended outward.

**point of tangency** (PT) The point where a curve meets a tangent.

**point of vertical intersection** (PVI) In a profile, the point where two tangent lines meet.

**point symbol** A point location marker. When you add points to a drawing, point symbols are created to represent the points. The point style referenced by a point describes how the point symbol is drawn.

**polyface** A 3-dimensional (polygon) mesh object. Each face is capable of having numerous vertices.

**PRC** Reverse Curve-Curve Intersect.

**prism** A faceted glass reflector used to return the signal from an EDM, whereby the EDM can determine the distance to its reflection point.

**prism constant** The distance between the point of plumb and the reflection point within the prism.

**prism offset** The vertical distance between the theodolite target point and the optical center of the reflector.

**profile** An object that contains elevation data along a horizontal alignment or other line. There are two main types of profiles: surface and layout. Profile data objects can be viewed within a profile view object.

**profile grade line** *See* layout profile (page 2476).

**profile view** An object that manages the graphic display of profile data objects within a drawing. A profile view is essentially a graph with two primary axes: the x-axis represents horizontal distance along the referenced horizontal alignment (or other linear feature). The y-axis represents elevations. Profile view objects can also include grid display components and data bands.

**project drawing** A drawing that has been added to a project.

**project objects** Objects that exist in a project drawing and have been designated as *shared*, which means that they can be accessed by others. *See also* drawing objects (page 2473).

**projected object** An object in plan view of a drawing that is projected into a profile view or section view. AutoCAD objects that can be projected include points, blocks, 3D solids, and polylines. AutoCAD Civil objects that can be projected include points, feature lines, and survey figures.

**projection lines** In a grading, the lines that designate face edges within a region for break points on the footprint or the daylight line, and for the facets of curves (corner cleanup, vertical curves).

**properties** The settings that apply to a particular instance of an object.

**property fields** The placeholders in labels that contain content, such as text or graphics, along with format modifiers unique to specific features. Property fields can be named and their values defined according to the feature with which they are associated. *See also* modifier (page 2478).

**Prospector tab** The part of Toolspace where you access drawing and project objects. Objects are arranged in a tree or hierarchy with folders and subfolders that you navigate in standard, Windows-Explorer fashion. *See also* Settings tab (page 2482).

**protected point** A project point that you cannot check out and therefore edit.

**proximity breakline** A breakline that is drawn as a polyline without snapping to points in the drawing. The northing, easting, and elevation of the breakline vertices are determined from the nearest point contained in the surface point data, after generating the surface.

**PT** Curve-Tangent Intersect. *See* point of tangency (page 2480).

**PVI** Point Of Vertical Intersection. *See* point of vertical intersection (page 2480).

**quadrant** One of the sections resulting from dividing a circle into four equal parts. Quadrant 1 is the NE corner, and quadrants 2, 3, and 4 proceed clockwise around the compass. Bearings are usually referenced by quadrant number.

**quantity takeoff** The analysis of detailed cut and fill requirements along an alignment. A quantity takeoff report provides information on the total volume of material required to create a finished grade surface, including the process of cutting existing ground and refilling it with a different material, such as coarse gravel.

**R** Right.

**radians** A system of measure in which 2 pi radians equals 360°.

**raw description** The original description of a point, before description key matching takes place. Often corresponds to the point description entered in the field by a surveyor.

**raw station** A station value on an alignment, either formatted or unformatted, that does not take into account any station equations applied to the alignment.

**RC** Reverse Crown.

**rear yard** The offset distance from the parcel rear segments to the setback line.

**reference object** Within a project drawing, the read-only geometry of an object that exists in another project drawing. Objects that can be referenced include surfaces, alignments, profiles, and pipe networks. The host drawing can apply local object styles and annotations, and perform some analysis on reference objects.

**Referenced Text** A label component that contains references to other AutoCAD Civil objects.

**region (grading)** The area where grading criteria are applied to a lot line or a feature line.

**region lines** The projection lines that designate the start and end of the grading regions (criteria or transition) by connecting the footprint to the daylight line.

**return period** A time period that represents an interval at which an event, such as a large storm, occurs. It is used to calculate various flow control methods in a pipe network or storm sewer drainage system.

**right-of-way** (ROW) The allowable work area for an alignment. Property lines of the property owners who reside adjacent to the construction site generally specify these limits, which are called right-of-way lines.

**right-of-way parcel** A parcel that is created from an alignment that crosses the original parent parcel.

**rod** A slender bar of wood or metal marked with some type of measurement used to measure elevation and/or distance.

**ROW** *See* right-of-way.

**sag curve** In a profile, a vertical curve at the bottom of a valley or similar location where the grade leading into the curve is less than the grade leading out of the curve. In a sag curve, the point of vertical intersection (PVI) for the tangents is below the curve.

**sample** The process of obtaining elevation information from an existing terrain model or surface.

**sample line** A line that typically cuts across an alignment, and that can be used for creating cross sections.

**SBO** Shoulder Breakover.

**SC** Spiral-Curve Intersect. *See* spiral to curve (page 2483).

**SDTS** *See* Spatial Data Transfer Standard (page 2482).

**section** An object that contains elevation data along a sample line.

**setback line** A closed polygon that is the result of offsetting and intersecting each parcel segment by its respective front/side/rear yard distance. The exterior of the setback line typically represents the area where permanent structures are not permitted.

**settings** A collection of properties and styles that apply to an object.

**Settings tab** The part of Toolspace where you access the styles for the different types of objects, including object labels and tables. *See also* Prospector tab (page 2481).

**setup** Instrument setups that are defined in the Survey database.

**shape codes** A set of standard codes that define the display and behavior of shapes used in subassemblies.

**shortcut** *See* data shortcut (page 2472).

**shortcut menu** A menu that is displayed when you select an object and right-click. Shortcut menus are context sensitive so that only commands that are relative to the object that you selected are displayed.

**side yard** The offset distance from the parcel side segments to the setback line.

**sideshot** A point that is created with a unique identifier, resulting from relative observations (such as angles, distances, vertical angles, and target heights) taken from a survey station or setup to locate a point that is not intended to be used as a base for the extension of the survey. For example, at one station (setup) in a traverse loop, you can survey points for stone walls, trees, buildings, and wetlands.

**simple spiral** A spiral where the large radius end has an infinite radius and the small radius end has a finite radius, therefore providing a smooth transition from a tangent (infinite radius end) to a curve (finite radius end). *See also* clothoid spiral (page 2470), compound spiral (page 2470).

**site** A collection of objects that are managed by means of common topology. The objects that participate in the topology are parcels, alignments, and grading. *See also* topology (page 2485).

**slope** A method of reporting surface inclination as a ratio that expresses the horizontal distance in which the elevation changes by one linear unit. For example, if the ground rises 3 units over a horizontal distance of 15 linear units (meters or feet), the slope is 5:1 (5 to 1). *See also* grade (page 2475).

**slope projection** The method of grading to a target that is either Slope (H:V value) or Grade (percentage value).

**south azimuth** Azimuths south of the equator are referenced to due South clockwise.

**Spatial Data Transfer Standard** A file format designed as a mechanism for the transfer of spatial data between various computer systems. The SDTS Format is designed to transfer data with complete content transfer (no loss of information).

**SPI** Reverse Spiral Tangent.

**spiral** *See* clothoid spiral (page 2470), compound spiral (page 2470), simple spiral (page 2482).

**spiral to curve** (SC) A point where a spiral meets a curve.

**spiral to tangent** (ST) A point where a spiral meets a tangent.

**split profile** A profile view that has a readjusted datum at a station where one or more profiles goes out of bounds. This condition happens if a profile view that has a user-defined height is not able to adequately portray the full extents of a profile.

**spot elevation** The elevation of a single point in the drawing. Used to define areas that are sparse in contour data when generating a TIN using contour information. Areas that may also need spot elevations are the top of hills, valleys, and bottom of swales.

**SS** Spiral-Spiral Intersect.

**SS_LRB:L** Simple Spiral Large Radius at Beginning.

**SS_LRE:STA** Simple Spiral Large Radius at End.

**SS_SRB:L** Simple Spiral Small Radius at Beginning.

**SS_SRE:STA** Simple Spiral Small Radius at End.

**ST** Spiral to Tangent Interesct. *See* spiral to tangent (page 2483).

**stacked profile views** A collection of related profiles drawn in separate, vertically arranged profile views. Typically, a centerline profile is contained in one profile view, and its left and right offsets are drawn in profile views that are placed above and below the centerline profile view.

**stacked text** When you drag a label from its point of origin, label text can be rearranged by specifying settings for text justification, text height, and relationship to borders.

**stadia** A technique of distance measurement using a rod and a stadia transit.

**stakeout** The process of placing stakes in the ground at control points on a site that is being developed. For example, after you place points in your drawing, or after you design an alignment, you can create stakeout reports that list the coordinates of each stake. Someone else can then use these stakeout reports to place (or adjust) the stakes at the site.

**standard breakline**  A breakline defined from selecting consecutive points or point numbers, or selected 3D polyline or 3D line objects.

**starshot** Determining azimuth by using a star rather than a compass.

**station** A distance along a horizontal alignment.

**station equation** A point on an alignment that defines a change in the station values after that point.

**stationing** The labeling that provides a reference when talking about a specific point along the reference baseline.

**stopping sight distance** The distance required to safely stop a vehicle, traveling at design speed, to avoid a collision with any other non-moving objects obstructing the travel path.

**stratum**  The difference between two surfaces that exist in a drawing, usually the existing ground surface and a finished ground surface, which is used for calculating volumes.

**structure object** A type of object used to visually represent structural components used in a pipe network, such as a headwall or a catch basin.

**style** A logical collection of settings that applies to a class of objects. Styles simplify the process of apply settings by simply referencing a style. Modifying a style affects all the objects referencing that style.

**subassembly** An AutoCAD drawing object (AECCSubassembly) that defines the geometry of a component used in a corridor section. The AutoCAD Civil tool palette and tool catalogs provide a variety of preconfigured subassemblies, such as travel lanes, curbs, shoulders, and ditches.

**subdivision** An unimproved tract of land surveyed and divided into parcels for purposes of sales.

**sunshot** Determining azimuth by making observations on the sun rather than by a compass.

**surface** A network of elevation data (either TIN or Grid). The points of a surface are connected into either triangles or a grid, which are then used to interpolate contours, and to generate profiles and cross sections. A surface represents the ground condition at a particular time or event.

**surface border** *See* border (page 2469).

**surface boundary** *See* boundaries (page 2469).

**surface distance** The distance between two points, measured along the ground surface. On a sloped surface, the distance between two points can also be measured as a horizontal distance and a vertical distance.

**surface profile** A profile object that represents existing ground elevations along a horizontal alignment or other linear feature that supports profile views. Typically this data is derived from an existing surface or data file, and consists of a series of connected vertical tangent lines without vertical curves defined. If necessary, you can add vertical curves.

**surface smoothing** A process that interpolates and extrapolates surface data to derive additional elevation values. Kriging and Natural Neighbor Interpolation (NNI) are the two methods of surface smoothing.

**survey command language** A language that you can use either with a data collector or when you enter survey data manually. This language describes survey observations. For example, you can use the AD [VA] command to enter an angle, distance, and vertical angle.

**survey database** Contains all the control points, known directions, observation measurements, traverse definitions, figures, and standard deviations based on equipment data for the Survey project. This includes observations imported from data collector files, entered from the Survey Toolspace tab (Traverse and Observation Editors, Survey Command Window and Batch File processing).

**Survey Point** A point that is created by the Survey features of AutoCAD Civil, such as importing a field book or LandXML file containing survey data. A survey point can represent a Control Point, Non-control Point, Setup, or Sideshot. When a survey point is placed in the AutoCAD Civil drawing, it creates a special AutoCAD Civil COGO point that prevents its location and description from being modified from outside the AutoCAD Civil Survey features. For example, a survey point location may be a traverse station whose location is dependent on many observations from previous traverse stations, all originating from a known control point and direction. In the AutoCAD Civil drawing the Survey Point displays a different icon than the AutoCAD Civil COGO point to indicate its origin.

**Survey tab** The tab in Toolspace where you access and manage survey settings, survey-related databases, and survey project data.

**tangent** A straight line segment that forms part of a horizontal alignment or profile. Tangent Distances are measured as the horizontal distance between the two end points.

**target** The element of grading design criteria that determines what the grading is going to intercept. A target can be a surface, absolute elevation, relative elevation, or distance.

**target line** *See* daylight line (page 2472).

**template** A collection of default settings and styles used to create a drawing.

**terminators** Graphics, such as arrowheads, ticks, or crow's feet, that display at the end of lines, arcs, or spirals.

**tessellation** The representation of curves by using short straight line segments.

**tessellation angle** Controls the angular spacing of breaklines that are supplemented along curve segments, such as around corners. Used for surface creation from grading objects.

**tessellation spacing** Controls the spacing of supplemental breaklines that are added to a grading along straight segments. Used for surface creation from grading objects.

**tick** A component of a label that is usually a mark (or short line) inserted in a series at perpendicular angles to another object, such as a line or curve.

**TIN** Triangular Irregular Network. A TIN surface is the most common method of interpolating elevation data. The points are connected into triangles that are used to interpolate for contours, and to generate profiles and cross sections. The lines that make up the surface triangulation are called TIN lines. *See also* 3D face (page 2467).

**TIN volume surface** A differential surface created from a composite of points based on base and comparison surface. Also known as a differential surface.

**Toolspace window** A window that provides an object-oriented view of your engineering data. Toolspace is divided into four parts or tabs: Prospector tab, Settings tab, Survey tab, and Toolbox tab.

**topography** The features of the actual surface of the Earth.

**topology** A set of geometric connections between objects. Objects linked by topology maintain their relationships with one another. In AutoCAD Civil, objects that share the same topology are grouped in a site. *See also* site (page 2482).

**transit rule** A method of balancing a traverse, in which one assumes that the closing errors are caused less by the errors in the observed angles than by the errors in measured distance. Corrections are distributed according to the ratio of the latitude and departure of each leg of the traverse, to the sums of the latitude and departures of the entire traverse. Use the Transit Rule option when it is assumed that closing errors are due less to the errors in the observed angles than to errors in the measured distances.

**transition region** An area of a grading that blends the control regions on either side of it. A transition region has no design criteria assigned to it.

**transparent command** A command that you can run while another command is in progress. Transparent commands begin with an apostrophe (').

**traverse** A method of surveying in which length and directions of lines between points on the Earth are obtained by or from field measurements, and used in determining positions of the points.

Traverse closure for closed or open loops is recognized by the observation to a control (fixed or known) point. A closed traverse begins and ends at the same control point. An open traverse closes at a different control point than the beginning point.

**triangle area** The 2-dimensional (2D) area of a triangle face computed from the northing and easting of each triangle point. The total triangle area is the sum of all 2D triangle areas with the surface boundaries.

**trim (surface)** The process of removing unwanted TIN lines from a surface, thereby removing triangles.

**TS** Tangent-Spiral Intersect.

**vault** A database that is managed by Autodesk Vault.

**Vault reference** A type of data reference between drawings within a Vault project.

**VCC** Vertical Compound Curve Intersect.

**VCCE** Vertical Compound Curve Intersect Elevation.

**VCCS** Vertical Compound Curve Intersect Station.

**vertical alignment** *See* profile (page 2480).

**vertical angle** An angle above or below the horizontal plane. The angle is expressed in DDMMSS from this horizon. Vertical angles expressing a downhill slope from the instrument station are described with a negative value. Zenith angles are similar to vertical angles, except that a zenith angle has a vertical reference plane.

**vertical curve** A curve used on a profile (most commonly on layout profiles) to provide a gradual change in slope from one tangent to the other. There are three types of vertical curve: parabolic, circular, and asymmetrical.

**vertical distance** A distance measured along a sloped surface. For example, if you measure a distance from point A to point B that is on a 3:1 grade, then that distance is longer than the distance measured horizontally.

**vertical exaggeration** An increase of vertical scale relative to horizontal scale, used to make grade changes easier to differentiate. *See* vertical scale (page 2487).

**vertical scale** The scale that is compared to the horizontal scale to calculate the vertical exaggeration in profiles and cross sections. It does not actually change the scale that is used when the drawing is plotted.

**vertical to horizontal** Vertical angles and distances are converted automatically to horizontal angles and distances when you adjust a traverse loop, or perform Least Squares adjustment on observed data.

**void region** An area along a footprint where grading has not been applied, creating a gap in the grading.

**volume surface** A surface that is created by calculating volumes using the grid (differential) or TIN (composite) methods. The surface is created from the two surfaces that make up the stratum. The elevation values of a volume surface are actually the difference between the two surfaces. For example, at point 1000,1000, the bottom surface has an elevation of 100, and the top surface has an elevation of 150. The elevation of point 1000,1000 on the volume surface is the difference between the two surfaces, which is 50.

**VRC** Vertical Reverse Curve Intersect.

**VRCE** Vertical Reverse Curve Intersect Elevation.

**VRCS** Vertical Reverse Curve Intersect Station.

**wall breakline** A breakline that represents surface features such as retaining walls, curbs, bridge abutments, and so on.

**water drop** A path drawn with a 2D or 3D polyline, which represents water as it flows downhill.

**watersheds** Catchment areas for rainfall that are delineated as the drainage areas producing runoff. Base flow in a stream also usually comes from the same area.

**weeding** The removal of points along a selected polyline representing a contour. The weeding factors determine the amount of points removed. You can use weeding to reduce the amount of point information taken from the contours that may not be necessary to generate an accurate surface. *See also* weeding factors (page 2487).

**weeding factors** The settings used to reduce redundant points along the contours by ignoring contour vertices that are close together or along a straight line. A larger distance and deflection angle will weed a greater number of points.

**widening** A type of dynamic offset alignment that expands the width of a roadway for a specified length to accommodate a feature such as a turn lane or bus bay. The widening usually includes a transition region at one or both ends.

**zenith angle** The point directly overhead or the point where an observer's vertical line pierces the celestial sphere. Opposite zenith is the nadir.
